Transport through H and replay through C preserve this shared threshold for both arithmetic rows. The provenance and local name rows P, N then package the same BHist route as the public $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^\uparrow}$ surface.

Since the carrier contains no row for quotient streams, selected limits, host real equality, or ambient completeness, the shared threshold obligation is exactly the displayed meet route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier sum product shared threshold`

Theorem 1485.13 (Real seal schedule nonescape obligation)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^\uparrow$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N),$$

the terminal $\mathsf{Real}^\uparrow$ *seal row* E *is reachable only through the finite schedule surface*

$$\mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, H, C, P, N$$

inside the displayed BHist *carrier. The seal preserves the same* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}}$ *route used by the source schedules, meet schedule, sum/product consumers, dyadic ledger,* $\mathsf{StreamName}^\uparrow$ *windows, and* $\mathsf{RegSeqRat}^\uparrow$ *readbacks. It exports no quotient stream, selected limit, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier real seal schedule nonescape`

Proof. Start from a consumer that requests the terminal seal row E. By Definition 1485.7, the consumer must pass through either the displayed sum route or the displayed product route before the Real-facing seal can be read.

The sum and product routes are already bound to the shared threshold by Definition 1485.12. Thus both routes expose $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before they reach the arithmetic consumer row that feeds E.

The common-tail obligation of Definition 1485.11 keeps the window and readback rows inside the same BHist surface. Transport H, replay C, provenance P, and local naming N therefore remain attached to the seal.

Consequently E is a schedule endpoint for the displayed arithmetic carrier. It is not an escape route to quotient streams, selected limits, host real equality, or ambient completeness. □

Theorem 1485.14 (Diagonal schedule dominates arithmetic consumers)**.** *Let* A *be an accepted* $\mathsf{CauchyModulusArithmetic}^\uparrow$ *carrier. Any displayed* $\mathsf{CauchyModulusDiagonal}^\uparrow$ *tail witness consumed by the sum or product route is admissible only after the two source schedules* μ_0, μ_1*, the shared meet row* $\mu_\wedge$*, the* $\mathsf{RegularCauchySum}^\uparrow$ *and* $\mathsf{RegularCauchyProduct}^\uparrow$ *rows, the* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance ledger* D*, the* $\mathsf{StreamName}^\uparrow$ *window ledger* W*, the* $\mathsf{RegSeqRat}^\uparrow$ *readbacks* R*, and the* $\mathsf{Real}^\uparrow$ *seal row* E *have all been exposed. Thus a diagonal tail witness is a downstream read of the displayed arithmetic route, not an independent schedule for choosing a hidden limit comparison.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier diagonal dominates sum product`

Proof. Read the carrier in the order of Definition 1485.1. The diagonal tail request has no coordinate before the two source schedules, the meet row, and the arithmetic consumer rows are present.

The tolerance and window rows then force the request through D and W. Their entries expose exactly the dyadic tolerance and finite stream windows from which the regular rational readbacks R are obtained.

Finally the consumer reaches E only through the regular sum or product handoff. The diagonal witness therefore remains below the displayed sum/product arithmetic route and cannot serve as a separate host limit comparison. □

Theorem 1485.15 (Product consumers reuse the meet threshold)**.** *Let A be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier. Every* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *consumer of A shares the same meet-threshold route as the* $\mathsf{RegularCauchySum}^{\uparrow}$ *consumer: it reads μ_0, μ_1, then $\mu_\wedge$, then the displayed ledger rows D, W, R, before reaching the product row π. In particular product compatibility is witnessed by the finite* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *route, not by a host comparison of completed limits.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier product meet compatibility`

Proof. Begin with a product request for π. Carrier admission places π after the two source schedules and the shared meet row, so the product consumer cannot bypass $\mu_0, \mu_1, \mu_\wedge$.

The same ledger rows used by the sum route are then read by the product route. The dyadic ledger D supplies the tolerance row, W supplies the inspected finite windows, and R supplies the regular rational readbacks.

Transport through H and replay through C preserve this common route. Since no completed-limit comparison coordinate is present in the carrier, product compatibility is exactly compatibility with the displayed meet threshold. □

Theorem 1485.16 (Real seal distribution through arithmetic rows)**.** *Let A be an accepted* $\mathsf{CauchyModulusArithmeti}$ *carrier. Every Real-facing consumer of the arithmetic-modulus packet distributes through* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *only by reading the finite rows*

$$\mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N.$$

No Real-facing consumer may distribute the seal through quotient streams, selected representatives, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier real seal distribution`

Proof. Start from a Real-facing request for the seal row E. By Definition 1485.7, the request must pass through the displayed sum or product handoff before the seal is available.

For the sum side, Definition 1485.6 supplies the source schedules, shared meet, tolerance ledger, windows, and readbacks. For the product side, Definition 1485.15 supplies the same meet-threshold route.

The structural rows H, C, P, N transport, replay, source, and name this finite route. Therefore distribution of the Real seal is distribution through the displayed arithmetic rows alone. □

Theorem 1485.17 (Cauchy-modulus arithmetic obligation closure)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier A, the obligation surface of the local packet is exhausted by carrier admission, classifier transport, the two source modulus schedules, the shared meet row, the sum and product consumer rows, dyadic tolerance exactness,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *row. No further obligation is supplied by quotient streams, selected limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier obligation closure`

Proof. Start with the carrier inventory of Definition 1485.1. It exposes exactly the two source streams, two modulus schedules, shared meet, arithmetic consumers, tolerance ledger, windows, readbacks, Real seal, and structural rows.

The local NameCert obligations are the five rows of Definition 1485.2. The first row admits the displayed packet, the second transports it through the classifier, the third stabilizes the source schedules and arithmetic consumers, the fourth fixes the dyadic tolerance ledger, and the fifth records replay, provenance, Real handoff, and local naming.

The sum route is locked to the shared meet by Definition 1485.6. Thus the arithmetic consumer rows cannot be read without the source schedules, shared threshold, dyadic tolerance ledger, finite windows, and regular rational readbacks.

The product and diagonal routes are locked to the same finite surface by Definition 1485.14 and Definition 1485.15. These routes cannot add a separate tail selector or a host comparison of completed limits.

Finally apply Definition 1485.7 and Definition 1485.16. The Real-facing consumer receives only the displayed route and cannot extract quotient streams, selected limits, host real equality, or ambient completeness. Hence the listed rows exhaust the obligation surface. □

Theorem 1485.18 (Cauchy-modulus arithmetic public exactness)**.** *Every Real-facing arithmetic read for an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *sum or product regular-Cauchy consumer is exact exactly when the two source schedules μ_0, μ_1, the shared meet threshold $\mu_\wedge$, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E are displayed in the same carrier together with H, C, P, N. Equivalently, the public sum/product read is accepted only through that one finite carrier surface and not through quotient streams, selected representatives, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier public exactness`

Proof. For the forward direction, start with an accepted Real-facing sum or product read. Apply Definition 1485.6 and Definition 1485.15; they force the sum and product consumers to reuse the two source schedules, the shared meet threshold, the dyadic tolerance ledger, finite windows, and regular rational readbacks.

The diagonal and common-tail rows keep the same public surface. Use Definition 1485.14 and Definition 1485.11 to place every diagonal or late-window read under the same $\mu_\wedge, D, W, R$ route.

Now apply Definition 1485.7 and Definition 1485.16. They put the Real-facing read behind E, H, C, P, N, so exactness is exactness of the displayed carrier rows.

Conversely, if all listed rows are displayed in the same carrier, the obligation closure theorem Definition 1485.17 supplies the finite NameCert surface. The same sum-meet, product-meet, diagonal, common-tail, boundary, and seal-distribution theorems then assemble the public read, with no coordinate left for the excluded host-level principles. □

Theorem 1485.19 (Cauchy-modulus arithmetic obligation scope package)**.** *The carrier, classifier, sum-meet closure, product meet compatibility, diagonal domination, Real-seal distribution, dyadic sum threshold, product tail bound, and Real-seal congruence rows jointly scope the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *NameCert surface over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *Every accepted arithmetic read must pass through the source schedules, shared meet threshold, arithmetic consumer rows, dyadic tolerance ledger, finite windows, regular rational readbacks, terminal Real seal, transport, replay, provenance, and local naming rows before it can expose a sum, product, or Real-facing output.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier obligation scope package`

Proof. Start with the carrier and classifier rows of Definition 1485.1 and Definition 1485.2. They expose the two source schedules, the shared meet row, the sum and product consumers, the dyadic ledger, the stream windows, the regular readback, the Real seal, and the structural rows.

For the arithmetic routes, use Definition 1485.6, Definition 1485.15, and Definition 1485.14. These force both $\mathsf{RegularCauchySum}^{\uparrow}$ and $\mathsf{RegularCauchyProduct}^{\uparrow}$ consumers to reuse $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before any output can be read.

For the Real-facing boundary, apply Definition 1485.16, Definition 1485.22, Definition 1485.23, and Definition 1485.24. These rows keep every terminal read attached to the same finite ledger and to the same H, C, P, N transport, replay, provenance, and local naming route.

Thus the scoped obligation package is finite: each named dependency is one displayed sibling or kernel row, and no quotient stream, selected limit, host real equality, or ambient completeness principle is introduced. □

Theorem 1485.20 (Cauchy-modulus arithmetic sum-product carrier admission)**.** *Every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *arithmetic packet exposes the sum row* σ*, product row* π*, diagonal schedule reads, meet threshold* $\mu_\wedge$*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *row* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *row* N *before any Real arithmetic consumer reads the result. The admission route is therefore a concrete finite* BHist *surface, not a quotient stream, selected limit, host real equality, or ambient completeness read.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier sum product carrier admission`

Proof. Project the carrier of Definition 1485.1. It already lists the sum and product consumers, the shared meet row, the dyadic tolerance ledger, the window ledger, the regular rational readbacks, the Real seal, and the structural rows.

Use the sum-meet closure of Definition 1485.6 and the product meet compatibility of Definition 1485.15. These two routes force σ and π to reuse $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before either arithmetic consumer can reach E.

The diagonal dominance theorem Definition 1485.14 keeps any diagonal schedule read downstream of the same rows. Finally Definition 1485.16 routes the Real-facing read through H, C, P, N, so the consumer receives only the displayed finite packet. □

Theorem 1485.21 (Cauchy-modulus arithmetic diagonal-meet stability)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *packet, any diagonal schedule read used by the sum or product consumer is stable only along the same meet threshold* $\mu_\wedge$ *and the same finite rows* D, W, R, E, H, C, P, N*.*

Thus diagonal refinement, meet-threshold transport, DyadicRatCore$^{\uparrow}$ *tolerance reads,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks,* Real$^{\uparrow}$ *sealing,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming remain one concrete route before any Real arithmetic consumer accepts the result.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier diagonal meet stability`

Proof. Begin with a diagonal schedule read. By Definition 1485.14, the read is admissible only after the source schedules, shared meet row, arithmetic consumers, tolerance ledger, windows, readbacks, and Real seal are visible.

Apply Definition 1485.15 to the product route and Definition 1485.6 to the sum route. Both consumers reuse the same meet threshold $\mu_\wedge$ and the same ledger rows D, W, R.

Transport and replay are then fixed by H and C. The provenance and local naming rows P, N record the same finite route, and the Real seal distribution theorem keeps the final arithmetic read inside it. Therefore diagonal stability is meet stability for the displayed packet, not a separate tail selector or host comparison. □

Theorem 1485.22 (Dyadic sum threshold obligation)**.** *Let A be an accepted* CauchyModulusArithmetic$^{\uparrow}$ *carrier. Every dyadic tolerance request consumed by the* RegularCauchySum$^{\uparrow}$ *row σ is answered by a finite threshold route through the source schedules μ_0, μ_1, the common-tail window, the shared meet row $\mu_\wedge$, and the split tolerance entries of D. The sum threshold therefore depends on the displayed* DyadicRatCore$^{\uparrow}$ *ledger and the* RegSeqRat$^{\uparrow}$ *readback row R, not on a quotient stream, selected limit, host real equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 1485.1. The sum consumer σ has access only to the two source schedules, the shared meet row, the dyadic ledger, finite stream windows, and regular rational readbacks.

Use the common-tail window of Definition 1485.11 to place the two late stream reads on one finite window surface. Then apply the sum-meet closure of Definition 1485.6 and the sum-product shared threshold of Definition 1485.12.

The split entries in D supply the dyadic tolerances read by σ, while R records the regular rational readback obtained from those windows. Since no other carrier coordinate can answer the request, the dyadic sum threshold is exactly this displayed finite route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier dyadic sum threshold obligation`

Theorem 1485.23 (Product tail bound obligation)**.** *Let A be an accepted* CauchyModulusArithmetic$^{\uparrow}$ *carrier. Every product tail bound consumed by the* RegularCauchyProduct$^{\uparrow}$ *row π is witnessed inside the same meet threshold $\mu_\wedge$ and the same rows D, W, R used by the sum route. Product bounds may refine the diagonal schedule read, but they remain downstream of $\mu_0, \mu_1, \mu_\wedge$ and upstream of the* Real$^{\uparrow}$ *seal row E.*

Proof. Begin with a product request for π. The product-meet compatibility theorem Definition 1485.15 forces the request through $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before the product row is available.

If the product request uses a diagonal tail witness, apply Definition 1485.14 and Definition 1485.21. These theorems keep diagonal refinement on the same meet threshold and the same finite ledger rows.

The product bound is then replayed through H and C and sourced by P, N. It cannot introduce a separate tail selector or compare completed limits, because the carrier has no coordinate for those principles. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier product tail bound`

Theorem 1485.24 (Real seal congruence obligation)**.** *Let A be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier. If two displayed arithmetic reads are transported by the componentwise* hsame *row H and share the same source schedules, meet threshold, dyadic ledger, stream windows, and regular rational readbacks, then every* $\mathsf{Real}^{\uparrow}$ *seal read through E is congruent along the same* Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *route. The congruence is a seal boundary for the displayed packet, not a proof of quotient-real equality or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier real seal congruence`

Proof. Project the two displayed arithmetic reads to their common rows. By the carrier definition and the classifier transport row, H can transport only the stream windows, source schedules, meet row, sum and product rows, dyadic ledger, readbacks, seal row, replay, provenance, and local name.

Use Definition 1485.16 to route both Real-facing reads through σ or π and then through $\mu_0, \mu_1, \mu_\wedge, D, W, R, E, H, C, P, N$. The Real seal schedule nonescape obligation Definition 1485.13 keeps the seal attached to that same finite route.

Thus congruence of the seal is exactly congruence along the displayed transport, replay, provenance, and local NameCert rows. No quotient-real equality or completeness principle is exported by the argument. □

Theorem 1485.25 (Cauchy-modulus arithmetic uniform product budget)**.** *Let A be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier. Any product consumer that reads a requested* $\mathsf{Real}^{\uparrow}$ *tolerance must first pass through the shared meet threshold $\mu_\wedge$, then the product tail-bound ledger over D, W, R, and then the Real-seal congruence row E, H, C, P, N. Consequently the exported product budget is uniform over the same* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks that the carrier already displays; it cannot be selected from a separate tail oracle, quotient real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier uniform product budget`

Proof. Project the carrier of Definition 1485.1. The product row π can read only the source schedules, the shared meet threshold, the dyadic ledger, the stream windows, the regular-rational readbacks, and the structural rows of the displayed packet.

Apply the product tail bound obligation Definition 1485.23. It places every product tail read downstream of $\mu_0, \mu_1, \mu_\wedge, D, W, R$ and upstream of the $\mathsf{Real}^{\uparrow}$ seal.

Use diagonal-meet stability, Definition 1485.21, to keep any diagonal refinement on the same shared threshold. Then apply Real seal congruence, Definition 1485.24, so the final seal read remains attached to E, H, C, P, N.

The budget exported to the product consumer is therefore the unique displayed route through the meet threshold, tail ledger, readback windows, seal, transport, replay, provenance, and local NameCert rows. No other carrier coordinate can supply a product budget. □

Theorem 1485.26 (Cauchy-modulus arithmetic scope window reuse)**.** *Every* $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier must reuse the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *carrier, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *row before exporting a shared threshold. The shared threshold is therefore scoped by the existing finite rows of the packet, not by a separate tail oracle, quotient-stream selector, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier scope window reuse`

Proof. Project the accepted carrier $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$. The displayed stream windows, dyadic ledger, regular-rational readbacks, Real seal, transport, replay, provenance, and naming rows are already part of the finite packet before any arithmetic consumer reads a threshold.

Apply the sum-meet closure and uniform product budget theorems. They force sum and product consumers through the same $\mu_\wedge$ threshold together with D, W, R, E, H, C, P, N.

For a downstream $\mathsf{Real}^{\uparrow}$ seal, use Real-seal distribution and congruence. Those results keep the seal read attached to the same displayed rows, so the consumer cannot select a new threshold from quotient streams, host real equality, or ambient completeness. □

Theorem 1485.27 (Cauchy-modulus arithmetic scoped evidence route)**.** *The scoped* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *marker is read through the carrier* $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *obligations, and the finite window rows* D, W, R, E, H, C, P, N*. In particular, scoped closure is supported by the two source* $\mathsf{StreamName}^{\uparrow}$ *windows, the two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *threshold, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *consumers, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows.*

Proof. Project the carrier of Definition 1485.1. It lists the exact tuple $S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N$ that the hub marker reads through the child file.

Apply the NameCert obligations theorem Definition 1485.2. Its carrier, classifier, stability, dyadic-exactness, replay, provenance, seal, and local-name rows bind the finite scope to those displayed coordinates.

Finally use scope-window reuse, Definition 1485.26. It forces sum, product, and Real-seal consumers to reuse D, W, R, E, H, C, P, N, so the scoped marker is tied to the child evidence rather than to a detached hub assertion. □

Theorem 1485.28 (Cauchy modulus arithmetic windowed product distributivity)**.** *Let* A *be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *packet whose sum and product modulus schedules expose the same* $\mathsf{StreamName}^{\uparrow}$ *window. Any Real consumer that reads the product distributivity budget for those schedules must route the comparison through the displayed* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *shared threshold, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it receives the product budget. The common window is therefore the only route by which distributivity of the finite product budget reaches a downstream Real consumer.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier windowed product distributivity`

Proof. Start with the NameCert obligations of Definition 1485.2. They expose the two source schedules, the shared threshold row, the arithmetic consumer rows, the dyadic tolerance ledger, the readback rows, the Real seal, and the structural transport rows as one packet.

Apply the sum and product shared-threshold route of Definition 1485.6 together with the product tail bound of Definition 1485.23. These clauses keep the product budget downstream of the same $\mathsf{StreamName}^{\uparrow}$ window and the same $\mathsf{CauchyModulusMeet}^{\uparrow}$ threshold used by the sum schedule.

Finally use the uniform product budget of Definition 1485.25 and Real-seal congruence, Definition 1485.24. The Real consumer receives only the route through the displayed tolerance ledger, readback rows, terminal seal, transport, replay, provenance, and local naming, so the common-window product distributivity obligation is exhausted by the carrier surface. □

Theorem 1485.29 (Cauchy-modulus arithmetic tail-meet exhaustion)**.** *Let $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E$ be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier. Every accepted carrier consumer that reads a* $\mathsf{RegularCauchySum}^{\uparrow}$ *row, a* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *row, or the downstream* $\mathsf{Real}^{\uparrow}$ *seal must expose the two source schedules μ_0, μ_1, the shared meet row $\mu_\wedge$, the dyadic ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R, and the structural rows H, C, P, N before it exports any threshold, product budget, or seal. Thus the sum, product, and Real-facing reads exhaust the same tail-meet surface rather than three separate consumer routes.*

Proof. Start with scope-window reuse from Definition 1485.26. It forces every sum, product, or $\mathsf{Real}^{\uparrow}$ seal consumer to reuse the displayed windows, dyadic ledger, readbacks, seal row, transport, replay, provenance, and local naming rows of the accepted packet.

For product-facing reads, apply the uniform product budget theorem Definition 1485.25. The product budget is downstream of the shared meet row and the same D, W, R, E, H, C, P, N surface, so it cannot be supplied by a separate tail oracle or a quotient stream.

Finally use Definition 1485.28. Its common-window route keeps the product-distributivity budget attached to the shared $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{CauchyModulusMeet}^{\uparrow}$ threshold, dyadic ledger, readbacks, and terminal $\mathsf{Real}^{\uparrow}$ seal. Repacking these three routes gives the claimed exhaustion of all downstream sum, product, and Real-seal reads through the single displayed meet-and-tail surface. □

Falsifiable prediction: An accepted $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ consumer that reaches a $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the two displayed $\mathsf{CauchyModulus}^{\uparrow}$ schedules, the $\mathsf{CauchyModulusMeet}^{\uparrow}$ shared-threshold row, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{StreamName}^{\uparrow}$ windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks refutes the carrier surface.

Independence witness: cauchymodulus, cauchymodulusmeet, regularcauchysum, regularcauchyproduct, real: no listed sibling supplies the whole arithmetic packet $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$, because each sibling contributes only a source schedule, a shared threshold, one arithmetic consumer, or the downstream real seal while this chapter binds the schedule-combination route with transport, replay, provenance, and local naming.

Theorem 1485.30 (Cauchy modulus arithmetic public export)**.** *Every public Real or Completion read of an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *packet is exported through the same finite carrier rows used by the local obligation surface: the two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *threshold, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *consumer rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P, N. Thus the public object surface*

is the displayed arithmetic carrier itself, not quotient streams, selected representatives, host real equality, or ambient completeness.

Proof. Start from the obligation closure of Definition 1485.17. It identifies the local NameCert surface with the displayed source schedules, shared meet row, arithmetic consumer rows, dyadic tolerance ledger, finite windows, regular readbacks, Real seal, transport, replay, provenance, and local naming.

Apply the public exactness row of Definition 1485.18. A public sum or product read is accepted only when those same rows are present in one carrier, so the public export does not introduce a second arithmetic object.

Finally use the scope package of Definition 1485.19. It keeps the exported packet inside the same BHist route over CauchyModulus$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, RegularCauchySum$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, and NameCert. □

Closure status for NameCert$_{\text{CauchyModulusArithmetic}^{\uparrow}}$.

Constructive story: A CauchyModulusArithmetic$^{\uparrow}$ packet is generated from two StreamName$^{\uparrow}$ windows, two CauchyModulus$^{\uparrow}$ schedules, one CauchyModulusMeet$^{\uparrow}$ shared-threshold row, RegularCauchySum$^{\uparrow}$ and RegularCauchyProduct$^{\uparrow}$ consumer rows, a DyadicRatCore$^{\uparrow}$ tolerance ledger, RegSeqRat$^{\uparrow}$ readbacks, a Real$^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyModulusArithmetic}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1485.31, Definition 1485.24, Definition 1485.25, Definition 1485.26, Definition 1485.27, Definition 1485.29, and Definition 1485.30 bind the finite modulus-arithmetic scope and public export surface over CauchyModulus$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, RegularCauchySum$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{CauchyModulusArithmetic}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier\_public\_exactness`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, host real equality, ambient completeness, or bridge checking.

Upgrade path: Bridge closure requires a checked standard-bridge theorem for the public arithmetic carrier surface.

Theorem 1485.31 (Cauchy-modulus arithmetic scoped route)**.** *Every accepted* CauchyModulusArithmetic$^{\uparrow}$ *packet scopes its arithmetic reads through the displayed carrier of Definition 1485.1, the NameCert obligation rows of Definition 1485.2, and the common-tail and scope-window routes of Definition 1485.11 and Definition 1485.26. Thus every sum, product, or Real-seal consumer must read* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows inside the same finite packet before exporting an arithmetic handoff.*

The scoped route cannot import quotient stream equality, selected limits, host natural-number search, host real equality, or ambient Real$^{\uparrow}$ *completeness. Those endpoints are absent from the carrier and from the child obligation rows that the hub inputs before this route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticScopedRoute`

Proof. Project the carrier

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$$

from Definition 1485.1. The rows D, W, R, H, C, P, N supply the dyadic tolerance ledger, finite stream windows, regular rational readbacks, componentwise transport, displayed replay, provenance, and local naming before an arithmetic consumer can read σ, π, or E.

Apply the NameCert obligation surface and the common-tail window obligation. These force every precision request through the displayed source schedules, shared meet threshold, common window, readback rows, and structural rows of the same BHist packet.

Finally use scope-window reuse. It keeps the Real-seal and arithmetic consumers on the existing finite rows rather than on a host search or quotient-stream comparison. Since the carrier has no coordinate for selected limits, host natural-number search, host real equality, quotient stream equality, or ambient completeness, the scoped route exports none of those endpoints. □

Theorem 1485.32 (Cauchy-modulus arithmetic diagonal meet route)**.** *Every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *packet whose consumers read both sum and product arithmetic must pass through the displayed meet schedule* $\mu_\wedge$*, the common finite window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the* $\mathsf{Real}^{\uparrow}$ *seal* E *before either arithmetic handoff is exported. Thus a paired consumer reads*

$$\mu_\wedge, W, D, R, E \longmapsto \sigma, \pi$$

inside the same finite BHist *packet, with the structural rows* H, C, P, N *preserving transport, replay, provenance, and local naming. The route exports no quotient stream equality, host natural-number search, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host real equality.*

Proof. Start with the scoped route of Definition 1485.31. It already forces every arithmetic read through the displayed carrier rows and the NameCert obligation surface before a sum, product, or Real-seal consumer can export a handoff.

Now restrict to a consumer that reads both σ and π. The carrier of Definition 1485.1 contains the meet schedule $\mu_\wedge$ and the common finite window W exactly for this paired read, so the consumer cannot use separate hidden schedules for the two arithmetic branches.

The dyadic and readback rows are then common. The ledger D supplies the tolerance accounting, R supplies the regular rational readback, and E seals the Real-facing endpoint after those finite rows have already been displayed.

Finally H, C, P, N keep the paired route inside one packet. Since the existing scoped route refuses quotient stream equality, host natural-number search, selected limits, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness, the diagonal meet route exports none of those endpoints. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticDiagonalMeetRoute`

Chapter 1486

A Concrete Naming Certificate for $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$

Following Bishop and Bridges' constructive-analysis use of explicit moduli, the $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ packet records pointwise continuity data for Cauchy names as a visible finite schedule rather than as a host continuity predicate. It sits between the explicit Cauchy schedule surface of chapter 292, the finite Cauchy-name transformer of chapter 1401, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the compact uniform consumer boundary of chapter 369. The pointwise packet records the threshold route for one displayed source Cauchy name and its target tolerances; it is not compactness, a uniform modulus over all inputs, or a host function equality principle.

Definition 1486.1 (Cauchy modulus of continuity carrier)**.** *A* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, \mu, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *window surface whose finite rational observations are inspected before a target tolerance is answered.*
2. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *window surface promised by the pointwise Cauchy-name transformer.*
3. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule assigned to each requested target tolerance, including the finite source-window bound that the consumer must inspect.*
4. *F is the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *transformer row that consumes S, μ and produces the displayed target windows T.*
5. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks for the source and target windows, with the target readback reached only through F and μ.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the target* $\mathsf{RegSeqRat}^{\uparrow}$ *readback after the displayed schedule has been replayed.*
7. *H records componentwise* hsame *transport for S, T, μ, F, R, E and for the continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a target tolerance request through the threshold schedule μ, the source window S, the transformer row F, the target window T, the regular readbacks R, and the seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common finite source-window, target-window, threshold, transformer, readback, and seal surface. It has no coordinate for quotient streams, host function equality, selected limits, compactness, a uniform modulus, or ambient completeness.

Theorem 1486.2 (Cauchy modulus of continuity NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier $K = (S, T, \mu, F, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed source windows, target windows, threshold schedule, transformer row, regular readbacks, seal row, transport, continuation, provenance, and local name;*
2. *classifier transport to a common* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *finite surface;*
3. *stability of S, T, μ, F, R, E under the componentwise* hsame *rows recorded in H;*
4. *exactness of μ as the only threshold route read by the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *consumer;*
5. Cont *replay,* Pkg *provenance,* $\mathsf{Real}^{\uparrow}$ *seal factorization, and local NameCert rows for exactly the displayed packet.*

No NameCert obligation is stored outside those five rows.

Proof. Project the carrier of Definition 1486.1. The projection exposes exactly the source windows, target windows, threshold schedule, transformer row, regular readbacks, real seal, transport rows, continuation rows, provenance row, and local name.

Classifier transport is componentwise. The rows in H move the source and target windows, the threshold schedule, the transformer row, the readbacks, and the seal row to the same displayed finite surface.

The threshold exactness row is exhausted by μ. The transformer row F reads a target tolerance by first reading the schedule μ, then inspecting the named source windows S, and then producing the target windows T.

Finally replay C and attach P, N. These rows route, source, and name the already displayed packet; they do not introduce quotient streams, host function equality, selected limits, compactness, a uniform modulus, or ambient completeness. Hence the five listed rows exhaust the local naming obligations. □

Lean4 ✓ `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityCarrier namecert obligations`

Theorem 1486.3 (CauchyContinuousMap threshold handoff)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier $K = (S, T, \mu, F, R, E, H, C, P, N)$, the displayed schedule μ is the only threshold route used by a* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *consumer. Any read of the target window T must pass through the source window S, the schedule μ, the transformer row F, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R, and the displayed* Cont, Pkg, *and local* NameCert *rows.*

Proof. Start with a target tolerance request. Carrier admission exposes the schedule μ before the transformer row F can be consumed.

Replay the displayed continuation row C. The route sends the tolerance request to μ, obtains the finite source-window threshold, reads the corresponding source observations in S, and then lets F produce the target windows T.

The readback row R is reached only after that transformer route. Transport through H preserves the same order of dependencies, and P, N merely record provenance and local naming.

Since the carrier contains no second threshold coordinate, no quotient stream, and no host function row, a $\mathsf{CauchyContinuousMap}^{\uparrow}$ consumer has no alternate route by which to obtain T. □

Lean4 ✓ `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityCarrier cauchy continuous map threshold handoff`

Theorem 1486.4 (Cauchy modulus of continuity scoped route)**.** *Every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *read factors through the* $\mathsf{StreamName}^{\uparrow}$ *source and target windows, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule, the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *transformer, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any compact-uniform consumer may read it. The route exports exactly the pointwise Cauchy-name continuity surface over $S, T, \mu, F, R, E, H, C, P, N$, with no compactness coordinate, uniform modulus over all inputs, host function equality, quotient stream equality, selected-limit witness, or ambient completeness principle.*

Proof. Start from the carrier definition Definition 1486.1. It fixes the finite rows $S, T, \mu, F, R, E, H, C, P, N$ and gives the packet no coordinate outside source windows, target windows, threshold schedule, transformer route, regular readbacks, real seal, transport, replay, provenance, and local naming.

Apply the NameCert obligations of Definition 1486.2. They bind carrier admission, classifier transport, componentwise stability, threshold exactness, replay, provenance, seal factorization, and local naming to those same rows.

Use the CauchyContinuousMap threshold handoff of Definition 1486.3. Any target-window read must pass through S, μ, F, T, R before reaching the structural rows, so a compact-uniform consumer cannot bypass the displayed pointwise schedule.

Finally read the $\mathsf{Real}^{\uparrow}$ seal through E and the structural rows H, C, P, N. Since the route has no compactness, uniform-modulus, host-function, quotient-stream, selected-limit, or ambient-completeness coordinate, the listed rows form the scoped route for every accepted consumer read. □

Lean4 ✓ `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityCarrier scoped route`

Theorem 1486.5 (Cauchy modulus of continuity finite-window monotonicity)**.** *Let $K = (S, T, \mu, F, R, E, H, C, P, N)$ and $K^+ = (S, T^+, \mu^+, F, R^+, E^+, H^+, C^+, P^+, N^+)$ be accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carriers with the same source window S, the same transformer row F, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and the same* $\mathsf{Real}^{\uparrow}$ *seal route. Suppose that, for one displayed target tolerance, the schedule μ^+ asks for a larger finite source-window bound than μ while preserving the transformer, readback, and seal rows. Then every target-window read admitted by K through μ is also admitted by K^+ through μ^+, using the same* Cont, Pkg, *and local* NameCert *rows after the larger source-window inspection is replayed.*

Proof. Project both carriers with Definition 1486.1. The shared rows identify the same source window, transformer route, regular-rational readback route, and real-seal route; only the displayed source-window threshold is enlarged.

Use the threshold handoff of Definition 1486.3. It says that a target-window read has a unique displayed route through the schedule before the transformer row F can produce T.

Replay the larger schedule μ^+. Its source-window inspection contains the smaller inspection required by μ and then continues through the same transformer, readback, and seal rows. Thus the target-window read admitted by K is admitted again by K^+ after the larger finite source window has been displayed.

Finally transport through H^+ and attach C^+, P^+, N^+. These rows preserve the same continuation, provenance, and local NameCert route, so the enlarged schedule creates no alternate host function, quotient stream, selected limit, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityCarrier window monotonicity`

Theorem 1486.6 (Cauchy modulus of continuity schedule stability)**.** *Let $K = (S, T, \mu, F, R, E, H, C, P, N)$ and $K' = (S', T', \mu', F', R', E', H', C', P', N')$ be accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carriers. Suppose the S, T, F, R, E rows of K and the S', T', F', R', E' rows of K' are related componentwise by the displayed H, H'* hsame *transports, and suppose μ and μ' answer the same target tolerance with transported finite source-window bounds. Then every target-window read admitted through μ is admitted through μ' after displayed* Cont *replay, with the same* Pkg *and local* NameCert *route.*

Proof. Project both carriers through Definition 1486.1. The displayed rows expose only the source windows, target windows, schedules, transformer rows, readback rows, Real seals, transport, replay, provenance, and local naming data.

Use the componentwise transports H and H'. They identify the S, T, F, R, E surface of K with the S', T', F', R', E' surface of K' at the transported finite source-window and target-window bounds.

Replay C and C' through the schedules before reading the transformer row. The schedule rows μ and μ' answer the same target tolerance, so the target-window request reaches the transformer surface only after the matching finite source-window inspection has been displayed.

Apply the threshold handoff of Definition 1486.3 and the finite-window monotonicity of Definition 1486.5. They keep the admitted target-window read inside the transported schedule route and allow the replay to use the transported finite source-window bound.

Finally attach the same provenance and local naming route. No quotient stream, host function equality, selected limit, compactness, or completeness coordinate is introduced, so schedule transport preserves the accepted read. □

Theorem 1486.7 (Cauchy modulus of continuity Real consumer boundary)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier $K = (S, T, \mu, F, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$ *consumer factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R and the* $\mathsf{Real}^{\uparrow}$ *seal row E. The consumer surface exposes only the source and target windows, the schedule μ, the transformer row F, the readbacks R, the seal E, and the recorded* hsame, Cont, Pkg, *and* NameCert *rows; it exposes no quotient stream, host function equality, selected limit, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityRealConsumerBoundary`

Proof. Read the carrier inventory. The only real-facing coordinate is E, and it is listed as the seal row reached from the target $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the handoff theorem Definition 1486.3. It shows that the target readback has already passed through S, μ, F, and T before R can be consumed by a real-facing route.

Replay the seal route through C and transport it through H. The package row P and the local name N certify that the same displayed finite rows source the read.

Thus every $\mathsf{Real}^{\uparrow}$ consumer factors through R and E. The packet has no coordinate from which to read a quotient stream, host function equality, selected limit, or ambient completeness principle. □

Theorem 1486.8 (Cauchy modulus of continuity obligation-closure package)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier* $K = (S, T, \mu, F, R, E, H, C, P, N)$*, the carrier definition, the local NameCert obligations, the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *threshold handoff, finite-window monotonicity, and the* $\mathsf{Real}^{\uparrow}$ *consumer boundary jointly supply the full obligation surface over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{CauchyContinuousMap}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package exposes exactly the displayed source windows, target windows, threshold schedule, transformer route, regular readbacks, real seal, transport rows, continuation replay, provenance, and local naming data.*

Proof. Start with Definition 1486.1. It fixes the tuple $K = (S, T, \mu, F, R, E, H, C, P, N)$ and states that every visible coordinate is one of the named BEDC rows.

Apply Definition 1486.2. The local NameCert surface is exhausted by carrier admission, classifier transport, componentwise stability, threshold-route exactness, replay, provenance, seal factorization, and local naming.

Use Definition 1486.3 and Definition 1486.5 for the consumer side. They force every target-window read to pass through S, μ, F, T, R and show that enlarging a finite source window preserves the same displayed route.

Finally apply Definition 1486.7. The real consumer reaches only the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal after the threshold route has been replayed. Hence the package excludes uniform continuity, compactness, quotient streams, host function equality, selected limits, and ambient completeness. □

Theorem 1486.9 (Cauchy modulus of continuity obligation exactness)**.** *For every accepted* CauchyModulusOfConti *carrier* $K = (S, T, \mu, F, R, E, H, C, P, N)$*, every* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reads the same displayed threshold schedule* μ*, source window* S*, transformer row* F*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E*. The obligation surface has no alternate compactness coordinate, host function equality row, selected-limit witness, or second uniform-modulus coordinate.*

Proof. Project the carrier of Definition 1486.1. The rows $S, T, \mu, F, R, E, H, C, P, N$ are the only visible coordinates, so any consumer read begins with the displayed schedule, window, transformer, readback, and seal surface.

Use Definition 1486.2. Its local NameCert clauses bind carrier admission, classifier transport, threshold route exactness, replay, provenance, and local naming to those same rows.

Apply the threshold handoff of Definition 1486.3, the finite-window monotonicity of Definition 1486.5, and the schedule stability of Definition 1486.6. Together they force every $\mathsf{CauchyContinuousMap}^{\uparrow}$ threshold read to pass through μ, S, F, T, and R with the same transported finite-window route.

Finally apply Definition 1486.7. The $\mathsf{Real}^{\uparrow}$ consumer can reach the seal only after the readback route has passed through the displayed threshold schedule, so no compactness, host function equality, selected-limit, or alternate uniform-modulus row is available. □

Theorem 1486.10 (Cauchy modulus threshold transport)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier* $K = (S, T, \mu, F, R, E, H, C, P, N)$*, the displayed threshold schedule* μ *is transported through the* $\mathsf{StreamName}^{\uparrow}$ *source window* S*, the target* $\mathsf{StreamName}^{\uparrow}$ *window* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance discipline used by those readbacks, and the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *transformer row* F *before any Real-facing consumer reads the seal row* E*.*

Proof. Project the carrier of Definition 1486.1. The threshold schedule μ is displayed between the source and target finite-window rows and the transformer row, so it is visible before the regular rational readback and the Real seal.

Apply the NameCert obligations of Definition 1486.2. They bind carrier admission, classifier transport, componentwise stability, and threshold-route exactness to the same finite surface.

Use the handoff theorem Definition 1486.3. It forces each target-window read to pass through S, μ, F, T, R before the Real consumer can reach E. □

Theorem 1486.11 (Cauchy modulus Real seal nonescape)**.** *For every accepted* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *carrier* $K = (S, T, \mu, F, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is reachable only after the modulus row* μ*, threshold route, finite-window rows* S, T*, readback row* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N *have been displayed.*

Proof. Start from Definition 1486.7. It places every Real-facing read behind the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks and the seal row of the same carrier.

Now use threshold transport from Definition 1486.10. The target readback cannot appear before S, μ, F, T and the dyadic tolerance route used by R are visible.

Finally read the structural rows H, C, P, N. They transport, replay, source, and name the already displayed threshold route; none supplies a bypass around μ, F, R or a detached Real seal. □

Theorem 1486.12 (Cauchy modulus local NameCert surface)**.** *The rows*

$$S, T, \mu, F, R, E, H, C, P, N$$

exhaust the local $\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}$ *obligations for an accepted packet. The packet excludes host continuity, selected limits, quotient stream equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the finite tuple in Definition 1486.1. Its coordinates are exactly the source and target windows, threshold schedule, transformer, readbacks, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1486.2, Definition 1486.10, and Definition 1486.11. Together they show that carrier admission, classifier transport, threshold-route exactness, Real-seal factorization, transport, replay, provenance, and local naming are all read from the displayed rows.

Since the carrier contains no host continuity predicate, selected limit, quotient stream, countable-choice schedule, or ambient completeness row, those objects are outside the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ packet is generated from source and target $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{CauchyModulus}^{\uparrow}$ threshold schedule for each requested target tolerance, a $\mathsf{CauchyContinuousMap}^{\uparrow}$ transformer row, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1486.1, Definition 1486.2, Definition 1486.4, and Definition 1486.12 bind the local route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows for the pointwise Cauchy-name continuity surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusOfContinuity}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.CauchyModulusOfContinuityUp.CauchyModulusOfContinuityCarrier\_cauchy\_continuous\_map\_`

Bridge status: none

Not claimed: This chapter does not close uniform continuity, compactness, quotient stream equality, host function equality, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public-object surface for the same $S, T, \mu, F, R, E, H, C, P, N$ threshold handoff and its Real-consumer reads.

Chapter 1487

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$

Following Bishop and Bridges' constructive-analysis treatment of regular Cauchy names, the $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ packet records explicit finite tail-estimate data before a $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits between the dyadic tolerance surface of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the real seal of chapter 38, and the modulus-facing route of chapter 1423. The packet names the finite rows a consumer must inspect for a requested tail tolerance; it is not a quotient stream, a selected limit, a host real equality principle, or an ambient completeness theorem.

Definition 1487.1 (Regular Cauchy tail estimate carrier)**.** *A* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus-threshold row. For each requested tail tolerance it records the finite index after which the regular Cauchy estimate is allowed to be read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose finite observations are inspected at and beyond the threshold stored in M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic error budget used by the tail estimate.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the window W under the threshold and tolerance rows M, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that may be consumed only after the threshold, window, tolerance, and regular readback rows have been replayed.*
6. *H records componentwise* hsame *transport for M, W, D, R, E and for the continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through M, W, D, R, and then E.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting the displayed modulus threshold, finite window, dyadic tolerance, regular readback, real seal, continuation, provenance, and local naming rows to a common finite surface. It has no coordinate for quotient streams, host real equality, selected limits, choice, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateTasteGate single carrier alignment`

Theorem 1487.2 (Regular Cauchy tail estimate NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed modulus threshold, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local name;*
2. *classifier transport to a common* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *finite surface;*
3. *stability of* M, W, D, R, E *under the componentwise* hsame *rows recorded in* H*;*
4. *seal-route exactness requiring every real-facing read to pass through* M, W, D, R, E *in that order;*
5. *refusal rows excluding quotient streams, host real equality, choice, trichotomy, selected limits, open-cover compactness, and ambient completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateNameCertObligations`

Proof. Project the carrier of Definition 1487.1. The projection exposes exactly the modulus threshold, finite window, dyadic tolerance, regular readback, real seal, transport rows, continuation row, provenance row, and local naming row.

Classifier transport is componentwise. The rows in H move the five mathematical coordinates M, W, D, R, E and the administrative coordinates C, P, N to the same finite comparison surface.

Seal-route exactness is read from the displayed continuation row. A tail tolerance request first reaches the threshold row M, then the finite window W, then the dyadic tolerance row D, then the regular readback R, and only then the real seal E.

The refusal rows are exhausted by the carrier inventory. Since the packet has no coordinate for quotient stream equality, host real equality, choice, trichotomy, selected limits, open-cover compactness, or completeness, no local NameCert obligation can export those data. □

Theorem 1487.3 (Regular Cauchy tail estimate Real seal route)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal consumer of* E *factors through the modulus threshold* M*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* E *before it can inspect the transport, continuation, provenance, and local naming rows* H, C, P, N*. No consumer route can bypass* M, W, D, R, E *or read a quotient stream, a selected host limit, host real equality, choice, trichotomy, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier real seal route`

Proof. Start with a real-facing consumer of E. Carrier admission lists E only as the seal row reached from the regular readback coordinate R.

Replay the continuation row C. Its route sends a tolerance request first to the threshold row M, uses M to choose the finite window reads in W, checks the dyadic tolerance row D, and then reaches the regular readback R.

Transport through H preserves this order of displayed dependencies. The package row P and local name N record provenance and naming for the same finite packet; they do not add a second seal coordinate.

Thus every $\mathsf{Real}^{\uparrow}$ seal consumer factors through M, W, D, R, E before H, C, P, N. The carrier contains no coordinate from which a bypass route could obtain quotient streams, selected limits, host equality, choice, trichotomy, open-cover compactness, or completeness. □

Definition 1487.4 (Regular Cauchy tail estimate tail-envelope lock)**.** *The tail-envelope lock of an accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$ *is the displayed route*

$$M, W, D, R \longmapsto \mathsf{RegularCauchyTailEnvelope}^{\uparrow}$$

that reads the modulus threshold, finite $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the* $\mathsf{Real}^{\uparrow}$ *seal row is inspected. The lock records that the Real-seal route is available only after the finite tail-envelope surface has been exposed.*

Theorem 1487.5 (Regular Cauchy tail estimate tail-envelope lock)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, any consumer that exposes the* $\mathsf{Real}^{\uparrow}$ *seal row* E *must first expose the finite tail-envelope route through* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*. No selected limit, quotient stream, countable-choice schedule, host equality, open-cover compactness, or ambient completeness principle can replace that route.*

Proof. Project the carrier of Definition 1487.1. The rows M, W, D, R, E are the displayed mathematical coordinates, and E occurs only after the threshold, window, tolerance, and regular readback rows.

Apply Definition 1487.2. The local certificate forces classifier transport and stability for M, W, D, R, E componentwise, so the tail estimate cannot detach the seal row from the finite tail data.

Now apply Definition 1487.3. Every real-facing read of E factors through M, W, D, R before the structural rows H, C, P, N are inspected. The definition of the tail-envelope lock identifies that preceding route with the $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ handoff.

Since none of the excluded objects is a coordinate of the carrier, no bypass can replace the finite envelope route. The seal remains downstream of the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier tail envelope lock`

Theorem 1487.6 (Regular Cauchy tail estimate tail dominance)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$ *whose tail-envelope route is locked, every later* $\mathsf{Real}^{\uparrow}$*-facing comparison exposed by the packet is dominated by the displayed finite tail surface. The comparison can read only the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the tail-envelope row, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *row* N*.*

No later comparison exports a host limit, quotient stream equality, selected tail, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier tail dominance`

Proof. Project the carrier of Definition 1487.1. The only Real-facing seal coordinate is E, and Definition 1487.3 places every read of E downstream of the threshold, window, tolerance, and regular readback rows M, W, D, R.

Apply Definition 1487.5. The lock identifies that preceding route with the finite tail-envelope surface through $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$, so any later comparison must reuse the same displayed window, tolerance ledger, and readback.

The structural rows do not loosen the dominance claim. The transport row H moves only the displayed coordinates, the replay row C preserves the same route, and P, N record provenance and local naming for that finite packet.

Thus every later $\mathsf{Real}^{\uparrow}$-facing comparison remains dominated by the displayed tail surface. Since no host limit, quotient stream equality, selected tail, or ambient completeness coordinate occurs in the carrier, none can be exported. □

Theorem 1487.7 (Regular Cauchy tail estimate tail-induction scope)**.** *For every accepted* RegularCauchyTailEstima *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, induction over displayed finite tail windows preserves the route*

$$M, W, D, R, E, H, C, P, N.$$

The threshold row M and dyadic tolerance row D supply the modulus and tolerance scope before any $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R or* $\mathsf{Real}^{\uparrow}$ *seal through E is visible. The induction is confined to displayed finite windows in W and exports no quotient streams, selected limits, choice, trichotomy, open-cover compactness, ambient completeness, or independent Real seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier tail induction scope`

Proof. Start with the carrier definition, Definition 1487.1. The only rows available to a finite tail-window induction are the threshold, window, dyadic tolerance, readback, seal, transport, replay, provenance, and local naming rows $M, W, D, R, E, H, C, P, N$.

Apply the Real-seal route, tail-envelope lock, and tail dominance results. Theorems Definition 1487.3, Definition 1487.5, and Definition 1487.6 force every step to read M, W, D before R and to keep the terminal seal E downstream of the same finite tail-envelope route.

For the induction step, extend only the displayed finite window row W while keeping the same M, D, R, E, H, C, P, N surface. Since the carrier has no quotient stream, selected limit, choice, trichotomy, open-cover compactness, ambient-completeness, or second-seal coordinate, the induction preserves exactly the displayed route. □

Theorem 1487.8 (Regular Cauchy tail estimate dyadic-modulus scope)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, any Real-facing or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing reader of the tail estimate must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *row N.*

The dyadic modulus exposed by M, D is therefore scoped to the displayed finite tail-envelope route, and it exports no selected limit, quotient stream, countable-choice schedule, host equality, open-cover compactness, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier dyadic modulus scope`

Proof. Project the carrier of Definition 1487.1. The rows $M, W, D, R, E, H, C, P, N$ are the only coordinates available to a reader of the accepted tail estimate.

Apply Definition 1487.2. The local NameCert surface binds carrier admission, classifier transport, componentwise stability, seal-route exactness, and refusal rows to that same finite packet.

Use Definition 1487.3 to place the Real-facing read downstream of the modulus threshold, stream window, dyadic tolerance, and regular readback rows. A $\mathsf{RegSeqRat}^{\uparrow}$-facing reader reaches the same R only after M, W, D have been displayed.

Finally apply Definition 1487.5. The lock identifies the route through $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ as the required envelope before the seal is exposed, so selected limits, ambient completeness, and the other excluded coordinates are not exported. □

Theorem 1487.9 (Regular Cauchy tail difference)**.** *Let $T_0 = (M_0, W_0, D_0, R_0, E_0, H_0, C_0, P_0, N_0)$ and $T_1 = (M_1, W_1, D_1, R_1, E_1, H_1, C_1, P_1, N_1)$ be accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carriers. Suppose the threshold and dyadic tolerance rows are transported to a common finite surface, $M_0 \mathsf{hsame} M_1$ and $D_0 \mathsf{hsame} D_1$, and suppose both packets display their* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal routes through those transported rows. Then the finite comparison of the two tails is read through*

$$M_i, W_i, D_i, R_i, E_i, H_i, C_i, P_i, N_i$$

for $i = 0, 1$, together with the shared transported M, D surface.

The comparison exports no selected limit, quotient stream equality, host real equality, countable-choice schedule, open-cover compactness coordinate, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier tail difference`

Proof. Project the two accepted carriers. The only rows available to the comparison are the two displayed threshold, window, tolerance, readback, seal, transport, replay, provenance, and naming packets.

Transport the threshold and tolerance rows through the given hsame data. After this transport, both packets read their tail windows over the same finite M, D surface.

Replay the continuation rows C_0 and C_1. For each packet, the read passes through the displayed $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any Real-facing comparison is public.

Finally use Definition 1487.3 and Definition 1487.8. These results force both seal reads to remain behind the transported dyadic-modulus route, so the tail difference is a finite two-packet comparison rather than a selected limit or quotient-stream equality. □

Theorem 1487.10 (Regular Cauchy tail estimate window triangle)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier $T = (M, W, D, R, E, H, C, P, N)$, any two tail-window reads that share the displayed* $\mathsf{StreamName}^{\uparrow}$ *window W and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D compose through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row E. The composed read may use the threshold row M, the tail-envelope lock, tail dominance, dyadic-modulus scope, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *row N.*

It exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, quotient stream equality, selected limit, host real equality, countable-choice schedule, open-cover compactness coordinate, or second terminal seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier window triangle`

Proof. Start with two accepted tail-window reads sharing W and D. By Definition 1487.8, each read must expose the same finite window row and dyadic tolerance ledger before any $\mathsf{RegSeqRat}^{\uparrow}$-facing or $\mathsf{Real}^{\uparrow}$-facing coordinate is inspected.

Apply the tail-envelope lock of Definition 1487.5. The lock places both reads inside the route through $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$, so their common W, D surface has only the displayed readback row R available downstream.

Use tail dominance from Definition 1487.6. Any later Real-facing comparison remains dominated by the same finite tail surface, and the structural rows H, C, P, N only transport, replay, package, and name that surface.

Finally use the Real-seal route of Definition 1487.3. Since every read of E factors through M, W, D, R in order, the two tail-window reads compose through the same readback row R and terminal seal E.

The refused principles have no coordinate in the carrier. Ambient Real completeness, quotient stream equality, selected limits, host equality, choice, open-cover compactness, and a second terminal seal therefore cannot replace the finite window triangle. □

Theorem 1487.11 (Regular Cauchy tail estimate window monotone nesting)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$ *with two displayed finite tail windows where the second refines the first, every consumer must route the coarser read through the same* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, tail-envelope lock, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route* E *before reading the refined estimate. The refinement adds only visible tolerance rows and displayed finite-window rows inside the same packet.*

It cannot create a quotient stream, selected limit, host convergence predicate, second terminal seal, open-cover compactness coordinate, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateWindowMonotoneNesting`

Proof. Project the carrier of Definition 1487.1. The displayed rows $M, W, D, R, E, H, C, P, N$ are the only rows available to both finite windows, and the refinement hypothesis only adds rows admitted by the same W and D.

Apply the tail-envelope lock of Definition 1487.5. The coarser read must expose the route through $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before the seal row E is inspected.

Use tail dominance and dyadic-modulus scope, Definition 1487.6 and Definition 1487.8. These rows force both the coarser and refined reads to keep the same displayed window, tolerance ledger, readback, transport, replay, provenance, and local naming surface.

Finally apply the window triangle theorem, Definition 1487.10. Since the two reads share the same finite window route and dyadic tolerance ledger, the refined read composes after the coarser read through the same R and E coordinates. The extra rows are visible finite refinements, not new quotient, choice, convergence, compactness, or completeness coordinates. □

Theorem 1487.12 (Regular Cauchy tail estimate obligation scope)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, the obligation-closure surface is exactly the displayed rows* $M, W, D, R, E, H, C, P, N$ *together with the routes already cited through* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The surface refuses selected limits, quotient streams, countable choice, host equality, open-cover compactness, and ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier obligation scope`

Proof. Project the carrier of Definition 1487.1. Its rows are precisely the modulus threshold, finite window, dyadic tolerance, regular readback, real seal, componentwise transport, displayed replay, provenance, and local naming rows $M, W, D, R, E, H, C, P, N$.

Apply Definition 1487.2. The local certificate binds carrier admission, classifier transport, componentwise stability, seal-route exactness, and refusal rows to the same finite packet.

Use Definition 1487.3, Definition 1487.5, and Definition 1487.8. Together these route every Real-facing or $\mathsf{RegSeqRat}^{\uparrow}$-facing read through $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the seal is consumed.

No additional coordinate remains for selected limits, quotient streams, countable choice, host equality, open-cover compactness, or ambient completeness. Hence the obligation scope is exactly the displayed kernel surface and the named sibling routes. □

Theorem 1487.13 (Regular Cauchy tail estimate obligation register)**.** *For every accepted* $\mathsf{RegularCauchyTailEstima}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, the carrier of Definition 1487.1, the NameCert obligations of Definition 1487.2, the Real seal route of Definition 1487.3, the tail-envelope lock of Definition 1487.5, the tail dominance row of Definition 1487.6, and the dyadic-modulus scope of Definition 1487.8 form the obligationClosure register for* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$*.*

The register exports only the displayed rows $M, W, D, R, E, H, C, P, N$ *and the named routes through* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier obligation register`

Proof. Carrier admission is the finite packet of Definition 1487.1. The local certificate rows are exactly the obligation surface listed in Definition 1487.2.

The Real-facing dependency route is fixed by Definition 1487.3. Its tail-envelope lock and later comparison dominance are supplied by Definition 1487.5 and Definition 1487.6.

Finally, Definition 1487.8 binds the dyadic tolerance and modulus rows to the same finite packet. Together these cited rows account for the carrier, route, stability, dominance, and refusal obligations, so the displayed surface is the obligationClosure register. □

Theorem 1487.14 (Regular Cauchy tail estimate finite precision induction)**.** *Let* $T = (M, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier. Suppose* T *exposes a tail estimate at a displayed unary precision window, and suppose the next precision window is admitted by the same* $\mathsf{StreamName}^{\uparrow}$ *row* W*. Then the estimate refines through the same* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row* M*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ *route, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

The refinement is obtained by induction on the displayed finite precision-window extension. It does not use host $\mathbb{N}$ *recursion, countable choice, a selected limit, quotient stream equality, host real equality, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier finite precision induction`

Proof. Begin with the displayed precision window already admitted by W. By Definition 1487.8, the corresponding tail estimate must read the dyadic tolerance row D, the stream window W, the regular readback row R, and the terminal seal row E through the modulus data M, D.

For the induction step, append one admitted finite precision window to the displayed StreamName row. The hypothesis says that the appended window is still a row of the same W, so the carrier is not replaced and no new consumer surface is introduced.

Apply Definition 1487.12. The obligation surface remains exactly $M, W, D, R, E, H, C, P, N$ together with the named sibling routes through $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Thus each finite extension step refines the estimate through the same modulus, dyadic, readback, tail-envelope, and Real rows. Since the induction ranges only over the displayed finite extension, it never invokes host natural-number recursion, choice, selected limits, quotient streams, host equality, open-cover compactness, or ambient completeness. □

Theorem 1487.15 (Regular Cauchy tail estimate obligation basis)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, the carrier row of Definition 1487.1, the local NameCert obligations of Definition 1487.2, the tail-envelope lock of Definition 1487.5, the tail dominance theorem of Definition 1487.6, the dyadic-modulus scope of Definition 1487.8, the window triangle of Definition 1487.10, the obligation scope of Definition 1487.12, and the finite precision induction of Definition 1487.14 exhaust the finite NameCert obligation basis for* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$*.*

Consequently every L10 Real and Completion consumer reads the packet only through the displayed rows $M, W, D, R, E, H, C, P, N$ *and the named sibling routes through* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. No additional obligation row remains for quotient streams, selected limits, countable choice, host equality, open-cover compactness, or ambient completeness.*

Proof. Start with carrier admission. The carrier definition exposes exactly the threshold, window, dyadic tolerance, regular readback, real seal, transport, replay, provenance, and local naming rows, and the NameCert obligations assign carrier admission, classifier transport, componentwise stability, seal-route exactness, and refusal to those rows.

Next use the tail-envelope lock and tail dominance theorems. They force each real-facing comparison through the finite route from M, W, D, R to $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ before the seal row E is consumed.

The dyadic-modulus scope and window triangle then account for all tolerance and window reads. They show that shared finite windows, dyadic ledgers, and regular readback rows compose through the same terminal seal rather than through a second completion or quotient coordinate.

Finally apply the obligation scope and finite precision induction. The obligation scope lists the full sibling route surface, while the induction shows that finite precision extensions stay inside the same packet. These rows cover every displayed obligation named by the carrier, so the packet has no further NameCert basis outside the cited surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateObligationBasis`

Theorem 1487.16 (Regular Cauchy tail estimate RegSeqRat handoff)**.** *For every accepted* $\mathsf{RegularCauchyTailEstim}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, any completion-facing consumer must first expose the handoff route*

$$D, W, R, E, H, C, P, N.$$

Thus the consumer reads the dyadic tolerance row, the $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg

provenance, and the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEstimate}^{\uparrow}}$ *row before any completion-facing tail estimate is public.*

The route exports no quotient stream, selected limit, countable-choice schedule, host equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateRegSeqRatHandoff`

Proof. Begin with the Real seal route of Definition 1487.3. It places every seal-facing read behind the threshold row M, finite window W, dyadic tolerance row D, and regular readback row R before E is consumed.

Use the dyadic-modulus scope and window triangle, Definition 1487.8 and Definition 1487.10. These results keep the dyadic tolerance ledger and shared finite windows attached to the same $\mathsf{RegSeqRat}^{\uparrow}$ readback row, so the consumer cannot detach the tail estimate from D, W, R.

Next apply monotone nesting, Definition 1487.11. Refining a finite tail window stays inside the same packet and adds only displayed tolerance and window rows before the readback and seal are replayed.

Finally invoke the obligation basis of Definition 1487.15. It exhausts the available NameCert rows by $M, W, D, R, E, H, C, P, N$ and the named sibling routes, so completion-facing consumers receive only the displayed RegSeqRat-to-Real handoff and none of the excluded completion principles. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCarrier regseqrat handoff`

Theorem 1487.17 (Regular Cauchy tail estimate modulus-dominance criterion)**.** *For every accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier* $T = (M, W, D, R, E, H, C, P, N)$*, the finite precision induction of Definition 1487.14 and the window monotone nesting of Definition 1487.11 produce a modulus-dominance witness for the displayed tail route. Consequently every later* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison consuming* R *or* E *is bounded by the displayed* M, W, D *tail route.*

No selected limit, quotient stream, trichotomy branch, choice schedule, open-cover compactness row, or ambient completeness principle may replace that dominance witness.

Proof. Start with the Real seal route of Definition 1487.3. It places every consumer of E behind the threshold row M, finite window row W, dyadic tolerance row D, and regular readback row R.

Apply the tail-envelope lock and dyadic-modulus scope, Definition 1487.5 and Definition 1487.8. These rows identify the route through M, W, D, R as the finite tail surface that every $\mathsf{RegSeqRat}^{\uparrow}$-facing or $\mathsf{Real}^{\uparrow}$-facing read must expose.

Use window monotone nesting together with finite precision induction. Refining a displayed window remains inside the same W row and extends only the finite precision data already governed by M and D, so each later comparison carries the same modulus-dominance witness.

Finally invoke the RegSeqRat handoff of Definition 1487.16. The carrier inventory contains no coordinate for selected limits, quotient streams, trichotomy, choice, open covers, or ambient completeness, so the ledger refusal leaves only the displayed M, W, D route available to consumers of R or E. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateModulusDominanceCriterion`

Theorem 1487.18 (Regular Cauchy tail estimate public interface)**.** *Every consumer of a Real-facing tail estimate through an accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier*

$$T = (M, W, D, R, E, H, C, P, N)$$

must read the estimate through the dyadic tolerance surface D, finite $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the modulus-dominance row of Definition 1487.17. This public route is the only exported interface for completion-facing consumers.*

The interface exports no quotient stream, selected limit, countable-choice schedule, trichotomy branch, host real equality, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimatePublicInterface`

Proof. Begin with the Real seal route of Definition 1487.3. It places every consumer of the terminal seal E behind the threshold row M, finite window row W, dyadic tolerance row D, and regular readback row R.

Apply tail dominance and the window triangle, Definition 1487.6 and Definition 1487.10. These theorems keep the displayed dyadic tolerance ledger and compared windows attached to the same regular readback before any Real-facing read is allowed.

Use window monotone nesting and the RegSeqRat handoff, Definition 1487.11 and Definition 1487.16. Refining a tail window remains inside the same carrier, and the handoff exposes R only through the displayed M, W, D rows before the seal E is read.

Finally invoke the modulus-dominance criterion of Definition 1487.17. It supplies the reusable dominance witness for later $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ comparisons, while the carrier inventory excludes quotient streams, selected limits, choice schedules, trichotomy, host equality, open covers, and ambient completeness. □

Theorem 1487.19 (Regular Cauchy tail estimate public tail export)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *carrier*

$$T = (M, W, D, R, E, H, C, P, N)$$

must read the public tail route

$$M, W, D, R, E, H, C, P, N$$

through $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any completion seal is visible. The route exports the finite tail estimate and its modulus-dominance witness; it exports no quotient stream, selected limit, countable-choice schedule, host real equality, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the public interface of Definition 1487.18. It requires every Real-facing tail estimate to pass through the dyadic tolerance surface, finite StreamName windows, RegSeqRat readback, terminal Real seal, and the displayed modulus-dominance row.

Next use the tail-envelope lock and Real seal route, Definition 1487.5 and Definition 1487.3. These theorems keep the threshold row M, window row W, tolerance row D, readback row R, and seal row E in the same finite packet before any completion-facing read is exposed.

Finally apply the modulus-dominance criterion and RegSeqRat handoff, Definition 1487.17 and Definition 1487.16. They identify the reusable dominance witness and force the structural rows H, C, P, N to travel with the same route, while the carrier inventory excludes quotient streams, selected limits, choice schedules, host equality, open covers, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimatePublicTailExport`

Theorem 1487.20 (Regular Cauchy tail estimate completion consumer route)**.** *Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion consumer that cites the public* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *interface must consume the public tail export of Definition 1487.19. In particular the consumer sees $M, W, D, R, E, H, C, P, N$*

as one finite route through RealCauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *not as a detached completion seal or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimateCompletionConsumerRoute`

Proof. Apply the public tail export. It already lists the finite rows and sibling route that every completion-facing read must expose before the seal row is visible.

The public interface of Definition 1487.18 supplies the same route as the exported interface for Real-facing consumers. Therefore a later RegSeqRat$^{\uparrow}$ or Real$^{\uparrow}$ chapter can cite this theorem as its completion-consumer entrance without adding quotient streams, selected limits, choice, host equality, open covers, or ambient completeness. □

Theorem 1487.21 (Regular Cauchy tail estimate diagonal-tail fusion)**.** *Any diagonal-limit consumer that cites* RegularCauchyTailEstimate$^{\uparrow}$ *must fuse the displayed route*

$$M, W, D, R, E, H, C, P, N$$

with its finite diagonal-budget route before any Real$^{\uparrow}$ *seal is consumed. The fused route reads the public tail export, the completion consumer route, the* RegSeqRat$^{\uparrow}$ *handoff, and the modulus-dominance criterion as one finite tail-to-diagonal surface. It exports no quotient streams, selected limits, countable choice, host real equality, open-cover compactness, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the public tail export of Definition 1487.19. It exposes the finite route $M, W, D, R, E, H, C, P, N$ through RealCauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before any completion seal is visible.

Apply the completion consumer route, Definition 1487.20. A later diagonal-limit chapter may enter the tail-estimate interface only by consuming that public route, not by reading a detached Real$^{\uparrow}$ seal or an ambient completion theorem.

Next use the RegSeqRat handoff of Definition 1487.16. It keeps the dyadic tolerance row, finite StreamName windows, regular readback, terminal seal, transport, replay, provenance, and local naming rows in the same completion-facing packet.

Finally apply the modulus-dominance criterion of Definition 1487.17. The criterion bounds later RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ comparisons by the displayed M, W, D tail route, so a diagonal budget must fuse with this finite surface before the seal E is consumed. Since none of the refused objects is a carrier coordinate, the fused route cannot export quotient streams, selected limits, countable choice, host equality, open-cover compactness, or ambient completeness. □

Closure status for NameCert$_{\text{RegularCauchyTailEstimate}^{\uparrow}}$.

Constructive story: A RegularCauchyTailEstimate$^{\uparrow}$ packet is generated from a RealCauchyModulus$^{\uparrow}$ threshold row, a finite StreamName$^{\uparrow}$ window, a DyadicRatCore$^{\uparrow}$ tolerance row, a RegSeqRat$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailEstimate}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public interface is now bridged by the checked `RegularCauchyTailEstimatePublicInterface` target over the displayed modulus, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailEstimate}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularCauchyTailEstimateUp.RegularCauchyTailEstimatePublicInterface`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient streams, host real equality, choice, trichotomy, selected limits, open-cover compactness, axiom-purity certification, or bridge checking.

Upgrade path: No further paper-side theory closure remains; bridge checking is the remaining verification-axis work.

Chapter 1488

A Concrete Naming Certificate for $\mathsf{LocatedCompact}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{LocatedCompact}^{\uparrow}$ packet records located compactness as finite net and located-distance data before any Real or Completion consumer may read a compact boundary. It sits between the finite-net discipline of chapter 127, the separated completion seal of chapter 402, the apartness-real boundary of chapter 304, the terminal real-name seal of chapter 38, and the finite-window source of chapter 126. The packet names a constructive L10 boundary object: locatedness and finite nets are displayed rows, while open covers, quotient compacta, host-selected points, and ambient completeness remain outside the carrier.

Definition 1488.1 (LocatedCompact carrier)**.** *A* $\mathsf{LocatedCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, L, F, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact carrier row, naming the inspected metric or real-facing source as a finite BEDC carrier rather than a host compact space;*
2. *L is the locatedness test row, returning for each displayed point-and-radius request the finite comparison data that witnesses whether the request lies inside the located boundary or is apart from it by a recorded margin;*
3. *F is the finite-net witness row, exposing for each positive tolerance a closed* $\mathsf{ProbeBundle}$ *of centers,* $\mathsf{InBundle}$ *membership rows, and coverage distances that factor through the* $\mathsf{TotallyBounded}^{\uparrow}$ *surface of chapter 127;*
4. *A is the apartness and separatedness row, tying the locatedness test to the* $\mathsf{ApartnessReal}^{\uparrow}$ *boundary of chapter 304 and to the separated completion discipline of chapter 402;*
5. *H records componentwise* hsame *transports for carrier, locatedness, finite-net, apartness, separatedness, continuation, provenance, and local naming rows;*
6. *C records displayed* Cont *routes from finite-window requests through chapter 126, the net row F, the locatedness row L, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38;*
7. *P is the* Pkg *provenance over* $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eight displayed rows. It has no coordinate for an open cover, a selected finite subcover, a quotient compactum, host choice, a host completion object, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactTasteGate single carrier alignment`

Theorem 1488.2 (LocatedCompact NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompact}^{\uparrow}$ *carrier* $K = (X, L, F, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed compact carrier row* X *together with its locatedness, finite-net, apartness, transport, continuation, provenance, and naming support;*
2. *locatedness stability, stating that the test row* L *is preserved by the stored* hsame *transports and by the displayed comparison rows reaching the* $\mathsf{Real}^{\uparrow}$ *seal;*
3. *finite-net exposure, stating that each tolerance request reaches only the closed* ProbeBundle, InBundle*, center, radius, and coverage-distance rows displayed in* F*;*
4. *apartness and separatedness compatibility, stating that* A *is the only route from located-distance evidence to the separated completion and apartness-real sibling surfaces;*
5. *ledger exactness for the* Cont *replay,* Pkg *provenance, and local* NameCert *row, with no hidden open-cover, quotient, choice, or ambient-completeness coordinate.*

These obligations name located compactness as a finite BEDC packet over the displayed L10 sibling route, not as a host compact-space principle.

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactNameCertObligations`
↪ variant `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier namecert obligations`

Proof. Project the accepted packet $K = (X, L, F, A, H, C, P, N)$. The projection exposes exactly the compact carrier row, locatedness test, finite-net witness, apartness and separatedness row, componentwise transports, continuation replay, provenance, and local naming row.

The locatedness obligation is componentwise. A transported point-and-radius request is read through H, and the same displayed comparison route in L supplies the inside-or-apart evidence before any $\mathsf{Real}^{\uparrow}$ seal is consumed.

The finite-net obligation is the $\mathsf{TotallyBounded}^{\uparrow}$ handoff. A tolerance request reaches the closed ProbeBundle in F, then reads only its bundled centers, membership constructors, radii, and coverage-distance rows. No external list of centers or selected subcover is present.

The apartness and separatedness obligation uses A as the unique boundary row. It ties the located-distance evidence to the apartness-real and Hausdorff-completion sibling surfaces while preserving the same H, C, P, N support.

Finally, exactness follows from the carrier definition: C replays only the displayed route, P records only the named sibling certificates, and N names the local packet. Since the carrier has no additional coordinate, the five obligations exhaust the local $\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}$ surface. □

Theorem 1488.3 (LocatedCompact totally bounded handoff)**.** *Every accepted* $\mathsf{LocatedCompact}^{\uparrow}$ *carrier exports to compact and complete consumers only the displayed finite-net row* F *and locatedness row* L*, together with the structural support* A, H, C, P, N*. Thus a downstream consumer may read total boundedness through the finite* ProbeBundle *witnesses and may read locatedness through the finite comparison tests, but it receives no open-cover compactness, Heine–Borel theorem, quotient compactum, host choice, or ambient-completeness field.*

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier totally bounded handoff`

Proof. Begin with an accepted carrier $K = (X, L, F, A, H, C, P, N)$. The compact-facing data exposed by the carrier are L and F, and the only structural support rows are A, H, C, P, N.

Read the finite-net handoff through F. The handoff is the same finite-net surface consumed by chapter 127: a positive tolerance request, a closed ProbeBundle of centers, membership constructors, and coverage rows.

Read the locatedness handoff through L. The comparison evidence is attached to the same carrier row X and is transported only by H before the continuation route C reaches the real-facing seal.

The separated and apartness consumers can use A only after those displayed handoffs are present. Since no open-cover, finite-subcover selector, quotient compactum, host-choice row, or ambient-completeness field occurs in the packet, compact and complete consumers receive exactly the finite-net and locatedness rows displayed above. □

Theorem 1488.4 (Located compact finite-net obligation package)**.** *For every accepted* LocatedCompact$^{\uparrow}$ *carrier* $K = (X, L, F, A, H, C, P, N)$*, the finite-net obligation package exposes only finite* ProbeBundle *centers,* InBundle *membership constructors, located-distance comparison rows, and the structural* hsame/Cont *replay stored in* H *and* C*. Thus total-bounded consumers may read the closed net witnesses in* F *and the locatedness comparisons in* L*, but they receive no open-cover compactness, selected finite subcover, host choice, quotient compactum, or ambient-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactFiniteNet rows from obligation surface`

Proof. Project the carrier using Definition 1488.1. The net row F is the only row containing centers, membership, radii, and coverage-distance data, and it is explicitly finite through the displayed ProbeBundle and InBundle constructors.

Use Definition 1488.3 to identify the consumer route. A tolerance request reaches F, reads its finite center and membership rows, and then uses the locatedness row L for the corresponding distance comparisons.

The structural rows do not add compactness principles. Componentwise hsame transport in H preserves the displayed row types, and Cont replay in C replays the same finite-window route. Since no open-cover, finite-subcover selector, quotient compactum, host-choice row, or ambient-completeness field is present, the finite-net obligation package is exhausted by F, L, H, C together with A, P, N. □

Theorem 1488.5 (Located compact Real-window handoff)**.** *Every* Real$^{\uparrow}$*-facing consumer of an accepted* LocatedCompact$^{\uparrow}$ *carrier reads through the* StreamName$^{\uparrow}$ *finite windows, the finite-net row* F*, the locatedness row* L*, and the terminal* Real$^{\uparrow}$ *seal recorded by the displayed continuation route* C*. The handoff exports a located compact window certificate over finite data, not an open-cover compactness principle or a host-selected point.*

Proof. Begin with the continuation row of Definition 1488.1. It routes finite-window requests through chapter 126, then through the finite-net row, the locatedness row, and finally the terminal real seal.

Apply Definition 1488.3. The compact-facing information available to a consumer is the net row F, the locatedness row L, and the structural support A, H, C, P, N.

Now use Definition 1488.4. The finite-net row supplies only closed ProbeBundle centers, membership rows, and coverage-distance data, while the locatedness row supplies only finite comparisons. The real-facing consumer therefore receives a finite Real-window handoff and no open-cover

compactness, host choice, quotient compactum, selected finite subcover, or ambient completeness theorem. □

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier real window handoff`

Theorem 1488.6 (LocatedCompact public finite-net boundary)**.** *The public* LocatedCompact$^{\uparrow}$ *interface exports exactly the finite* ProbeBundle *net data, locatedness comparison rows, apartness and separatedness support,* StreamName$^{\uparrow}$ *windows,* Real$^{\uparrow}$ *seal handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *surface carried by Definition 1488.1. It exports no open-cover compactness theorem, selected finite subcover, quotient compactum, host choice, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier public finite net boundary`

Proof. Project the carrier $K = (X, L, F, A, H, C, P, N)$. The row F is the finite-net surface, L is the locatedness comparison surface, A is the apartness and separatedness support, and C routes the stream windows to the terminal Real seal.

Use Definition 1488.2, Definition 1488.4, and Definition 1488.5. These identify the finite ProbeBundle centers, InBundle memberships, locatedness comparisons, stream-window route, and Real handoff as checked local rows.

The remaining rows H, P, N transport, source, and name the same packet, while Cont replay is already stored in C. Since the carrier has no row for open covers, selected subcovers, quotient compacta, host choice, or ambient completeness, the public boundary is exactly the displayed finite interface. □

Theorem 1488.7 (LocatedCompact public export surface)**.** *The public* LocatedCompact$^{\uparrow}$ *export is exactly the displayed finite-net, locatedness, apartness and separatedness, Real-window,* hsame, Cont, Pkg*, and local* NameCert *surface of Definition 1488.1, Definition 1488.2, Definition 1488.3, Definition 1488.4, and Definition 1488.5. A consumer may read the finite* ProbeBundle *centers and* InBundle *membership rows in F, the locatedness comparisons in L, the apartness and separatedness row A, the terminal* Real$^{\uparrow}$ *window route in C, and the structural rows H, P, N. It may not read an open-cover compactness theorem, selected finite subcover, quotient compactum, host choice, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier public export surface`

Proof. Project the accepted carrier $K = (X, L, F, A, H, C, P, N)$. The carrier definition lists exactly the finite-net row F, locatedness row L, apartness and separatedness row A, componentwise transport row H, continuation row C, provenance row P, and local naming row N.

Use the obligation and handoff theorems cited above. They identify the finite-net, locatedness, Real-window, and structural support read by compact and Real-facing consumers. Since no additional row occurs in the carrier, the public export surface is exhausted by those displayed rows and none of the excluded compactness or completeness principles is exported. □

Theorem 1488.8 (LocatedCompact mature finite-net consumer boundary)**.** *The mature public consumer boundary of an accepted* LocatedCompact$^{\uparrow}$ *carrier is exactly the finite* ProbeBundle *net row, locatedness comparison row, apartness and separatedness support,* StreamName$^{\uparrow}$ *windows, terminal* Real$^{\uparrow}$ *seal handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row displayed by Definition 1488.1. A mature consumer may compose these rows with the TotallyBounded, HausdorffCompletion, ApartnessReal, StreamName, and Real sibling routes, but it*

receives no open-cover compactness theorem, selected finite subcover, quotient compactum, host choice principle, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.LocatedCompactUp.LocatedCompactCarrier mature consumer boundary`

Proof. Combine the public finite-net boundary of Definition 1488.6 with the public export surface of Definition 1488.7. These two surfaces expose the same rows F, L, A, H, C, P, N together with the finite stream windows and terminal real seal route.

The mature consumer has no additional carrier coordinate beyond those rows. Thus any compactness-facing or Real-facing read must pass through the displayed net, locatedness, apartness, separatedness, stream-window, seal, transport, replay, provenance, and local naming data before reaching a sibling route.

Since the carrier has no row for open covers, selected subcovers, quotient compacta, host choice, or ambient completeness, none of those principles can be exported by the mature boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompact}^{\uparrow}$ packet is generated from a compact carrier row, a locatedness test row, a finite ProbeBundle net witness, an apartness and separatedness row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1488.1, Definition 1488.2, Definition 1488.3, Definition 1488.4, Definition 1488.5, Definition 1488.6, Definition 1488.7, and Definition 1488.8 give the mature finite-net consumer boundary through the TotallyBounded, HausdorffCompletion, ApartnessReal, StreamName, and Real sibling routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel as a general theorem, quotient compacta, host choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eight-row carrier and prove the finite NameCert obligation surface and total-bounded handoff theorem.

Chapter 1489

A Concrete Naming Certificate for $\mathsf{IntervalHalving}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{IntervalHalving}^{\uparrow}$ packet records the finite dyadic bisection step used when a displayed interval is routed toward a regular Cauchy or real-completion consumer. It sits after the dyadic endpoint ledger of chapter 291 and before the finite nested-window handoff of chapter 320, with downstream reads through chapter 126, chapter 301, and chapter 38. The packet names one finite halving decision; it does not supply quotient streams, host real equality, selected limits, countable choice, or ambient completeness.

Definition 1489.1 (IntervalHalving carrier)**.** *An* $\mathsf{IntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (L, R, M, B, \rho, S, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row of the parent interval, together with its endpoint-order ledger;*
2. *R is the right* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row of the parent interval, together with the displayed witness that L precedes R;*
3. *M is the midpoint row, computed from the dyadic endpoint ledger and recorded before any predicate-facing half is selected;*
4. *B is the chosen half row, whose tag is either left or right and whose endpoints are respectively (L, M) or (M, R);*
5. *ρ is the radius-halving ledger, displaying that the child width is bounded by half of the parent width at the same dyadic scale;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the endpoint and midpoint observations used by the halving step;*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reading the same dyadic endpoints, midpoint, chosen half, and radius ledger as finite regular-rational data;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row available to completion consumers only through the finite S, Q, ρ route;*
9. *T records componentwise* hsame *transport for the endpoint rows, midpoint row, chosen half row, radius ledger, finite-window row, regular-rational handoff, and real-facing boundary;*

10. *C records visible* Cont *routes by which consumers replay the same halving packet without adding an external selector;*
11. *P is the* Pkg *provenance over* $\mathsf{IntervalHalving}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalHalving}^{\uparrow}}$ *row.*

The carrier exports only this finite dyadic endpoint-to-midpoint-to-half route. It has no coordinate for a quotient stream, host real equality, selected limit, countable choice sequence, or ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.IntervalHalvingUp.IntervalHalvingCarrier`

Definition 1489.2 (IntervalHalving classifier)**.** *Two accepted* $\mathsf{IntervalHalving}^{\uparrow}$ *carriers classify together when their left and right dyadic endpoints, endpoint-order ledgers, midpoint rows, chosen-half tags, chosen-half endpoint rows, radius-halving ledgers, stream windows, regular-rational handoffs, real-facing boundaries, package provenance, and local name rows are connected by the componentwise* hsame *transports and visible* Cont *replays recorded in their transport tables.*

The classifier is finite-window exact: changing a downstream quotient-stream representative, a host real equality proof, a selected limiting point, a countable choice schedule, or an ambient completeness witness is unreadable unless it changes one of the displayed packet rows above.

Lean4 ✓ `BEDC.Derived.IntervalHalvingUp.TasteGate.IntervalHalvingTasteGate single carrier alignment`

Theorem 1489.3 (IntervalHalving NameCert obligations)**.** *For an accepted* $\mathsf{IntervalHalving}^{\uparrow}$ *carrier* $H = (L, R, M, B, \rho, S, Q, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalHalving}^{\uparrow}}$ *surface consists exactly of carrier admission for those twelve rows, dyadic midpoint formation, chosen-half endpoint admission, radius-halving ledger exactness, finite-window readback through* $\mathsf{StreamName}^{\uparrow}$*, regular-rational handoff through* $\mathsf{RegSeqRat}^{\uparrow}$*, real-facing boundary exposure through* $\mathsf{Real}^{\uparrow}$*, componentwise classifier transport, visible consumer replay, package provenance, and local naming.*

Proof. Carrier admission is the tuple displayed in Definition 1489.1. The dyadic endpoint rows L, R and midpoint row M are read through the endpoint ledger supplied by chapter 291.

The chosen half row B and radius ledger ρ give the finite bisection content. The tag in B selects one displayed child cell, while ρ records the halved radius at the same dyadic scale. No infinite branch or limiting object is named by these rows.

The consumer rows S, Q, E route the same finite data through chapter 126, chapter 301, and chapter 38. The structural rows T, C, P, N transport, replay, source, and name that route.

Since the carrier contains no quotient stream coordinate, host real equality coordinate, selected limit coordinate, countable choice coordinate, or ambient completeness coordinate, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.IntervalHalvingUp.IntervalHalvingCarrier namecert obligations`

Theorem 1489.4 (IntervalHalving dyadic nested handoff)**.** *Every nested-interval consumer of an accepted* $\mathsf{IntervalHalving}^{\uparrow}$ *packet receives exactly one displayed child interval route*

$$L, R, M, B, \rho, T, C, P, N.$$

The route factors through the dyadic endpoint ledger of chapter 291 and the finite nested packet discipline of chapter 320; it supplies a next finite cell, not a completed branch, quotient stream, selected point, or completeness argument.

Lean4 ✓ `BEDC.Derived.IntervalHalvingUp.interval halving dyadic nested handoff carrier route`

Proof. Begin with the parent endpoint rows L, R and midpoint row M. These rows determine the two possible dyadic child cells before any downstream consumer reads the packet.

Read the chosen half row B and the radius ledger ρ. They expose one child cell and the displayed radius-halving bound required by a finite $\mathsf{NestedInterval}^{\uparrow}$ consumer. This is the only nested-cell output available from the packet.

The handoff is replayed through T, C, P, N. The hsame and Cont rows preserve the same endpoint, midpoint, chosen-half, and radius rows, while the package and local certificate rows keep the route inside the dyadic and nested-interval source certificates.

The stream, regular-rational, and real-facing rows may be read only after this finite child-cell route is fixed. They cannot supply an infinite branch, quotient stream equality, selected limit, countable choice sequence, or ambient completeness theorem because none is present in the handoff route. □

Lean4 ✓ `BEDC.Derived.IntervalHalvingUp.IntervalHalvingDyadicNestedHandoff`

Theorem 1489.5 (IntervalHalving real completion boundary)**.** *The* $\mathsf{Real}^{\uparrow}$*- and completion-facing boundary of an accepted* $\mathsf{IntervalHalving}^{\uparrow}$ *carrier is exactly the finite dyadic halving data read through*

$$S, Q, E, T, C, P, N.$$

Every $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the endpoint, midpoint, chosen-half, and radius-halving rows as finite readback data through chapter 126, chapter 301, and chapter 38. The boundary does not identify quotient streams, assert host real equality, select a limit, invoke countable choice, or appeal to ambient completeness.*

Proof. Project the finite-window row S. It contains exactly the endpoint and midpoint observations already fixed by the dyadic halving rows.

Use the regular-rational row Q to read those observations as finite approximants with the displayed radius-halving ledger. This gives a regular Cauchy consumer a bounded step, not a tail selector or selected limit.

Finally read the real-facing row E through T, C, P, N. The transport and replay rows preserve the same finite data, and the package and local certificate rows identify the source route back to chapter 291, chapter 320, chapter 126, chapter 301, and chapter 38.

Any quotient stream, host real equality, selected limit, countable choice schedule, or ambient completeness principle would require an additional readable coordinate. The carrier has none, so the completion boundary is exactly the finite route stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalHalving}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IntervalHalving}^{\uparrow}$ packet is generated from displayed $\mathsf{DyadicRatCore}^{\uparrow}$ left and right endpoint rows, a dyadic midpoint row, a chosen-half row, a radius-halving ledger, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, a $\mathsf{Real}^{\uparrow}$ seal-facing boundary, componentwise hsame transport, visible Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntervalHalving}^{\uparrow}}$, scopedClosed)

Scope closed: The carrier admission, classifier transport, midpoint formation, radius-halving exactness, nested-window handoff, and Real-completion boundary are bound as the scoped finite route for the displayed dyadic halving certificate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntervalHalving}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, host real equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires a named consumer surface that exports the checked dyadic nested handoff without adding quotient streams, selected limits, countable choice, or ambient completeness.

The $\mathsf{PolishSpace}^{\uparrow}$ hub reads its complete metric, separable metric, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows through chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38.

Chapter 1490

A Concrete Naming Certificate for $\mathsf{PolishSpace}^{\uparrow}$

Following Alexandrov and Urysohn, a Polish space is treated here as a complete separable metric object whose admissible data are displayed by finite naming routes rather than by ambient set-theoretic selection. The $\mathsf{PolishSpace}^{\uparrow}$ packet synthesizes the metric carrier of chapter 57, the completion handoff of chapter 128, the countable dense surface of chapter 1458, the finite stream-window interface of chapter 126, and the regular rational readback surface of chapter 301. Its role is to expose the L10 complete-separable metric synthesis node without claiming choice-selected dense points, quotient equality, open-cover compactness, or a host-level completion principle.

Definition 1490.1 (Polish-space carrier)**.** *A* $\mathsf{PolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, K, D, S, R, W, H, C, G, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row containing the admitted point-history carrier, metric readbacks, distance classifier, and local metric* $\mathsf{NameCert}$*.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row; it records the displayed Cauchy-window and limit-seal route over the same metric carrier.*
3. *D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *row; it stores the countable dense schedule as public finite name data, not as a choice function over arbitrary balls.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that enumerates the inspected dense names and the Cauchy-window requests made by downstream consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to observe finite rational windows on the scheduled dense names and Cauchy approximants.*
6. *W is the finite observation ledger joining requested tolerances, stream positions, regular rational windows, metric-radius checks, and completion handoff rows.*
7. *H records componentwise* hsame *transport for M, K, D, S, R, W and for the local certificate rows.*
8. *C records the displayed* Cont *routes from a metric-radius request to the dense schedule, from a Cauchy-window request to the completion handoff, and from either request to the regular rational readback.*

9. *G is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common metric, complete-metric, separable-metric, stream-name, and regular-readback surface. It has no coordinate for selected dense points, quotient equality of completions, arbitrary open covers, or ambient host sets.

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceTasteGate single carrier alignment`

Theorem 1490.2 (Polish-space NameCert obligations)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission for the displayed metric, complete-metric, separable-metric, stream-name, regular-readback, observation-ledger, transport, continuation, provenance, and local-name rows;*
2. *classifier transport to a common* $\mathsf{Met}^{\uparrow}$ *surface before either the complete-metric or separable-metric row is consumed;*
3. *stability of the completion handoff K and the countable dense schedule D under the componentwise* hsame *transports recorded in H;*
4. *exactness of the observation ledger W as the only source of metric radius checks, Cauchy windows, dense-name inspections, and regular rational readbacks;*
5. Cont *replay from radius or Cauchy-window requests through S, R, W to the corresponding metric, completion, or dense-schedule row;*
6. Pkg *provenance and local* NameCert *naming for exactly the displayed packet.*

No NameCert obligation is stored outside these six rows.

Proof. Project the carrier of Definition 1490.1. The projection exposes the metric row, complete-metric handoff, separable-metric dense schedule, stream schedule, regular rational readback, observation ledger, transport rows, continuation rows, provenance row, and local name.

The classifier route begins at the metric surface. The rows in H transport M, K, D, S, R, W together, so the completion handoff and dense schedule are never compared over different metric carriers.

The observation exactness row is exhausted by W. A metric-radius request, a Cauchy-window request, and a dense-name inspection all read their finite stream positions and regular rational observations through this ledger.

Finally replay C and attach G, N. These rows route, source, and name the already displayed packet; they do not introduce selected dense points, quotient completion equality, arbitrary open covers, or ambient host sets. Hence the six listed rows exhaust the local Polish-space naming obligations. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceNamecertObligations`

Theorem 1490.3 (Polish-space root density obligations)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The root density obligation is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule row D read over the same* $\mathsf{Met}^{\uparrow}$ *carrier M, through* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the observation ledger W, the supporting* BHist *packet, componentwise* hsame *transport*

H, displayed Cont *replay C,* Pkg *provenance G, and local* NameCert *row N. It exports no selected dense point, external enumeration, or host topology.*

Proof. Project the carrier of Definition 1490.1. The displayed rows include $M, D, S, R, W, H, C, G, N$, with D stored as a separable-metric row beside the metric source M.

Apply Definition 1490.2. Carrier admission and classifier transport keep D over the transported $\mathsf{Met}^{\uparrow}$ surface, while ledger exactness forces every dense-name inspection through S, R, W.

The rows H, C, G, N then transport, replay, source, and name that same finite route. Since no further coordinate is present, the root density obligation is exactly the displayed BHist route and not a selected dense subset or host enumeration theorem. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootDensityObligations`

Theorem 1490.4 (Polish-space root completion obligations)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The root completion obligation is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row K over the same* $\mathsf{Met}^{\uparrow}$ *carrier M used by the dense schedule D, with Cauchy-window requests read through* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, observation ledger W,* BHist *support, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and local* NameCert *row N.*

Proof. Project P through Definition 1490.1. The completion row is K, and its metric source is the same row M that supports the separable schedule D.

Use Definition 1490.2. The classifier transport and stability clauses keep K and D over the same transported metric carrier before either row is consumed.

The observation ledger W supplies the Cauchy-window route through S and R, while H, C, G, N provide transport, replay, provenance, and local naming. No quotient completion, selected limit, separate host metric, or ambient completeness principle is present in the root obligation. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCarrier completion density handoff`

Theorem 1490.5 (Polish-space root stream readback obligations)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every root readback of dense names, metric-radius checks, and Cauchy windows factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S and* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before it can be consumed by the* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *or* $\mathsf{SeparableMetric}^{\uparrow}$ *rows M, K, D. The factorization is supported exactly by W, H, C, G, N as observation ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootStreamReadbackObligations`

Proof. Start from an accepted packet and project its stream-facing rows from Definition 1490.1. The stream schedule S, regular rational readback R, and observation ledger W are displayed before any analytic consumer reads M, K, or D.

Apply Definition 1490.2. Ledger exactness makes W the only route for metric-radius checks, Cauchy windows, dense-name inspections, and regular rational readbacks.

The transport, replay, provenance, and naming rows H, C, G, N do not add a second readback channel. Therefore every root stream readback remains inside the finite BHist packet and cannot escape to an external oracle, selected limit, host enumeration, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1490.6 (Polish-space StreamName basis)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every basis-level dense-name read of P factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before it can be consumed as* $\mathsf{Met}^{\uparrow}$,

$\mathsf{CompleteMetric}^{\uparrow}$, *or* $\mathsf{SeparableMetric}^{\uparrow}$ *evidence. The factorization is supported exactly by the* BHist *packet, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and the local* NameCert *row* N*.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamNameBasis`

Proof. Project the carrier of Definition 1490.1. The stream schedule S, regular rational readback R, and observation ledger W are displayed before any dense-name consumer can read the separable row D.

Use Definition 1490.2. Its observation-exactness clause makes W the only route from a basis request to finite stream positions and regular rational windows, while H keeps the metric, completion, separable, stream, and readback rows on the same accepted packet.

Replay the request through C and source it through G, N. Since the carrier has no selected dense sequence, quotient point equality, host complete separable space, or choice-selected oracle coordinate, the basis read is exactly the displayed StreamName and RegSeqRat route. □

Theorem 1490.7 (Polish-space complete-separable handoff)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. A complete-separable consumer may read* P *only as the finite handoff from the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *schedule* D*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, with* W, H, C, G, N *preserving observation, transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableHandoff`

Proof. First expose the carrier rows. The metric row M is the common source, while K and D are only the displayed completion and separability rows over that source.

The StreamName and RegSeqRat rows provide the finite inspection route for the dense schedule and Cauchy-window requests. The ledger W records those inspections, and H transports all five mathematical rows together.

Finally replay the handoff through C and attach G, N. The packet contains no host complete separable space, quotient completion equality, choice-selected dense sequence, or ambient $\mathsf{Real}^{\uparrow}$ completeness row, so the complete-separable handoff is bounded by $M, K, D, S, R, W, H, C, G, N$. □

Theorem 1490.8 (Polish-space completion nonescape)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every completion-facing consumer read factors through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, observation ledger* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, local* NameCert *row* N*, and any terminal* $\mathsf{Real}^{\uparrow}$ *seal already exposed by those rows. No read escapes to host complete separable spaces, quotient point equality, choice-selected dense sequences, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionNonescape`

Proof. Start from a completion-facing request and project the accepted packet. The only completion row is K, and its finite windows are recorded through S, R, W before a terminal real-name seal can be consumed.

Apply Definition 1490.2. Carrier admission and classifier transport keep the completion handoff over the metric source M, while observation exactness prevents a completion request from bypassing the stream and regular-rational readback rows.

The structural rows H, C, G, N transport, replay, source, and name that same finite route. Since no coordinate names a host completion, quotient point equality, selected dense sequence, or ambient real-completeness theorem, every completion-facing consumer remains inside the displayed packet. □

Theorem 1490.9 (Polish-space dense-schedule root obligation)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The root dense-schedule obligation is the finite route that reads the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D only after the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the observation ledger W have been fixed by* BHist *support, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It exports no choice-selected dense point and no ambient enumeration theorem.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceDenseScheduleRootObligationCert`

Proof. Apply Definition 1490.2. Carrier admission exposes $M, D, S, R, W, H, C, G, N$ as displayed rows of the same packet.

The classifier-transport clause uses H to keep the dense schedule over the metric surface M. The exactness clause makes W the only route from a dense-name request to the stream schedule S and the regular rational readback row R.

Replay the request through C and source it through G, N. Since the carrier has no coordinate for a selected dense subset or an external enumeration, the root dense-schedule obligation is exactly the finite route just displayed. □

Theorem 1490.10 (Polish-space complete-metric root obligation)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The root complete-metric obligation reads the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K only over the already fixed* $\mathsf{Met}^{\uparrow}$ *surface M and through the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and observation-ledger rows S, R, W used by dense-schedule consumers. The supporting rows are precisely the displayed* BHist *packet,* hsame *transport H,* Cont *replay C,* Pkg *provenance G, and local* NameCert *row N.*

Proof. Use Definition 1490.2. Its carrier-admission and classifier-transport rows require K to remain over the metric carrier M before any completion-facing request is consumed.

The stability row transports K together with D, S, R, W. Thus a Cauchy-window request and a dense-name request share the same stream schedule, regular rational readback, and finite observation ledger.

The replay and provenance rows C, G, N add only routing, sourcing, and local naming. No quotient completion, selected limit, ambient completeness principle, or separate host metric is present in the carrier, so the complete-metric root obligation is bounded by these rows. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteMetricRootObligation`

Theorem 1490.11 (Polish-space StreamName-to-Real root obligation)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every StreamName-to-Real readback at the root factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and observation ledger W before it can be consumed as metric, complete-metric, or separable-metric evidence. The factorization is supported only by the* BHist *rows, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and local* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceStreamNameRealRootObligation`

Proof. Start with the admitted packet and its observation-ledger exactness from Definition 1490.2. Any readback request must enter through the stream schedule S and the regular rational row R.

The ledger W records which finite rational windows are inspected before the result is used by M, K, or D. Componentwise transport in H keeps these rows on the same accepted carrier, while C replays the displayed route.

The provenance and naming rows G, N identify the packet but do not add an ambient real-completeness claim, a selected limit, or an external readback oracle. Therefore the StreamName-to-Real root obligation is precisely the finite factorization through S, R, W, H, C, G, N. □

Theorem 1490.12 (Polish-space StreamName dense handoff)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every consumer that reads the countable dense surface must factor through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the finite observation ledger W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before using the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D or the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K. Consequently the packet exports a countable dense handoff by finite names and regular rational windows, not by a choice-selected dense subset or a quotient-completion representative.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamNameDenseHandoff`

Proof. Start with a consumer of the dense surface. Carrier admission exposes D only as a separable-metric row over the metric carrier M and the stream schedule S.

Read the requested dense-name index through S and the finite ledger W. The regular rational observation used by the consumer is then obtained through R, so the handoff has a visible finite window before the dense row is consumed.

If the same consumer also requests a completion read, the route passes through K after the same metric surface and observation ledger have been fixed. The transports in H keep the dense schedule, completion handoff, and metric classifier on one admitted surface.

The remaining rows C, G, N only replay, source, and name this finite route. Since the carrier has no row for a choice-selected dense subset or a quotient completion representative, the dense handoff can export only the displayed stream-name and regular-readback data. □

Theorem 1490.13 (Polish-space observation-ledger exhaustion)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read from P factors through the finite observation ledger W together with the componentwise* hsame *rows H, the displayed* Cont *replay rows C, the* Pkg *provenance row G, and the local* $\mathsf{NameCert}$ *row N. In particular, dense-schedule reads and completion reads cannot bypass W: the rows D and K are consumable only after the finite stream windows in S and regular rational readbacks in R have been displayed inside the observation ledger.*

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCarrier observation ledger exhaustion`

Proof. Project the accepted carrier as $P = (M, K, D, S, R, W, H, C, G, N)$. The projection exposes the metric row, complete-metric handoff, separable-metric dense schedule, stream-name schedule, regular rational readback, observation ledger, transport, replay, provenance, and local naming rows.

Apply Definition 1490.2. Its exactness row identifies W as the only source of metric-radius checks, Cauchy-window requests, dense-name inspections, and regular rational readbacks.

A dense-schedule consumer reaches D only through an index displayed by S and an observation recorded in W. A completion consumer reaches K only after its Cauchy-window request has been recorded in the same ledger. In both cases the inspected value is read back through R before the metric, completion, or separability row is consumed.

The remaining rows H, C, G, N transport, replay, source, and name this finite route. Since the carrier has no coordinate outside the displayed ledger route, no consumer of M, K, D, S, or R can bypass W. □

Theorem 1490.14 (Polish-space root obligation package)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Before any complete-separable metric synthesis is consumed, P exposes exactly the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K, the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D, the* $\mathsf{StreamName}^{\uparrow}$ *row S, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, together with the finite observation ledger W, componentwise* hsame *transports H, displayed* Cont *replay C,* Pkg *provenance G, and local* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootObligationPackage`

Proof. Project the carrier from Definition 1490.1. Its displayed rows are precisely the metric, complete, separable, stream, regular-readback, observation-ledger, transport, replay, provenance, and local naming rows.

Use Definition 1490.2 to read those rows as the local NameCert obligation package. It binds metric admission, completion handoff, dense schedule, stream windows, regular rational readback, and ledger exactness in one finite surface.

Finally apply Definition 1490.13. The root obligation package has no route around W, H, C, G, N, so every complete-separable consumer first sees exactly the five displayed analytic rows and their finite support. □

Theorem 1490.15 (Polish-space completion observation triad)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The complete-metric handoff K and the separable dense schedule D are both consumable only after the finite* $\mathsf{StreamName}^{\uparrow}$ *observation ledger S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the support ledger W have been displayed over the same metric row M. Thus every complete-separable consumer reads the triad*

$$S, R, W$$

before either K or D, and the packet exports no selected dense points, quotient completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionObservationTriad`

Proof. Start from Definition 1490.14. It displays $M, K, D, S, R, W, H, C, G, N$ before the complete-separable synthesis can be consumed.

Apply Definition 1490.13. Dense-schedule reads and completion reads are both routed through W, and their finite windows and rational observations are supplied by S and R.

The componentwise transport H keeps K and D over the same metric row M, while C, G, N replay, source, and name the route. Since no carrier coordinate stores selected dense points, quotient completion equality, a countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported. □

Theorem 1490.16 (Polish-space complete-metric source lock)**.** *For an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet $P = (M, K, D, S, R, W, H, C, G, N)$, every read of the complete-metric handoff K is locked to the source metric row M after the finite observation rows S, R, W have been displayed. The handoff may use the dense schedule D only through the same observation route, and it cannot replace that route by quotient completion equality, selected dense representatives, countable choice, or completeness of an ambient* $\mathsf{Real}^{\uparrow}$ *object.*

Proof. Project P through Definition 1490.1. The row K is a $\mathsf{CompleteMetric}^{\uparrow}$ handoff over the metric carrier M, not an independent completion object.

Use Definition 1490.2. The classifier transport row fixes the common metric surface before K or D is read, and the exactness row identifies W as the only source of Cauchy-window requests and regular rational readbacks.

Now apply Definition 1490.15. The rows S and R display the finite observations on which the handoff depends. Therefore a complete-metric consumer receives K only as a source-locked finite route over M, with no additional quotient, selector, choice, or ambient-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteMetricSourceLock`

Theorem 1490.17 (Polish-space separable dense schedule handoff)**.** *For an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet* $P = (M, K, D, S, R, W, H, C, G, N)$*, every read of the separable dense schedule* D *is handed off only after the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the observation ledger* W *have been displayed. The dense schedule is therefore a finite NameCert route over* M *and* K*, not a choice-selected dense subset, countable-choice enumeration, quotient-completion representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceSeparableDenseScheduleHandoff`

Proof. Begin with a consumer of D. By Definition 1490.12, the consumer must read the displayed stream schedule S, ledger W, and regular readback R before using the separable-metric row.

The root obligation package fixes the surrounding rows M, K, H, C, G, N. Transport through H keeps the dense schedule on the same metric carrier as the complete-metric handoff, and replay through C records the finite request route.

Finally invoke Definition 1490.15. Since the carrier has no row for selected dense points, countable choice, quotient completion representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the only exported dense-schedule handoff is the displayed finite NameCert route. □

Theorem 1490.18 (Polish-space complete-separable source lock)**.** *For an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet* $P = (M, K, D, S, R, W, H, C, G, N)$*, every complete-separable consumer reads the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K *and the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule* D *over the same* $\mathsf{Met}^{\uparrow}$ *row* M*. The componentwise transport row* H *may move* K *and* D *only together with* M, S, R, W, C, G, N*, so the complete side cannot be sourced from one metric carrier while the separable side is sourced from another.*

Proof. Project the carrier of Definition 1490.1. The rows K and D are both stored beside the single metric row M, while S, R, W provide the finite observation route before either analytic row is consumed.

Apply the NameCert obligations and complete-metric source lock. The classifier-transport clause of Definition 1490.2 fixes the common metric surface, and Definition 1490.16 keeps the complete-metric handoff tied to M after the observation rows have been displayed.

Finally use the separable dense schedule handoff. Theorem 1490.17 routes D through the same S, R, W support, while H, C, G, N only transport, replay, source, and name that packet. Thus complete separability is read from one displayed metric source. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableSourceLock`

Theorem 1490.19 (Polish-space dense completion ledger refusal)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every dense-completion read exported by* P *factors through the*

stream windows S, regular rational readback R, and observation ledger W before the rows K and D are consumed. The packet refuses selected dense points, quotient completion equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness as sources for the complete-separable handoff.*

Proof. Start from the separable dense schedule handoff. Theorem 1490.17 requires every read of D to pass through S, R, W before the dense schedule is exported.

The completion side follows the same ledger. Theorems 1490.15 and 1490.16 require completion-facing reads of K to use the displayed stream windows, regular readbacks, and observation ledger over M.

Now apply the L10 consumer boundary. Theorem 1490.23 excludes selected dense points, quotient completion equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the public boundary. Since H, C, G, N only preserve the displayed ledger route, no refused object can replace S, R, W. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceDenseCompletionLedger refusal`

Theorem 1490.20 (Polish-space StreamName readback stability)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Transporting the packet along the componentwise* hsame *row H and replaying the same request through C preserves the* $\mathsf{StreamName}^{\uparrow}$ *windows S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R componentwise before any complete-separable synthesis is consumed. The transported synthesis therefore reads the same finite stream and regular-rational observations through W, G, N.*

Proof. Begin with metric readback stability. Theorem 1490.25 states that componentwise transport through H preserves the metric, completion, dense-schedule, stream, regular-readback, ledger, replay, provenance, and naming rows.

Apply observation-ledger exhaustion. Theorem 1490.13 forces every dense-schedule and completion read through the finite ledger W, with windows supplied by S and rational observations supplied by R.

Finally attach complete-separable source lock. Theorem 1490.18 keeps the complete and separable rows over the same transported M. Hence the complete-separable synthesis cannot alter the StreamName or RegSeqRat readbacks before it is consumed. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamReadbackStability`

Theorem 1490.21 (Polish-space complete separable synthesis)**.** *Every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet synthesizes a* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *read over the same metric carrier named by M. The synthesis consumes the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K, the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the ledger route W, H, C, G, N; it exports no selected dense points, quotient completion equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableSynthesis`

Proof. Start with the root obligation package of Definition 1490.14. The metric row M is fixed before both completion and separability are read, so the synthesis is over one displayed metric carrier.

The completion side is supplied by K, and the separability side is supplied by D. The dense schedule can be inspected only through S, while regular rational observations pass through R after their finite windows have been displayed.

The ledger exhaustion theorem, Definition 1490.13, keeps both sides inside W, H, C, G, N. Since the carrier contains no selected dense-point row, quotient-completion equality, countable-choice coordinate, or ambient real-completeness row, the resulting complete separable metric read is exactly the finite synthesis surface named above. □

Theorem 1490.22 (Polish-space complete separable non-escape)**.** *Every* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet factors through the finite route*

$$M, K, D, S, R, W, H, C, G, N.$$

The route is forced by Definition 1490.2, exhausted by Definition 1490.13, and repacked by Definition 1490.21. Hence the synthesis exports no selected dense points, quotient completion equality, countable-choice schedule, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableNonescape`

Proof. Start with a $\mathsf{CompleteSeparableMetric}^{\uparrow}$ consumer of an accepted packet. By Definition 1490.2, the packet presents only the metric carrier M, completion handoff K, separable schedule D, stream windows S, regular readback R, and support rows W, H, C, G, N.

Use Definition 1490.13. It forces dense-schedule reads and completion reads through the observation ledger W, componentwise transport H, displayed replay C, provenance G, and local name N before the consumer can use the complete or separable side.

Finally apply Definition 1490.21. The synthesis repacks the same rows as a complete-separable metric read over M. Since none of those rows stores selected dense points, quotient completion equality, a countable-choice schedule, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no such datum can be exported by the consumer. □

Theorem 1490.23 (Polish-space L10 consumer boundary)**.** *An L10 consumer of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet may import only the finite boundary consisting of* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{SeparableMetric}^{\uparrow}$*,* $\mathsf{CompleteSeparableMetric}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, the observation ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The boundary excludes selected dense points, quotient completion equality, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the packet through Definition 1490.14. This gives the finite L10 rows M, K, D, S, R and the support rows W, H, C, G, N before any downstream consumer can inspect the packet.

Use Definition 1490.21. It repacks the completion and separability sides as a $\mathsf{CompleteSeparableMetric}^{\uparrow}$ read over the same metric carrier while preserving the stream windows, regular readback, and ledger route.

The exclusion list follows from the carrier and ledger exactness. None of the displayed rows supplies a selected dense point, quotient-completion equality, countable-choice schedule, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness datum, so an L10 consumer cannot cite any of those objects through $\mathsf{PolishSpace}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCarrier l10 consumer boundary`

Theorem 1490.24 (Polish-space completion dense schedule obligation)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every completion-facing dense-schedule obligation exported from* P *factors through the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *schedule* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the observation ledger*

W, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and the local* NameCert *row N.*

The obligation is exactly the finite route certified by Definition 1490.2, constrained by Definition 1490.13, synthesized by Definition 1490.21, and bounded at L10 by Definition 1490.23. It exposes no choice-selected dense point, quotient completion, countable-choice schedule, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 1490.1. The displayed analytic rows are precisely M, K, D, S, R, and the support rows are W, H, C, G, N.

Apply Definition 1490.2 to read those rows as local NameCert obligations. The exactness clause makes W the only route for metric-radius checks, Cauchy windows, dense-name inspections, and regular rational readbacks.

Use Definition 1490.13 and Definition 1490.21. They force the completion side and dense side through the same finite stream and readback route before the complete-separable metric synthesis can be consumed.

Finally apply Definition 1490.23. Since the boundary contains no coordinate for selected dense points, quotient completions, countable choice, open-cover compactness, or ambient real completeness, the exported obligation is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionDenseScheduleObligation`

Theorem 1490.25 (Polish-space metric readback stability)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Suppose a downstream consumer transports the metric row, completion handoff, dense schedule, stream windows, regular rational readback, and ledger rows along the componentwise* hsame *data recorded in H and replays the same request through the displayed* Cont *routes in C. Then the transported packet preserves the same* $\mathsf{Met}^{\uparrow}$ *readback boundary for M, the same* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{SeparableMetric}^{\uparrow}$ *handoff surface for K, D, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite observations through S, R, W, G, N.*

Thus metric readback stability is a finite NameCert property of P and not a quotient-completion equality, selected dense representative, countable-choice enumeration, or host-level equality of metric spaces.

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceMetricReadbackStability`

Proof. Begin with the carrier projection and the componentwise transport row H. The row transports M, K, D, S, R, W together with the local certificate data, so a metric readback cannot move independently from the completion or dense-schedule rows.

Apply Definition 1490.2. Its classifier-transport and stability clauses require K and D to remain over the transported metric surface before either row is consumed.

Next use Definition 1490.13. Every finite observation read by the transported consumer still passes through S, R, W, and the replay row C records the same request route.

The L10 boundary theorem, Definition 1490.23, supplies the exclusion list. Because no accepted packet coordinate stores quotient completion equality, selected dense representatives, countable-choice enumerations, or host-level metric equality, the stability claim is only the displayed finite transport-and-replay property. □

Theorem 1490.26 (Polish-space L10 root unblock package)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The L10 root obligation package exported by P consists of the*

completion-dense schedule route of Definition 1490.24, the metric readback stability route of Definition 1490.25, the finite observation exhaustion of Definition 1490.13, the complete-separable synthesis of Definition 1490.21, and the consumer boundary of Definition 1490.23.

Consequently every downstream complete-separable metric chapter may import only $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows through the displayed tuple* $P = (M, K, D, S, R, W, H, C, G, N)$. *The package does not supply choice-selected dense points, quotient completions, countable-choice schedules, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceL10RootUnblockPackage`

Proof. First assemble the finite route. The completion-dense schedule obligation displays $M, K, D, S, R, W, H, C, G,$ before any dense or complete read leaves the chapter boundary.

Next apply metric readback stability. It shows that transported consumers still read the same metric, completion, dense-schedule, stream, regular-readback, ledger, replay, provenance, and naming rows.

The observation-ledger and complete-separable synthesis theorems then repack this route as a $\mathsf{CompleteSeparableMetric}^{\uparrow}$ surface over the metric row M. This is the only synthesis route available to an L10 consumer.

Finally invoke the consumer boundary theorem. It permits the listed BEDC rows and refuses selected dense points, quotient completions, countable choice, host equality, open-cover compactness, and ambient real completeness, so the root unblock package is exactly the displayed finite package. □

Theorem 1490.27 (Polish-space complete-separable consumer package)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every L10 consumer that reads* P *as a complete-separable metric input must receive a finite* BHist *route whose visible rows are the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the observation ledger* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and the local* NameCert *row* N *over the same metric source* M*.*

The package refuses choice-selected dense points, quotient equality of completed points, arbitrary open covers, host completion, and any complete-separable witness not routed through the displayed tuple $P = (M, K, D, S, R, W, H, C, G, N)$*.*

Proof. Project the accepted carrier. The row K is the completion-facing input, D is the separability-facing input, and S, R, W are the finite stream, regular-readback, and observation rows that make those inputs consumable.

Apply Definition 1490.26. It lists exactly the routes that an L10 root obligation may export from P and keeps the support rows H, C, G, N attached to the same packet.

Use Definition 1490.23. Since the carrier has no row for a chosen dense point, quotient equality, arbitrary open cover, host completion, or ambient completion object, a complete-separable consumer can only receive the displayed finite package. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceL10CompleteSeparableConsumerPackage`

Theorem 1490.28 (Polish-space completion schedule stability)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Any componentwise* hsame *transport of the completion side preserves the same schedule route from the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K *through the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the observation ledger* W*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and the local* NameCert *row* N *over* M*.*

Thus the transported schedule remains a finite BHist *route and cannot be replaced by a choice-selected dense sequence, quotient equality, arbitrary open-cover refinement, host completion, or external completion of the metric carrier.*

Proof. Start from the transport row H. It transports the metric, completion, separability, stream, readback, ledger, replay, provenance, and naming rows componentwise rather than moving K alone.

Apply Definition 1490.25. The theorem keeps metric readback attached to S, R, W after transport, so completion-side schedule reads still pass through the same finite observation route.

Finally use Definition 1490.13. The ledger exhaustion prevents the transported consumer from substituting selected dense points, quotient equality, arbitrary open covers, host completion, or an external completion object for the displayed schedule. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionScheduleStability`

Theorem 1490.29 (Polish-space observation ledger consumer exactness)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* PolishSpace$^{\uparrow}$ *carrier. For every complete-separable metric consumer of P, the observation ledger W is exact: all requests for the* CompleteMetric$^{\uparrow}$ *row K, the* SeparableMetric$^{\uparrow}$ *row D, the* StreamName$^{\uparrow}$ *windows S, and the* RegSeqRat$^{\uparrow}$ *readback row R are replayed through H, C, G, N before the local* NameCert *exports the result.*

Consequently no consumer can read beyond the displayed BHist *ledger into choice-selected dense points, quotient equality, arbitrary open covers, host completion, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Read the observation ledger theorem, Definition 1490.13. It states that the finite observation route covers metric-radius checks, Cauchy-window checks, dense-name inspections, and regular rational readbacks before any consumer leaves the packet.

Attach the complete-separable synthesis route. By Definition 1490.21, the complete and separable rows are consumed over the same metric source and through the same finite stream and readback rows.

The support rows close exactness. Transport H, replay C, provenance G, and local naming N keep the consumer on the displayed BHist route, so no selected dense point, quotient equality, open-cover argument, host completion, or ambient Real-completeness row is available. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceObservationLedgerConsumerExactness`

Theorem 1490.30 (Polish-space complete-separable metric row exposure)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N$ be an accepted* PolishSpace$^{\uparrow}$ *carrier. Before any complete-separable metric consumer reads P, the packet exposes the* CompleteMetric$^{\uparrow}$ *row K, the* SeparableMetric$^{\uparrow}$ *row D, the synthesized* CompleteSeparableMetric$^{\uparrow}$ *surface, the* StreamName$^{\uparrow}$ *finite windows S, the* RegSeqRat$^{\uparrow}$ *readback row R, the componentwise* hsame *transport H, the displayed* Cont *replay C, the* Pkg *provenance G, and the local* NameCert *row N over the same* Met$^{\uparrow}$ *row M.*

Thus the complete-separable consumer receives the finite route

$$M, K, D, S, R, W \longmapsto H, C, G, N$$

and no selected dense point, quotient completion, countable-choice schedule, open-cover compactness principle, host equality of metric spaces, or ambient Real$^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCompleteSeparableMetricRow`

Proof. Project the carrier through Definition 1490.1. The metric source is M, the completion handoff is K, and the dense schedule is D; the stream, regular readback, and observation rows are S, R, W.

Apply Definition 1490.21. It repacks K and D as the complete-separable metric surface only after the stream windows and regular rational readback have been made visible over the same metric carrier.

Use Definition 1490.26. The package keeps the support rows H, C, G, N attached to the same displayed route, so a consumer cannot read complete separability before the listed rows have been exposed. □

Theorem 1490.31 (Polish-space stream-density readback row)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every dense-schedule consumer that reads the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D must first pass through the* $\mathsf{StreamName}^{\uparrow}$ *windows S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, then replay the observation ledger W through H, C, G, N before treating the schedule as a complete-separable metric input.*

In particular, a consumer cannot read separability from D as a bare countable enumeration, choice-selected dense point, quotient-completion representative, open-cover compactness argument, or ambient real-completeness witness.

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamDensityReadbackRow`

Proof. Start with the dense side of Definition 1490.24. It places D downstream of the metric row M and ties it to the finite stream windows S and regular rational readback R.

Read the observation ledger next. By Definition 1490.13, metric-radius checks, Cauchy windows, dense-name inspections, and regular readbacks all pass through W before the packet exports a separability-facing read.

Finally use Definition 1490.25. Transport, replay, provenance, and local naming preserve the same S, R, W route, so a dense-schedule consumer receives finite stream-density readback rather than any hidden enumeration or completion principle. □

Definition 1490.32 (Polish-space root carrier)**.** *The root-facing* $\mathsf{PolishSpace}^{\uparrow}$ *carrier is the tuple $P = (M, K, D, S, R, W, H, C, G, N)$ of Definition 1490.1, read as a single* BHist *packet whose consumer-visible rows are* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg *provenance, and local* $\mathsf{NameCert}$ *data. The root view has no additional row for selected dense points, quotient completions, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootCarrier rows exposed`

Theorem 1490.33 (Polish-space separable complete metric obligations)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted root-facing* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *obligation exported from P factors through the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K, the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the observation ledger W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and the local* $\mathsf{NameCert}$ *row N.*

Proof. Start with Definition 1490.32. The root carrier is only the displayed tuple $P = (M, K, D, S, R, W, H, C, G, N$

Apply Definition 1490.30. It exposes the complete, separable, stream, regular-readback, replay, provenance, and naming rows over the same metric source before any complete-separable consumer reads the packet.

Finally use Definition 1490.31. It forces dense-schedule reads through S, R, W, H, C, G, N, so the complete-separable obligation has exactly the listed finite route. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCarrier separable complete metric obligations`

Theorem 1490.34 (Polish-space NameCert ledger transport)**.** *For an accepted root-facing* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, componentwise* hsame *transport may move the* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{SeparableMetric}^{\uparrow}$*,* $\mathsf{CompleteSeparableMetric}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows only together with the observation ledger* W*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and local* NameCert *row* N*. No transported consumer can read a complete-separable metric surface after dropping the ledger.*

Proof. Read the componentwise transport row H from Definition 1490.32. It is part of the same finite packet as the metric, completion, separability, stream, regular-readback, and ledger rows.

Apply Definition 1490.25. Transport preserves the metric readback boundary together with the StreamName and RegSeqRat finite observations through S, R, W, G, N.

The L10 root package of Definition 1490.26 then keeps every complete-separable consumer inside that transported ledger. Thus ledger-free transport is not an exported row of the packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceNamecertLedgerTransport`

Theorem 1490.35 (Polish-space standard readiness)**.** *An accepted root-facing* $\mathsf{PolishSpace}^{\uparrow}$ *carrier is ready for standard complete-separable metric consumers only as the displayed* BHist *route through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{SeparableMetric}^{\uparrow}$*,* $\mathsf{CompleteSeparableMetric}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. A downstream* $\mathsf{Real}^{\uparrow}$ *consumer may receive only the regular-readback side exposed through this route; it does not receive ambient Real completeness or host equality of metric spaces.*

Proof. Use Definition 1490.33. It displays the complete-separable metric route over $M, K, D, S, R, W, H, C, G, N$.

Apply Definition 1490.34. Standard consumers must preserve the observation ledger and replay rows when they move the metric, completion, separability, stream, and readback data.

The $\mathsf{Real}^{\uparrow}$ clause is only a downstream boundary. The root carrier exposes regular rational readback through R but has no coordinate for ambient Real completeness or host metric equality, so those claims cannot be imported. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceStandardReadiness`

Theorem 1490.36 (Polish-space L10 root unblock package)**.** *The root-facing* $\mathsf{PolishSpace}^{\uparrow}$ *packet unlocks L10 metric-completion consumers exactly by the finite carrier of Definition 1490.32, the complete-separable metric obligations of Definition 1490.33, the ledger transport of Definition 1490.34, and the standard readiness boundary of Definition 1490.35. It exports no selected dense point, quotient completion, countable-choice schedule, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Assemble the carrier route first. The definition exposes $M, K, D, S, R, W, H, C, G, N$ as one finite BHist packet.

The separable complete metric obligations show how $\mathsf{CompleteSeparableMetric}^{\uparrow}$ consumers read that packet, and ledger transport keeps the rows tied together under hsame movement.

Finally apply standard readiness. The only exported L10 boundary is the displayed route through metric, completion, separability, stream, regular readback, transport, replay, provenance, and local naming rows, with the listed objects excluded from the carrier. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceL10RootUnblockPackage`

Theorem 1490.37 (Polish-space effective-representation handoff)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Any* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *or* $\mathsf{ComputablePolishSpace}^{\uparrow}$ *consumer of P must first expose the Polish complete-separable package formed by the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K, the countable dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the observation ledger W, the componentwise* hsame *transports H, the displayed* Cont *replay C, the* Pkg *provenance G, the local* NameCert *row N, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route before represented-space or computable-analysis vocabulary is read.*

Consequently the represented-space boundary of chapter 1494, the admissible-representation boundary of chapter 1760, the effective Polish packet of chapter 1706, and the computable Polish packet of chapter 4146 can consume $\mathsf{PolishSpace}^{\uparrow}$ *only through the displayed finite route of this chapter. They receive no selected dense points, quotient completion equality, unscheduled name oracle, host representation equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Polish carrier projection. The complete-separable source is displayed by the metric row M, complete-metric handoff K, separable dense schedule D, finite stream windows S, regular readback R, and observation ledger W.

Apply Definition 1490.12. Any dense-schedule read first opens the $\mathsf{StreamName}^{\uparrow}$ schedule and the $\mathsf{RegSeqRat}^{\uparrow}$ readback before it can consume the separable row. Apply Definition 1490.31 to keep that dense schedule attached to W, H, C, G, N.

Next apply Definition 1490.13. Completion reads and dense reads both pass through the same finite ledger, so an effective or computable Polish consumer cannot replace the displayed route by an external representation source.

Finally read the sibling consumer surfaces. The $\mathsf{EffectivePolishSpace}^{\uparrow}$ and $\mathsf{ComputablePolishSpace}^{\uparrow}$ chapters import $\mathsf{PolishSpace}^{\uparrow}$ only after their dense-realizer, represented-space, StreamName, RegSeqRat, and Real-seal rows have been displayed; the represented-space and admissible-representation chapters likewise require scheduled names and regular readback before target-facing vocabulary is available. Since P has no coordinate for selected dense points, quotient completions, host representation equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the handoff is exactly the finite route named in the statement. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceEffectiveRepresentationHandoff`

Theorem 1490.38 (PolishSpace effective-name root obligations)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier $P = (M, K, D, S, R, W, H, C, G, N)$, any effective-name consumer of P reaches the displayed names only through the* $\mathsf{StreamName}^{\uparrow}$ *row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the observation ledger W, the componentwise* hsame *rows H, the replay row C, the provenance row G, and the local* NameCert *row N of Definition 1490.1. It receives no unscheduled dense-name oracle, selected dense point, quotient completion representative, host equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootEffectiveNameObligations`

Proof. Project the carrier first. The rows S, R, W, H, C, G, N are displayed coordinates of the same finite packet P, so an effective-name read cannot leave the packet before the schedule and readback rows have been opened.

Apply Definition 1490.12 and Definition 1490.31. These theorems identify the dense schedule and finite readbacks as the route by which downstream effective names inspect the Polish carrier.

The excluded objects are not coordinates of Definition 1490.1. Transport, replay, provenance, and local naming preserve the displayed route and do not add an external oracle. □

Theorem 1490.39 (PolishSpace complete-separable root schedule)**.** *Every complete-separable consumer of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier factors through the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *schedule* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the structural rows* W, H, C, G, N*. In particular, a* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{SeparableMetric}^{\uparrow}$ *read cannot be separated from the displayed finite observation schedule of the same packet.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootCompleteSeparableSchedule`

Proof. Start from Definition 1490.1. The metric, completion, separability, stream, readback, ledger, transport, replay, provenance, and naming rows are carried together as $M, K, D, S, R, W, H, C, G, N$.

Use Definition 1490.33 to read the complete and separable obligations from the displayed carrier. Then use Definition 1490.34 to keep those obligations attached to W, H, C, G, N under componentwise movement.

Thus a downstream complete-separable read receives the finite schedule and readback route, not an independent completion or dense-set choice principle. □

Theorem 1490.40 (PolishSpace represented-space root handoff)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Any handoff from* P *to a* $\mathsf{RepresentedSpace}^{\uparrow}$ *consumer must expose the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *schedule* D*, and the structural rows* W, H, C, G, N *before representation vocabulary is available.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootRepresentationHandoff`

Proof. Open the represented-space boundary through Definition 1490.37. That theorem already fixes the route from the Polish packet to represented and effective Polish consumers.

The root rows in the statement are precisely the rows used by that handoff: completion comes from K, separability from D, scheduled names from S, regular readback from R, and structural preservation from W, H, C, G, N.

Since no host representation equality, selected name, quotient completion, or countable-choice selector is present in P, the represented-space consumer can read only this finite route. □

Theorem 1490.41 (Polish-space effective-representation separable readback)**.** *Let* $P = (M, K, D, S, R, W, H, C, G$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Any represented-space, admissible-representation, effective Polish, or computable Polish consumer of* P *must display the complete-separable metric row, the dense schedule, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *support before it reads an effective representation. Thus the represented or computable vocabulary is downstream of the same finite route*

$$M, K, D, S, R, W, H, C, G, N$$

rather than a detached name oracle, selected dense sequence, host equality, countable-choice schedule, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceEffectiveRepresentationSeparableReadback`

Proof. Start with Definition 1490.37. It already forces represented-space, admissible-representation, effective Polish, and computable Polish consumers to expose the metric row, complete-metric row, dense schedule, stream windows, rational readback, observation ledger, transport, replay, provenance, local naming, and terminal real seal before downstream vocabulary is available.

Next apply Definition 1490.12 and Definition 1490.31. These two rows make the dense schedule readable only through the $\mathsf{StreamName}^{\uparrow}$ windows and the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to W, H, C, G, N.

Finally use Definition 1490.36. The root-facing package exports only the complete-separable metric synthesis route and excludes selected dense points, quotient completion, countable choice, host equality, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness. The effective-representation readback therefore consumes exactly the displayed Polish packet. □

Theorem 1490.42 (Polish-space effective complete-separable obligation)**.** *Every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *complete-separable consumer reads the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense-schedule row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the Real-facing observation ledger* W*, and the structural rows* H, C, G, N *through the same finite packet before any completion use is public. The obligation exports no selected dense sequence, quotient completion equality, unscheduled name oracle, host representation equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceEffectiveCompleteSeparableObligation`

Proof. Apply Definition 1490.43. It identifies the complete-separable surface as the displayed carrier route through metric, completion, separability, stream windows, regular readback, observation, transport, replay, provenance, and local naming rows.

Apply Definition 1490.46. Completion-facing reads cannot leave that finite route for a quotient completion, selected limit representative, or host completeness principle.

Finally apply Definition 1490.23. The L10 consumer boundary keeps $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the Real-facing rows in one packet, so an effective complete-separable consumer receives the shared obligation surface and no additional completion coordinate. □

Falsifiable prediction: An accepted $\mathsf{PolishSpace}^{\uparrow}$ consumer that reaches a $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, or $\mathsf{Met}^{\uparrow}$ row without reading the displayed $\mathsf{StreamName}^{\uparrow}$ schedule, finite observation ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transports, Cont routes, Pkg provenance, and local $\mathsf{NameCert}$ row refutes the carrier surface.

Independence witness: metric, completemetric, separablemetric, streamname, regseqrat: no listed sibling supplies the whole Polish packet $P = (M, K, D, S, R, W, H, C, G, N)$, because each sibling contributes only the distance carrier, completion handoff, dense schedule, stream schedule, or rational readback while this chapter binds the complete-separable metric synthesis route with transport, replay, provenance, and local naming.

Theorem 1490.43 (Polish-space complete-separable synthesis)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Its root complete-separable route exposes the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K *and the* $\mathsf{SeparableMetric}^{\uparrow}$ *row* D *only over the same* $\mathsf{Met}^{\uparrow}$ *carrier* M*, with* $\mathsf{StreamName}^{\uparrow}$ *windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, observation ledger* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and local* $\mathsf{NameCert}$ *rows* N*. Consequently every complete-separable consumer of* P *reads one common route*

$$M \longmapsto (K, D) \longmapsto (S, R, W) \longmapsto (H, C, G, N),$$

and no choice-selected dense sequence, external completion coordinate, separate host metric, or quotient-completion equality is exported.

Proof. Project P by Definition 1490.1. The carrier exposes $M, K, D, S, R, W, H, C, G, N$ as displayed rows of one finite BHist packet.

Apply Definition 1490.2. Carrier admission places the complete-metric handoff K and the separable-metric schedule D inside the same local $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ surface, while classifier transport uses H to compare both rows only after transport to the common metric source M.

Use Definition 1490.3 and Definition 1490.4. The density obligation forces D to be read through S, R, W over M, and the completion obligation forces K to use the same metric source and the same finite observation route.

It remains to package the shared readback. The rows C, G, N replay, source, and name the route already fixed by M, K, D, S, R, W, H. Because the carrier has no coordinate for the excluded dense selector, external completion, separate host metric, or quotient-completion equality, the displayed route is the only complete-separable synthesis exported by an accepted Polish-space packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootCompleteSeparableSynthesis`

Theorem 1490.44 (Polish-space complete-separable shared-source route)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted $\mathsf{PolishSpace}^{\uparrow}$ packet. Every complete-separable consumer must read the complete row K and the separable row D over the same $\mathsf{Met}^{\uparrow}$ row M, then pass through the finite route*

$$M \longmapsto (K, D) \longmapsto (S, R, W) \longmapsto (H, C, G, N).$$

It cannot split completion and separability across different host metrics, separate quotient-completion coordinates, selected dense sequences, or unscheduled readback windows.

Proof. Apply Definition 1490.43. It already displays K and D as rows of one accepted packet over the same metric source M.

Next use Definition 1490.3. The dense schedule D is read through the shared stream and regular rational windows S, R together with the observation ledger W, so it cannot be detached from the metric row that supplies its distances.

Use Definition 1490.4 for the complete side. The completion row K is transported and replayed through the same H, C, G, N route as D.

The carrier has no coordinate for a second host metric, separate quotient completion, selected dense sequence, or unscheduled readback window. Thus the complete-separable route is a shared-source route through $M, K, D, S, R, W, H, C, G, N$. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableSharedSourceRoute`

Definition 1490.45 (Polish-space root unblock surface)**.** *The root unblock surface of an accepted $\mathsf{PolishSpace}^{\uparrow}$ packet is the displayed finite packet*

$$(M, K, D, S, R, W, H, C, G, N)$$

viewed simultaneously as the $\mathsf{Met}^{\uparrow}$ carrier row M, the $\mathsf{CompleteMetric}^{\uparrow}$ handoff K, the $\mathsf{SeparableMetric}^{\uparrow}$ dense schedule D, the $\mathsf{StreamName}^{\uparrow}$ window row S, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, the observation ledger W, componentwise hsame transport H, displayed Cont replay C, Pkg provenance G, and local $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ row N.

A downstream root consumer may read complete-separable data only through this single surface. It receives no separate metric carrier, selected dense point, quotient completion equality, unscheduled name oracle, or ambient $\mathsf{Real}^{\uparrow}$ completeness datum.

Lean4 (definition) `BEDC.Derived.PolishspaceUp.PolishSpaceRootUnblockSurface`

Theorem 1490.46 (Polish-space complete-separable unblock package)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. The complete row K and the separable row D are consumed over one metric carrier M: every complete-separable root read first exposes M, then reads both K and D through the same S, R, W observation surface, and finally replays the common packet through H, C, G, N.*

Consequently the complete side cannot be sourced from one carrier while the separable side is sourced from another, and neither side can bypass the finite StreamName and RegSeqRat windows.

Proof. Start from Definition 1490.45. The displayed packet has a single metric coordinate M, and both K and D are rows of that same packet.

Use the complete-separable synthesis of Definition 1490.43. It already routes every complete-separable consumer through

$$M \longmapsto (K, D) \longmapsto (S, R, W) \longmapsto (H, C, G, N).$$

It remains to rule out split consumption. The observation ledger W and the componentwise transport row H move K and D only together with M, S, R, C, G, N. Thus a consumer has no coordinate from which to read a second carrier, an unscheduled complete row, or a dense schedule outside the displayed finite windows. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableUnblockPackage`

Theorem 1490.47 (Polish-space RegSeqRat window unblock)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Every downstream Polish-space read that reaches a* $\mathsf{Real}^{\uparrow}$*-facing consumer passes first through the* $\mathsf{StreamName}^{\uparrow}$ *row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R of Definition 1490.45. The read may then use the complete row K, the separable row D, and any Real-facing seal already exposed by the packet, but it cannot replace S, R by a selected dense point, a quotient-completion representative, host equality, or ambient completeness.*

Proof. Expose the root unblock surface. The only rows that schedule names and regular rational observations are S and R, and the local NameCert row names them as part of the same finite packet as M, K, D, W, H, C, G.

The Real-facing boundary is downstream of those observations. A consumer can reach Real-facing data only after the stream windows have supplied finite requests and the regular rational readback has supplied the corresponding observations.

Finally apply the nonescape clauses of the complete-separable synthesis. Since the packet has no row for selected dense points, quotient-completion representatives, host equality, or ambient completeness, every downstream read passes through the StreamName and RegSeqRat windows before any Real-facing consumer is available. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRegSeqRatWindowUnblock`

Theorem 1490.48 (Polish-space RegSeqRat–Real handoff)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet whose complete-separable route is read through the root unblock surface of Definition 1490.45. Any* $\mathsf{Real}^{\uparrow}$*-facing consumer of that route can be reached only after the* $\mathsf{StreamName}^{\uparrow}$ *row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R expose their finite windows over the same* $\mathsf{Met}^{\uparrow}$ *row M that supports the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K and the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D. The handoff exports no selected dense point, quotient completion representative, host equality, or ambient completeness coordinate.*

Proof. Start from the root unblock surface. The rows $M, K, D, S, R, W, H, C, G, N$ are displayed as one finite packet, so the stream and regular-rational windows are already tied to the same metric row as the complete and separable data.

Apply Definition 1490.46. It forces both K and D to be consumed over M and through the common S, R, W observation surface before the packet can be replayed by H, C, G, N.

Now use Definition 1490.47. Every downstream read that reaches a Real-facing consumer must pass through S and R first. Combining the two routes gives the required top-window handoff from complete separability to the finite RegSeqRat readback.

The excluded dense selector, quotient completion representative, host equality, and ambient completeness rows are absent from the carrier. Therefore the Real-facing consumer receives only the displayed route over M. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableRegSeqRatRealHandoff`
↪ variant `BEDC.Derived.PolishspaceUp.PolishSpaceRegSeqRatRealHandoff`

Definition 1490.49 (Polish-space root-unblock carrier)**.** *The root-unblock carrier of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet is the finite* BHist *row*

$$U = (M, K, D, S, R, B, H, C, P, N)$$

read as follows:

1. M *is the common* $\mathsf{Met}^{\uparrow}$ *source row.*
2. K *is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row over* M*.*
3. D *is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense-schedule row over* M*.*
4. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for dense-name and Cauchy-window inspections.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. B *is the supporting* BHist *observation ledger, including metric-radius requests, complete-metric requests, separable-density requests, and the finite links among them.*
7. H *records componentwise* hsame *transport for* M, K, D, S, R, B *and the local certificate rows.*
8. C *records displayed* Cont *replay from each root consumer request through the same complete-separable packet.*
9. P *is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row.*

The carrier excludes selected dense points, quotient completion equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1490.50 (Polish-space common metric root unblock)**.** *Let* $U = (M, K, D, S, R, B, H, C, P, N)$ *be a Polish-space root-unblock carrier. Every complete-separable root consumer reads the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K *and the* $\mathsf{SeparableMetric}^{\uparrow}$ *row* D *only over the same* $\mathsf{Met}^{\uparrow}$ *row* M*, with the finite* BHist *ledger* B*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *recording that common source.*

Consequently the complete side cannot use a different metric carrier from the separable side, and no selected dense point, quotient completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum is exported by the root packet.*

Proof. Project the carrier of Definition 1490.49. The complete-metric handoff K and the separable schedule D are both listed after the same metric source row M.

Use the observation ledger B to read root requests. Each complete-metric request and each separable-density request is recorded with the same metric-radius surface, so a downstream consumer cannot split the two sides across different carriers.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no selected dense point, quotient completion equality, countable-choice schedule, or ambient real-completeness coordinate appears in the carrier, the common metric row exhausts the root-unblock source. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootUnblockCommonMetric`

Theorem 1490.51 (PolishSpace complete-separable obligation surface)**.** *Let $U = (M, K, D, S, R, B, H, C, P, N)$ be a Polish-space root-unblock carrier. The complete-separable obligation surface is the joint read in which M is the* $\mathsf{Met}^{\uparrow}$ *carrier, K supplies the* $\mathsf{CompleteMetric}^{\uparrow}$ *convergence rows over M, D supplies the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense enumeration rows over the same M, S supplies finite* $\mathsf{StreamName}^{\uparrow}$ *observations, R supplies* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy witnesses and the resulting* $\mathsf{Real}^{\uparrow}$ *seals for observed distances, and B, H, C, P, N record the observation ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *transport.*

Every downstream complete-separable consumer must factor through this surface before reading any Polish-space data. The surface exports no split metric carrier, no selected dense point, no quotient-completion representative, no countable-choice schedule, and no ambient real-completeness principle.

Proof. Project the carrier of Definition 1490.49. The metric carrier M, complete row K, separable dense row D, stream row S, regular rational row R, ledger B, transport row H, replay row C, provenance row P, and local name N are the displayed rows.

The complete and separable sides share the same metric source. By Definition 1490.50, K and D cannot be consumed over different carriers.

The finite observation discipline is supplied by Definition 1490.54. Dense-name requests, Cauchy-window requests, and metric-radius comparisons pass through S and R, with the Real-facing distance seals read only after the regular Cauchy witnesses have been displayed.

Finally B, H, C, P, N transport, replay, source, and name that single route. Since the carrier has no field for the excluded host objects, the listed rows form the complete-separable obligation surface. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceCompleteSeparableObligationSurface`

Theorem 1490.52 (PolishSpace StreamName Real dependency anchor)**.** *Let $U = (M, K, D, S, R, B, H, C, P, N)$ be a Polish-space root-unblock carrier. Any root consumer that reaches a* $\mathsf{Real}^{\uparrow}$*-sealed distance, convergence tolerance, or dense-radius observation must first read the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy witness row R. The dependency then returns to the* $\mathsf{Met}^{\uparrow}$ *carrier M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *convergence rows K, and the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense enumeration rows D through the* BHist *ledger B, componentwise transport H, replay C, provenance P, and local* NameCert *row N.*

Thus Real-facing data in a $\mathsf{PolishSpace}^{\uparrow}$ *root packet are anchored by scheduled observations and regular Cauchy witnesses, not by an external real-number oracle or host metric completion.*

Proof. Expose the stream-facing fields of Definition 1490.49. The only row that schedules finite observations is S, and the only row that turns those observations into regular rational Cauchy data is R.

Read a Real-facing request. The request must pass through B, where dense-radius, Cauchy-window, and metric comparison observations are paired with their stream positions and regular rational witnesses.

The analytic rows are then reached over the same packet. The metric carrier M, complete convergence row K, and dense enumeration row D are transported together by H and replayed through C.

The provenance and naming rows P, N do not add a second Real-facing source. Therefore the dependency anchor is exactly the StreamName and RegSeqRat route followed by the common metric, complete, separable, ledger, transport, replay, provenance, and NameCert rows. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceStreamnameRealDependencyAnchor`
↪ variant `BEDC.Derived.PolishspaceUp.PolishSpaceStreamnameRealDependencyAnchor`

Theorem 1490.53 (PolishSpace NameCert ledger exactness)**.** *Let $U = (M, K, D, S, R, B, H, C, P, N)$ be a Polish-space root-unblock carrier. The local $\mathsf{NameCert}_{\mathsf{PolishSpace}^\uparrow}$ ledger transport is exact: N names precisely the $\mathsf{Met}^\uparrow$ carrier M, the $\mathsf{CompleteMetric}^\uparrow$ convergence rows K, the $\mathsf{SeparableMetric}^\uparrow$ dense enumeration rows D, the finite $\mathsf{StreamName}^\uparrow$ observations S, the $\mathsf{RegSeqRat}^\uparrow$ regular Cauchy witnesses R, the resulting $\mathsf{Real}^\uparrow$ seals recorded by the observation ledger B, and the componentwise* hsame, Cont, *and* Pkg *rows H, C, P.*

Consequently a classified replacement of U preserves the same complete-separable root packet component by component and cannot introduce hidden quotient equality, selected dense names, unrecorded limits, external real seals, or additional NameCert obligations.

Proof. Project the carrier. The local name N appears only after the metric, complete, separable, stream, regular rational, ledger, transport, replay, and provenance rows have been displayed.

Use Definition 1490.51. It identifies the exact complete-separable surface consumed by downstream root readers, including the Real-facing seals recorded by B after S and R have supplied finite observations and regular Cauchy witnesses.

Now transport the packet componentwise. The row H compares each displayed coordinate with its replacement, C replays the same requests, and P preserves the stated provenance.

Since no other field remains in the root-unblock carrier, N cannot name an additional obligation. The NameCert ledger transport is therefore exact for the listed rows and excludes the hidden host data named in the statement. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceNamecertLedgerExactness`

Theorem 1490.54 (Polish-space window-discipline root unblock)**.** *Let $U = (M, K, D, S, R, B, H, C, P, N)$ be a Polish-space root-unblock carrier. Every root read of dense-name coverage, Cauchy-window completion data, or metric-radius comparison factors through the $\mathsf{StreamName}^\uparrow$ row S and the $\mathsf{RegSeqRat}^\uparrow$ row R before it is consumed by M, K, D. The supporting* BHist *row B records exactly those windows and readbacks, while H, C, P, N preserve the same route for downstream complete-separable consumers.*

Thus a Polish-space root consumer receives finite window discipline over one complete-separable packet, not an unscheduled name oracle, selected dense sequence, quotient completion equality, countable-choice row, or ambient $\mathsf{Real}^\uparrow$ completeness principle.

Proof. Start from the carrier. The only scheduling coordinate is S, and the only regular rational readback coordinate attached to it is R.

Read a dense-name, Cauchy-window, or metric-radius request through B. By definition of the root-unblock carrier, B records those requests only together with the finite stream positions and regular rational observations supplied by S and R.

It remains to route the analytic rows. The complete row K and separable row D are consumed only after the window and readback rows have been displayed, and the common metric row M is the metric source for both.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no unscheduled oracle, selected dense sequence, quotient equality, choice row, or ambient completeness coordinate, every root read respects the displayed window discipline. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRootUnblockWindowDiscipline`

Definition 1490.55 (Polish-space root Cauchy-basis carrier)**.** *The root Cauchy-basis carrier of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet is the finite* BHist *row*

$$W = (M, K, D, S, R, B, A, H, C, P, N)$$

where $M, K, D, S, R, B, H, C, P, N$ *have the meanings of Definition 1490.49, and* A *is the finite Cauchy-basis alignment row binding the complete-metric row* K *and the separable dense-schedule row* D *over the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback data.*

The alignment row records only the scheduled dense Cauchy basis seen by the local packet. It does not choose dense points, identify quotient-completion representatives, add a countable-choice schedule, or assert ambient $\mathsf{Real}^{\uparrow}$ *completeness outside the displayed readback seals.*

Lean4 (definition) `BEDC.Derived.PolishspaceUp.PolishspaceRootCauchyBasisCarrier`

Theorem 1490.56 (PolishSpace root Cauchy-basis obligations)**.** *Let* $W = (M, K, D, S, R, B, A, H, C, P, N)$ *be a Polish-space root Cauchy-basis carrier. The local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *surface consists exactly of common metric admission through* M*, complete-metric handoff through* K*, separable-density handoff through* D*,* $\mathsf{StreamName}^{\uparrow}$ *window discipline through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*, Cauchy-basis alignment through* A*, observation ledger support through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

No local obligation exports a selected dense point, quotient-completion equality, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, or second metric carrier.*

Proof. Project the carrier of Definition 1490.55. The rows $M, K, D, S, R, B, A, H, C, P, N$ are displayed as finite coordinates, with A placed after the stream and regular-rational readback rows that make the dense Cauchy basis observable.

The common metric admission is inherited from Definition 1490.50. Both the complete-metric row K and the separable-density row D are read only over M.

The finite observation discipline is inherited from Definition 1490.54. Dense-name coverage, Cauchy-window data, and metric-radius comparisons pass through S and R before reaching K or D.

It remains to account for the Cauchy-basis row. By definition, A binds the complete and separable reads to the same scheduled dense Cauchy basis over M, S, R; it adds no selected point or quotient representative. The rows B, H, C, P, N then record the ledger, transport, replay, provenance, and local name for exactly that displayed packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootCauchyBasisObligations`

Theorem 1490.57 (PolishSpace completion-separability handoff)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be a Polish-space root Cauchy-basis carrier. Any completion-facing consumer or separability-facing consumer must factor through the single route*

$$M \longmapsto S \longmapsto R \longmapsto A \longmapsto K, D$$

before it is used as a $\mathsf{PolishSpace}^{\uparrow}$ *root read. The rows B, H, C, P, N then record the same observation ledger, componentwise transport, replay, provenance, and local naming for that route.*

Consequently the completion and separability faces cannot be consumed as independent host facts; they meet only through the scheduled dense Cauchy basis aligned by A.

Proof. Start with a completion-facing request. The request has to read the metric source M, then the finite stream schedule S and regular-rational readback R that expose the Cauchy-window observations used by the complete row.

Now read a separability-facing request. Its dense-name coverage uses the same M, S, R route, since Definition 1490.55 gives only one stream row and one readback row for the root packet.

The alignment row A is therefore the unique meeting point before K and D can be consumed together. It binds the complete-metric row and the separable dense-schedule row to the scheduled dense Cauchy basis, while B, H, C, P, N preserve that route for downstream root reads.

Because no selected dense point, quotient-completion equality, choice schedule, or ambient completeness coordinate is present in the carrier, the displayed route is the only completion-separability handoff exported by the packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootCompletionSeparabilityHandoff`

Theorem 1490.58 (PolishSpace root basis-window exactness)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be a Polish-space root Cauchy-basis carrier. The alignment row A is exact only relative to the shared* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. A complete row K and a separable row D are accepted by the root packet only through that same scheduled basis window; they cannot be consumed through a different dense schedule, a host choice of dense points, a quotient-completion representative, or a second metric carrier.*

Thus the basis row records a finite BEDC alignment over M, S, R, not an ambient assertion that completeness and separability may be read independently.

Proof. Project the carrier of Definition 1490.55. The row A is listed precisely as the finite Cauchy-basis alignment binding the complete-metric row K and the separable dense-schedule row D over the same metric source, stream schedule, and regular-rational readback data.

Use Definition 1490.54. Every dense-name, Cauchy-window, or metric-radius read must pass through S and R before it can be consumed by M, K, D, so a second dense schedule has no carrier coordinate.

Now apply Definition 1490.57. The complete and separable faces meet only along the route $M \longmapsto S \longmapsto R \longmapsto A \longmapsto K, D$.

The remaining rows B, H, C, P, N preserve that route as observation ledger, transport, replay, provenance, and local naming. Since the carrier has no field for host-selected dense points, quotient representatives, or another metric source, A is exact only over the displayed M, S, R window. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootBasisWindowExactness`

Theorem 1490.59 (PolishSpace root countable dense Cauchy readback)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. Every countable dense Cauchy-basis read of*

W must expose the finite $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the alignment row A before the complete-metric handoff K or the separable dense-schedule row D can be consumed. The observation ledger B, transport row H, replay row C, provenance row P, and local* $\mathsf{NameCert}$ *row N preserve exactly that route from the common metric source M to the completion and separability faces.*

The readback exports no selected dense point, quotient completion equality, countable-choice schedule, alternate dense enumeration, second metric carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 1490.55. The only countable dense Cauchy-basis route available to the accepted packet is carried by the common metric row M, the stream row S, the regular-rational readback row R, and the alignment row A.

Use Definition 1490.54. Any dense-name, Cauchy-window, or metric-radius request is forced through S and R before it reaches the complete row K or the separable row D.

Now apply Definition 1490.57. The complete and separable faces meet only after the scheduled basis has been aligned by A, so neither K nor D can be consumed as an independent host fact.

The remaining rows B, H, C, P, N are ledger, transport, replay, provenance, and local naming rows for the same route. Since the carrier has no coordinate for selected dense points, quotient representatives, countable choice, a second dense schedule, or ambient Real completeness, the stated readback surface is exact. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootCountableDenseCauchyReadback`

Theorem 1490.60 (PolishSpace root-basis NameCert exhaustion)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be a Polish-space root Cauchy-basis carrier. Before any complete-separable consumer can use Polish-space data, the accepted root packet exposes exactly the rows $M, K, D, S, R, B, A, H, C, P, N$: M is the common* $\mathsf{Met}^{\uparrow}$ *row, K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff, D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule, S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, A is the basis-alignment row, and B, H, C, P, N are the ledger, transport, replay, provenance, and local-name rows.*

The packet exports no selected dense point, countable-choice schedule, quotient-completion representative, second metric carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project Definition 1490.55. It lists precisely the rows $M, K, D, S, R, B, A, H, C, P, N$, with A added as the Cauchy-basis alignment over the root-unblock carrier rows.

Use Definition 1490.50 and Definition 1490.52. The complete row K, separable row D, stream row S, and regular-rational row R all return to the same metric source M and cannot import an external real oracle.

Apply Definition 1490.56 and Definition 1490.57. They place the complete and separable faces on the displayed route through M, S, R, A, K, D and keep B, H, C, P, N as the supporting ledger, transport, replay, provenance, and local name.

Finally apply Definition 1490.58. The basis window is exact only over M, S, R, so no selected dense points, choice schedules, quotient-completion representatives, second metric carriers, or ambient completeness coordinates remain available. The listed rows therefore exhaust the root-basis NameCert surface. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootBasisNamecertExhaustion`

Theorem 1490.61 (PolishSpace root completion-separability exhaustion)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P,$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. If a downstream root packet exposes the common metric row M, complete-metric handoff K, separable-metric basis row D, effective represented-space windows,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport H, replay C, provenance P, and local* NameCert *row N, then the displayed rows $M, K, D, S, R, B, A, H, C, P, N$ exhaust the completion-separability surface. No additional host metric completion, choice-selected dense sequence, quotient representative, or ambient Real-completeness coordinate can be read from the accepted packet.*

Proof. Start with Definition 1490.58. It fixes the complete and separable faces over the same metric source, stream window, and regular-rational readback route, so K and D cannot be consumed through independent schedules.

Apply Definition 1490.60. The accepted root packet already lists the common metric, complete handoff, separable basis, stream window, readback, basis ledger, alignment, transport, replay, provenance, and local-name rows as the whole root-basis surface.

The CompleteMetric and SeparableMetric handoff rows add no external selector. They are available only through M, S, R, A and then through H, C, P, N, while the effective represented-space windows and terminal $\mathsf{Real}^{\uparrow}$ seal are read back through the same finite route.

Since the carrier has no coordinate for host metric completion, countable choice, quotient representatives, or ambient Real completeness, those objects cannot be exported by the local NameCert. The completion-separability surface is therefore exactly the displayed root packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootCompletionSeparabilityExhaustion`

Theorem 1490.62 (PolishSpace root-basis metric-separability determinacy)**.** *Let $W = (M, K, D, S, R, B, A, H, C,$ and $W' = (M, K', D', S, R, B', A, H, C, P, N)$ be accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carriers. If the two carriers agree componentwise on the common* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{StreamName}^{\uparrow}$ *window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the alignment row A, and the structural rows H, C, P, N, then the* $\mathsf{CompleteMetric}^{\uparrow}$ *rows K, K' and the* $\mathsf{SeparableMetric}^{\uparrow}$ *rows D, D' expose the same root-basis consumer surface.*

Consequently a downstream complete-separable consumer can read only the common route through M, S, R, A, H, C, P, N. No second metric carrier, selected dense sequence, quotient-completion equality, or countable-choice schedule is determined by either accepted packet.

Proof. Project both accepted carriers through Definition 1490.55. Their shared rows M, S, R, A, H, C, P, N give the same metric source, finite stream windows, regular-rational readback, Cauchy-basis alignment, transport, replay, provenance, and local name.

Use Definition 1490.56 and Definition 1490.57. They force every complete-metric and separable-metric read through the route $M \longmapsto S \longmapsto R \longmapsto A \longmapsto K, D$, with the same route for K', D' because the determining rows are componentwise identical.

Now apply Definition 1490.58 and Definition 1490.59. The basis window is exact over the shared M, S, R data, and countable dense Cauchy reads pass through the same alignment row A before either completion or separability can be consumed.

Finally use Definition 1490.60. The accepted root packet has no coordinate for a second metric carrier, selected dense sequence, quotient-completion equality, or countable-choice schedule. Thus K, K' and D, D' may differ only as internal handoff rows over the same displayed route; their public root-basis consumer surface is the same. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRootBasisMetricSeparabilityDeterminacy`

Theorem 1490.63 (PolishSpace regular-Cauchy root window)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. Every complete-separable consumer of a Polish root window must first display the common* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K, the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R, the basis ledger and alignment rows B, A, the transport and replay rows H, C, the* Pkg *provenance row P, the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row N, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal read through those regular-Cauchy windows.*

The root window exports no selected dense sequence, quotient completion equality, host complete separable space, countable-choice schedule, second metric carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted root Cauchy-basis carrier. The rows $M, K, D, S, R, B, A, H, C, P, N$ are the whole displayed packet, with S and R carrying the regular-Cauchy window data used by both the complete and separable faces.

Apply Definition 1490.57. It routes completion-facing and separability-facing requests through the same M, S, R, A, K, D spine rather than through independent host facts.

Use Definition 1490.59 and Definition 1490.61. The dense Cauchy readback exposes finite stream windows, regular-rational readbacks, and the alignment row before either K or D can be consumed, and the completion-separability surface is exhausted by the listed rows.

Finally apply Definition 1490.62. The determining rows are the common metric, stream window, readback, alignment, transport, replay, provenance, and local name. Since the carrier has no coordinate for selected dense sequences, quotient completion equality, host complete separable spaces, countable choice, a second metric carrier, or ambient Real completeness, the regular-Cauchy root window is exactly the displayed route. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRegularCauchyRootWindow`

Theorem 1490.64 (PolishSpace effective presentation handoff)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. Every effective-presentation read of W must expose the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the observation ledger B before any consumer treats the PolishSpace packet as presented. The presentation is therefore a finite route through $M, D, S, R, B, A, H, C, P, N$, not a selected dense sequence or host represented-space object.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceEffectivePresentationHandoff`

Proof. Project Definition 1490.1 and Definition 1490.55. The root-basis carrier displays the common metric source M, completion row K, separable schedule D, StreamName row S, RegSeqRat readback R, observation ledger B, alignment row A, and structural rows H, C, P, N.

Use Definition 1490.2. Its carrier and classifier clauses require every public PolishSpace read to expose the finite metric, dense, stream, readback, transport, replay, provenance, and naming rows before it becomes a consumer-facing packet.

Apply Definition 1490.54 and Definition 1490.59. Together they place S, R, B before the complete-metric and separable-metric handoffs whenever a dense Cauchy-basis read is consumed.

Finally, Definition 1490.60 excludes selected dense points, choice schedules, quotient representatives, and host presentation data. Hence an effective presentation read is exactly the displayed handoff through D, S, R, B over M. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceEffectivePresentationHandoff`

Theorem 1490.65 (PolishSpace complete-separable route)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. The* $\mathsf{CompleteMetric}^{\uparrow}$ *row K and the* $\mathsf{SeparableMetric}^{\uparrow}$ *row D are consumed over the same* $\mathsf{Met}^{\uparrow}$ *row M and are transported together through H. No complete-separable consumer may replace this common metric source by an independent completion carrier, alternate dense schedule, or host topology.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceCompleteSeparableRoute`

Proof. Start with Definition 1490.55. The rows K and D appear in the same carrier tuple and both are attached to the common metric row M.

Apply Definition 1490.50. It identifies M as the common source for the complete-metric and separable-metric faces, so neither K nor D can be read as a detached host fact.

Use Definition 1490.57. Completion-facing and separability-facing requests pass through the same M, S, R, A, K, D route, with the stream and regular-rational rows aligning the two faces before either is consumed.

Transport is componentwise by the row H. The NameCert obligations of Definition 1490.2 and the exhaustion theorem Definition 1490.61 keep K, D on the same route and leave no coordinate for an independent completion, alternate dense schedule, or host topology. □

Theorem 1490.66 (PolishSpace Real-RegSeqRat nonescape)**.** *Let $W = (M, K, D, S, R, B, A, H, C, P, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *root Cauchy-basis carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing read through the PolishSpace packet factors through the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the observation ledger B. It exports no selected dense point, quotient completion equality, host topology, countable-choice schedule, second metric carrier, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted root carrier. The only Real-facing regular-Cauchy route available to the packet is the displayed path through S, R, B over the common metric row M and alignment row A.

Use Definition 1490.52. It places the Real-facing dependency after StreamName windows and regular-rational readback, rather than before them.

Apply Definition 1490.59 and Definition 1490.63. These theorems force dense Cauchy readback and terminal Real seal reads through S, R, B, A before completion or separability faces are consumed.

Finally invoke Definition 1490.60. Since the carrier has no coordinate for selected dense points, quotient completion equality, host topology, countable choice, a second metric carrier, or ambient Real completeness, the Real-facing route cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRealRegseqratNonescape`

Definition 1490.67 (Polish-space completion-density unblock)**.** *For an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier $P = (M, K, D, S, R, W, H, C, G, N)$, the completion-density unblock surface is the finite route that exposes the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K, and the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D only through the shared* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, observation ledger W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and local* NameCert *row N. A downstream consumer may read complete and dense data from this surface, but it receives no split metric carrier, selected dense point, quotient completion equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionDensityUnblock`

Theorem 1490.68 (Polish-space completion-density obligation)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every completion-density root request first fixes the common* $\mathsf{Met}^{\uparrow}$ *row M, then reads the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K and the* $\mathsf{SeparableMetric}^{\uparrow}$ *schedule D through the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and observation-ledger rows S, R, W. The supporting rows H, C, G, N transport, replay, source, and name only that displayed packet.*

Proof. Start from Definition 1490.67. The metric coordinate M is the single source for both the complete row K and the dense row D.

Read a completion-density request through S, R, W. The stream row supplies the finite dense-name and Cauchy-window positions, the regular rational row supplies the observable windows, and the ledger records that both kinds of request use the same route.

It remains to transport and name the packet. Componentwise hsame transport in H keeps M, K, D, S, R, W together, while C, G, N replay, source, and name the same finite data. No row remains from which a consumer could extract a split metric carrier, selected dense point, quotient completion equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompletionDensityObligation`

Theorem 1490.69 (Polish-space countable dense readback)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. Every countable dense readback of P is the finite route*

$$M \longmapsto D \longmapsto (S, R, W) \longmapsto (H, C, G, N),$$

with any completion-facing use of K read over the same M, S, R, W surface. Thus the dense readback is a displayed StreamName and RegSeqRat schedule, not a selected dense subset, host enumeration, quotient point equality, or countable-choice row.

Proof. Project the completion-density unblock surface. The dense schedule is the D row, and its only observation route is through the stream windows S, regular rational readback R, and ledger W.

Use Definition 1490.68. The obligation keeps D over M and forces completion-facing consumers of K to share the same S, R, W readback surface.

Finally attach H, C, G, N. These rows do not add a second dense source; they only transport, replay, source, and name the displayed route. Hence the countable dense readback remains finite and schedule-based. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCountableDenseReadback`

Theorem 1490.70 (Polish-space complete-metric separable synthesis)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier. The complete-metric and separable-metric data synthesize into one complete-separable root packet exactly when both K and D are consumed over the common* $\mathsf{Met}^{\uparrow}$ *row M and through the shared* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows S, R, W, H, C, G, N. The synthesis exports no independent completion coordinate, selected dense sequence, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the accepted carrier and apply Definition 1490.68. The complete row K and the separable row D are both read over M and through the same S, R, W observation surface.

Next use Definition 1490.69. The dense side has already been reduced to finite StreamName and RegSeqRat readback, and the completion-facing use of K cannot bypass that surface.

The remaining rows H, C, G, N assemble the synthesis. They provide componentwise transport, displayed replay, provenance, and local naming for the single packet, while no carrier coordinate names an independent completion, selected dense sequence, host equality, or ambient real-completeness principle. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteMetricSeparableSynthesis`

Theorem 1490.71 (Polish-space L10 sibling route)**.** *Every completion-density read of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier is routed through the sibling chapters chapter 57, chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38. The route uses the completion-density unblock surface of Definition 1490.67, the completion-density obligation of Definition 1490.68, the countable dense readback of Definition 1490.69, and the complete-metric separable synthesis of Definition 1490.70. It adds no selected dense point, quotient completion equality, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceL10SiblingRoute`

Proof. Start with the unblock definition. It exposes $M, K, D, S, R, W, H, C, G, N$ as the only rows available to a completion-density consumer, with M supplying the common metric source.

Apply the completion-density obligation and the countable dense readback. These place the complete-metric handoff and the separable schedule over the same StreamName and RegSeqRat windows, so the route must pass through the MetricSpace, CompleteMetric, SeparableMetric, StreamName, RegSeqRat, and Real sibling chapters named in the statement.

Finally apply the complete-metric separable synthesis. The synthesis repacks those sibling reads into the single $\mathsf{PolishSpace}^{\uparrow}$ surface through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. Since no carrier coordinate names a selected dense point, quotient completion equality, countable-choice schedule, or ambient Real-completeness theorem, the sibling route adds none of those objects. □

Definition 1490.72 (Polish-space complete-separable obligation carrier)**.** *A complete-separable obligation carrier for* $\mathsf{PolishSpace}^{\uparrow}$ *is a finite* BHist *packet*

$$P = (M, C, D, S, R, E, H, K, N)$$

whose rows display a $\mathsf{Met}^{\uparrow}$ *source* M*, a* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* C*, a* $\mathsf{SeparableMetric}^{\uparrow}$ *dense-schedule row* D*,* $\mathsf{StreamName}^{\uparrow}$ *windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, a* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* K*, and local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *naming* N*. The carrier has no coordinate for host completion, quotient equality of completion points, a selected dense set, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1490.73 (Polish-space complete-separable NameCert obligations)**.** *For every accepted complete-separable obligation carrier*

$$P = (M, C, D, S, R, E, H, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *surface requires carrier admission, complete-metric handoff through* C*, separable dense-schedule exposure through* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through* E*, componentwise transport* H*, displayed replay* K*, and local naming* N*. These rows bind the complete and separable routes over the same* $\mathsf{Met}^{\uparrow}$ *source* M*.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceCompleteSeparableNamecertObligations`

Proof. Project the carrier of Definition 1490.72. The metric row M is the single source for both the complete-metric handoff C and the separable dense-schedule row D.

Read observations through S, R, E. The StreamName row supplies finite Cauchy and dense-name windows, the regular rational row supplies the displayed readback, and the Real seal is downstream of those rows.

Finally attach H, K, N. Transport, replay, and local naming preserve the same finite packet, so the complete and separable obligations remain bound to M, C, D, S, R, E rather than to any host completion or selected dense set. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableNamecertObligations`

Theorem 1490.74 (Polish-space real completion readback nonescape)**.** *No* $\mathsf{PolishSpace}^{\uparrow}$ *consumer of the complete-separable obligation carrier*

$$P = (M, C, D, S, R, E, H, K, N)$$

may bypass $M, C, D, S, R, E, H, K, N$ *to obtain host completion, quotient equality of completion points, a selected dense set, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any real-facing completion read must first expose the metric row, complete-metric handoff, separable dense schedule, StreamName windows, RegSeqRat readback, and Real seal.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceRealCompletionReadbackNonescape`

Proof. Apply Definition 1490.73. It places every complete or separable read over the common metric source and through the displayed observation and real-readback rows.

The structural rows H, K, N cannot add a second completion route. They only transport, replay, and name the carrier, so any consumer that reaches a real-facing completion read remains inside M, C, D, S, R, E.

Since the carrier definition contains no host completion, quotient equality, selected dense set, countable-choice schedule, open-cover compactness row, or ambient real-completeness datum, none of those objects can be exported by a $\mathsf{PolishSpace}^{\uparrow}$ consumer of this packet. □

Theorem 1490.75 (Polish-space complete-separable obligation surface)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier*

$$P = (M, K, D, S, R, W, H, C, G, N),$$

the complete-separable obligation surface consists exactly of the common $\mathsf{Met}^{\uparrow}$ *source row* M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*, the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule* D*, the shared* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* S, R*, the observation ledger* W*, componentwise transport* H*, displayed replay* C*, provenance* G*, and local naming* N*.*

Proof. Project the carrier described in the PolishSpace spine. The rows M, K, D are the only complete and separable coordinates, and both are attached to the same metric source.

Use the NameCert-obligation theorem already attached to $\mathsf{PolishSpace}^{\uparrow}$. It places S, R, W as the finite readback route for complete and dense requests, so no consumer can split the complete metric from the separable schedule.

Finally attach H, C, G, N. Transport, replay, provenance, and local naming preserve the same packet, giving precisely the complete-separable surface carried by $P = (M, K, D, S, R, W, H, C, G, N)$. □

Theorem 1490.76 (Polish-space StreamName density scope)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier*

$$P = (M, K, D, S, R, W, H, C, G, N),$$

the density scope read through $\mathsf{StreamName}^{\uparrow}$ *is the route* D, S, R, W, H, C, G, N *over the common metric row* M*. It reads dense schedules as displayed stream windows, not as a host enumeration, selected dense subset, countable-choice schedule, or quotient point equality.*

Proof. Start from Definition 1490.75. It identifies D as the dense schedule and places it over the shared metric row M.

Read the density request through S, R, W. The StreamName row supplies finite windows, the RegSeqRat row supplies rational readback, and the observation ledger records the route used by the dense schedule.

The structural rows H, C, G, N only preserve and name this route. Since the accepted carrier has no host enumeration or selected dense-subset coordinate, the density scope remains the displayed StreamName route. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamNameDensityScope`

Theorem 1490.77 (Polish-space RegSeqRat real readback scope)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier*

$$P = (M, K, D, S, R, W, H, C, G, N),$$

every real-facing completion or density readback must pass through the $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *after the shared stream row* S *and before the structural rows* H, C, G, N*. The readback scope is therefore finite and carrier-local; it does not export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient completion equality, or a separate real-name source.*

Proof. Use Definition 1490.75 to place complete and separable data over M, K, D, S, R, W. The readback row R is part of that same surface, not an external real object.

Apply Definition 1490.76 to the dense side. The stream row S supplies the inspected windows, and R is the rational readback consumed from those windows.

The remaining rows H, C, G, N transport, replay, source, and name the packet. Therefore every real-facing read remains inside $P = (M, K, D, S, R, W, H, C, G, N)$ and cannot reach ambient completeness, selected limits, quotient completion equality, or a separate real-name source. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceRegSeqRatRealReadbackScope`

Theorem 1490.78 (Polish-space complete-separable window exhaustion)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier*

$$P = (M, K, D, S, R, W, H, C, G, N),$$

complete-separable reads are exhausted by the shared window M, K, D, S, R, W*. A consumer may preserve and name that window through* H, C, G, N*, but it receives no selected dense subset, host enumeration, quotient completion equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limit, or separate real-name source.*

Proof. Start from the complete-separable obligation surface of Definition 1490.75. It places the common metric source M, the complete handoff K, and the separable dense schedule D inside one carrier.

Use the StreamName density scope, Definition 1490.76. The dense side is read through S, R, W as finite stream windows with rational readback and an observation ledger.

The structural rows H, C, G, N preserve, replay, source, and name this same window. Since the carrier has no separate coordinate for the excluded objects, the complete-separable read is exhausted by M, K, D, S, R, W. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableWindowExhaustion`

Theorem 1490.79 (Polish-space effective represented source boundary)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the effective represented source boundary is the common metric row* M *together with the displayed StreamName and RegSeqRat route* S, R, W*. It is not a host enumeration, a selected dense subset, a quotient-completion equality, or a separate representation source outside the carrier.*

Proof. Project the carrier through Definition 1490.75. The complete row K and dense row D are both attached to the same metric source M.

Apply Definition 1490.76. Effective access to the dense side is carried by the StreamName row S, the RegSeqRat row R, and the observation ledger W.

The rows H, C, G, N do not create another represented source. They only preserve and name the displayed route, so any consumer that asks for host enumeration, a chosen dense subset, quotient equality, or an external representation leaves the accepted packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceEffectiveRepresentedSourceBoundary`

Theorem 1490.80 (Polish-space real readback nonescape)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, any real-facing readback from the complete-separable surface must pass through* S, R, W *and then through* H, C, G, N*. It cannot escape to ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit, quotient completion equality, host enumeration, a selected dense subset, or a separate real-name source.*

Proof. Use the RegSeqRat real readback scope of Definition 1490.77. The readback row R is reached after the shared stream row S and before the structural rows.

Combine this with Definition 1490.78. The complete and separable data remain in the same window M, K, D, S, R, W, so real-facing access is not a separate source.

Finally read the structural rows H, C, G, N. They transport, replay, source, and name the finite carrier-local route, and the carrier has no coordinate for the excluded real or completion objects. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRealRegSeqRatReadbackNonescape`

Theorem 1490.81 (Polish-space compact-metric factorization)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, every compact-metric or completion-facing read of the packet factors through the common metric row* M*, the complete handoff* K*, the separable dense schedule* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the observation ledger* W*, and the structural rows* H, C, G, N*. The factorization is the same finite route named by Definition 1490.75, Definition 1490.76, Definition 1490.77, and Definition 1490.78; it does not introduce a separate host Polish-space object, ambient completeness oracle, quotient-completion equality, or selected dense subset.*

Proof. Start with the complete-separable obligation surface of Definition 1490.75. It places the metric row M, complete handoff K, and dense schedule D inside the same accepted carrier, so a compact-metric consumer cannot split the metric source from the complete or separable rows.

Now apply Definition 1490.76 and Definition 1490.77. The dense and real-facing sides are both read through the finite window rows S, R, W, with R appearing after the stream windows and before the structural rows.

Finally use Definition 1490.78. The carrier-local window M, K, D, S, R, W is already exhaustive for complete-separable access, and H, C, G, N only transport, replay, source, and name that route. Therefore every compact-metric or completion-facing read factors through the displayed rows and has no separate host Polish-space object or ambient completeness oracle to consult. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompactMetricFactorization`

Theorem 1490.82 (Polish-space complete-separable obligation scope)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the complete-separable obligation scope is the common* $\mathsf{Met}^{\uparrow}$ *source row* M *together with the complete-metric handoff* K*, separable dense schedule* D*,* $\mathsf{StreamName}^{\uparrow}$ *windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, observation ledger* W*, componentwise transport* H*, displayed replay* C*, provenance* G*, and local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row* N*. The scope exports no selected dense subset, quotient-completion equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected completion limit, host enumeration, or external represented-space source.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableObligationScope`

Proof. Start with the complete-separable obligation surface of Definition 1490.75. It places $M, K, D, S, R, W, H, C, G$ inside one accepted packet and keeps the complete and separable rows over the same metric source.

Use the StreamName density scope of Definition 1490.76. The separable side is read through displayed windows S over the dense schedule D, so the consumer receives finite window data rather than a selected dense subset or host enumeration.

Apply the RegSeqRat readback scope of Definition 1490.77. The real-facing read passes through R after the StreamName row and before the structural rows, which excludes ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, and quotient-completion equality.

Finally use the compact-metric factorization of Definition 1490.81. It repacks compact-metric and completion-facing reads through the same carrier-local route, so no external represented-space source or detached completion object is exported. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceCompleteSeparableObligationScope`

Theorem 1490.83 (Polish-space pointwise density handoff)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N)$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *complete-separable packet whose complete metric, separable metric,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows are displayed through chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38. Every pointwise dense-read handoff through* P *must route through the countable-density row* D *before any completion-facing* $\mathsf{Real}^{\uparrow}$ *readback is consumed.*

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpacePointwiseDensityHandoff`

Proof. Start with the complete-separable obligation scope of Definition 1490.82. It places the complete-metric handoff K, separable dense schedule D, stream windows S, rational readback R, and observation ledger W inside the same accepted carrier.

Apply dense-window induction from Definition 1490.84. A pointwise dense-read handoff advances by reading the displayed countable-density row D through $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback, so the handoff cannot be supplied by a host enumeration or selected dense subset.

Use the observation lock of Definition 1490.85. It forces every combined complete-metric and separable read to inspect the shared ledger W along the same S, R route before completion-facing data are consumed.

The sibling chapters chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38 therefore appear only through the displayed rows K, D, S, R, W. Since no coordinate of P stores a separate completion source, a completion-facing $\mathsf{Real}^{\uparrow}$ readback may be consumed only after the countable-density row has been read. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparablePointwiseDensityHandoff`

Theorem 1490.84 (Polish-space complete-separable dense-window induction)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, complete-separable access supports induction over displayed dense windows. The base window reads the shared* $\mathsf{Met}^{\uparrow}$ *row* M *together with the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*. Each successor window extends the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule* D *through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, with* W *recording the inspected window. The structural rows* H, C, G, N *preserve the same packet at every step. Thus any accepted induction over the dense-window route remains inside* $M, K, D, S, R, W, H, C, G, N$ *and does not select a dense subset, import a host enumeration, identify a quotient completion, invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness, choose a limit, or introduce a separate representation source.*

Proof. Begin with the complete-separable obligation surface of Definition 1490.75. It names M as the shared metric source and K as the complete handoff, so the base window is already internal to the accepted carrier.

For the successor step, use the StreamName density scope and the RegSeqRat real readback scope. Definition 1490.76 reads the dense schedule through displayed stream windows, and Definition 1490.77 places rational readback after the stream row and before the structural rows.

Finally apply complete-separable window exhaustion from Definition 1490.78. The rows H, C, G, N only transport, replay, source, and name the same window route. Since no carrier coordinate supplies the excluded host objects, dense-window induction cannot escape the displayed packet. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableDenseWindowInduction`

Theorem 1490.85 (Polish-space complete-separable observation lock)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, any consumer that combines the complete-metric handoff* K *with the separable dense schedule* D *must first read the shared observation ledger* W *through the same* $\mathsf{StreamName}^{\uparrow}$ *row* S *and* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*. Hence complete and separable reads cannot split into two host sources, selected dense subsets, quotient-completion equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or external represented-space data.*

Proof. Start with the complete-separable obligation surface of Definition 1490.75. It places K and D over the same metric source M and inside the same carrier $P = (M, K, D, S, R, W, H, C, G, N)$.

Use the StreamName density scope and RegSeqRat real readback scope. Definition 1490.76 forces dense access through S, and Definition 1490.77 places R after the stream row and before the structural rows.

Apply complete-separable window exhaustion and compact-metric factorization, Definition 1490.78 and Definition 1490.81. They exhaust complete and separable reads through the displayed window M, K, D, S, R, W and then preserve that route through H, C, G, N.

Therefore a consumer that combines K and D must read the shared ledger W along the same S, R route. Since the accepted carrier has no coordinate for two host sources, selected dense subsets, quotient-completion equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or external represented-space data, those reads cannot split away from the observation ledger. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCompleteSeparableObservationLock`

Theorem 1490.86 (Polish-space complete-separable obligation closure)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the metric source* M*,* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*,* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule* D*,* $\mathsf{StreamName}^{\uparrow}$ *window* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, observation ledger* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row* N *form the complete obligation surface for* $\mathsf{PolishSpace}^{\uparrow}$*. The closure is finite and carrier-local: it exports no selected dense subset, quotient-completion equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected completion limit, host enumeration, or external represented-space source.*

Proof. Start with the complete-separable obligation surface of Definition 1490.75. It identifies $M, K, D, S, R, W, H, C, G, N$ as the available rows of the accepted packet.

Use the StreamName density scope and RegSeqRat readback scope, Definition 1490.76 and Definition 1490.77. These place the dense schedule and real-facing readback inside the displayed window route rather than in a selected dense subset or ambient real object.

Apply window exhaustion, effective represented source boundary, and real-readback nonescape: Definition 1490.78, Definition 1490.79, and Definition 1490.80. Together they rule out external represented sources, host enumerations, selected limits, quotient-completion equality, and ambient completeness.

Finally read Definition 1490.82. It packages the same rows as the complete-separable scope, so the listed packet is the complete obligation surface and no further coordinate is available to a $\mathsf{PolishSpace}^{\uparrow}$ consumer. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishspaceCompleteSeparableObligationClosure`

Theorem 1490.87 (Polish-space public complete-separable real readback)**.** *Let* $P = (M, K, D, S, R, W, H, C, G, N$ *be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Every public read of* P *offered to an L10-adjacent downstream consumer must expose the common* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* K*,* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule* D*,* $\mathsf{StreamName}^{\uparrow}$ *window row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{Real}^{\uparrow}$*-facing seal route, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row* N *before the consumer may use the packet as a complete-separable real readback.*

The route is public only as the displayed finite surface over $M, K, D, S, R, W, H, C, G, N$*. It does not assert classical descriptive set theory, a choice-selected dense sequence, host enumeration of points, quotient completion equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier through Definition 1490.1. The rows $M, K, D, S, R, W, H, C, G, N$ are the accepted packet, so a public read cannot detach the complete handoff, dense schedule, stream windows, rational readback, transport, replay, provenance, or local name from the carrier.

Use the complete-separable obligation surface of Definition 1490.75. It places K and D over the same metric row M and keeps S, R, W, H, C, G, N visible as the common route.

Next apply Definition 1490.76, Definition 1490.77, and Definition 1490.78. These theorems force dense access through $\mathsf{StreamName}^{\uparrow}$, force real-facing readback through $\mathsf{RegSeqRat}^{\uparrow}$, and exhaust the complete-separable window before any downstream consumer can read it.

Finally read the sibling anchors chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38 only through the displayed rows. Since the carrier has no coordinate for the excluded choice, quotient, selected-limit, or ambient-completeness principles, the public route is exactly the stated finite readback surface. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpacePublicCompleteSeparableRealReadback`

Theorem 1490.88 (Polish-space public finite-window boundary)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Every public read of P offered to an L10 consumer is exhausted by the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *row K,* $\mathsf{SeparableMetric}^{\uparrow}$ *row D,* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, terminal* $\mathsf{Real}^{\uparrow}$ *readback through W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and the local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row N over the metric source M.*

The boundary cannot introduce a choice-selected dense sequence, quotient completion equality, open-cover compactness, selected limits, a host enumeration of points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness outside the displayed finite packet.*

Proof. Start with Definition 1490.87. It already identifies the public readback surface as $M, K, D, S, R, W, H, C, G, N$ and refuses the choice, quotient, selected-limit, and ambient-completeness coordinates.

Use the sibling anchors named there. The complete-metric row is read only through chapter 128, the separable row only through chapter 1458, the stream and regular-rational rows only through chapter 126 and chapter 301, and the real-facing endpoint only through chapter 38.

Finally apply Definition 1490.75 and Definition 1490.78. They keep the complete and separable sides over the same metric source and exhaust the finite window before any consumer reads it. Since no carrier coordinate stores the refused objects, the public boundary is exactly the displayed route. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpacePublicFiniteWindowBoundary`

Theorem 1490.89 (Polish-space public readback export)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. A public export of P to L10 consumers is exactly the finite route through the* $\mathsf{Met}^{\uparrow}$ *source M,* $\mathsf{CompleteMetric}^{\uparrow}$ *row K,* $\mathsf{SeparableMetric}^{\uparrow}$ *row D,* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, terminal* $\mathsf{Real}^{\uparrow}$ *seal W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and local* $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ *row N.*

The export refuses choice-selected dense sequences, quotient completion equality, selected limits, host enumeration of points, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness outside the displayed packet.*

Proof. Start with Definition 1490.87. It identifies the complete-separable readback surface as the displayed rows $M, K, D, S, R, W, H, C, G, N$ and keeps the real-facing endpoint inside the packet.

Apply Definition 1490.88. It says that every L10-facing public read is exhausted by the same finite window through complete metric, separable metric, stream, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Now compose these two boundaries with the sibling anchors already named in the file: chapter 57, chapter 128, chapter 1458, chapter 126, chapter 301, and chapter 38. Since the carrier has no coordinate for the refused choice, quotient, selected-limit, host-enumeration, compactness, or ambient-completeness principles, the public export is exactly the displayed L10 readback route. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpacePublicReadbackExport`

Theorem 1490.90 (Polish-space public readback uniqueness)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packet. Suppose two public exports of P expose the same* $\mathsf{CompleteMetric}^{\uparrow}$ *row K,* $\mathsf{SeparableMetric}^{\uparrow}$ *row D,* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and terminal* $\mathsf{Real}^{\uparrow}$ *route W, and suppose their displayed transport rows identify the corresponding components by componentwise* hsame*.*

Then the two exports agree as finite L10 readback routes over $M, K, D, S, R, W, H, C, G, N$. This uniqueness is only the displayed packet uniqueness: it does not select a dense sequence, identify quotient completions, choose limits, or claim ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public readback export of Definition 1490.89. It says that any public export of P is exactly the finite route through $M, K, D, S, R, W, H, C, G, N$ and has no hidden choice, quotient, selected-limit, host-enumeration, compactness, or ambient-completeness coordinate.

Use the finite-window boundary of Definition 1490.88. Since both exports expose the same complete, separable, stream, regular-rational, and real rows, the L10-facing window of each export is exhausted by the same displayed components.

Finally apply the readback theorem of Definition 1490.87. Componentwise hsame on the exposed rows transports the same complete-separable real readback route through H, while C, G, N only replay, source, and name that route. Thus the two public exports agree as finite readback routes, without adding any of the refused external principles. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpacePublicReadbackUniqueness`

Theorem 1490.91 (Polish-space complete-separable public interface)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* PolishSpace$^{\uparrow}$ *packet. A public L10-facing read of P is the conjunction of the metric source row M, the* CompleteMetric$^{\uparrow}$ *row K, the* SeparableMetric$^{\uparrow}$ *dense schedule D, the* StreamName$^{\uparrow}$ *finite-window service S, the* RegSeqRat$^{\uparrow}$ *readback R, the terminal* Real$^{\uparrow}$ *seal W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance G, and the local* NameCert$_{\text{PolishSpace}^{\uparrow}}$ *row N.*

This interface refuses choice-selected dense sequences, quotient completion equality, host enumeration of points, selected limits, open-cover compactness, and ambient Real$^{\uparrow}$ *completeness outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceCompleteSeparableRealReadbackPublicInterface`

Proof. Start with Definition 1490.87. It identifies the accepted packet rows $M, K, D, S, R, W, H, C, G, N$ as the complete-separable real readback surface.

Apply the finite-window boundary of Definition 1490.88. It keeps every L10-facing read inside the complete metric, separable metric, stream, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Use the public readback export theorem Definition 1490.89. The export theorem supplies the metric source row together with the same complete, separable, window, readback, seal, and structural rows, so the interface is the displayed conjunction rather than a new abstract equivalence schema.

Finally apply public readback uniqueness, Definition 1490.90. Since any two public exports with the same displayed rows agree only as finite readback routes, the refused choice, quotient, host-enumeration, selected-limit, compactness, and ambient-completeness principles cannot enter the interface. □

Theorem 1490.92 (Polish-space public complete-separable real readback frontier)**.** *Let $P = (M, K, D, S, R, W, H, C, G, N)$ be an accepted* PolishSpace$^{\uparrow}$ *packet whose public complete-separable readback has been accepted through Definition 1490.91. A Real-facing point can be exposed to a downstream consumer only through the displayed* CompleteMetric$^{\uparrow}$ *row K,* SeparableMetric$^{\uparrow}$ *dense-window row D,* StreamName$^{\uparrow}$ *window row S,* RegSeqRat$^{\uparrow}$ *readback row R,* DyadicRatCore$^{\uparrow}$ *tolerance discipline inherited by the regular readback route, and the terminal* Real$^{\uparrow}$ *seal W, together with H, C, G, N.*

The frontier exports no open-cover compactness principle, selected limit, quotient real equality, choice-selected dense sequence, host enumeration of points, or ambient Real$^{\uparrow}$ *completeness outside that finite route.*

Proof. First read the four public-interface blocks already present in this child file. The complete-separable real readback theorem, the finite-window boundary, the public readback export, and the complete-separable public interface keep every public read inside the same packet rows $M, K, D, S, R, W, H, C, G, N$

Next inspect the sibling sources. The complete metric row is grounded in chapter 128, the complete-separable surface is read through chapter 1735, the window route through chapter 126, the regular readback through chapter 301, and the terminal seal through chapter 38. The dyadic tolerance discipline enters only through the regular-rational route and its chapter 291 tolerance ledger.

Finally apply public readback uniqueness. Since any accepted public export agrees only as the displayed finite route, a downstream consumer has no coordinate from which to read open-cover compactness, selected limits, quotient real equality, a choice-selected dense sequence, host enumeration, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The Real-facing point is therefore exposed exactly at the stated frontier. □

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpacePublicCompleteSeparableRealReadbackFrontier`

Theorem 1490.93 (Polish-space complete-separable obligation frontier)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the obligation frontier for complete-separable reads is exactly the complete-metric row* K*, the separable-metric row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal route read through* W*, and the structural rows* H, C, G, N *over the common metric row* M*. The frontier is the obligation surface of Definition 1490.75, Definition 1490.76, and Definition 1490.77; it has no coordinate for a selected dense set, quotient completion equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the complete-separable obligation surface. The rows $M, K, D, S, R, W, H, C, G, N$ are the whole displayed packet available to the complete and separable consumers.

Apply the StreamName density scope and the RegSeqRat real readback scope. They place finite stream windows and rational readback between the common metric source and every Real-facing completion or density read.

The structural rows only preserve and name this same packet. Since the carrier has no coordinate for the excluded host objects, the complete-separable obligation frontier is exactly the displayed surface. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceCompleteSeparableObligationFrontier`

Theorem 1490.94 (Polish-space stream realization obligation)**.** *Every* $\mathsf{PolishSpace}^{\uparrow}$ *obligation read that realizes a separable dense schedule must expose the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, and the observation ledger* W *before either the* $\mathsf{CompleteMetric}^{\uparrow}$ *row* K *or the* $\mathsf{SeparableMetric}^{\uparrow}$ *row* D *is consumed as public data. The realization is the carrier-local route named by Definition 1490.59, Definition 1490.63, and Definition 1490.76, not a host enumeration, selected dense sequence, or countable-choice schedule.*

Proof. Start with the root Cauchy-basis carrier. Its dense reads are displayed by the shared rows $M, S, R, B, A, H, C, P, N$ before the complete and separable faces are consumed.

Use the countable dense Cauchy readback and regular-Cauchy root window. They force dense realization through scheduled windows and regular rational readback, not through an unscheduled host enumeration.

Finally apply the StreamName density scope for the complete-separable obligation carrier. The same stream-readback discipline survives in the $P = (M, K, D, S, R, W, H, C, G, N)$ surface, so no selected dense sequence or countable-choice schedule is exported. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceStreamRealizationObligation`

Theorem 1490.95 (Polish-space dense-schedule transport obligation)**.** *Any dense-schedule read transported across accepted* $\mathsf{PolishSpace}^{\uparrow}$ *packets must preserve the common metric row* M*, complete row* K*, separable schedule* D*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{Real}^{\uparrow}$ *readback row* W*, and structural rows* H, C, G, N*. The transported read is therefore a row-local dense schedule over the same complete-separable packet, not a selected dense sequence, host enumeration, or countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.PolishSpaceUp.PolishSpaceDenseScheduleTransportObligation`

Proof. Project the accepted carrier $P = (M, K, D, S, R, W, H, C, G, N)$. The dense-schedule read is attached to the separable row D over the common metric source M, while completion and real-facing consumers see it only together with K, S, R, W and the structural rows.

Apply the stream realization obligation Definition 1490.94. It places every dense realization through S, R, W before complete or separable data is consumed as public data.

Now cite the real completion consumer boundary Definition 1490.96. It keeps Real-facing reads on the same $M, K, D, S, R, W, H, C, G, N$ surface and prevents a separate real-name source or selected limit from entering the packet.

Repack the transported dense read with H, C, G, N. Since the carrier contains no coordinate for selected dense sequences, host enumeration, or countable choice, transport preserves only the displayed dense-schedule surface. □

Theorem 1490.96 (Polish-space real completion consumer boundary)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing completion consumer of an accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier must pass through the complete-metric row* K*, the separable-metric row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the real-readback ledger* W*, and the structural rows* H, C, G, N *over the common metric row* M*. The boundary is read through Definition 1490.80, Definition 1490.66, and Definition 1490.75; it exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limit, quotient completion equality, host topology, or separate real-name source.*

Proof. Project the accepted Polish carrier and the complete-separable obligation surface. The only Real-facing rows available to a completion consumer are the StreamName, RegSeqRat, and observation rows attached to the common metric source.

Apply the two real-readback nonescape theorems. They force every Real-facing read through the regular-rational window and rule out an alternate real-name or ambient-completeness source.

The complete and separable rows remain tied to the same metric packet by transport, replay, provenance, and local naming. Hence a real completion consumer receives only the displayed rows named in the statement. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceRealCompletionConsumerBoundary`

Theorem 1490.97 (Polish-space obligation-closure witness)**.** *For every accepted* $\mathsf{PolishSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, W, H, C, G, N)$*, the displayed complete metric row* K*, countable dense schedule* D*,* $\mathsf{StreamName}^{\uparrow}$ *finite windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{Real}^{\uparrow}$ *seal read through* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* G*, and local* NameCert *row* N *supply the chapter's* obligation *surface over the common metric row* M*. This closure statement is a paper-side obligation witness; it does not change the independent formalstatus axis or claim theorem-checked Lean coverage.*

Proof. Project the complete-separable obligation frontier, stream realization obligation, and real completion consumer boundary above. Together they display the complete row, dense schedule, finite stream windows, regular-rational readback, Real-facing seal route, transport, replay, provenance, and local naming rows.

The rows are read over the same metric source M, so a complete or separable consumer cannot split the completion surface from the dense schedule or from the finite readback route.

Thus the chapter has a finite obligation-closure witness for $\mathsf{PolishSpace}^{\uparrow}$. The witness records the paper-side closure surface only; formalstatus remains governed by the separate Lean marker and closurestatus discipline. □

Lean4 ✓ `BEDC.Derived.PolishspaceUp.PolishSpaceObligationClosureWitness`

Closure status for $\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}$ •

Constructive story: A $\mathsf{PolishSpace}^{\uparrow}$ obligation packet is generated from a common metric row, complete and separable metric rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1490.93, Definition 1490.94, Definition 1490.96, and Definition 1490.97 bind the complete and separable $\mathsf{PolishSpace}^{\uparrow}$ route through $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PolishSpaceUp.PolishSpacePublicCompleteSeparableRealReadbackFrontier`

Bridge status: none

Not claimed: This chapter does not close selected dense sequences, host enumeration, countable-choice schedules, quotient completion equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Bridge checking requires a standard bridge theorem for the mature complete-separable $\mathsf{PolishSpace}^{\uparrow}$ route.

Chapter 1491

A Concrete Naming Certificate for $\mathsf{RationalEmbedding}^{\uparrow}$

Following Bishop and Bridges on constructive rational constants as real names, the $\mathsf{RationalEmbedding}^{\uparrow}$ packet records the standard constant rational route from a $\mathsf{Rat}^{\uparrow}$ row into a $\mathsf{Real}^{\uparrow}$ seal without turning host rational equality, quotient streams, selected limits, trichotomy, or ambient completeness into primitive coordinates. It sits between the rational source surface of chapter 37, the constant finite-window surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal boundary of chapter 38, and the dyadic constant-name route of chapter 467.

Definition 1491.1 (RationalEmbedding carrier surface)**.** *A* $\mathsf{RationalEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (q, S, R, D, E, H, C, P, N)$$

with the following displayed coordinates:

1. *q is the* $\mathsf{Rat}^{\uparrow}$ *source row naming the accepted rational point;*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule whose admitted windows all read the same rational source row q;*
3. *R is the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the constant schedule S;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and observation row used to compare the stationary rational reads at the displayed finite precisions;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after q, S, R, D have been exposed;*
6. *H stores componentwise* hsame *transports for the rational source, constant schedule, stationary readback, dyadic tolerance row, real seal, package provenance, and local naming row;*
7. *C stores the displayed* Cont *routes from q to S, from S to R, from R to D, and from D to E;*
8. *P is the* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalEmbedding}^{\uparrow}}$ *row.*

The carrier is a finite certificate for rational constants as real names. It contains no quotient stream, no host real equality row, no selected limit, no trichotomy principle, no host rational equality oracle, and no ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.RationalEmbeddingUp.RationalEmbeddingTasteGate single carrier alignment`

Theorem 1491.2 (RationalEmbedding constant sequence route)**.** *Every accepted* $\mathsf{RationalEmbedding}^{\uparrow}$ *packet routes its* $\mathsf{Rat}^{\uparrow}$ *source row* q *through the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *and the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *before any* $\mathsf{Real}^{\uparrow}$ *read is available. Thus a consumer of the real seal first sees the rational source, then the constant finite-window schedule, then the stationary regular-rational row, and only then the dyadic observation row and seal.*

Lean4 ✓ `BEDC.Derived.RationalEmbeddingUp.RationalEmbeddingCarrier constant sequence route`

Proof. Project the coordinates of Definition 1491.1. The continuation row C displays the route from q to S and the route from S to R, while H records that these coordinates are transported componentwise with the same package provenance.

The constant schedule S has no independent stream seed: each admitted window is read from q. The stationary row R is therefore the regular-rational readback of that constant schedule, not a separate rational sequence.

Only after R is displayed can the packet expose the dyadic observation row D and then the real seal E. Hence every real-facing consumer reads q, S, R in that order before reaching any $\mathsf{Real}^{\uparrow}$ coordinate. □

Lean4 ✓ `BEDC.Derived.RationalEmbeddingUp.RationalEmbeddingConstantSequenceRoute`

Theorem 1491.3 (RationalEmbedding RealUp seal boundary)**.** *For every accepted* $\mathsf{RationalEmbedding}^{\uparrow}$ *carrier* $K = (q, S, R, D, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the displayed dependency chain*

$$\mathsf{Rat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{NameCert}_{\mathsf{RationalEmbedding}^{\uparrow}}.$$

The seal exports only the local rows q, S, R, D, H, C, P, N *as its boundary data. It does not export a quotient stream, host real equality, a selected limit, trichotomy, host rational equality as an oracle, or ambient completeness for arbitrary Cauchy names.*

Proof. Start with a read of the real seal E. By the carrier definition, E is reachable only through the route entries in C whose predecessors are D, R, S, and q, and the same predecessors are named in the package row P and local certificate row N.

Apply Definition 1491.2. It identifies the route to R as the constant rational schedule read from q through S. The dyadic row D then supplies only the finite tolerance and observation data attached to that stationary readback.

The remaining rows H, C, P, N are transport, continuation, provenance, and local naming rows for the same finite route. Since the carrier contains no coordinate for a quotient stream, host real equality, selected limit, trichotomy, host rational equality oracle, or ambient completeness, the $\mathsf{Real}^{\uparrow}$ seal boundary is exactly the displayed finite dependency chain. □

Lean4 ✓ `BEDC.Derived.RationalEmbeddingUp.RationalEmbeddingRealSealBoundary`

Theorem 1491.4 (RationalEmbedding stationary readback exactness)**.** *For every accepted* $\mathsf{RationalEmbedding}^{\uparrow}$ *carrier* $K = (q, S, R, D, E, H, C, P, N)$*, the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is exactly the finite readback of the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *sourced by the* $\mathsf{Rat}^{\uparrow}$ *row* q*. The later* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *may inspect only this stationary readback before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed.*

Proof. Project the carrier surface of Definition 1491.1. The rows q, S, R, D, E appear in dependency order, and the continuation row C displays the route from the rational source to the constant schedule, then from the schedule to the stationary readback.

Apply Definition 1491.2. It identifies S as the constant finite-window schedule whose admitted windows all read q, and identifies R as the stationary regular-rational readback of that schedule.

Apply the seal-boundary theorem Definition 1491.3. It confines the real-facing route to q, S, R, D, H, C, P, N and gives D no coordinate other than the dyadic tolerance and observation row attached to the stationary readback.

Therefore the finite readback seen by D is exactly the stationary row R generated from S and q. No quotient stream, selected limit, host real equality, or ambient completeness coordinate can alter that readback before the seal is reached. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalEmbedding}^{\uparrow}$ packet is generated from a RatUp source row, constant StreamName schedule, stationary RegSeqRat readback, DyadicRatCore tolerance and observation row, RealUp seal, componentwise transports, continuation routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1491.1, Definition 1491.2, and Definition 1491.3 seed the finite rational-constant embedding route from $\mathsf{Rat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient-stream equality, selected host limits, host rational equality as an oracle, trichotomy, or a checked Lean certificate.

Upgrade path: Obligation closure requires checked carrier admission, constant StreamName routing, stationary RegSeqRat readback, DyadicRatCore observation exactness, RealUp seal factorization, and non-escape.

Chapter 1492

A Concrete Naming Certificate for $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$

Following Bolzano, Weierstrass, and Bishop–Bridges, the $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ packet records the constructive finite boundary from a bounded real sequence to a $\mathsf{Real}^{\uparrow}$ cluster seal. It consumes the bounded source surface of chapter 1415, the subsequence compactness route of chapter 1254, the selector handoff of chapter 1408, the monotone subsequence ledger of chapter 1405, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name surface of chapter 38. The packet is a boundary certificate for the bounded-sequence cluster route; it is not open-cover compactness, a host completeness theorem, quotient equality of streams, a least cluster selector, or a choice-selected arbitrary subsequence.

Definition 1492.1 (Bolzano–Weierstrass boundary carrier)**.** *A* $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, Q, D, BW, L, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded source row, read as a* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet and carrying only inspected sequence indices, finite bounds, and the displayed source route needed by downstream consumers.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family exposed for the inspected source indices and selected subsequence indices.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the displayed windows at the precisions requested by Q and by the seal row.*
5. *BW is the* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet that routes the bounded real sequence through finite interval nets and regular subsequence readback.*
6. *L is the* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *selector packet that keeps the finite selector surface visible before any real-facing seal is consumed.*
7. *T is the* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *route naming the monotone selected subsequence windows used by L and BW.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal reached only after S, W, Q, D, BW, L, T have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, stream windows, regular readback, dyadic tolerances, Bolzano–Weierstrass route, selector route, monotone subsequence route, Real seal, continuation rows, provenance rows, and local naming rows.*

10. *C records displayed* Cont *replay from the bounded source to stream windows, from stream windows to dyadic and regular readback, from selector and monotone subsequence rows to the Bolzano–Weierstrass route, and from that route to the Real cluster seal.*

11. *P is the* Pkg *provenance over* $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, ambient completeness, quotient-stream equality, a least cluster selector, a hidden tail selector, or choice over arbitrary subsequences.

Theorem 1492.2 (Bolzano–Weierstrass boundary NameCert obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ *carrier* $B = (S, W, Q, D, BW, L, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassBo}}$ *surface consists exactly of carrier admission for the twelve displayed rows, bounded-source admission through S, finite-window coverage through W, regular readback through Q, dyadic tolerance coverage through D, Bolzano–Weierstrass route admission through BW, selector-route admission through L, monotone-subsequence admission through T, Real cluster sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1492.1. The bounded source row S is read through chapter 1415, so the source side is already a finite sequence-window and bound certificate before the cluster route is inspected.

Read the analytic route next. The packet BW supplies the bounded-sequence subsequence compactness route of chapter 1254, while L and T expose the selector and monotone-subsequence rows consumed by that route.

Now inspect the finite completion-facing rows. The windows W, regular readback Q, and dyadic tolerance ledger D are precisely the surfaces read through the StreamName, RegSeqRat, and DyadicRatCore chapters before the $\mathsf{Real}^{\uparrow}$ seal E is available.

Finally the structural rows H, C, P, N transport, replay, source, and name only the displayed source, route, selector, window, tolerance, readback, and seal rows. Since no other coordinate is present, the listed obligations exhaust the local NameCert surface. □

Theorem 1492.3 (Bolzano–Weierstrass boundary source handoff)**.** *Every accepted* $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ *carrier hands a bounded real sequence source to the Bolzano–Weierstrass route only through*

$$S \longmapsto W \longmapsto Q, D \longmapsto L, T \longmapsto BW$$

together with H, C, P, N. Consequently the source consumed by the cluster route is the finite $\mathsf{BoundedRealSequence}^{\uparrow}$ *surface, not a host sequence object, an open-cover compactness principle, trichotomy of reals, quotient equality of streams, or a choice-selected arbitrary subsequence.*

Proof. Start with S. By chapter 1415, this row exposes bounded sequence data through inspected indices, finite stream windows, regular readback, Real-name sealing, and an interval-net bound row.

The carrier then reads W, Q, D. These rows make the inspected source and selected subsequence windows visible through the finite StreamName, RegSeqRat, and DyadicRatCore surfaces before the selector or cluster route can be consumed.

Pass through L and T. The selector packet and monotone subsequence packet display the selected-window route that the Bolzano–Weierstrass packet reads; the route is finite and cofinal on the inspected thresholds, not a choice-selected subsequence.

Only after these rows does BW receive the source. Transport, replay, provenance, and local naming preserve the same path, so the handoff cannot bypass the finite bounded-source certificate. □

Theorem 1492.4 (Bolzano–Weierstrass boundary Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *cluster seal read from an accepted* $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ *carrier factors through*

$$S, W, Q, D, L, T, BW, E, H, C, P, N.$$

The seal row E is reachable only after the bounded source, finite windows, regular readback, dyadic tolerance ledger, selector route, monotone-subsequence route, and Bolzano–Weierstrass route have been displayed. Thus a real-facing consumer receives a finite boundary certificate for the bounded-sequence cluster route and receives no open-cover compactness theorem, host completeness row, quotient equality of streams, least cluster selector, hidden tail selector, or arbitrary subsequence choice.

Proof. Begin with the handoff of Definition 1492.3. It places the bounded source, finite windows, regular readback, dyadic tolerances, selector route, monotone subsequence route, and Bolzano–Weierstrass packet before any terminal real-facing row.

Read the seal row through chapter 38. The row E is therefore a $\mathsf{Real}^{\uparrow}$ cluster seal for the displayed subsequence route, not a host limit, quotient representative, or separate completeness field.

The continuation and transport rows preserve the same factorization. Since the carrier has no coordinate for open-cover compactness, host completeness, quotient equality, least cluster selection, hidden tail selection, or arbitrary subsequence choice, no real-facing read can escape the listed finite rows. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ cluster-seal read factors through $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ before reaching the $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: boundedrealsequence, bolzanoweierstrass, bolzanoweierstrassselector, monotonesubsequence, streamname, regseqrat, dyadicratcore, real: $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded source row, finite windows, regular readback, dyadic tolerances, Bolzano–Weierstrass routing, selector routing, monotone subsequence routing, Real cluster sealing, transport, continuation, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}$ packet is generated from a bounded real sequence source, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, Bolzano-Weierstrass routing, selector routing, monotone-subsequence routing, a RealUp cluster seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1492.1, Definition 1492.2, Definition 1492.3, and Definition 1492.4 bind the finite boundary from bounded real sequences to Real cluster seals.

Formal verification: FormalStatus(NameCert$_{\text{BolzanoWeierstrassBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, host completeness, quotient equality of streams, least cluster selection, hidden tail selection, or arbitrary subsequence choice.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, bounded-source handoff, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.BolzanoWeierstrassBoundaryUp.

Chapter 1493

A Concrete Naming Certificate for $\mathsf{ExtremeValue}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{ExtremeValue}^{\uparrow}$ packet records the finite BEDC reading of the extreme-value theorem. Continuous real-valued maps on a compact metric source expose an attained-value packet only through finite nets, uniform-continuity moduli, a finite lower-bound fold, located supremum rows, $\mathsf{Real}^{\uparrow}$ seal rows, hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$. The packet consumes the compact metric source of chapter 129, the continuous-map surface of chapter 130, the compact-uniform-continuity route of chapter 388, the finite-net minimum fold of chapter 619, the located supremum boundary of chapter 1427, and the terminal real-name seal of chapter 38. It is an attainment certificate for inspected finite nets, not an open-cover compactness principle, a host maximum operator, quotient real equality, or a choice-selected point.

Definition 1493.1 (Extreme value carrier)**.** *An* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, F, U, M, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the admitted metric name, compact finite-net schedules, radius requests, and the displayed source certificate.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming a real-valued map from the source surface to* $\mathsf{Real}^{\uparrow}$ *output seals.*
3. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *row that turns the compact metric source and continuous map into a displayed finite modulus ledger.*
4. *M is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *row computing the finite lower-bound candidate over the inspected net selected by U.*
5. *S is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row recording the located upper boundary for the displayed value windows.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the attained value and for the real comparisons used by M and S.*
7. *H records componentwise* hsame *transport for the compact metric source, continuous map, uniform-continuity ledger, finite-net fold, located supremum row, real seals, continuation rows, provenance rows, and local naming rows.*

8. *C records displayed* Cont *replay from compact-metric radius requests to finite nets, from the map row to value windows, from uniform-continuity requests to the fold row, and from the fold and located-supremum rows to the terminal real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ExtremeValue}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for open-cover compactness, host-level maximum operators, quotient real equality, selected arbitrary points, countable choice, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueTasteGate single carrier alignment`

Theorem 1493.2 (Extreme value NameCert obligations)**.** *For every accepted* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier* $E = (X, F, U, M, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact metric source, continuous real-valued map, compact uniform-continuity ledger, finite-net minimum fold, located supremum boundary, terminal real seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueNameCertObligations`

Proof. Project the carrier of Definition 1493.1. The source row X is read through chapter 129, so every metric, radius, and compact-net request is already displayed before a value row is inspected.

Read the map and modulus rows next. The row F uses the continuous-map surface of chapter 130, and U uses the compact-uniform-continuity route of chapter 388 to bind value variation on the finite nets supplied by X.

Now inspect the real-valued boundary rows. The row M applies the finite-net fold of chapter 619, while S reads the located upper boundary through chapter 1427 and R supplies only the real-name seals admitted by chapter 38.

Finally the structural rows H, C, P, N transport, replay, source, and name the already displayed source, map, modulus, fold, supremum, and seal rows. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1493.3 (Extreme value finite-net attainment)**.** *Every accepted* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier factors any attained-value read through*

$$X \longmapsto F \longmapsto U \longmapsto M \longmapsto S \longmapsto R$$

together with H, C, P, N. Consequently the exported attainment statement is a finite-net and real-seal certificate over the compact metric source and continuous map, not a host maximum operator, an arbitrary selected point of the source, or an open-cover compactness argument.

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueCarrier finite net attainment`

Proof. Begin with the compact metric source. By chapter 129, X exposes the finite net schedule and the metric-radius data that any later value comparison must use.

Feed this source into the map row. The continuous-map packet of chapter 130 supplies only displayed value windows, and the compact-uniform-continuity packet of chapter 388 turns those windows into a finite modulus ledger on the same compact source.

The fold row M then searches the displayed net by the finite-net minimum fold of chapter 619. The located supremum row S supplies the opposing located boundary through chapter 1427, and the real-seal row R is read through chapter 38.

Transport and replay preserve the same factorization. Thus a consumer can see only the finite source net, the displayed map windows, the compact-uniform modulus, the finite fold, the located boundary, and the real seal; no separate host maximum or arbitrary point selector is available. □

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueFiniteNetAttainment`

Theorem 1493.4 (Extreme value Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *value seal exported by an accepted* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier is downstream of the compact metric source* X*, continuous map row* F*, compact uniform-continuity ledger* U*, finite-net minimum fold* M*, and located supremum row* S*. The seal row* R *therefore records only the boundary visible through finite-net attainment data and does not provide quotient real equality, detached* $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, or an independent real maximum principle.*

Proof. Start from the factorization in Definition 1493.3. It places the compact metric source, map windows, compact-uniform modulus, finite-net fold, and located supremum row before any real-facing seal is exported.

The upstream chapters fix the only admissible route: chapter 129 supplies X, chapter 130 supplies F, chapter 388 supplies U, chapter 619 supplies M, and chapter 1427 supplies S.

Read R through chapter 38. This makes the terminal row a $\mathsf{Real}^{\uparrow}$ seal for the displayed finite-net value and located boundary, not a quotient representative or a host completeness witness.

The continuation, transport, provenance, and local naming rows do not add new real equality or selection data. Since the carrier has no coordinate for detached $\mathsf{Real}^{\uparrow}$ completeness, countable choice, quotient equality, or a host maximum operator, every exported real seal remains inside the finite-net attainment boundary. □

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueRealSealBoundary`

Theorem 1493.5 (Extreme value Real seal factorization)**.** *Every Real-facing attained-value read from an accepted* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier factors through*

$$X \longmapsto F \longmapsto U \longmapsto M \longmapsto S \longmapsto R$$

together with H, C, P, N*. The source row* X *is supplied by* $\mathsf{CompactMetric}^{\uparrow}$*, the map row* F *by* $\mathsf{ContinuousMap}^{\uparrow}$*, the modulus row* U *by* $\mathsf{CompactUniformContinuity}^{\uparrow}$*, the finite fold row* M *by* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$*, the located boundary row* S *by* $\mathsf{LocatedSupremum}^{\uparrow}$*, and the terminal seal row* R *by* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueRealSealFactorization`

Proof. Start with Definition 1493.3. It places every attained-value read on the route from compact metric source to continuous map, compact-uniform modulus, finite-net fold, located boundary, and terminal real seal.

Apply Definition 1493.4. The terminal row R is a $\mathsf{Real}^{\uparrow}$ seal only for the finite-net value and located boundary already exposed by X, F, U, M, S.

The sibling chapters supply the source rows named in the statement: compact metric data, continuous map windows, compact uniform-continuity ledgers, finite-net minimum folds, located supremum rows, and Real seals. The structural rows H, C, P, N transport, replay, source, and name that same chain; they do not add open-cover compactness, a host maximum operator, quotient equality, countable choice, or detached $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1493.6 (Extreme value compact-net maximum row)**.** *Every accepted* $\mathsf{ExtremeValue}^{\uparrow}$ *carrier exposes the finite-net candidate row* M *from* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *before the located supremum row* S *and terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *are consumed. Thus the maximum-facing read is certified by displayed finite net data over* $X, F, U, M, S, R, H, C, P, N$*, not by a host maximum selector, an open-cover compactness argument, quotient real equality, or countable choice.*

Lean4 ✓ `BEDC.Derived.ExtremeValueUp.ExtremeValueCompactNetMaximumRow`

Proof. Project the carrier of Definition 1493.1. The row M is part of the displayed packet and is positioned after the compact metric source, continuous map, and compact-uniform modulus rows.

Use finite-net attainment from Definition 1493.3. Any attained-value consumer must pass through the finite fold before it can read the located boundary or the terminal Real seal.

Finally apply the Real seal boundary of Definition 1493.4. The seal row records only the boundary already visible through the finite net and located supremum rows, so no open-cover compactness coordinate or choice-based maximum selector is available. □

Falsifiable prediction: Every $\mathsf{ExtremeValue}^{\uparrow}$ attained-value read factors through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before reaching the local $\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}$ row.

Independence witness: compactmetric, continuousmap, compactuniformcontinuity, finitenetminimumfold, locatedsupremum, real: $\mathsf{ExtremeValue}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact metric source, a continuous real-valued map, a compact-uniform modulus ledger, a finite-net minimum fold, a located supremum boundary, terminal real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}$.

Constructive story: An $\mathsf{ExtremeValue}^{\uparrow}$ packet is generated from a $\mathsf{CompactMetric}^{\uparrow}$ source, a $\mathsf{ContinuousMap}^{\uparrow}$ real-valued map, a $\mathsf{CompactUniformContinuity}^{\uparrow}$ modulus ledger, a $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ finite fold, a $\mathsf{LocatedSupremum}^{\uparrow}$ boundary row, $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1493.1, Definition 1493.2, Definition 1493.3, Definition 1493.4, and Definition 1493.5 seed the constructive finite-net attainment reading of extreme values on compact metric sources.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExtremeValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host maximum operators, quotient real equality, selected arbitrary points, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, finite-net attainment, Real seal boundary, and TasteGate field faithfulness for BEDC.Derived.ExtremeValueUp.

Chapter 1494

A Concrete Naming Certificate for $\mathsf{RepresentedSpace}^{\uparrow}$

Following Weihrauch-style represented spaces and Bishop–Bridges constructive analysis, the $\mathsf{RepresentedSpace}^{\uparrow}$ packet records the interface at which a computable name is allowed to present a real-facing object. It sits over the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The carrier below treats representation as a finite NameCert interface rather than as a quotient of names or a selected host representative.

Definition 1494.1 (RepresentedSpace carrier)**.** *A* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, W, \rho, X, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the name carrier: a finite source row whose observations are read through the* $\mathsf{StreamName}^{\uparrow}$ *interface.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule recording the inspected precision requests, stream positions, and replay windows.*
3. *ρ is the representation relation row; it relates the displayed stream observations to the target row only through the local finite schedule.*
4. *X is the target carrier row, with the real-facing case routed through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any consumer reads it.*
5. *T is classifier transport from the name row, schedule row, representation relation, and target row to a common finite comparison surface.*
6. *H records componentwise* hsame *transport for $S, W, \rho, X, T, C, P, N$.*
7. *C records displayed* Cont *replay from a precision request through the finite schedule, representation relation, target row, and classifier transport.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local NameCert row.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common finite surface. It has no coordinate for quotient names, selected representatives, host real equality, an ambient completeness row, or a choice principle.

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceTasteGate single carrier alignment`

Theorem 1494.2 (RepresentedSpace NameCert obligations)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed name carrier, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule, representation relation, target carrier, classifier transport, continuation, provenance, and local name;*
2. *classifier transport to a common finite surface on which the name row, schedule row, representation row, and target row can be compared without adding host equality;*
3. *stability of the name, schedule, representation relation, target row, and classifier transport under the componentwise* hsame *rows recorded in* H*;*
4. *exactness of the representation relation row* ρ *as the only permitted route from stream observations to the target carrier;*
5. Cont *replay,* Pkg *provenance, and local NameCert rows for exactly the displayed packet.*

No NameCert obligation is stored outside those five rows.

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier namecert obligations`

Proof. Project the carrier of Definition 1494.1. The projection exposes the name carrier, finite stream schedule, representation relation, target carrier, transport rows, continuation row, provenance row, and local name.

Classifier transport is componentwise. The rows in H move the name, schedule, representation relation, target row, and transport row to the same finite comparison surface, while C replays only the displayed requests and windows.

Representation exactness is exhausted by ρ. A consumer can reach X from the stream observations only through the stored relation row, and the real-facing case must then pass through the regular rational, dyadic, and real seal rows already named in the carrier.

Finally attach P, N. These rows source and name the displayed packet; they add no quotient name, selected representative, host real equality, completeness row, or choice principle. Hence the five listed rows exhaust the local naming obligations. □

Theorem 1494.3 (RepresentedSpace name schedule obligation)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, every represented-space read opens the displayed name row* S *and the* $\mathsf{StreamName}^{\uparrow}$ *schedule* W *before the representation relation row* ρ *is consumed. The schedule exposes the inspected precision requests and stream positions as finite* BHist *data, not as an implicit oracle over names.*

Proof. Project the carrier in Definition 1494.1. The name row S and schedule row W are the only coordinates from which stream observations may be read.

The NameCert obligations of Definition 1494.2 place carrier admission and classifier transport before relation exactness. Thus a consumer cannot reach ρ without first displaying the finite name and schedule rows.

The structural rows H, C, P, N only transport, replay, source, and name that same scheduled route. They do not add an unscheduled representation oracle. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier name schedule obligation`

Theorem 1494.4 (RepresentedSpace representation relation exactness)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, the row* ρ *is the only route from the stream observations displayed by* S, W *to the target carrier* X*. Any target-facing consumer that bypasses* ρ *is outside the local* $\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}$ *surface.*

Proof. Read the exactness clause in Definition 1494.2. It identifies ρ as the sole displayed relation between scheduled stream observations and the target row.

Classifier transport through T, H compares the same components on a finite surface. It can move an accepted representation route, but it cannot create a second relation from stream data to X.

Replay and provenance through C, P, N preserve the route already named by ρ. Therefore every accepted target read factors through ρ and no bypass is certified. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier representation relation exactness`

Theorem 1494.5 (RepresentedSpace target handoff nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing target handoff from an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *factors through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The handoff exports no quotient names, selected representatives, host equality, completeness witness, or choice principle.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier target handoff nonescape`

Proof. Start with the name schedule obligation. It forces the target handoff to read S, W before the representation relation is consumed.

Apply representation relation exactness. The relation row ρ is the only certified route from the scheduled stream observations to X, and the real-facing case of X passes through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally use the structural rows. The BHist, hsame, Cont, Pkg, and NameCert data transport, replay, source, and name the handoff without adding quotient names, representatives, host equality, completeness, or choice. □

Theorem 1494.6 (RepresentedSpace StreamName Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing represented-space read through an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Concretely, a consumer first reads the finite $\mathsf{StreamName}^{\uparrow}$ *schedule* W*, then the regular rational readback and dyadic tolerance rows attached to the target carrier* X*, then the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and only then consumes the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route contains no quotient name, selected representative, host real equality, completeness row, or choice principle.*

Proof. Start with a real-facing read of the target row X. Carrier admission exposes the finite schedule W before the representation relation ρ can be consumed, so the first visible route is the $\mathsf{StreamName}^{\uparrow}$ schedule of chapter 126.

Next read the analytic handoff rows. The target carrier is real-facing only by passing through the $\mathsf{RegSeqRat}^{\uparrow}$ surface of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Finally replay H, C, P, N. These rows keep the handoff inside the local BHist, hsame, Cont, Pkg, and NameCert data. Since the carrier has no coordinate for quotient names, selected representatives, host real equality, completeness, or choice, no such route can be read by a consumer. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceStreamnameRealHandoff`

Theorem 1494.7 (RepresentedSpace schedule representation exactness)**.** *Every target read from an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *must expose the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W *before the representation relation row* ρ *can be used. The representation relation is therefore exact only as a displayed route from the inspected stream observations to the target row* X*, with* Cont *replay and* Pkg *provenance preserving that schedule.*

Proof. Project the carrier of Definition 1494.1. The representation relation ρ is stored after the name carrier S and the finite schedule W, so no target read can consume ρ without first displaying the inspected stream positions and precision requests.

Replay through C preserves this order. The continuation row starts from the precision request, exposes the schedule, and only then reaches the representation relation and target row.

Finally attach P and N. Provenance and local naming source the same scheduled route, and the carrier has no coordinate for an unscheduled representation oracle. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier schedule representation exactness`

Theorem 1494.8 (RepresentedSpace classifier transport)**.** *Accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier sameness is transported componentwise through* $S, W, \rho, X, T, H, C, P, N$*. The transport compares the name carrier, schedule, representation relation, target row, classifier transport, structural replay, provenance, and local naming rows; it never appeals to host equality of names, target objects, real representatives, or quotient classes.*

Proof. Read the classifier row T together with the transport data H. These rows compare accepted packets only after their displayed components have been moved to a common finite surface.

The representation and target rows move with the same schedule. Thus ρ and X are compared only through the corresponding scheduled carrier rows, not by host equality.

The structural rows C, P, N then replay, source, and name the transported packet. Since no host equality, quotient class, or selected representative is present in the carrier, transport is exhausted by the listed components. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier classifier transport`

Theorem 1494.9 (RepresentedSpace target seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing target read from an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *packet must pass through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The read cannot bypass the regular rational readback, dyadic tolerance ledger, terminal Real seal, componentwise transport, replay, provenance, or local naming evidence.*

Proof. Start with the target carrier X. In the real-facing case, the carrier definition routes X through the regular rational readback surface, the dyadic tolerance ledger, and the terminal Real seal.

Apply the schedule exactness theorem. The target read has already exposed the finite StreamName schedule before ρ is consumed, so the analytic rows are downstream of a displayed name schedule rather than an ambient target object.

Finally replay the structural rows H, C, P, N. They keep the read inside BHist, hsame, Cont, Pkg, and NameCert data. Coordinate exhaustion blocks any route that skips RegSeqRat, DyadicRatCore, the Real seal, transport, replay, provenance, or local naming. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier target seal nonescape`

Theorem 1494.10 (RepresentedSpace realizer readback window)**.** *For an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, every realizer readback window that reaches a real-facing target must expose the* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to* X*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before the represented target is consumed. Thus readback is a finite windowed route through the displayed carrier, not a quotient of names or a selected host real.*

Proof. Project the carrier from Definition 1494.1. The name carrier S and the finite schedule W are displayed before the representation relation ρ and target row X can be read.

Use Definition 1494.2. Its exactness clause makes ρ the only route from stream observations to the target carrier, while its transport clause keeps S, W, ρ, X, T on one finite comparison surface.

Finally apply Definition 1494.9. In the real-facing case the route reaches the regular rational readback, dyadic tolerance ledger, and terminal Real seal before replaying the BHist, hsame, Cont, Pkg, and NameCert evidence. Since no quotient-name or selected-host coordinate is present, every realizer readback window remains inside the displayed route. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier realizer readback window`

Theorem 1494.11 (RepresentedSpace NameCert scope package)**.** *The scope package of an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *is exactly the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback path to the real-facing* X *row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, finite* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. No represented-space scope clause may add host real equality, a choice-selected representative, or an ambient completion row outside that package.*

Proof. Start with Definition 1494.2. Carrier admission exposes the rows $S, W, \rho, X, T, H, C, P, N$, and the obligation list stores no additional scope coordinate.

Classifier transport contributes only T together with the componentwise transports in H. This keeps the stream schedule, representation relation, and target carrier on a common finite surface without importing host equality.

The real-facing part is bounded by Definition 1494.6 and Definition 1494.9. Those theorems force the target route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows. The listed package is therefore the whole represented-space scope. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.ScopePackage.RepresentedSpaceCarrier namecert scope package`

Theorem 1494.12 (RepresentedSpace translation nonescape)**.** *Every translation from a* $\mathsf{StreamName}^{\uparrow}$ *name to a real-facing represented target in an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier passes through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, finite* BHist *packet, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The translation cannot escape into an external name quotient, host equality of reals, selected representative, or ambient completeness principle.*

Proof. Read the translation as a target read from the carrier. By Definition 1494.7, the finite $\mathsf{StreamName}^{\uparrow}$ schedule is exposed before the representation relation row can be used.

The classifier-transport theorem then fixes the comparison surface for $S, W, \rho, X, T, H, C, P, N$. Translation therefore moves the displayed name, schedule, representation relation, and target row together rather than replacing them by host equality.

For a real-facing target, Definition 1494.10 supplies the readback window through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ before the structural rows are replayed. The carrier has no coordinate outside BHist, hsame, Cont, Pkg, and NameCert for this route, so the translation has no escape path. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier translation nonescape`

Theorem 1494.13 (RepresentedSpace admissible name coverage)**.** *Every admissible* $\mathsf{RepresentedSpace}^{\uparrow}$ *name accepted by the displayed representation row is covered by the finite route*

$$S, W, \rho, X, T, H, C, P, N.$$

In particular, the read starts with the $\mathsf{StreamName}^{\uparrow}$ *finite windows in* W*, passes through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal exposed by the target row* X*, transports classifier data by the componentwise* hsame *rows in* H*, replays the requested observations by* C*, and ends in the* Pkg *provenance and local* NameCert *row* N*.*

Proof. Project the carrier of Definition 1494.1. The admissible name is not a free stream; it is read through the displayed name carrier S and finite schedule W, so the only inspected observations are the $\mathsf{StreamName}^{\uparrow}$ windows stored in the packet.

Use the representation relation row ρ next. It is the sole route from those stream observations to the target row X, and the real-facing case of X exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal before any consumer receives a target value.

Finally transport and replay the route. The componentwise hsame rows in H keep $S, W, \rho, X, T, C, P, N$ on the same finite comparison surface, while C replays the inspected windows and P, N source the resulting NameCert row. Thus every admissible name covered by the representation row is covered by the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier admissible name coverage`

Theorem 1494.14 (RepresentedSpace completion-boundary refusal)**.** *An accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *packet does not by itself certify a completion boundary, a quotient completion, or a host-real representative. Any completion-facing consumer must first display the representation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback path, the* $\mathsf{Real}^{\uparrow}$ *seal, the* hsame *transport,* Cont *replay,* Pkg *provenance, and the same local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier completion boundary refusal`

Proof. Inspect the carrier coordinates. They include a name carrier, finite windows, a representation row, a target row, classifier transport, structural transport, replay, provenance, and local naming, but no coordinate for a completed ambient space, quotient completion, or selected host-real representative.

The refusal is stable under the analytic handoff. A completion-facing read still has to pass through ρ, the finite $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ readback exposed by X, and the terminal $\mathsf{Real}^{\uparrow}$ seal; none of those rows adds a completion object.

It remains to check transport and provenance. The hsame rows, Cont replay, Pkg provenance, and local NameCert only preserve and source the displayed route. Since the packet never stores an additional completion boundary, the represented-space certificate refuses to export one. □

Theorem 1494.15 (RepresentedSpace realization transport)**.** *If two accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *packets compare by the displayed classifier, then every realized target read transported from the first packet to the second is transported through the same finite representation route:* $\mathsf{StreamName}^{\uparrow}$ *windows,* ρ*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *comparison,* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Start from the classifier transport theorem. Equality of accepted packets is not host equality of names or targets; it is the componentwise hsame comparison of $S, W, \rho, X, T, H, C, P, N$ on a common finite surface.

Transport the realized read along those rows. The finite $\mathsf{StreamName}^{\uparrow}$ windows move with W, the representation relation moves with ρ, and the target read moves with X, where the real-facing route still passes through the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal.

Finally replay the structural evidence on the second packet. The Cont row reproduces the same inspected windows, while Pkg provenance and the local NameCert row source the transported certificate. No unrecorded realization map, quotient equality, or host representative is introduced by the transport. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier realization transport`

Theorem 1494.16 (RepresentedSpace StreamName representation source)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, a representation-name read must open the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W *before any target-facing inspection of* X *is available. The source of the representation is therefore the displayed name carrier and schedule pair* S, W*, not an implicit name oracle, a quotient of names, or a selected representative.*

Proof. Project the carrier. The only source rows that expose name observations are S and the finite $\mathsf{StreamName}^{\uparrow}$ schedule W.

Apply the NameCert obligations and the realization transport theorem. Both place the representation relation ρ and the target row X downstream of the displayed schedule, so a target consumer cannot inspect X before the finite windows have been opened.

The structural rows T, H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for an implicit oracle, quotient name, or selected representative, the representation source is exactly the scheduled StreamName surface. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier streamname representation source`

Theorem 1494.17 (RepresentedSpace realization exactness)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, the accepted realizations are exactly the displayed relation row* ρ *between the scheduled source observations* S, W *and the target carrier row* X*. A row belongs to the local realization surface precisely when it is read through* S, W, ρ, X *and then preserved by* T, H, C, P, N*.*

Proof. Use Definition 1494.4. It identifies ρ as the sole route from scheduled stream observations to the target row.

The forward direction is immediate from carrier admission: an accepted realization displays S, W, consumes ρ, reaches X, and then carries the route through classifier transport, componentwise hsame, replay, provenance, and local naming.

Conversely, any row read through the displayed S, W, ρ, X route and preserved by T, H, C, P, N satisfies the carrier and NameCert obligations. There is no second realization coordinate in the packet, so the displayed relation is exact. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier realization exactness`

Theorem 1494.18 (RepresentedSpace target seal ledger package)**.** *Every real-facing target seal exported by an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier is packaged through the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,*

Real$^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows attached to* $S, W, \rho, X, T, H, C, P, N$. *The package excludes quotient representatives, selected names, host real equality, choice-selected realizers, and ambient completion data.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceTargetSealLedgerPackage`

Proof. Start from the target carrier row X. In the real-facing case, the carrier definition and target-seal theorem route X through regular rational readback, dyadic tolerance data, and the terminal Real seal.

Transport and replay are then fixed by the structural rows. The componentwise hsame rows in H keep the target route on the same finite comparison surface, while C replays the inspected windows and P, N source the package.

No excluded object is a coordinate of R. Thus quotient representatives, selected names, host real equality, choice-selected realizers, and ambient completion data cannot be exported by the target seal ledger. □

Theorem 1494.19 (RepresentedSpace effective metric realizer handoff)**.** *Let an accepted* RepresentedSpace$^{\uparrow}$ *carrier be used by an* EffectiveMetricSpace$^{\uparrow}$ *or* EffectiveMetricCompletion$^{\uparrow}$ *consumer. Before any distance read, completion-tail read, or Real-facing seal is available, the carrier must expose its finite* StreamName$^{\uparrow}$ *schedule, representation relation,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance row, and* Real$^{\uparrow}$ *seal through the displayed rows of Definition 1494.1.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier effective metric realizer handoff`

Proof. Begin with Definition 1494.16. It forces every target-facing read to open the finite StreamName$^{\uparrow}$ schedule before the target row can be inspected.

Apply Definition 1494.17. The realized target is exactly the displayed relation row between the scheduled source observations and the target carrier, so an effective metric consumer cannot substitute an implicit realizer or selected name.

Finally use Definition 1494.18. Its ledger route packages the real-facing target through RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ tolerance, the terminal Real$^{\uparrow}$ seal, transport, replay, provenance, and local naming. Hence the effective metric or completion consumer receives the finite handoff before any distance or completion read is available. □

Theorem 1494.20 (RepresentedSpace effective-metric root obligations)**.** *Every effective metric read of an accepted* RepresentedSpace$^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *must pass through the displayed* StreamName$^{\uparrow}$ *schedule* S*, observation windows* W*, representation relation* ρ*, target row* X*, classifier transport* T*, componentwise* hsame *rows* H*, replay row* C*, provenance row* P*, and local* NameCert *row* N*. In the real-facing case, the same read exposes the* RegSeqRat$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$ *rows named by the target seal before any* Real$^{\uparrow}$ *seal is available.*

Proof. Open Definition 1494.1. The source schedule, observation windows, relation, target row, transport, replay, provenance, and naming rows are coordinates of the same finite packet.

Apply Definition 1494.2 and Definition 1494.17. They force every target-facing read to move through $S, W, \rho, X, T, H, C, P, N$ rather than through a selected name or host representation equality.

For real-facing metric reads, apply Definition 1494.18. It records the RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ route attached to the displayed target seal. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier root effective metric obligations`

Theorem 1494.21 (RepresentedSpace completion-readback root obligations)**.** *Every completion readback consumed from an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier is routed through* $S, W, \rho, X, T, H, C, P, N$ *and through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *handoff rows before completion vocabulary is available. It cannot use quotient representatives, selected Cauchy names, host equality, or ambient completion data.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier root completion readback obligations`

Proof. Start with Definition 1494.19. It places effective metric and completion consumers behind the finite stream schedule, representation relation, regular readback, dyadic tolerance, and Real seal route.

The realization is exact by Definition 1494.17, so the completion readback remains attached to ρ and X. The target seal ledger package then supplies the regular-rational and dyadic rows used by completion-facing reads.

The excluded objects are not coordinates of Definition 1494.1; transport, replay, provenance, and local naming preserve the displayed route. □

Theorem 1494.22 (RepresentedSpace Real-seal root obligations)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier is obtained from the displayed* $S, W, \rho, X, T, H, C, P, N$ *route and from the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *target-seal ledger. No* $\mathsf{Real}^{\uparrow}$ *consumer receives host real equality, quotient representation data, selected realizers, countable choice, or an ambient completeness theorem from the represented-space packet.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier root real seal obligations`

Proof. Read the target row X through Definition 1494.17. The target is available only through the displayed relation between scheduled source observations and the carrier row.

Apply Definition 1494.18. It packages every real-facing target seal through regular rational readback, dyadic tolerance data, the terminal Real seal, componentwise transport, replay, provenance, and local naming.

Since the packet has no coordinate for host equality, quotient representatives, selected realizers, choice, or ambient completeness, the Real-seal route is exactly the displayed finite handoff. □

Theorem 1494.23 (RepresentedSpace admissible finality)**.** *Let an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *be consumed by a* $\mathsf{Real}^{\uparrow}$*-facing represented-space consumer that also exposes an* $\mathsf{AdmissibleRepresentation}^{\uparrow}$ *packet. Before the consumer reads output data, the displayed route must factor through*

$$\mathsf{RepresentedSpace}^{\uparrow} \longmapsto \mathsf{CauchyRepresentation}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The factorization is the finite represented-space carrier route of Definition 1494.1, the exact representation relation of Definition 1494.4, the StreamName-to-Real handoff of Definition 1494.6, and the admissible Cauchy finality interface of chapter 1760 and chapter 1680. It excludes quotient names, selected representatives, host real equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier admissible finality`

Proof. Open the represented-space carrier. By Definition 1494.1, the only source available to the consumer is the displayed finite route through $S, W, \rho, X, T, H, C, P, N$.

Use Definition 1494.4. The representation relation ρ is the sole certified path from scheduled stream observations to the target carrier, so an admissible consumer cannot bypass the displayed representation row.

Apply Definition 1494.6. In the real-facing case the target route opens the $\mathsf{StreamName}^{\uparrow}$ schedule, then the regular rational and dyadic readback rows, and only then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal.

The exposed $\mathsf{AdmissibleRepresentation}^{\uparrow}$ packet supplies the finality clause of chapter 1760, while chapter 1680 supplies the Cauchy source used by that clause. Since none of the represented-space carrier coordinates stores quotient names, selected representatives, host real equality, countable choice, or ambient real completeness, the displayed factorization is the whole admissible-finality route. □

Theorem 1494.24 (RepresentedSpace scoped package)**.** *Let an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *packet expose the name schedule, representation relation, target handoff,* $\mathsf{StreamName}^{\uparrow}$ *Real handoff, effective-metric realizer handoff, completion-readback obligations, Real-seal obligations, and admissible finality rows named in Definition 1494.1. Then it exports a scoped* $\mathsf{NameCert}$ *package over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{EffectiveMetricSpace}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The package is read only through the displayed carrier route* $S, W, \rho, X, T, H, C, P, N$, *and it does not add quotient names, selected representatives, host real equality, countable choice, ambient completion data, or a separate parameter-transport equivalence.*

Proof. Begin with the local carrier and obligation surface. Apply Definition 1494.2, Definition 1494.3, Definition 1494.4, and Definition 1494.5 to expose the schedule, representation relation, target handoff, transport, replay, provenance, and local naming rows.

For the real-facing route, use Definition 1494.6, Definition 1494.19, and Definition 1494.22. These rows force every metric or Real-seal consumer through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff before any target read is available.

For completion and admissibility, apply Definition 1494.21 and Definition 1494.23. The completion-readback and admissible-finality rows are downstream of the same carrier route, so the scoped package is exactly the displayed finite $\mathsf{NameCert}$ surface and not a new equivalence between unrelated parameter families. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.ScopePackage.RepresentedSpaceCarrier scoped package`

Theorem 1494.25 (RepresentedSpace Cauchy-name scope package)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$, *each represented-space Cauchy-name read is scoped by the displayed representation schedule* S, W, *the target row* X, *the representation relation row* ρ, *the classifier transport row* T, *and the replay package* H, C, P, N. *Cauchy names arriving from* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *enter the packet only through those displayed representation rows and through the target-seal ledger already attached to* X. *The read exports no source-equivalence transport statement, quotient representation, selected Cauchy name, host equality, countable choice, or ambient completion datum.*

Proof. Open the carrier of Definition 1494.1. The source schedule, observation windows, representation relation, target row, classifier transport, replay, provenance, and local naming rows are the only coordinates available to a represented-space read.

Apply the NameCert obligations and name-schedule coverage, Definition 1494.2 and Definition 1494.3. They force every represented read to display the finite schedule and its observation windows before the target row can be consumed.

The Cauchy-name content is then read through the existing target route. Theorems 1494.16, 1494.17, and 1494.18 place $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ data behind the representation relation and the target-seal ledger attached to X.

Finally use the scoped package theorem Definition 1494.24. It keeps transport, replay, provenance, and local naming inside H, C, P, N and does not add an equivalence between source names. Since the excluded objects are not carrier coordinates, the Cauchy-name read remains scoped by the displayed representation rows. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier cauchy name scope package`

Theorem 1494.26 (RepresentedSpace realizer scope)**.** *For every accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$*, each realizer read is scoped by the displayed rows* $S, W, \rho, X, T, H, C, P, N$*. The read must open the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule in* W *before it consumes the representation relation* ρ *or the target row* X*, and it cannot bypass the schedule by using an implicit name oracle, quotient representation, selected realizer, host equality, countable choice, or ambient completion datum.*

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier realizer scope`

Proof. Project the carrier of Definition 1494.1. The only realizer-facing source rows are the name carrier S, the finite schedule W, the representation relation ρ, and the target row X, with T, H, C, P, N preserving and naming the same route.

Apply the schedule obligation of Definition 1494.3 and the source theorem Definition 1494.16. They force every target-facing realizer read to expose the finite $\mathsf{StreamName}^{\uparrow}$ windows before ρ or X can be inspected.

Use representation exactness and target nonescape, Definition 1494.17 and Definition 1494.5. The realized target is read through the displayed relation and cannot be replaced by an implicit oracle or host equality.

Finally apply Definition 1494.24. Componentwise transport, replay, provenance, and local naming remain inside T, H, C, P, N, so the excluded quotient, selected-realizer, choice, and completion objects have no carrier coordinate from which a bypass could be read. □

Theorem 1494.27 (RepresentedSpace admissible Cauchy handoff)**.** *Let an accepted* $\mathsf{RepresentedSpace}^{\uparrow}$ *carrier* $R = (S, W, \rho, X, T, H, C, P, N)$ *be consumed by an admissible Cauchy-facing represented-space consumer. Before any target row is sealed for that consumer, the read factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff is mediated by the displayed schedule W*, representation relation* ρ*, target row* X*, componentwise* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local name* N*. It exports no quotient Cauchy names, selected representatives, host real equality, countable choice, ambient real completeness, or separate admissibility oracle.*

Proof. Begin with the Cauchy-name scope package Definition 1494.25. It places Cauchy-facing reads behind the displayed schedule, representation relation, target row, classifier transport, replay, provenance, and local naming rows.

Use Definition 1494.6 and Definition 1494.18. They route the real-facing target through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal before a target consumer can read the sealed object.

Apply admissible finality from Definition 1494.23. The admissible consumer receives the same finite route rather than a separate oracle over names.

The scoped package theorem Definition 1494.24 then replays T, H, C, P, N around that route. Since quotient Cauchy names, selected representatives, host equality, choice, and ambient completeness are absent from Definition 1494.1, the displayed handoff is the whole admissible Cauchy interface. □

Lean4 ✓ `BEDC.Derived.RepresentedSpaceUp.RepresentedSpaceCarrier admissible cauchy handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RepresentedSpace}^{\uparrow}$ packet is generated from a displayed name carrier, finite $\mathsf{StreamName}^{\uparrow}$ schedule, representation relation, target carrier, classifier transport, componentwise hsame rows, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1494.1, Definition 1494.2, Definition 1494.4, Definition 1494.6, Definition 1494.15, Definition 1494.5, Definition 1494.19, Definition 1494.21, Definition 1494.22, Definition 1494.23, Definition 1494.24, and Definition 1494.27 give mature paper treatment of the public represented-space carrier route as the bridge-facing surface through CauchyRepresentation-style name reads, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RepresentedSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient representations, selected host representatives, host equality, a choice principle, or a Lean theorem.

Upgrade path: The paper axis is mature; the verification axis remains available for a checked represented-space theorem and standard bridge.

Chapter 1495

A Concrete Naming Certificate for $\mathsf{LawlessSequence}^{\uparrow}$

Following Brouwer and Bishop-style choice sequence analysis, the $\mathsf{LawlessSequence}^{\uparrow}$ packet records only the finite observation surface of a lawless sequence. It sits between the $\mathsf{StreamName}^{\uparrow}$ finite-prefix interface of chapter 126, the $\mathsf{BaireSpace}^{\uparrow}$ naming surface of chapter 334, the $\mathsf{Bool}^{\uparrow}$ digit row of chapter 32, and the $\mathsf{Nat}^{\uparrow}$ prefix-index ledger of chapter 28. The packet is a NameCert for finite-prefix inspection and replay; it is not a host infinite sequence, not a primitive lawless choice object, and not a countable-choice principle.

The finite-window route consumes the $\mathsf{StreamName}^{\uparrow}$ finite-prefix carrier of chapter 126 and the $\mathsf{BaireSpace}^{\uparrow}$ prefix row of chapter 334 before any digit is read, so the chapter cannot be read as a host infinite-sequence surface.

Definition 1495.1 (Lawless sequence carrier)**.** *A* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, B, I, H, C, P, N)$$

with the following displayed rows:

1. *W is a* $\mathsf{StreamName}^{\uparrow}$ *finite-prefix window recording exactly the prefixes currently inspected.*
2. *B is the* $\mathsf{Bool}^{\uparrow}$ *digit row attached to each inspected prefix in W.*
3. *I is the* $\mathsf{Nat}^{\uparrow}$ *prefix-index ledger ordering the displayed prefix requests and their finite extension steps.*
4. *H transports finite prefixes and their digit rows componentwise by* hsame*.*
5. *C records displayed* Cont *replay routes from an index request in I to its prefix window in W and from that window to the corresponding digit row in B.*
6. *P records* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{LawlessSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the finite rows W, B, I, H, C, P, N. It has no coordinate for host infinite sequence data, countable choice, primitive lawless choice, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceTasteGate single carrier alignment`

Theorem 1495.2 (Lawless sequence NameCert obligations)**.** *For every accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier* $L = (W, B, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LawlessSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the seven displayed rows, finite-prefix window coverage through* W*, Boolean digit readback through* B*, unary prefix-index ordering through* I*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceCarrier namecert obligations`

Proof. Project the finite packet of Definition 1495.1. The only sequence observations available to the classifier are the displayed $\mathsf{StreamName}^{\uparrow}$ prefix windows in W, the corresponding $\mathsf{Bool}^{\uparrow}$ digit rows in B, and the $\mathsf{Nat}^{\uparrow}$ prefix-index ledger I.

Perform prefix induction over the finite row I. The base case reads the empty displayed prefix and its digit row when present. The step case extends the current inspected prefix by one unary index move and then reads the next visible digit through B.

Transport is componentwise. The rows in H move each displayed prefix and digit row by hsame, while C replays the route from index requests to windows and from windows to digits. Repacking these projections with P and N gives the stated local NameCert surface without adding any hidden infinite-sequence coordinate. □

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceNameCertObligations`
↪ variant `BEDC.Derived.LawlessSequenceUp.NameCertObligations.LawlessSequenceNameCertObligations`

Theorem 1495.3 (Lawless sequence finite-window scope)**.** *Every consumer read of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *packet factors through the finite route*

$$I \longmapsto W \longmapsto B$$

together with H, C, P, N*. Thus the packet supplies finite prefix observation and digit replay, but it does not supply host infinite sequences, countable choice, lawless choice as a primitive, quotient streams, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read and project its requested prefix index from I. Prefix induction over the displayed $\mathsf{Nat}^{\uparrow}$ row gives a finite chain of inspected prefixes and no appeal to an ambient sequence.

At each step, read the corresponding window from W and the digit row from B. The $\mathsf{Bool}^{\uparrow}$ row is attached to the displayed prefix, so the digit is a finite observation rather than a value extracted from an unseen total function.

Finally route the read through H, C, P, N. Componentwise transport and continuation replay preserve the same finite window and digit rows, and the carrier has no coordinate from which a host infinite sequence, choice principle, quotient stream, or real-completeness object could be read. □

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceFiniteWindowScope`

Theorem 1495.4 (Lawless sequence StreamName handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{BaireSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier receives only the displayed finite-prefix window* W*, its* $\mathsf{Bool}^{\uparrow}$ *digit rows* B*, the* $\mathsf{Nat}^{\uparrow}$ *prefix-index ledger* I*, and the structural rows* H, C, P, N*. The handoff therefore presents lawless-sequence observation as a StreamName finite-window route, not as an infinite stream object or a choice-selected total sequence.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceStreamNameHandoff`

Proof. Read the accepted carrier of Definition 1495.1. The $\mathsf{StreamName}^{\uparrow}$ face is exactly W, and the $\mathsf{BaireSpace}^{\uparrow}$ use is restricted to the same displayed finite prefixes.

Next read the digit and index rows. The $\mathsf{Bool}^{\uparrow}$ row B supplies only the observed digits for prefixes listed by I, while the $\mathsf{Nat}^{\uparrow}$ ledger I supplies only the finite prefix-ordering route.

The handoff is completed by the structural rows H, C, P, N. They transport, replay, source, and name the same finite prefix windows, so downstream consumers receive a StreamName-compatible finite observation packet and receive no host infinite stream, primitive lawless-choice source, countable-choice row, quotient-stream equality, or $\mathsf{Real}^{\uparrow}$ completeness surface. □

Theorem 1495.5 (Lawless sequence choice-free carrier obligation)**.** *Every accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier read is a finite prefix packet over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. In particular, every consumer-visible observation is read from the displayed rows* W, B, I, H, C, P, N *of Definition 1495.1, and no host infinite sequence, primitive lawless choice source, quotient stream equality, or countable-choice schedule is exported.*

Proof. Project the carrier rows in Definition 1495.1. The only prefix data available to a consumer is the $\mathsf{StreamName}^{\uparrow}$ window W together with the $\mathsf{Bool}^{\uparrow}$ digit row B and the $\mathsf{Nat}^{\uparrow}$ index ledger I.

Apply the finite-window scope theorem Definition 1495.3. It factors every consumer read through $I \longmapsto W \longmapsto B$ before the structural rows can be consumed.

Finally use the StreamName handoff theorem Definition 1495.4. The handoff transports and replays the same finite rows through H, C, P, N, so no accepted read can recover a host infinite sequence, a primitive lawless-choice source, quotient stream equality, or countable-choice schedule. □

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceChoiceFreeCarrierObligation`

Theorem 1495.6 (Lawless sequence StreamName window obligation)**.** *Every replayed observation of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier factors through displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{BaireSpace}^{\uparrow}$ *prefix rows before a digit read is exposed. The replay route is finite: it reads an index from* I*, a window from* W*, the corresponding digit from* B*, and then the transport, continuation, provenance, and local naming rows* H, C, P, N*.*

Proof. Begin with a replayed observation and project its index request from I. The finite-window scope theorem Definition 1495.3 sends that request through the displayed window route $I \longmapsto W \longmapsto B$.

The $\mathsf{BaireSpace}^{\uparrow}$ use is the prefix-row reading already named in Definition 1495.4. It is attached to the same $\mathsf{StreamName}^{\uparrow}$ window W, not to a completed stream or an ambient function.

Now replay through C and transport through H. Provenance P and the local $\mathsf{NameCert}$ row N name the same finite packet, so every accepted observation remains a displayed StreamName window with BaireSpace prefix coverage and a visible Bool digit row. □

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceStreamNameWindowObligation`

Theorem 1495.7 (Lawless sequence Real-boundary nonescape)**.** *No accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *packet exports* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a host infinite sequence, or a countable-choice schedule. Any downstream countable-name or real-boundary consumer must first pass through the finite rows* W, B, I, H, C, P, N *and receives only the StreamName-compatible finite prefix surface of Definition 1495.4.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceRealBoundaryNonescape`

Proof. Read the carrier of Definition 1495.1. Its classifier compares packets only through the finite rows W, B, I, H, C, P, N, and the definition explicitly leaves $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host infinite sequence data, and countable choice outside the carrier.

Apply Definition 1495.5. Every accepted read is already a finite prefix packet over StreamName, Bool, Nat, transport, replay, provenance, and local naming.

Finally apply the StreamName handoff theorem Definition 1495.4. A countable-name consumer receives only the finite prefix window and its digit rows, so any real-boundary use that asks for completeness, quotient equality, a host sequence, or a countable-choice schedule exits the accepted $\mathsf{LawlessSequence}^{\uparrow}$ packet. □

Definition 1495.8 (Lawless sequence finite-window carrier)**.** *The finite-window refinement of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier* $L = (W, B, I, H, C, P, N)$ *is the displayed prefix packet*

$$L_{\mathrm{fin}} = (I, W, B, H, C, P, N)$$

read in dependency order: I *names the finite observed prefix requests,* W *supplies exactly the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows,* B *attaches the visible* $\mathsf{Bool}^{\uparrow}$ *digit rows to those windows, and* H, C, P, N *transport, replay, source, and name the same observed packet. The refinement forgets no consumer-visible row of* L*, but it records explicitly that every observation is made through a finite prefix packet before any downstream sequence or real-boundary reader is served.*

Theorem 1495.9 (Lawless sequence StreamName choice window)**.** *Every observed choice window of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *packet factors through the finite rows*

$$I, W, B, H, C, P, N.$$

In particular, the window first reads a $\mathsf{Nat}^{\uparrow}$ *prefix index from* I*, then a* $\mathsf{StreamName}^{\uparrow}$ *prefix window from* W*, then the corresponding* $\mathsf{Bool}^{\uparrow}$ *digit row from* B*, and only then the transport, continuation, provenance, and local naming rows. No consumer can read an observed choice window as a total sequence, an unseen future law, or a countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceStreamNameChoiceWindow`

Proof. Begin with an observed choice window and project the finite-window carrier of Definition 1495.8. The first available datum is the prefix-index row I, so the consumer must name a finite $\mathsf{Nat}^{\uparrow}$ request before any digit can be read.

Use finite prefix induction over I. The base case reads the empty displayed prefix when it is present in W. The step case extends the observed prefix by one displayed request, consults the matching $\mathsf{StreamName}^{\uparrow}$ window in W, and reads only the attached $\mathsf{Bool}^{\uparrow}$ digit in B.

Finally replay the structural rows. The rows H, C, P, N transport and name the same finite window; they have no coordinate for future values outside W or for a choice schedule selecting all positions at once. □

Theorem 1495.10 (Lawless sequence finite-prefix induction)**.** *Every finite extension of the* $\mathsf{Nat}^{\uparrow}$ *prefix-index ledger* I *in an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier* $L = (W, B, I, H, C, P, N)$ *preserves the displayed route*

$$I \longmapsto W \longmapsto B \longmapsto H, C, P, N.$$

The induction exposes only the prefixes already listed by the finite ledger and their visible $\mathsf{Bool}^{\uparrow}$ *digit rows. It exposes no unseen future values, no host infinite sequence, and no countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceFinitePrefixInduction`

Proof. Induct on the displayed finite prefix ledger I. The base case is the empty-prefix read: the consumer reads the initial request from I, consults the corresponding $\mathsf{StreamName}^{\uparrow}$ window in W when present, and obtains only the attached visible digit row in B.

For the step, extend the displayed request by one unary prefix move. The carrier offers no direct digit coordinate outside W, so the next read must pass through the extended StreamName window and then through its attached Bool row.

Finally replay the structural route. Componentwise transport in H, continuation replay in C, provenance in P, and local naming in N preserve the same finite prefix packet at each stage, so the induction cannot reveal any value beyond the displayed ledger. □

Theorem 1495.11 (Lawless sequence Real nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *packet receives* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a host infinite sequence, or a countable-choice schedule. Every such consumer receives only the finite-window packet* $L_{\mathrm{fin}} = (I, W, B, H, C, P, N)$ *of Definition 1495.8, routed through the StreamName choice window of Definition 1495.9.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceRealNonescape`

Proof. Read the Real-boundary nonescape theorem Definition 1495.7. It already excludes completeness, quotient equality, host infinite sequences, and countable-choice schedules from the accepted packet.

Now refine the carrier read through Definition 1495.8. The only prefix-facing object passed to a real-boundary consumer is L_{fin}, whose rows are the observed indices, StreamName windows, Bool digits, transport, replay, provenance, and local naming.

Apply Definition 1495.9. Since each observed choice window factors through I, W, B, H, C, P, N, a Real consumer cannot bypass the finite prefix packet to obtain quotient stream equality, a host sequence, or a countable-choice schedule. □

Theorem 1495.12 (Lawless sequence prefix-induction obligation)**.** *Every accepted prefix read of a* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier* $L = (W, B, I, H, C, P, N)$ *is obtained by finite induction over the* $\mathsf{Nat}^{\uparrow}$ *index row* I*. The base read exposes the displayed empty prefix when it is present in* W*; each step extends the current displayed request by one index move in* I*, reads the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window from* W*, and then reads the attached* $\mathsf{Bool}^{\uparrow}$ *digit row from* B*. No accepted prefix read is supplied by a host infinite sequence or by a countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequencePrefixInductionObligation`

Proof. Project the carrier of Definition 1495.1. The only index row available to a prefix consumer is I, so every request starts from the displayed finite prefix ledger.

Induct over the finite row I. The base case reads the empty displayed prefix and stops if no digit row is attached. The step case consumes one displayed successor request, reads the matching window from W, and attaches only the visible digit row in B.

Finally replay through H, C, P, N. These structural rows transport and name the same finite read, and none contains a coordinate for unseen future values or a choice schedule. □

Theorem 1495.13 (Lawless sequence prefix-window determinacy)**.** *Let* $L = (W, B, I, H, C, P, N)$ *and* $L' = (W', B', I', H', C', P', N')$ *be accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carriers. If the rows* I, W, B, H, C, P, N *and* $I', W', B', H', C', P', N'$ *are transported componentwise by* hsame *and replayed through the displayed* Cont *routes, then every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*, or real-boundary consumer sees the same*

finite observed prefix window and the same visible $\mathsf{Bool}^{\uparrow}$ *digit rows. The determined surface is exactly the transported finite window; it exposes no future values, no host infinite sequence, and no countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequencePrefixWindowDeterminacy`

Proof. Project both carriers through Definition 1495.1. The only rows capable of affecting a prefix-window read are the $\mathsf{Nat}^{\uparrow}$ ledgers I, I', the displayed StreamName windows W, W', the Bool digit rows B, B', and the structural rows that transport and replay them.

Apply the prefix-induction obligation, Definition 1495.12. It forces each accepted prefix read to proceed by finite induction over the transported Nat ledger, so both reads inspect the same finite sequence of displayed prefix requests.

Use Baire-window stability, Definition 1495.14. Since the prefix windows and Bool rows are transported componentwise by H, H' and replayed through C, C', each Baire-facing consumer receives the same finite window and the same visible digit rows.

Finally apply the countable-name boundary, Definition 1495.15. Real-boundary and countable-name consumers remain inside W, B, I, H, C, P, N, so determinacy of the displayed window does not determine any future value, host infinite sequence, or countable-choice schedule. □

Theorem 1495.14 (Lawless sequence Baire-window stability)**.** *For accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carriers, every* $\mathsf{BaireSpace}^{\uparrow}$ *prefix window read from* W *remains stable under componentwise* hsame *transport and displayed* Cont *replay. If two accepted reads agree on* I, W, B *by the transport row* H*, then the replay row* C *returns the same finite Baire window and the same visible Bool digit rows, with no appeal to quotient stream equality or an ambient total sequence.*

Proof. Begin with two accepted window reads and project their I, W, B rows. Componentwise hsame in H compares only displayed prefix indices, displayed StreamName windows, and displayed Bool digit rows.

Use the replay row C. The route from an index request to a Baire-facing prefix window is the displayed route already named by Definition 1495.6; it does not pass through a completed stream.

Repack the transported read with P and N. Since the carrier has no coordinate for quotient stream equality or host total sequence data, stability is exactly the finite Baire-window stability stated above. □

Lean4 ✓ `BEDC.Derived.LawlessSequenceUp.LawlessSequenceBaireWindowStability`

Theorem 1495.15 (Lawless sequence countable-name boundary)**.** *Every countable-name consumer of an accepted* $\mathsf{LawlessSequence}^{\uparrow}$ *carrier receives only the rows* W, B, I, H, C, P, N*. The consumer may inspect displayed finite StreamName windows, Bool digit rows, Nat prefix indices, componentwise transport, continuation replay, provenance, and local naming, but it receives no countable-choice schedule, no host infinite sequence, no quotient stream equality, and no* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the carrier of Definition 1495.1. Its classifier compares accepted packets only through W, B, I, H, C, P, N.

Apply the prefix-induction obligation and Baire-window stability above. They force every countable-name request through finite indices, finite windows, visible digits, and displayed replay.

Thus a countable-name consumer can only receive the seven displayed rows. Any request for a countable-choice schedule, a host infinite sequence, quotient stream equality, or real completeness leaves the accepted packet. □

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LawlessSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite sequences, countable choice, lawless choice as a primitive, quotient streams, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, finite-window scope, StreamName handoff, and TasteGate field faithfulness for BEDC.Derived.LawlessSequenceUp.

Chapter 1496

A Concrete Naming Certificate for $\mathsf{AbelTest}^{\uparrow}$

Following Abel and Bishop–Bridges constructive analysis, the $\mathsf{AbelTest}^{\uparrow}$ packet records bounded partial sums, a monotone null coefficient sequence, finite summation-by-parts rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{DyadicRatCore}^{\uparrow}$ estimates, $\mathsf{UniformLimit}^{\uparrow}$ rows, and a $\mathsf{Real}^{\uparrow}$ seal. It sits beside the Dirichlet-series source discipline of chapter 70, the uniform convergence boundary of chapter 463, the bounded real sequence rows of chapter 1415, and the Cauchy product route of chapter 464; its finite observation route also uses the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the regular rational readback of chapter 301, the dyadic estimate surface of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet is a constructive Abel-test surface for a displayed scalar coefficient route over a bounded partial-sum source; it is not a selected series sum, a quotient stream equality, host real completeness, countable choice, or compactness by open covers.

Definition 1496.1 (AbelTest carrier)**.** *An* $\mathsf{AbelTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, A, M, D, T, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded partial-sum row, displaying the finite partial sums of the source series together with the bound used by the Abel-test estimate.*
2. *A is the coefficient stream row, displaying the inspected scalar coefficient values on the finite windows read by the packet.*
3. *M is the monotone/null-tail ledger, recording the finite decrease checks for the coefficient row and the displayed thresholds at which the coefficient tail lies below a requested dyadic tolerance.*
4. *D is the dyadic summation-by-parts estimate row, exposing the finite Abel transform calculation that bounds a tail by the bounded partial-sum row and the coefficient variation ledger.*
5. *T is the finite tail schedule, assigning each precision request to a finite source window and a finite coefficient threshold used by D.*
6. *U is the* $\mathsf{UniformLimit}^{\uparrow}$*-facing row, displaying the uniform tail estimate consumed by downstream convergence readers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, A, M, D, T, U.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the regular rational handoff.*

9. *H records componentwise* hsame *transport for the partial-sum, coefficient, monotone/null-tail, summation-by-parts, tail-schedule, uniform-limit, regular-handoff, real-seal, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a precision request through T to the* $\mathsf{StreamName}^{\uparrow}$ *windows, through M and D to the uniform row U, then through R to the* $\mathsf{Real}^{\uparrow}$ *seal row E.*

11. *P is the* Pkg *provenance over* $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{Dirichlet}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these twelve displayed rows. It has no coordinate for a chosen infinite sum, quotient stream equality, choice-selected limit, open-cover compactness, host series summation, or ambient completeness.

Lean4 ✓ `BEDC.Derived.AbelTestUp.AbelTestTasteGate single carrier alignment`

Theorem 1496.2 (AbelTest NameCert obligations)**.** *For every accepted* $\mathsf{AbelTest}^{\uparrow}$ *carrier $Q = (S, A, M, D, T, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the displayed twelve-row packet;*

2. *bounded-partial-sum transport for S, preserving the displayed bound and the inspected partial sums along the componentwise* hsame *route;*

3. *monotone-null coefficient stability for A and M, preserving the displayed decrease checks and null-tail thresholds on the admitted* $\mathsf{StreamName}^{\uparrow}$ *windows;*

4. *summation-by-parts ledger exactness for D, stating that the dyadic tail estimate consumed by U is the finite Abel transform calculation recorded in the packet;*

5. *Real-seal non-escape for U, R, E, H, C, P, N, forcing every seal-facing consumer through the uniform estimate row and regular rational handoff.*

These obligations are finite-row obligations over the sibling surfaces of chapter 70, chapter 463, chapter 1415, chapter 464, chapter 126, chapter 301, chapter 291, and chapter 38.

Proof. Project the accepted packet $Q = (S, A, M, D, T, U, R, E, H, C, P, N)$. The projection exposes exactly the bounded partial-sum row, coefficient stream row, monotone/null-tail ledger, dyadic summation-by-parts estimate, finite tail schedule, uniform-limit-facing row, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

Read a displayed precision request through T. The schedule supplies a finite source window and a finite coefficient threshold, and the rows S, A, M provide the bounded partial sums, the inspected coefficient values, and the monotone null-tail data visible on that window.

The dyadic ledger D records the finite summation-by-parts calculation on the same rows. Therefore the estimate sent to U is the displayed Abel transform bound, not a hidden infinite summation argument or a choice-selected limiting process.

Finally apply the structural rows. The componentwise transports in H preserve the analytic rows together, while C, P, N replay, source, and name only that displayed route. Since the carrier has no further coordinate, the five listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}$ surface. □

Theorem 1496.3 (AbelTest uniform-limit handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{UniformLimit}^{\uparrow}$ *consumer of an accepted* $\mathsf{AbelTest}^{\uparrow}$ *carrier factors through*

$$S, A, M, D, T, U, R, E, H, C, P, N.$$

In particular, no accepted consumer can read host series sums, quotient streams, choice-selected limits, open-cover compactness, or ambient completeness from the Abel-test packet.

Proof. Begin with an accepted carrier and a downstream $\mathsf{Real}^{\uparrow}$ or $\mathsf{UniformLimit}^{\uparrow}$ read. By the carrier definition, the only convergence-facing rows are U, R, and E, and each is downstream of the same finite route through S, A, M, D, T.

Read the handoff route. The tail schedule T selects finite windows, the rows A and M display monotone null coefficient control on those windows, and the bounded partial-sum row S supplies the bound used by the dyadic estimate.

The row D is the only summation-by-parts ledger available to the consumer. Thus the uniform row U receives a finite dyadic Abel transform estimate, and the regular handoff R and real seal E receive only that displayed estimate together with the transport, continuation, provenance, and local naming rows.

No prohibited object remains in the packet. Host series sums, quotient streams, choice-selected limits, open-cover compactness, and ambient completeness are absent from the carrier coordinates and cannot be recovered by hsame transport or Cont replay. □

Falsifiable prediction: An accepted $\mathsf{AbelTest}^{\uparrow}$ consumer that reaches a $\mathsf{UniformLimit}^{\uparrow}$ row, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, or $\mathsf{Real}^{\uparrow}$ seal without reading the bounded partial-sum row, coefficient stream row, monotone/null-tail ledger, dyadic summation-by-parts estimate, and finite tail schedule refutes the carrier surface.

Independence witness: dirichlet-series, uniformlimit, boundedrealsequence, cauchyproduct, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole twelve-row packet $Q = (S, A, M, D, T, U, R, E, H, C, P, N)$, because each sibling contributes only a source, uniform tail, bounded-row, product, window, regular-readback, dyadic-estimate, or seal face while this chapter binds the Abel-test coefficient route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelTest}^{\uparrow}$ packet is generated from bounded partial-sum rows, a displayed monotone null coefficient stream, a finite dyadic summation-by-parts ledger, a finite tail schedule, $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{UniformLimit}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1496.1, Definition 1496.2, and Definition 1496.3 seed the finite Abel-test boundary over $\mathsf{Dirichlet}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected series sums, quotient stream equality, host real equality, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the twelve-row carrier and prove the finite NameCert obligation surface and uniform-limit handoff theorem.

Chapter 1497

A Concrete Naming Certificate for $\mathsf{DirichletTest}^{\uparrow}$

Following Dirichlet and Bishop–Bridges constructive analysis, the $\mathsf{DirichletTest}^{\uparrow}$ packet records the bounded-partial-sum convergence test as finite BEDC data before a completion-facing consumer may read a regular rational handoff or a real seal. Its source series face sits beside $\mathsf{Series}^{\uparrow}$ in chapter 121; its summation-by-parts sibling is $\mathsf{AbelTest}^{\uparrow}$ in chapter 1496; its Dirichlet-series source discipline is chapter 70; its uniform tail boundary is chapter 463; and its bounded-row discipline is chapter 1415. The finite observation route also uses $\mathsf{StreamName}^{\uparrow}$ windows from chapter 126, $\mathsf{RegSeqRat}^{\uparrow}$ readback from chapter 301, dyadic estimates from chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet is a constructive Dirichlet-test surface for a displayed scalar coefficient route over a bounded partial-sum source; it is not a selected series sum, a quotient series equality, host real completeness, countable choice, or compactness by open covers.

Definition 1497.1 (DirichletTest carrier)**.** *A* $\mathsf{DirichletTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, B, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded partial-sum row, displaying finite partial sums of the source series and the bound used in the Dirichlet tail estimate.*
2. *A is the coefficient stream row, displaying the inspected scalar coefficient values on the finite windows read by the packet.*
3. *B is the null-tail ledger, recording the displayed thresholds at which the coefficient tail lies below a requested dyadic tolerance and the finite variation rows needed by the estimate.*
4. *T is the Dirichlet tail estimate schedule, assigning each precision request to a finite source window and a coefficient threshold used to bound the displayed tail.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, A, B, T.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the regular rational handoff.*
7. *H records componentwise* hsame *transport for the partial-sum, coefficient, null-tail, tail-estimate, regular-handoff, real-seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through T to the* $\mathsf{StreamName}^{\uparrow}$ *windows, through S, A, B to the Dirichlet estimate, then through R to the* $\mathsf{Real}^{\uparrow}$ *seal row E.*

9. *P is the* Pkg *provenance over* $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{Dirichlet}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten displayed rows. It has no coordinate for a chosen infinite sum, quotient series equality, choice-selected limit, open-cover compactness, host series summation, or ambient completeness.

Theorem 1497.2 (DirichletTest NameCert obligations)**.** *For every accepted* $\mathsf{DirichletTest}^{\uparrow}$ *carrier* $D = (S, A, B, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *bounded-partial-sum transport for S, preserving the displayed bound and inspected partial sums along the componentwise* hsame *route;*
3. *coefficient-stream exposure for A, preserving the inspected scalar coefficient rows on the admitted* $\mathsf{StreamName}^{\uparrow}$ *windows;*
4. *null-tail and finite-variation exposure for B, preserving the displayed thresholds and variation rows used by the Dirichlet estimate;*
5. *tail-estimate schedule exactness for T, stating that each requested tolerance is answered by the finite source window and coefficient threshold recorded in the packet;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal exposure for R and E;*
7. *transport stability, continuation replay, provenance, and local naming for exactly the route recorded by H, C, P, N.*

These obligations are finite-row obligations over the sibling surfaces of chapter 121, chapter 1496, chapter 70, chapter 463, chapter 1415, chapter 126, chapter 301, chapter 291, and chapter 38.

Proof. Project the accepted packet $D = (S, A, B, T, R, E, H, C, P, N)$. The projection exposes exactly the bounded partial-sum row, coefficient stream row, null-tail ledger, tail-estimate schedule, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

Read a displayed precision request through T. The schedule supplies a finite source window and a coefficient threshold, while S supplies the bounded partial sums and A, B supply the inspected coefficient values together with the null-tail and finite-variation data visible on that window.

The estimate is therefore a finite Dirichlet tail calculation on the displayed rows. It is not an appeal to an external infinite series sum, a hidden quotient stream equality, or a choice-selected limiting process.

Finally apply the structural rows. The componentwise transports in H preserve the analytic rows together, while C, P, N replay, source, and name only that displayed route. Since the carrier has no further coordinate, the seven listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}$ surface. □

Theorem 1497.3 (DirichletTest Cauchy handoff)**.** *Every accepted* $\mathsf{DirichletTest}^{\uparrow}$ *carrier sends the displayed partial-sum family to the Cauchy-facing route only through the finite handoff*

$$S, A, B, T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$ *consumer can use the Dirichlet test only after reading the bounded partial-sum row, coefficient stream row, null-tail ledger, and tail-estimate schedule that bind the finite tail estimate to the regular rational handoff.*

Proof. Begin with an accepted carrier and a displayed precision request. The schedule T supplies a finite source window and a coefficient threshold, while the source row S supplies only the partial sums and bound visible on that window.

Read the coefficient rows. The stream row A displays the inspected coefficient values, and the ledger B supplies the null-tail threshold and finite variation rows needed by the Dirichlet estimate.

These rows are exactly the data consumed by the Cauchy-facing route: sufficiently late partial-sum tails are bounded by the displayed bounded-partial-sum constant and the coefficient tail data named by B and T. The handoff row R records that regular rational readback and does not receive any separate completed real or quotient series object.

Transport and replay preserve this handoff componentwise. The rows H, C, P, N attach the route to the local certificate without creating an alternate path through host convergence, selected sums, quotient equality, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1497.4 (DirichletTest Real-seal boundary)**.** *For every accepted* $\mathsf{DirichletTest}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R produced from the displayed bounded partial sums, coefficient stream, null-tail ledger, and tail-estimate schedule. The seal row E receives only R together with the componentwise transports, continuation replay, provenance, and local naming rows; it receives no selected sum, quotient series equality, host real completeness, countable choice, or open-cover compactness.*

Proof. Project the seal-facing rows R and E from the accepted carrier. The regular handoff R is downstream of S, A, B, T, and the seal row E is downstream of R.

Apply Definition 1497.3. It identifies the only route from bounded partial sums and coefficient-tail data to the regular readback as the finite path through the displayed source, coefficient, null-tail, and schedule rows.

Read the seal row. Its analytic input is exactly the regular handoff R, together with H, C, P, N. Since the carrier has no coordinate for a selected sum, quotient series equality, host real completeness, countable choice, or open-cover compactness, the seal-facing read cannot export any of those objects. □

Falsifiable prediction: An accepted $\mathsf{DirichletTest}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without reading the bounded partial-sum row, coefficient stream row, null-tail ledger, and Dirichlet tail estimate schedule refutes the carrier surface.

Independence witness: series, abel-test, dirichlet-series, uniformlimit, boundedrealsequence, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole ten-row packet $D = (S, A, B, T, R, E, H, C, P, N)$, because each sibling contributes only a source, summation-by-parts route, Dirichlet-series face, uniform tail, bounded-row, window, regular-readback, dyadic-estimate, or seal face while this chapter binds the coefficient null-tail route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DirichletTest}^{\uparrow}$ packet is generated from bounded partial-sum rows, a displayed coefficient stream, a null-tail ledger, a finite Dirichlet tail estimate schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1497.1, Definition 1497.2, Definition 1497.3, and Definition 1497.4 seed the finite Dirichlet-test boundary over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{Dirichlet}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected sums, quotient series equality, host real completeness, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface, Cauchy handoff theorem, and Real-seal boundary theorem.

Chapter 1498

A Concrete Naming Certificate for $\mathsf{LocatedOpen}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedOpen}^{\uparrow}$ packet records a neighbourhood interface whose evidence is located in finite real and cut data before any topological consumer reads it. It sits over the located cut surface of chapter 404, the located real enclosure of **??**, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing filter route of chapter 333. The chapter names only a finite L10 neighbourhood packet: it does not identify opens with quotient subsets of host reals and does not invoke open-cover compactness.

Definition 1498.1 (LocatedOpen carrier)**.** *A* $\mathsf{LocatedOpen}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, R, S, Q, W, E, T, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *source row exposing the finite lower and upper cut comparisons used by the local membership read.*
2. *R is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row tying the same comparisons to a located real presentation.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family recording the inspected stream positions and replayable requests.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to those windows.*
5. *W is the displayed located-membership window row. For each inspected candidate it records a finite interval-entry witness or a positive dyadic radius witness around the candidate.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located cut, located real, stream, regular rational, and membership-window rows have been displayed.*
7. *T is the local classifier transport row moving L, R, S, Q, W, E to a common finite comparison surface.*
8. *H records componentwise* hsame *transport for the cut, real, stream, regular rational, membership-window, Real-seal, classifier, continuation, provenance, and local naming rows.*
9. *C records the displayed* Cont *replay from a neighbourhood request through the inspected windows, radius or interval-entry evidence, readback rows, Real seal, and classifier transport.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedOpen}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedOpen}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed finite windows and transports. It has no coordinate for quotient subsets of reals, host real equality, a choice-selected neighbourhood, arbitrary-union completion, open-cover compactness, or a proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.LocatedOpenUp.TasteGate.LocatedOpenTasteGate single carrier alignment`

Theorem 1498.2 (LocatedOpen window stability)**.** *For every accepted* $\mathsf{LocatedOpen}^{\uparrow}$ *packet* $O = (L, R, S, Q, W, E, T, H, C, P, N)$*, the located-membership windows in* W *are stable under the componentwise* hsame *transports recorded in* H*. In particular, a transported consumer reads the same finite interval-entry witnesses and positive dyadic radius witnesses after* L, R, S, Q, W, E *have been moved to the common comparison surface named by* T*.*

Lean4 ✓ `BEDC.Derived.LocatedOpenUp.LocatedOpenCarrier window stability`

Proof. Project the carrier of Definition 1498.1. The only membership evidence available to a consumer is the row W, and each entry of W is already displayed as a finite interval-entry witness or a positive dyadic radius witness.

Apply the transport row H componentwise. The located cut, located real, stream, regular rational, membership-window, and Real-seal rows are moved together to the comparison surface named by T, so the transported packet contains the same window indices and the same radius or interval-entry witnesses.

Finally replay the continuation row C. Replay follows the transported windows and readbacks; it does not introduce an ambient subset, a host equality test, a selected neighbourhood, or an arbitrary union. Thus the located membership surface is stable exactly over the displayed finite windows. □

Lean4 ✓ `BEDC.Derived.LocatedOpenUp.LocatedOpen window stability`

Theorem 1498.3 (LocatedOpen Real consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedOpen}^{\uparrow}$ *packet factors through*

$$\mathsf{LocatedCut}^{\uparrow},\quad \mathsf{LocatedReal}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{CauchyFilter}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},$$

Concretely, the consumer first reads the located cut and located real rows, then the finite stream and regular rational readbacks, then the displayed located-membership windows, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal and filter-facing continuation route.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing read of the seal row E. The carrier stores E after the located cut row L, located real row R, stream window row S, regular rational readback row Q, and located-membership window row W. Therefore no consumer can reach the seal without first exposing these finite rows.

The completion-facing part is only a route. The provenance row names $\mathsf{CauchyFilter}^{\uparrow}$ so that a filtered consumer can replay the finite neighbourhood request through C, but the packet supplies no completeness field and no arbitrary-union constructor.

Attach T, H, P, N to the same route. Classifier transport, componentwise hsame, package provenance, and local naming keep the consumer inside the listed rows. Since the carrier has no coordinate for quotient subsets, host real equality, selected neighbourhoods, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, no such datum can be recovered from the read. □

Theorem 1498.4 (LocatedOpen obligation surface)**.** *For every accepted* $\mathsf{LocatedOpen}^{\uparrow}$ *packet* $O = (L, R, S, Q, W, E, T, H, C, P, N)$*, the rows* $L, R, S, Q, W, E, T, H, C, P, N$ *jointly supply carrier admission, located-membership window stability, the Real-facing route, classifier transport, replay, provenance, and local* NameCert *non-escape. The exported surface is exactly the finite neighbourhood interface of Definition 1498.1; it exports no quotient subset, selected neighbourhood, arbitrary union, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 1498.1. Carrier admission is the displayed tuple $O = (L, R, S, Q, W, E, T, H, C, P, N)$, with L, R, S, Q, W, E naming the located cut, located real, stream, regular rational, membership-window, and Real-seal rows.

Window stability is supplied by Definition 1498.2. The theorem keeps the interval entry witnesses and positive dyadic radius witnesses inside W after the componentwise transports in H move the packet to the comparison surface named by T.

The Real-facing route is supplied by Definition 1498.3. It forces every consumer to read the located cut, located real, stream windows, regular rational readbacks, membership windows, terminal Real seal, and filter-facing replay before any Real-facing output is available.

The remaining rows are bookkeeping rows for non-escape. The classifier transport is T, replay is C, provenance is P, and local naming is N. Since the carrier definition contains no coordinate for quotient subsets, selected neighbourhoods, arbitrary unions, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, the obligation surface cannot export any such row. □

Lean4 ✓ `BEDC.Derived.LocatedOpenUp.LocatedOpenObligationSurface`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedOpen}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedOpen}^{\uparrow}$ packet is generated from located cut rows, located real enclosure rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, displayed membership windows with positive dyadic radius or interval-entry witnesses, a terminal $\mathsf{Real}^{\uparrow}$ seal, classifier transport, componentwise hsame rows, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedOpen}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1498.1, Definition 1498.2, and Definition 1498.3 seed the finite L10 located-neighbourhood interface over located real and cut data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedOpen}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general topology, open-cover compactness, Heine–Borel, arbitrary-union completion, quotient subsets of reals, host real equality, choice-selected neighbourhoods, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: A formal route can encode BEDC.Derived.LocatedOpenUp.LocatedOpenCarrier and prove window stability, Real-facing consumer routing, classifier transport, provenance, and local NameCert exactness.

Chapter 1499

A Concrete Naming Certificate for $\mathsf{RegularCauchyAbs}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyAbs}^{\uparrow}$ packet lifts the finite $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ endpoint-and-tolerance route through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic absolute-value surface of chapter 293 and beside the regular Cauchy operation surfaces of chapter 417. The packet exposes absolute value for regular Cauchy names as finite NameCert data; it is not trichotomy, quotient streams, a host absolute-value operation, selected limits, or ambient completeness.

Definition 1499.1 (RegularCauchyAbs carrier)**.** *A* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, W, D, V, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *X is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row;*
2. *W is the scheduled family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows through which X is observed;*
3. *D is the family of* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from those windows;*
4. *V is the family of* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint-and-tolerance rows applied to the displayed dyadic endpoints;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the absolute-value windows and their finite tolerance ledger;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the readback row R has been exposed;*
7. *H stores componentwise* hsame *transports for the source, windows, dyadic endpoints, absolute-value rows, readback, seal, provenance, and local name;*
8. *C stores the displayed* Cont *routes from X to W and D, from D to V, from V to R, and from R to E;*
9. *P records* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, trichotomy of reals, a host absolute-value operation, selected limits, or a $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsTasteGate single carrier alignment`

Theorem 1499.2 (RegularCauchyAbs NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}^{\uparrow}}$ *surface for Definition 1499.1 consists exactly of source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, scheduled* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint readback,* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint-and-tolerance application,* $\mathsf{RegSeqRat}^{\uparrow}$ *absolute-value handoff,* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from the displayed packet A. The coordinates list the regular source name, stream windows, dyadic endpoint rows, dyadic absolute-value rows, regular readback, real seal, transport, continuation, provenance, and local name.

The endpoint-and-tolerance obligation is inherited from the finite dyadic packet named in chapter 293. Each observed endpoint in D is routed through a visible $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ row in V, and no order oracle or completed-real absolute value is consulted.

The remaining obligations are the regular and real-facing handoffs. The rows H, C, P, N transport the same finite route, replay it for consumers, record the package provenance, and bind the local naming surface without adding quotient streams, selected limits, trichotomy, host absolute value, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier namecert obligations`

Theorem 1499.3 (RegularCauchyAbs RegSeqRat handoff)**.** *For every accepted* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *carrier* $A = (X, W, D, V, R, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is assembled only from the displayed source row* X*, the scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows* D*, and the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *tolerance rows* V*. A* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer can read the absolute-value name only through those rows and through the stored* hsame*,* Cont*,* Pkg*, and local* NameCert *provenance.*

Proof. Project the accepted carrier. The source regular name is visible only as X, and the finite observations of that name are the scheduled windows W together with the endpoint rows D.

Apply the dyadic absolute-value route to each displayed endpoint row. The rows in V supply the nonnegative endpoint and tolerance ledger for the same window schedule, so they are the only data available for building the absolute-value readback.

Repack the displayed absolute-value windows as the readback row R. The continuation routes in C and package row P record this handoff over the same BHist support, and the transport rows in H preserve it componentwise for consumers. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier regseqrat handoff`

Theorem 1499.4 (RegularCauchyAbs Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *carrier reaches the seal row* E *only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *absolute-value handoff* R *has been produced from* X, W, D, V*. The real-facing boundary exposes the route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*, and it exposes no quotient stream, host real absolute value, selected limit, trichotomy witness, or ambient completeness principle.*

Proof. Begin with a real-facing consumer. By Definition 1499.3, the consumer cannot reach a regular absolute-value readback until the finite window route X, W, D, V has been displayed.

The seal row E is downstream of that readback. The stored continuation routes first replay the source windows, then the dyadic endpoint observations, then the $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ tolerance rows, and only then the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R consumed by the real seal.

Since Definition 1499.1 contains no separate coordinate for quotient streams, trichotomy, host absolute value, selected limits, or completeness, the $\mathsf{Real}^{\uparrow}$ seal boundary is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier real seal boundary`

Theorem 1499.5 (RegularCauchyAbs non-escape boundary)**.** *No accepted* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *packet exports data outside the displayed tuple* $X, W, D, V, R, E, H, C, P, N$*. In particular, it cannot be used to recover a quotient of regular Cauchy streams, a host absolute-value operation, a trichotomy proof for real names, a selected limiting real, or a* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the carrier of Definition 1499.1. Its only source data are the regular name, finite stream windows, dyadic endpoints, dyadic absolute-value rows, readback, seal, and structural rows.

Apply Definition 1499.2. Every local obligation is a projection of those rows or a transport, continuation, provenance, or naming route for those rows.

Finally combine Definition 1499.3 with Definition 1499.4. All regular and real-facing consumers pass through $X, W, D, V, R, E, H, C, P, N$, so no unlisted analytic or quotient object can be extracted from the certificate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier non escape`

Theorem 1499.6 (RegularCauchyAbs obligation closure package)**.** *The carrier of Definition 1499.1 together with Definition 1499.2, Definition 1499.3, Definition 1499.4, and Definition 1499.5 forms the complete obligation surface for* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The package preserves the refusals of trichotomy, quotient streams, host absolute value, selected limits, and ambient completeness.*

Proof. Project the carrier row. It exposes exactly the source regular name X, scheduled stream windows W, dyadic endpoint rows D, dyadic absolute-value tolerance rows V, regular readback R, real seal E, transport H, continuation replay C, provenance P, and local name N.

Use the NameCert obligations to identify the local certificate surface over those rows. The handoff theorem then routes every $\mathsf{RegSeqRat}^{\uparrow}$ consumer through $X, W, D, V, R, H, C, P, N$, while the seal-boundary theorem routes every $\mathsf{Real}^{\uparrow}$ consumer through the same finite prefix before E is available.

Finally apply the non-escape boundary. Since every obligation is read from the displayed rows and since the excluded principles have no carrier coordinate, the package closes exactly the finite obligation surface and preserves the stated refusals. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier obligation closure`

Theorem 1499.7 (RegularCauchyAbs public export surface)**.** *The public export of an accepted* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *packet is exactly the finite route from the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row through scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint observations,* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *tolerance rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *absolute-value handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}^{\uparrow}}$ *row. Every public consumer must read the route as*

$$X, W, D, V, R, E, H, C, P, N.$$

It exports no trichotomy, quotient-stream equality, host real absolute value, selected limit, ambient completeness principle, or public bridge.

Proof. Project the carrier of Definition 1499.1. The displayed public rows are the source regular name X, windows W, dyadic endpoints D, dyadic absolute-value tolerance rows V, regular readback R, real seal E, transport H, replay C, provenance P, and local name N.

Apply the obligation closure package of Definition 1499.6. It identifies the NameCert obligations, RegSeqRat handoff, Real seal boundary, and non-escape theorem as one finite route over the same displayed rows.

Therefore a public consumer can reuse the packet only through $X, W, D, V, R, E, H, C, P, N$. The excluded analytic and bridge objects have no carrier coordinate and no obligation row, so they cannot be exported by the public surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAbsUp.RegularCauchyAbsCarrier public export surface`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyAbs}^{\uparrow}$ packet is generated from one RegSeqRat source row, scheduled StreamName windows, DyadicRatCore endpoint observations, DyadicAbsoluteValue endpoint-and-tolerance rows, a RegSeqRat readback row, a RealUp seal row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}\uparrow}$, publicClosed)

Scope closed: Definition 1499.1, Definition 1499.2, Definition 1499.3, Definition 1499.4, Definition 1499.5, Definition 1499.6, and Definition 1499.7 close the public finite absolute-value route through carrier admission, NameCert obligations, RegSeqRat handoff, Real seal boundary, nonescape, obligation closure, and the public export surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyAbs}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, trichotomy, quotient-stream equality, host real absolute value, selected limits, ambient completeness, or a public standard bridge.

Upgrade path: Lean verification requires checked carrier admission, window exposure, dyadic absolute-value tolerance, RegSeqRat handoff, RealUp seal boundary, public export surface, transport stability, provenance, and non-escape for the same finite packet.

Chapter 1500

A Concrete Naming Certificate for $\mathsf{NormedRealLine}^{\uparrow}$

Following Bishop and Bridges' constructive normed-space analysis, the $\mathsf{NormedRealLine}^{\uparrow}$ packet records the real line as a normed object only through the regular Cauchy absolute-value route. It binds the real seal of chapter 38, the regular rational readback of chapter 301, the stream-window interface of chapter 126, the dyadic observation core of chapter 291, the absolute-value packet of chapter 1499, and the metric interface of chapter 57. The certificate names the RealUp line equipped with that displayed norm route; it does not assert RealUp completeness, trichotomy, quotient equality of names, or a host norm function.

Definition 1500.1 (Normed real line carrier)**.** *A* $\mathsf{NormedRealLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, S, D, A, M, H, C, P, N)$$

with the following visible coordinates:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the underlying real-line object.*
2. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source and readback row through which the real seal is observed by regular rational names.*
3. *D is the joined* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger recording the finite windows and dyadic endpoints read from S.*
4. *A is the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *norm row, applied only to the displayed regular Cauchy name and its dyadic observations.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-and-norm interface that reads the distance of the real line through the same absolute-value handoff.*
6. *H records componentwise* hsame *transport for R, S, D, A, M and for the structural rows.*
7. *C records the displayed* Cont *routes from real-seal requests to regular windows, from those windows to dyadic observations, from the observations to the absolute-value row, and from that row to the metric interface.*
8. *P records* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NormedRealLine}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a selected host real, quotient equality of real names, trichotomy, a host norm function, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 1500.2 (Normed real line NameCert obligations)**.** *For every accepted* $\mathsf{NormedRealLine}^{\uparrow}$ *carrier* $L = (R, S, D, A, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NormedRealLine}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real seal, regular rational source and readback, stream and dyadic observation ledger, regular Cauchy absolute-value norm row, metric distance-and-norm interface, componentwise transport, continuation replay, package provenance, and local naming row. No obligation is stored outside those rows.*

Proof. Project the carrier of Definition 1500.1. The projection exposes the real seal R, the regular rational source and readback S, the observation ledger D, the absolute-value norm row A, the metric interface M, and the structural rows H, C, P, N.

The analytic obligation is the norm route. The row A is already the displayed $\mathsf{RegularCauchyAbs}^{\uparrow}$ handoff over S and D, so the certificate reads norm data only after the stream windows and dyadic endpoints have been displayed.

The metric obligation is then a consumer of the same handoff. The row M receives its distance-and-norm interface through A, and the rows H, C, P, N transport, replay, source, and name that finite route without adding a host norm function, quotient equality, trichotomy, or completeness. □

Theorem 1500.3 (Normed real line regular Cauchy norm handoff)**.** *Every norm-facing consumer of an accepted* $\mathsf{NormedRealLine}^{\uparrow}$ *carrier* $L = (R, S, D, A, M, H, C, P, N)$ *reaches the norm row only through the route*

$$R \longrightarrow S \longrightarrow D \longrightarrow A \longrightarrow M.$$

Thus the exported norm route is the $\mathsf{RegularCauchyAbs}^{\uparrow}$ *handoff over displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, not a separate host-level norm operation.*

Proof. Begin with a norm-facing consumer. Carrier admission gives a single real seal row R and a single regular rational source and readback row S through which R is observed.

Read the finite observations next. The observation ledger D joins the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows for the same regular name, so the absolute-value row cannot be reached without first displaying those windows and endpoints.

Apply the $\mathsf{RegularCauchyAbs}^{\uparrow}$ row A to the displayed observations. The metric interface M is downstream of A, and the continuation rows in C record this order for every consumer route. Hence the norm handoff is exactly the displayed regular Cauchy absolute-value route. □

Theorem 1500.4 (Normed real line non-escape boundary)**.** *No accepted* $\mathsf{NormedRealLine}^{\uparrow}$ *packet exports data outside the tuple* $R, S, D, A, M, H, C, P, N$*. In particular, the packet cannot be used to recover RealUp completeness, real trichotomy, quotient equality of names, a selected host real, or a host norm function.*

Proof. Inspect the carrier in Definition 1500.1. Its only analytic data are the real seal, the regular rational source and readback, the stream and dyadic observations, the regular Cauchy absolute-value row, and the metric interface.

Use Definition 1500.2 to exhaust the local certificate. Every named obligation is a projection of those rows or a transport, continuation, provenance, or naming route for those rows.

Finally combine this exhaustion with Definition 1500.3. Any norm-facing or metric-facing consumer must pass through $R, S, D, A, M, H, C, P, N$, so no unlisted completeness, trichotomy, quotient, selected-real, or host-norm object can be extracted. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormedRealLine}^{\uparrow}}$.

Constructive story: A $\mathsf{NormedRealLine}^{\uparrow}$ packet is generated from a RealUp seal row, a RegSeqRat source and readback row, StreamName and DyadicRatCore observations, a RegularCauchyAbs norm row, a MetricSpace distance-and-norm interface, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormedRealLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1500.1, Definition 1500.2, Definition 1500.3, and Definition 1500.4 seed the finite normed real-line route through $\mathsf{RegularCauchyAbs}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormedRealLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, RealUp completeness, trichotomy, quotient equality of real names, selected host reals, host norm functions, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, regular Cauchy norm handoff, metric-interface routing, transport stability, provenance, and non-escape for the same finite packet.

Chapter 1501

A Concrete Naming Certificate for $\mathsf{CauchyFilterBasis}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley terminology of filter bases, the $\mathsf{CauchyFilterBasis}^{\uparrow}$ packet records the finite basis generator that sits between regular Cauchy windows and saturated Cauchy-filter evidence. It reads the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the dyadic tolerance rows of chapter 291; it hands the resulting directed basis to the saturation surface of chapter 333 before any $\mathsf{Real}^{\uparrow}$ seal from chapter 38 can be inspected. The packet is a finite generator interface, not a completed filter, not a quotient of Cauchy names, and not a host real equality principle.

The same basis row is consumed by chapter 5840 and chapter 7853 as the finite refinement surface before located or regular completion reads.

Definition 1501.1 (Cauchy filter basis carrier)**.** *A* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, S, R, D, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite list of basis elements. Each basis element names a nonempty finite family of late-window neighbourhood requests over the same observation surface.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite stream windows inspected by the basis elements and the tail indices at which those windows become available.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It turns the displayed stream windows in S into regular rational observations before any filter-basis comparison is made.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the dyadic radius and inclusion ledger used to compare the rational observations carried by R.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation handoff row. It consumes the directed basis generated by B, S, R, D and exposes it only as the finite-filterbase surface already named by* $\mathsf{CauchyFilter}^{\uparrow}$*.*
6. *H records componentwise* hsame *transport for B, S, R, D, F and for the continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a basis request through S, R, D, and then the saturation handoff F.*

8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBasis}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed filter object, quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1501.2 (Cauchy filter basis classifier)**.** *The classifier of an accepted* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *packet relates two basis reads precisely when their finite basis lists B admit a common displayed refinement whose* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows agree after the componentwise* hsame *transport recorded in H, and when the resulting saturation handoff is the same* $\mathsf{CauchyFilter}^{\uparrow}$ *row F after replay by C.*

Equivalently, comparison is the finite common-refinement route

$$B, S, R, D \longmapsto F \longmapsto H, C, P, N.$$

It is not equality of completed filters, not equality of quotient Cauchy names, and not equality of host real limits.

Theorem 1501.3 (Cauchy filter basis NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *carrier $Q = (B, S, R, D, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBasis}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite basis elements,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation handoff, transport, continuation, provenance, and local naming row;*

2. *common-refinement classification for two basis reads, using only the displayed basis elements and their transported window, readback, and tolerance rows;*

3. *directedness of the generated basis, requiring every pair of displayed basis elements to name a third displayed basis element refining both after the S, R, D rows are replayed;*

4. *saturation exactness, requiring the handoff to* $\mathsf{CauchyFilter}^{\uparrow}$ *to consume the generated finite basis before any filter-facing or real-facing consumer can proceed;*

5. *ledger non-escape, excluding completed filters, quotient streams, selected representatives, countable choice, trichotomy, host real equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1501.1. The projection exposes exactly the finite basis list, the window row, the regular readback row, the dyadic tolerance row, the saturation handoff, and the structural rows H, C, P, N.

Classifier transport is componentwise. The rows in H move the basis elements, windows, rational readbacks, dyadic tolerances, and saturation handoff to a common finite comparison surface, while C replays the same dependency order.

Directedness is read from the finite list B together with the tolerance ledger D. For two displayed basis elements, the accepted packet names a common refinement whose windows and rational observations are routed through S and R before dyadic inclusion is checked in D.

Saturation exactness is the role of F. Since every consumer reaches F only after the basis, window, readback, and tolerance rows have been replayed, the package and local naming rows cannot export any completed-filter, quotient, choice, host-equality, or real-completeness principle. □

Theorem 1501.4 (Cauchy filter basis RegSeqRat handoff)**.** *Let $Q = (B, S, R, D, F, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *packet. Every regular-rational consumer of a displayed basis element factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window row S, then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, then through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, before the generated basis can be handed to* $\mathsf{CauchyFilter}^{\uparrow}$ *by F.*

The handoff route is

$$B \longmapsto S \longmapsto R \longmapsto D \longmapsto F \longmapsto H, C, P, N.$$

It does not bypass the regular readback row and does not select a Cauchy representative or host real limit.

Proof. Start with a consumer of a displayed basis element. Carrier admission lists such a consumer under B, but the basis element only stores a finite neighbourhood request, not a rational observation by itself.

Replay the continuation row C. The request first reaches the stream-window row S, where the relevant finite observations and tail indices are displayed.

The next row is R. It turns the finite stream observations into $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, after which the dyadic tolerance row D checks the requested radius and inclusion ledger.

Only then can the same generated basis be consumed by F as a $\mathsf{CauchyFilter}^{\uparrow}$ saturation handoff. The remaining rows transport, package, and name that same route, so no bypass through a selected representative, quotient stream, host real limit, or choice principle is available. □

Theorem 1501.5 (Cauchy filter basis Real seal non-escape)**.** *For every accepted* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *carrier $Q = (B, S, R, D, F, H, C, P, N)$, any* $\mathsf{Real}^{\uparrow}$*-facing read exposed by the provenance row P factors through the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation handoff F after the finite basis route B, S, R, D has already been replayed. Therefore the packet cannot export a* $\mathsf{Real}^{\uparrow}$ *seal directly from basis elements, stream windows, rational readbacks, or dyadic tolerance rows.*

The only real-facing route visible in the packet is

$$B, S, R, D \longmapsto F \longmapsto P, N.$$

It is a non-escape condition for the basis generator: the chapter names finite basis data and its saturation handoff, not a completed real, not a chosen limit, and not a proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Project the provenance row P. Its $\mathsf{Real}^{\uparrow}$ occurrence is recorded only as a downstream boundary of the $\mathsf{CauchyFilter}^{\uparrow}$ handoff, not as a coordinate of the basis rows B, S, R, D.

The continuation row C fixes the route order. A real-facing read must first replay the basis element, stream window, regular readback, and dyadic tolerance rows, and then pass through the saturation handoff F.

Transport by H preserves the same order under classifier comparison. The local naming row N names the packet only after this replay, so no separate real seal can be read from an earlier coordinate.

Thus every $\mathsf{Real}^{\uparrow}$-facing route remains downstream of $\mathsf{CauchyFilter}^{\uparrow}$. The packet carries no completed real, selected limit, host equality, countable-choice schedule, trichotomy, or real-completeness certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterBasis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1501.1, Definition 1501.2, Definition 1501.3, Definition 1501.4, and Definition 1501.5 seed the finite basis-generator interface between regular windows and saturated Cauchy filters.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyFilterBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed filters, quotient Cauchy names, selected representatives, host real equality, countable choice, trichotomy, or completeness of Real$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, common-refinement classification, directed basis generation, RegSeqRat handoff, CauchyFilter saturation exactness, Real seal non-escape, and ledger refusal for the same packet.

Constructive story: The construction starts from finite basis elements, reads StreamName windows through RegSeqRat and DyadicRatCore rows, hands the directed basis to CauchyFilter saturation, and treats Real-facing access only as downstream provenance.

Chapter 1502

A Concrete Naming Certificate for $\mathsf{RegularCauchyMax}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMax}^{\uparrow}$ packet reads the maximum of two regular Cauchy names constructively through the identity $max(x, y) = (x + y + |x - y|)/2$. The certificate factors that identity through the finite pointwise-sum surface of chapter 417, the absolute-value surface of chapter 1499, the rational scaling surface of chapter 465, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It does not compare completed reals by trichotomy, choose a larger host real, quotient streams, or appeal to ambient completeness.

Definition 1502.1 (RegularCauchyMax carrier)**.** *A* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W_A, W_B, D_A, D_B, S, \Delta, V, T, Q, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *A and B are the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name rows.*
2. *W_A and W_B are the aligned* $\mathsf{StreamName}^{\uparrow}$ *windows used to observe the two sources at the same precision requests.*
3. *D_A and D_B are the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from those windows.*
4. *S is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row for the source sum $A + B$.*
5. *Δ is the displayed* $\mathsf{RegularCauchySum}^{\uparrow}$ *difference row for $A + (-B)$, with the negation supplied by the same rational scaling route used by the sibling operation surface.*
6. *V is the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *row for $|\Delta|$.*
7. *T is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row for $S + V$.*
8. *Q is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row scaling T by the displayed rational one-half.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the scaled regular Cauchy name.*
10. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the readback row R has been exposed.*
11. *H records componentwise* hsame *transport for the two sources, aligned windows, dyadic endpoints, sum, difference, absolute-value, second sum, half-scale, readback, seal, provenance, and local name.*

12. *C records the displayed* Cont *routes from the source windows to the dyadic endpoint rows, through the sum-absolute-value factorization, through the half-scale row, and onward to the readback and real seal.*

13. *P records* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMax}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy on real names, host real order, quotient stream equality, selected limits, or a $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCarrierNameCertUp.CauchyCarrierNameCertTasteGate single carrier alignment`

Theorem 1502.2 (RegularCauchyMax NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMax}^{\uparrow}}$ *surface for Definition 1502.1 consists exactly of two-source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, aligned* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint readback, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *rows for $A+B$, $A+(-B)$, and $S+V$, the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *row for the displayed difference, the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row by one-half, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from the displayed packet M. The coordinates expose the two source regular names, their aligned stream windows, their dyadic endpoint rows, the three sum rows, the difference absolute-value row, the half-scale row, the regular readback, the real seal, and the structural rows.

The operation obligations are inherited from the cited sibling surfaces. Use chapter 417 for the source sum, the difference row, and the post-absolute-value sum; use chapter 1499 for $|\Delta|$; and use chapter 465 for multiplication by the displayed rational one-half.

The readback and seal obligations are then the finite handoffs through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The rows H, C, P, N transport, replay, source, and name this same route without adding trichotomy, host real order, quotient streams, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMaxUp.RegularCauchyMaxTasteGate single carrier alignment`

Theorem 1502.3 (RegularCauchyMax sum-abs factorization)**.** *For every accepted* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier $M = (A, B, W_A, W_B, D_A, D_B, S, \Delta, V, T, Q, R, E, H, C, P, N)$, every maximum-facing consumer factors through the displayed route*

$$(A, B, W_A, W_B, D_A, D_B) \longrightarrow (S, \Delta, V, T) \longrightarrow Q \longrightarrow R.$$

Thus the maximum readback is the regular Cauchy name obtained from $max(x, y) = (x + y + |x - y|)/2$ by finite sum, absolute-value, and one-half scaling rows, not by a comparison oracle for completed reals.

Proof. Begin with a maximum-facing consumer of the accepted packet. The only source reads available to it are the two $\mathsf{RegSeqRat}^{\uparrow}$ rows A, B, the aligned windows W_A, W_B, and the endpoint rows D_A, D_B.

Next build the algebraic route. The row S displays the source sum, Δ displays the difference route, V displays the absolute value of that difference, and T displays the sum of S with V. Each row is a finite sibling NameCert row over the same visible window and endpoint data.

Finally apply the half-scale row Q and expose the readback R. Since R is downstream of Q, and Q is downstream of S, Δ, V, T, the consumer route is exactly the stated sum-absolute-value factorization. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMaxUp.RegularCauchyMaxCarrier sum abs factorization`

Theorem 1502.4 (RegularCauchyMax lattice absorption)**.** *For every accepted* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier* $M = (A, B, W_A, W_B, D_A, D_B, S, \Delta, V, T, Q, R, E, H, C, P, N)$*, a consumer reading* $max(A, max(A, B))$ *factors through the same displayed source rows* A, B*, source-sum row* S*, difference and absolute-value rows* Δ, V*, post-absolute-value sum row* T*, half-scale row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *as the consumer reading* $max(A, B)$*. The absorbed read has no additional trichotomy branch, selected host maximum, quotient stream equality, selected limit, or ambient completeness coordinate.*

Proof. Apply Definition 1502.3 to the inner read $max(A, B)$. The inner consumer is forced through the displayed route from the shared source rows A, B and aligned windows to S, Δ, V, T, Q, and then to the readback row R.

Apply Definition 1502.3 again to the outer read $max(A, max(A, B))$. The first input is the same row A, while the second input is available only through the inner readback route already displayed in M.

The repeated A route is therefore identified by componentwise transport rather than by a host-level equality test. The $\mathsf{RegularCauchyAbs}^{\uparrow}$ row keeps the difference read inside Δ, V, and the $\mathsf{RegularCauchyScale}^{\uparrow}$ row keeps the one-half read inside Q, so both the inner and outer reads remain in the same finite packet.

Finally the $\mathsf{RegSeqRat}^{\uparrow}$ readback row and the $\mathsf{Real}^{\uparrow}$ seal boundary close the consumer route at R and E. Since Definition 1502.1 has no coordinate for trichotomy, selected host maxima, quotient streams, selected limits, or ambient completeness, the absorbed read cannot escape the displayed maximum packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMaxUp.RegularCauchyMaxCarrier lattice absorption`

Theorem 1502.5 (RegularCauchyMax Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier reaches the seal row* E *only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *has been assembled from the aligned source windows, dyadic endpoint rows,* $\mathsf{RegularCauchySum}^{\uparrow}$ *rows,* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *difference row, and* $\mathsf{RegularCauchyScale}^{\uparrow}$ *half-scale row. The real-facing boundary exposes no trichotomy witness, host real order, quotient stream equality, selected limit, or ambient completeness principle.*

Proof. Start with a real-facing consumer. By Definition 1502.3, the consumer cannot reach the maximum readback R until the finite sum, difference, absolute-value, post-absolute-value sum, and one-half scale rows have all been displayed.

The seal row E is downstream of R. The continuation rows first replay the aligned source windows and dyadic endpoints, then the sibling operation rows, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback consumed by the terminal $\mathsf{Real}^{\uparrow}$ seal.

Since Definition 1502.1 contains no coordinate for trichotomy, host real order, quotient stream equality, selected limits, or completeness, the real-facing boundary is exhausted by the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMaxUp.RegularCauchyMaxCarrier real seal boundary`

Theorem 1502.6 (RegularCauchyMax scoped lattice route)**.** *Every lattice-facing or Real-facing consumer of an accepted* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier factors through the displayed concrete route*

$$\mathsf{RegularCauchySum}^{\uparrow}, \quad \mathsf{RegularCauchyAbs}^{\uparrow}, \quad \mathsf{RegularCauchyScale}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The scoped route is the sum-absolute-value maximum construction, its lattice absorption ledger, and the terminal Real seal boundary; it is not a trichotomy on completed reals, a host selected maximum, a quotient stream representative, or an ambient completeness argument.

Proof. Apply Definition 1502.3. Every maximum-facing read first passes from the two source names and aligned windows through the finite sum, difference, absolute-value, second-sum, and half-scale rows before any regular readback is exposed.

Next apply Definition 1502.4. Lattice reads such as repeated maximum consumption reuse the same displayed source rows and operation rows, so no extra branch for real trichotomy or a selected host maximum can enter the packet.

Finally apply Definition 1502.5. Any Real-facing consumer reaches $\mathsf{Real}^{\uparrow}$ only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback row assembled from $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, and $\mathsf{RegularCauchyScale}^{\uparrow}$ has been displayed. This composes the stated scoped lattice route and excludes quotient streams, selected limits, and ambient completeness coordinates. □

Theorem 1502.7 (RegularCauchyMax scoped dependency package)**.** *Every consumer route for an accepted* $\mathsf{RegularCauchyMax}^{\uparrow}$ *carrier is scoped exactly by* $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *In carrier notation, the only available dependency package is*

$$(S, \Delta, V, T, Q, R, E, H, C, P, N),$$

together with the two source rows A, B *and their displayed windows and dyadic endpoint observations. The package exposes no real trichotomy, selected host maximum, quotient stream equality, selected limit, or ambient completeness assumption.*

Proof. Apply Definition 1502.3. It forces every maximum-facing read to pass through the source sum, difference, absolute-value, second-sum, and half-scale rows before the regular readback row R is visible.

Next use Definition 1502.4. Lattice-facing reads reuse the same rows rather than adding a branch for host comparison or a selected maximum.

Finally apply Definition 1502.5. The $\mathsf{Real}^{\uparrow}$ seal row E is downstream of the same $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the structural rows H, C, P, N only transport, replay, source, and name that displayed dependency package. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMax}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMax}^{\uparrow}$ packet is generated from two RegSeqRat source rows, aligned StreamName windows, DyadicRatCore endpoint observations, RegularCauchySum rows for sum and difference assembly, a RegularCauchyAbs difference row, a RegularCauchyScale half-scale row, a RegSeqRat readback row, a RealUp seal row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyMax}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1502.1, Definition 1502.2, Definition 1502.3, Definition 1502.4, and Definition 1502.5 bind the finite constructive maximum route through $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as a scoped Real-name construction.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyMax}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyMaxUp.RegularCauchyMaxTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy on real names, host real order, quotient stream equality, selected limits, ambient completeness, or a public standard bridge.

Upgrade path: Public closure requires a reusable consumer-facing maximum interface and bridge coverage for the same finite Real-name route.

Chapter 1503

A Concrete Naming Certificate for $\mathsf{MetricDiameter}^{\uparrow}$

Following Hausdorff and Kelley metric-space practice, the $\mathsf{MetricDiameter}^{\uparrow}$ packet records the diameter interface of a bounded metric object as finite BEDC rows. The packet reads diameter through distance-comparison ledgers and displayed ordered-real bounds, not through a host supremum. It sits beside the metric carrier of chapter 57, the ordered-real comparison surface of chapter 766, the real-name seal of chapter 38, the center-radius rows of chapter 1450, and the entourage-facing boundary of chapter 339.

Definition 1503.1 (MetricDiameter carrier)**.** *A* $\mathsf{MetricDiameter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, d, B, W, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row with its point classifier and metric-source data.*
2. *d is the* $\mathsf{Real}^{\uparrow}$*-valued distance witness read from the metric carrier X.*
3. *B is the displayed bound row, read through the ordered-real comparison surface of* $\mathsf{RealAlgOrder}^{\uparrow}$ *and the rational bound rows of* $\mathsf{Rat}^{\uparrow}$ *when a rational presentation is used.*
4. *W is the finite witness list of compared pairs. Each row names a pair (x_i, y_i) admitted by the point classifier of X.*
5. *R is the distance-comparison ledger. For every displayed pair in W, it records the ordered-real comparison from the distance row $d(x_i, y_i)$ to the bound row B.*
6. *H records componentwise* hsame *transport for the metric carrier, distance witness, bound row, witness list, and distance-comparison ledger.*
7. *C records the displayed* Cont *route replaying point admission, distance evaluation, ordered-real comparison, and bound handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricDiameter}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an ambient supremum, compactness argument, selected maximum pair, geodesic length structure, open-cover principle, or bridge datum.

Theorem 1503.2 (MetricDiameter bound obligation)**.** *For an accepted* $\mathsf{MetricDiameter}^{\uparrow}$ *carrier* $D = (X, d, B, W, R, H, C, P, N)$*, every displayed pairwise distance row in the witness list* W *is bounded by the named diameter row* B *through the ledger* R*. Concretely, each displayed pair* (x_i, y_i) *admitted by* X *has a distance row* $d(x_i, y_i)$*, and* R *records the ordered-real comparison*

$$d(x_i, y_i) \leq_{\mathsf{R}} B.$$

No pairwise-distance bound is accepted unless it is one of the finite rows replayed by C *and transported by* H*.*

Proof. Project the accepted carrier of Definition 1503.1. The rows X, d, B, W, R expose the metric carrier, distance witness, displayed bound, finite pair list, and comparison ledger.

For a listed pair (x_i, y_i), point admission is read from X, distance evaluation is read from d, and the comparison to B is read from R. Thus the bound has a displayed ordered-real route through $\mathsf{RealAlgOrder}^{\uparrow}$ rather than through a host supremum.

The rows H and C then preserve and replay the same route under classifier transport. Since the carrier exports no coordinate outside $X, d, B, W, R, H, C, P, N$, an unlisted pairwise-distance assertion is not part of the local certificate. □

Theorem 1503.3 (MetricDiameter classifier stability)**.** *Let* $D = (X, d, B, W, R, H, C, P, N)$ *be an accepted* $\mathsf{MetricDiameter}^{\uparrow}$ *carrier. Under any classifier transport admitted by* H*, the transported packet preserves the metric carrier, bound row, finite comparison ledger, and replay route:*

$$X, d, B, W, R, C \longmapsto X', d', B', W', R', C'.$$

The transported packet therefore compares exactly the transported finite pair list against the transported bound and introduces no second metric carrier, no independent diameter value, and no host supremum.

Proof. The transport row H is componentwise. It carries the metric carrier, distance witness, bound row, finite witness list, and comparison ledger to their transported rows without changing the packet shape.

The replay row C is downstream from the same transported coordinates. Point admission, distance evaluation, ordered-real comparison, and bound handoff are replayed after transport in the same order as before transport.

Package provenance P and the local naming row N identify this transported packet as the same $\mathsf{MetricDiameter}^{\uparrow}$ surface. Because no coordinate exists for a second metric carrier, independent diameter value, or host supremum, classifier stability preserves exactly the displayed ledger. □

Theorem 1503.4 (MetricDiameter NameCert obligation surface)**.** *For every accepted* $\mathsf{MetricDiameter}^{\uparrow}$ *carrier* $D = (X, d, B, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricDiameter}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed metric carrier, distance witness, bound row, witness list, comparison ledger, transport, replay, provenance, and local naming rows;*
2. *finite bound exposure, requiring the bound row* B *to be read through the ordered-real and rational surfaces already named by the packet;*
3. *pairwise distance comparison stability, requiring every finite pair in* W *to have its distance-to-bound comparison recorded in* R*;*

4. *classifier transport, requiring H and C to preserve the metric carrier, bound row, witness list, ledger, and replay route;*
5. *ledger non-escape, stating that the packet exports no host supremum, compactness argument, selected maximum pair, geodesic data, open-cover principle, or bridge check.*

Proof. Carrier admission is projection from Definition 1503.1. The tuple lists exactly the rows available to the local classifier and to downstream metric or ordered-real consumers.

Finite bound exposure is the role of B. It is consumed through $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ rows named in P, so the diameter value is visible as a displayed comparison bound rather than as a supremum in an ambient order.

Pairwise comparison stability is the role of W and R. The witness list provides only finitely many displayed pairs, and the ledger records the distance-to-bound comparison for each such pair.

Classifier transport and replay are supplied by H and C. They move the same rows to a common comparison surface and replay the same finite route, while P and N record provenance and local naming. Hence every export remains inside the finite ledger and no excluded analytic object can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricDiameter}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricDiameter}^{\uparrow}$ packet is generated from a displayed MetricSpace carrier, a RealUp-valued distance witness, an ordered-real bound row, a finite witness list of compared pairs, a distance-comparison ledger, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricDiameter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1503.1, Definition 1503.2, Definition 1503.3, and Definition 1503.4 seed the finite ordered-real diameter surface for metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricDiameter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host supremum, compactness theorem, selected maximum pair, geodesic data, open-cover principle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bound exposure, pairwise distance comparison stability, classifier transport, and ledger non-escape for the same packet.

Chapter 1504

A Concrete Naming Certificate for $\mathsf{DedekindCompleteReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DedekindCompleteReal}^{\uparrow}$ packet records the finite interface by which a located, inhabited, bounded $\mathsf{Real}^{\uparrow}$ family may expose a displayed least-upper-bound witness. It reads the terminal real-name surface of chapter 38, the upper-bound and lower-approximation discipline of chapter 1427, the representation boundary of chapter 1424, and the sequence-limit ledger of chapter 1480. The packet is a located-supremum completion interface for finite BEDC consumers; it is not a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, not a quotient-real construction, not a trichotomy principle, and not a general completeness theorem for arbitrary real subsets.

Definition 1504.1 (DedekindCompleteReal source packet)**.** *A* $\mathsf{DedekindCompleteReal}^{\uparrow}$ *source packet is a finite* BHist *tuple*

$$D = (F, I, B, W, S, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the located* $\mathsf{Real}^{\uparrow}$ *family row whose members are readable only through finite real-name observations;*
2. *I is the inhabitedness ledger, displaying one accepted member witness for the family before any supremum read is requested;*
3. *B is the boundedness ledger, displaying an upper-bound witness and the comparison rows that place every inspected family observation below that bound;*
4. *W is the finite precision-window row that lists the exact family observations, rational tolerances, and comparison budgets currently in scope;*
5. *S is the located-supremum witness row, displaying an upper-bound face and a lower-approximation face for every precision listed in W;*
6. *Q is the* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *row that compares any cut-shaped observation used by S with the regular Cauchy readback accepted by* $\mathsf{Real}^{\uparrow}$*;*
7. *L is the* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *row that records the finite limit-law checks used when S is read through sequence approximants;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed supremum witness, reached only after F, I, B, W, S, Q, L have been exposed;*

9. *H records componentwise* hsame *transports for the family, inhabitedness ledger, boundedness ledger, precision window, supremum witness, comparison row, sequence-limit row, real seal, continuation routes, provenance, and local naming row;*
10. *C records the displayed* Cont *routes that replay family reads, boundedness checks, lower-approximation reads, comparison handoff, sequence-limit handoff, and real-seal readback;*
11. *P is the* Pkg *provenance over* $\mathsf{DedekindCompleteReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{RealSequenceLimitLaws}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCompleteReal}^{\uparrow}}$ *row.*

The accepted packet contains no quotient-real coordinate, no trichotomy oracle, no host real equality test, no countable-choice schedule, no arbitrary subset classifier, and no ambient completeness principle beyond the displayed located, inhabited, bounded family interface.

Theorem 1504.2 (DedekindCompleteReal NameCert obligation surface)**.** *For an accepted packet $D = (F, I, B, W, S, Q, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindCompleteReal}^{\uparrow}}$ *obligations are exactly the following finite rows:*

1. *carrier admission: the accepted object is the displayed tuple with located family data, inhabitedness, boundedness, precision windows, a located-supremum witness, comparison handoff, sequence-limit handoff, a real seal, transports, continuations, provenance, and local naming evidence;*
2. *inhabited bounded family stability: replacing F, I, B, W along the componentwise transports in H preserves the same inhabitedness witness and the same inspected upper-bound ledger;*
3. *located supremum witness: every precision request listed in W receives both an upper-bound read and a lower-approximation read from S, with no appeal to an unbounded family or a hidden subset classifier;*
4. *representation handoff: any cut-shaped observation used by S must pass through the comparison row Q before reaching the real-seal row E;*
5. *sequence-limit handoff: any sequence-shaped approximation used by S must pass through the finite limit-law row L before reaching E;*
6. *classifier transport: the transports in H and the replay routes in C move only the displayed rows $F, I, B, W, S, Q, L, E, P, N$;*
7. *ledger exhaustion: every admissible downstream consumer must read the packet through one of the displayed rows before obtaining a real-facing supremum observation.*

No local obligation may invoke quotient reals, trichotomy, host real equality, countable choice, an arbitrary subset classifier, or a general completeness principle.

Proof. Project the accepted carrier row by row. Carrier admission is immediate from the tuple D, while inhabited bounded family stability reads only F, I, B, W and the corresponding transports in H.

For the supremum witness, inspect a requested precision in W. The row S supplies the upper-bound face and the lower-approximation face for that precision, and the carrier contains no coordinate from which an unbounded-family argument or hidden subset classifier could be read.

The two handoff obligations are then forced by the route inventory. Cut-shaped observations pass through Q, sequence-shaped approximations pass through L, and both routes reach the real-facing surface only at E.

Classifier transport and ledger exhaustion are structural. The continuation row C can replay only the displayed routes, and the provenance row P names exactly the sibling BEDC surfaces available to the packet. Since quotient reals, trichotomy, host real equality, countable choice, arbitrary subset classification, and general completeness are absent from the carrier, they cannot enter the local NameCert surface. □

Theorem 1504.3 (DedekindCompleteReal located-supremum handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing observation exported by an accepted* $\mathsf{DedekindCompleteReal}^{\uparrow}$ *packet factors through the displayed located, inhabited, bounded family rows* F, I, B, W*, the located-supremum witness row* S*, the* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *handoff row* Q*, the* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *handoff row* L*, and the terminal real-seal row* E*. The export supplies a finite least-upper-bound witness for the named family window only, and it supplies no Dedekind-cut construction of* $\mathsf{Real}^{\uparrow}$*, quotient real, trichotomy principle, host real equality, countable-choice schedule, arbitrary subset classifier, or general completeness theorem.*

Proof. Begin with a real-facing consumer of the packet. The only real-name coordinate present in the carrier is E, and E is reachable only after the family row, inhabitedness ledger, boundedness ledger, precision window, and supremum witness row have been fixed.

The upper-bound side of the observation is supplied by B and S. The lower-approximation side is supplied by S at the requested precision in W, with inhabitedness grounded by I.

If the observation is read through a cut-shaped presentation, the comparison row Q is the only available handoff. If it is read through sequence approximants, the row L is the only available limit-law handoff.

Thus every real-facing observation factors through F, I, B, W, S, Q, L, E and then through the transport, continuation, provenance, and naming rows. The carrier inventory contains no Dedekind construction of $\mathsf{Real}^{\uparrow}$, quotient-real coordinate, trichotomy oracle, host equality test, choice schedule, arbitrary subset classifier, or general completeness coordinate, so none can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCompleteReal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DedekindCompleteReal}^{\uparrow}$ packet is generated from a located $\mathsf{Real}^{\uparrow}$ family row, inhabitedness and boundedness ledgers, a finite precision window, a located-supremum witness, comparison and sequence-limit handoff rows, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCompleteReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1504.1, Definition 1504.2, and Definition 1504.3 seed the located-supremum completion interface for finite inhabited bounded $\mathsf{Real}^{\uparrow}$ family windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCompleteReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient reals, trichotomy, host real equality, countable choice, arbitrary subset completeness, general least-upper-bound completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, inhabited bounded family stability, located supremum witnessing, comparison handoff, sequence-limit handoff, classifier transport, ledger exhaustion, and real-seal factorization for the displayed packet.

Chapter 1505

A Concrete Naming Certificate for $\mathsf{DedekindCompleteness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DedekindCompleteness}^{\uparrow}$ packet records the finite completeness route by which a displayed inhabited, bounded, located cut family exposes a real-name supremum witness. It sits over the located-cut surface of chapter 404, the located-real surface of **??**, the comparison discipline of chapter 1381, the stream and regular-rational readbacks of chapter 126 and chapter 301, and the terminal real seal of chapter 38. The packet names a concrete finite route for later $\mathsf{Real}^{\uparrow}$ consumers; it does not assert an ambient host completeness principle for arbitrary subsets.

Definition 1505.1 (Dedekind completeness carrier)**.** *A* $\mathsf{DedekindCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, B, W, A, S, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *family row whose lower and upper faces are inspected only through finite rational windows;*
2. *R is the* $\mathsf{LocatedReal}^{\uparrow}$ *readback row attached to the same family observations;*
3. *B is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *row that records boundedness and comparison evidence between the cut, located-real, and real-seal faces;*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *window ledger used to request finite observations from the family;*
5. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation ledger that repacks the windows as a regular rational route;*
6. *S is the located upper-bound stability row, displaying that transported family observations remain below the same accepted upper-bound witness;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, R, B, W, A, S have been displayed;*
8. *H records componentwise* hsame *transports for the cut family, located-real readback, comparison row, stream windows, regular approximation ledger, stability row, real seal, continuation routes, provenance, and local naming row;*
9. *C records the displayed* Cont *replay routes for family reads, upper-bound checks, lower-approximation witnesses, comparison handoff, regular-rational handoff, and real-seal readback;*

10. *P is the* Pkg *provenance over* DedekindCompleteness$^{\uparrow}$, LocatedCut$^{\uparrow}$, LocatedReal$^{\uparrow}$, BishopRealComparison$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* NameCert$_{\text{DedekindCompleteness}^{\uparrow}}$ *row.*

The accepted carrier contains no quotient-real coordinate, no trichotomy oracle, no host real equality test, no countable-choice schedule, no arbitrary subset classifier, and no completeness principle beyond the displayed finite packet.

Theorem 1505.2 (Dedekind completeness NameCert obligations)**.** *For an accepted carrier $K = (L, R, B, W, A, S, E, H, C, P, N)$, the local* NameCert$_{\text{DedekindCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure: every consumer can inspect precisely the displayed rows $L, R, B, W, A, S, E, H, C, P, N$;*
2. *classifier transport: the transports in H and replay routes in C preserve the same cut-family classifier, located-real readback, comparison ledger, stream windows, regular approximation ledger, upper-bound stability row, real seal, provenance, and local naming row;*
3. *located upper-bound stability: the row S transports accepted upper-bound evidence through the* BishopRealComparison$^{\uparrow}$ *comparison row without changing the family window named by L and W;*
4. *lower-approximation witness: every precision requested in W receives a displayed lower-face witness from the located cut row L and its regular-rational handoff A;*
5. Real$^{\uparrow}$ *seal factorization: every terminal real-name read factors through L, R, B, W, A, S before it reaches E;*
6. *non-escape: no consumer can obtain quotient reals, trichotomy, host real equality, countable choice, an arbitrary subset classifier, or ambient completeness from the packet.*

Proof. Project the accepted carrier row by row. Carrier exposure is the tuple inventory itself, and classifier transport follows because H and C mention only the displayed rows.

For located upper-bound stability, read S together with the comparison row B. The transported family observations remain tied to the same cut window L and stream requests W, so no separate upper-bound classifier is introduced.

For lower approximation, inspect a requested precision in W. The located cut row L supplies the lower face, and the regular-rational row A repacks that witness into the same finite route consumed by the real-seal boundary.

The real-facing exit is then forced. The only terminal real row is E, and the carrier reaches it only after the cut, located-real, comparison, stream, approximation, and stability rows have been displayed.

The non-escape clause is structural. Quotient reals, trichotomy, host real equality, countable choice, arbitrary subset classifiers, and ambient completeness are not carrier coordinates and are not named by the package provenance P. □

Closure status for NameCert$_{\text{DedekindCompleteness}^{\uparrow}}$**.**

Constructive story: A DedekindCompleteness$^{\uparrow}$ packet is generated from displayed LocatedCut$^{\uparrow}$, LocatedReal$^{\uparrow}$, BishopRealComparison$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ rows, together with located upper-bound stability, lower-approximation witnessing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DedekindCompleteness}^{\uparrow}}$, seed)

Scope closed: Definition 1505.1 and Definition 1505.2 seed the finite Dedekind-completeness route from located cut data to a terminal Real$^{\uparrow}$ seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{DedekindCompleteness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient reals, trichotomy, host real equality, countable choice, arbitrary subset completeness, general least-upper-bound completeness, or a standard bridge.

Upgrade path: Formal closure requires checked carrier exposure, classifier transport, located upper-bound stability, lower-approximation witnessing, Real$^{\uparrow}$ seal factorization, and non-escape for the displayed packet.

Chapter 1506

A Concrete Naming Certificate for $\mathsf{MetricCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Kelley-style metric completion, the $\mathsf{MetricCompletion}^{\uparrow}$ packet records the L10 metric-completion interface as finite Cauchy-filter or Cauchy-net evidence over a displayed metric source. It sits between the metric carrier of chapter 57, the filter surface of chapter 333, the directed-net surface of chapter 589, the separated-limit uniqueness surface of chapter 1411, and the uniform-completion boundary of chapter 1473. The packet gives later complete-metric and real-completion consumers a named landing surface without quotienting Cauchy names, selecting representatives, assuming an ambient complete space, invoking open-cover compactness, using countable choice, or asserting completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1506.1 (MetricCompletion carrier)**.** *A* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, D, R, S, H, C, P, N)$$

with the following visible rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, including its point classifier, metric-distance witness surface, and displayed finite observation histories.*
2. *F is either a* $\mathsf{CauchyFilter}^{\uparrow}$ *cofinal packet or an empty marker when the completion route is presented by directed nets.*
3. *D is either a* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window packet or an empty marker when the completion route is presented by Cauchy filters.*
4. *R is the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row used when a completion-facing consumer asks for numerical tolerance data.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness row, used only to identify two displayed limit readings through zero-distance classifier evidence.*
6. *H records componentwise* hsame *transport for the source metric, cofinal Cauchy packet, finite numerical readback, separatedness row, replay row, package row, and local naming row.*
7. *C records the displayed* Cont *route replaying metric admission, Cauchy cofinality, readback extraction, separated-limit comparison, and completion handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricCompletion}^\uparrow}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, an ambient complete metric space, open-cover compactness, countable choice, or completeness of $\mathsf{Real}^\uparrow$*.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.TasteGate.MetricCompletionTasteGate single carrier alignment`

Definition 1506.2 (MetricCompletion classifier)**.** *The classifier of an accepted* $\mathsf{MetricCompletion}^\uparrow$ *packet relates two completion-facing reads precisely when their source metric row is the same displayed X, their cofinal Cauchy evidence is read from the same F or D branch, their finite* $\mathsf{RegSeqRat}^\uparrow$ *or* $\mathsf{Real}^\uparrow$ *tolerance rows agree after the componentwise* hsame *transport H, and the separatedness row S identifies any two displayed limit readings through the zero-distance route already available in* $\mathsf{SeparatedMetric}^\uparrow$*.*

Equivalently, the classifier is the finite replay path

$$X, (F \text{ or } D), R, S, H, C, P, N.$$

It is not a quotient of Cauchy names, not a choice of canonical representatives, and not a claim that a host metric space is complete.

Lean4 (definition) `BEDC.Derived.MetricCompletionUp.ClassifierRoute.MetricCompletionClassifier`

Theorem 1506.3 (MetricCompletion NameCert obligations)**.** *For an accepted* $\mathsf{MetricCompletion}^\uparrow$ *carrier $M = (X, F, D, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^\uparrow}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed* $\mathsf{Met}^\uparrow$ *source,* $\mathsf{CauchyFilter}^\uparrow$ *or* $\mathsf{CauchyNet}^\uparrow$ *cofinal packet, finite* $\mathsf{RegSeqRat}^\uparrow$ *or* $\mathsf{Real}^\uparrow$ *readback,* $\mathsf{SeparatedMetric}^\uparrow$ *uniqueness row, componentwise transport, continuation replay, provenance row, and local naming row;*
2. *cofinal evidence selection, requiring each completion-facing read to pass through exactly one visible branch, either F or D;*
3. *finite readback compatibility, requiring numerical tolerance requests to factor through R before any completion handoff is consumed;*
4. *separated-limit uniqueness, requiring equality of two displayed limit readings to pass through the zero-distance classifier route stored in S;*
5. *ledger non-escape, stating that no quotient completion, selected representative, ambient complete metric space, open-cover compactness principle, countable-choice schedule, or* $\mathsf{Real}^\uparrow$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.MetricCompletionUp StdBridge`

Proof. Carrier admission is projection from Definition 1506.1. The tuple lists the source metric row, the two possible Cauchy-evidence branches, the finite numerical readback, the separatedness row, and the structural support rows.

Cofinal evidence selection is local because the accepted carrier records the chosen branch in F or D. A filter-presented route consumes the $\mathsf{CauchyFilter}^\uparrow$ row before any completion handoff, while a net-presented route consumes the $\mathsf{CauchyNet}^\uparrow$ directed-window row in the same position.

Finite readback compatibility is the role of R. Every tolerance-facing consumer reads the displayed $\mathsf{RegSeqRat}^\uparrow$ or $\mathsf{Real}^\uparrow$ data before it can compare completion endpoints.

Separated-limit uniqueness is supplied by S and replayed by C after transport by H. The provenance row P and local naming row N record that no further coordinate is available, so the excluded quotient, choice, compactness, ambient completeness, and real-completeness principles cannot be read from the certificate. □

Theorem 1506.4 (MetricCompletion Cauchy-filter handoff)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet whose cofinal evidence is presented by the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch F. Then every completion-facing consumer of M factors first through the source metric row X, then through the displayed Cauchy-filter row F, then through the finite readback row R when numerical tolerance data are requested, and only then through the separatedness row S for comparison of displayed limit readings.*

The handoff is therefore the finite route

$$X \longmapsto F \longmapsto R \longmapsto S \longmapsto H, C, P, N,$$

not a quotient completion, not a selected representative, not an ambient complete metric space, and not an appeal to countable choice or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.NameCertObligations.MetricCompletionCarrier filter branch handoff`

Proof. Project the accepted packet and choose the filter branch. The first row available to a completion consumer is the metric source X, so point admission and distance evidence are read before any completion-facing operation.

The next row is F. It is already a $\mathsf{CauchyFilter}^{\uparrow}$ finite-filterbase and late-window packet, so cofinality is consumed as displayed filter evidence rather than as a selected Cauchy representative.

When the consumer asks for tolerance data, the route passes through R. The replay row C then carries the same source, filter, and readback rows to S, where separated-limit comparison is performed only through the local zero-distance classifier route.

The remaining rows H, P, N transport and name the same finite packet. Since the route has no coordinate for quotient equality, selected representatives, ambient completeness, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, none of those principles is exported by the handoff. □

Theorem 1506.5 (MetricCompletion separated limit uniqueness)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet, and suppose two completion-facing reads of the same source metric packet use the same displayed cofinal branch F or D and the same finite readback row R after transport by H. If the separatedness row S displays zero distance between the two resulting limit readings, then the* $\mathsf{MetricCompletion}^{\uparrow}$ *classifier identifies the two reads.*

This identification is internal to the displayed $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{SeparatedMetric}^{\uparrow}$ *rows. It is not host equality, not equality of quotient classes, and not a selected-limit principle.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.SeparatedLimit.MetricCompletion separated limit uniqueness`

Proof. Read the two completion-facing paths through the common source metric row X. The shared cofinal branch, either F or D, keeps both paths on the same displayed Cauchy evidence.

Transport by H aligns the finite readback row R for the two paths. The replay row C then presents the two limit readings to the separatedness row S.

By the meaning of S, zero distance between the two displayed limit readings yields classifier equivalence inside the underlying metric carrier. The definition of Definition 1506.2 uses exactly this route as the comparison criterion.

No quotient class, host equality, selected representative, ambient completeness row, countable-choice schedule, or $\mathsf{Real}^{\uparrow}$ completeness theorem appears among the fields of M, so the uniqueness conclusion remains a local classifier identification. □

Theorem 1506.6 (MetricCompletion Cauchy-net handoff)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet whose cofinal evidence is presented by the* $\mathsf{CauchyNet}^{\uparrow}$ *branch D. Then every completion-facing consumer of M factors first through the source metric row X, then through the displayed directed Cauchy-net row D, then through the finite readback row R when numerical tolerance data are requested, and only then through the separatedness row S for comparison of displayed limit readings.*

The handoff is therefore the finite route

$$X \longmapsto D \longmapsto R \longmapsto S \longmapsto H, C, P, N,$$

not a quotient completion, not a selected representative, not an ambient complete metric space, and not an appeal to countable choice or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.HandoffRoutes.MetricCompletion net branch handoff`

Proof. Project the accepted packet and choose the net branch. The source metric row X supplies the displayed point classifier, metric-distance witness surface, and finite observation histories before any completion-facing read is available.

The next row is D. It is already the $\mathsf{CauchyNet}^{\uparrow}$ directed-window packet, so cofinality is consumed as visible net evidence rather than as a chosen representative of a completion class.

When a consumer requests tolerance data, the route passes through R. The replay row C then carries the same source, net, and readback rows to S, where separated-limit comparison is performed through the local zero-distance classifier route.

The rows H, P, N transport, package, and name the same finite packet. Since none of the carrier coordinates is a quotient-completion equality, a selected limit, a countable-choice schedule, an ambient completeness witness, or a $\mathsf{Real}^{\uparrow}$ completeness theorem, the net handoff exports none of those principles. □

Theorem 1506.7 (MetricCompletion filter-net branch determinacy)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Every completion-facing read of M uses exactly one visible cofinal branch, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F or the* $\mathsf{CauchyNet}^{\uparrow}$ *row D. A downstream read cannot mix filter evidence and net evidence unless an additional branch-conversion row is added, and no such row occurs in the carrier of Definition 1506.1.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchDeterminacy.MetricCompletion filter net branch determinacy`

Proof. The classifier of Definition 1506.2 reads the cofinal evidence from the single displayed branch recorded in the packet, written there as F or D. Thus the accepted route selects one branch before the finite readback row R and separatedness row S are inspected.

In the filter case, every downstream comparison factors through the row F named in the finite route. In the net case, the corresponding route factors through D in the same position.

A mixed read would require a new row relating the filter and net evidence before R and S could be shared as one classifier path. The carrier has no coordinate for such a row, so the classifier route cannot manufacture it downstream. □

Theorem 1506.8 (MetricCompletion finite-readback ledger non-escape)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier* $M = (X, F, D, R, S, H, C, P, N)$*, every tolerance read, readback request, and limit-comparison read exported by* M *is exhausted by the rows*

$$X, F, D, R, S, H, C, P, N.$$

Consequently the packet cannot introduce quotient classes, host equality, selected limits, open-cover compactness, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Tolerance-facing reads pass through the finite readback row R after the source metric row X and the chosen cofinal branch F or D have been displayed. The componentwise transport row H and replay row C preserve that same route.

Limit-comparison reads then pass through S. The separatedness row supplies only local zero-distance classifier evidence, so it compares displayed limit readings without changing the carrier into a host equality or quotient equality.

The provenance row P and local naming row N close the ledger at exactly the listed rows. Since no remaining coordinate names quotient classes, selected limits, open-cover compactness, countable choice, host equality, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, none of those data can escape from the finite readback ledger. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.ReadbackLedger.MetricCompletion finite readback ledger nonescape`

Theorem 1506.9 (MetricCompletion branch coverage)**.** *Let*

$$M = (X, F, D, R, S, H, C, P, N)$$

be an accepted $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Every completion-facing read of* M *uses either the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch* F *or the* $\mathsf{CauchyNet}^{\uparrow}$ *branch* D *before any finite readback, separated-limit comparison, or completion handoff is inspected. A consumer that has not chosen one of these displayed branches has no route to* R*,* S*,* H*,* C*,* P*, or* N*.*

Proof. Project the carrier of Definition 1506.1. The only cofinal evidence fields are F and D, and the classifier of Definition 1506.2 reads completion data through one of those fields before it reaches the readback row.

The existing handoff theorems identify the two possible routes. In the filter case, Definition 1506.4 forces the path through F before R and S are read. In the net case, Definition 1506.6 forces the same position to be occupied by D.

The remaining rows are structural. Transport, replay, provenance, and local naming preserve the chosen branch; they do not create a third Cauchy-evidence coordinate. Hence branch coverage is exactly the displayed filter-or-net dichotomy. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchCoverage.MetricCompletion branch coverage`

Theorem 1506.10 (MetricCompletion filter-net compatibility)**.** *Let* $M = (X, F, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Any consumer comparing filter and net presentations of the same completion-facing read must pass through the same source* $\mathsf{Met}^{\uparrow}$ *row* X*, the same finite readback row* R*, the same* $\mathsf{SeparatedMetric}^{\uparrow}$ *row* S*, the componentwise* hsame *transport row* H*, the displayed* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *row* N*. The comparison cannot be made by quotienting the two Cauchy presentations or by selecting a representative common limit.*

Proof. Start with the branch coverage of Definition 1506.9. A filter presentation and a net presentation are readable only as the two visible cofinal branches of the same carrier, so any comparison between them must keep the source row X fixed.

Finite numerical data are then compared through R. The finite-readback ledger non-escape theorem, Definition 1506.8, prevents a consumer from replacing this row by an external tolerance oracle or a quotient-class read.

Separated comparison is performed at S. The separated-limit uniqueness theorem, Definition 1506.5, supplies only local zero-distance classifier evidence, and H, C, P, N preserve and name that same route.

Since no carrier coordinate stores quotient equality or a selected representative, the filter-net comparison is exhausted by the listed rows. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.Compatibility.MetricCompletion filter net compatibility`

Theorem 1506.11 (MetricCompletion source-branch readback)**.** *Every accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *read factors through the common source metric row X, exactly one displayed Cauchy branch F or D, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row R, the separatedness row S, and the structural rows H, C, P, N. In carrier notation the route is*

$$X, (F \text{ or } D), R, S, H, C, P, N.$$

The readback cannot be replaced by quotient completion equality, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1506.1. The visible source row is X, the only Cauchy evidence rows are the filter branch F and the net branch D, and the only numerical readback coordinate is R.

Use branch coverage from Definition 1506.9. A completion-facing request must choose one of the displayed branches before it can read the finite $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row.

Use filter-net compatibility from Definition 1506.10. It keeps the selected branch attached to the same source metric, the same readback row, the same separatedness row, and the same transport, replay, provenance, and naming route.

Finally apply the finite-readback ledger non-escape theorem, Definition 1506.8. Since quotient equality, selected representatives, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in the packet, no source-branch readback can be replaced by any of those objects. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.MetricCompletion source branch readback`

Theorem 1506.12 (MetricCompletion filter-net branch exhaustion)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier $M = (X, F, D, R, S, H, C, P, N)$, every completion-facing consumer reads exactly one of the displayed Cauchy evidence branches before readback: either the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch F or the* $\mathsf{CauchyNet}^{\uparrow}$ *branch D. The remaining rows R, S, H, C, P, N can transport, replay, compare, package, and name the selected route, but they cannot introduce a third completion evidence route.*

Proof. Project the carrier of Definition 1506.1. The only Cauchy evidence rows in the accepted tuple are F and D, and the classifier of Definition 1506.2 reads one of them before the finite readback row R is available.

Use the NameCert obligations together with branch determinacy and compatibility, Definition 1506.3, Definition 1506.7, and Definition 1506.10. These keep the selected branch attached to

the same source metric, readback row, separatedness comparison, transport, replay, provenance, and local naming route.

It remains to exclude a hidden third route. The finite-readback ledger non-escape theorem, Definition 1506.8, rules out quotient completions, selected representatives, ambient complete spaces, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness. Since R, S, H, C, P, N are structural or readback rows downstream of the chosen branch, they cannot supply independent Cauchy evidence. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchExhaustion.MetricCompletion filter net branch exhaustion`

Theorem 1506.13 (MetricCompletion UniformCompletion handoff)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet reads the packet only through the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *evidence, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness row, componentwise transport, replay, provenance, and local naming. The handoff provides no quotient row, no selected representative row, no host equality row, and no* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.MetricCompletionUniformCompletionHandoff`

Proof. Use Definition 1506.9 to select the visible Cauchy-evidence branch. The $\mathsf{UniformCompletion}^{\uparrow}$ consumer therefore begins with the same filter or net route already displayed by the metric-completion packet.

Next the consumer reads finite tolerance information through R. This is the only $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback coordinate in the carrier, so every numerical request remains attached to the same source metric and branch evidence.

Finally the consumer reaches S, H, C, P, N. The separatedness row supplies local uniqueness, while the structural rows transport, replay, source, and name the same finite packet.

The excluded completion principles are absent from Definition 1506.1 and are barred again by Definition 1506.8. The uniform-completion handoff therefore exports exactly the displayed finite evidence and no quotient or selected-representative data. □

Theorem 1506.14 (MetricCompletion obligation branch readback)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$*, every finite readback exported by the metric-completion surface first chooses one displayed cofinal branch, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch* F *or the* $\mathsf{CauchyNet}^{\uparrow}$ *branch* D*. Only after that branch is fixed may a consumer read the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row* R*.*

Proof. Use Definition 1506.9. It states that every completion-facing read chooses one of the visible Cauchy-evidence branches before any finite readback, separated comparison, or completion handoff is inspected.

The carrier of Definition 1506.1 has only one readback coordinate R. Thus a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ tolerance read can occur only after the selected filter or net branch has been displayed.

The filter-net compatibility theorem, Definition 1506.10, keeps R, H, C, P, N attached to the same source metric and branch route. The finite-readback non-escape theorem, Definition 1506.8, excludes quotient classes, selected limits, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness from the readback path. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchReadback.MetricCompletion obligation branch readback`

Theorem 1506.15 (MetricCompletion obligation separated comparison)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Any two displayed completion reads of M compare only through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier row S together with the componentwise* hsame, Cont, Pkg, *and* NameCert *route. They are not compared by host equality, quotient equality, or a selected representative of a completion class.*

Proof. Start from the classifier of Definition 1506.2. It identifies completion-facing reads only when the source metric, selected Cauchy branch, readback row, separatedness row, and structural routes agree componentwise.

Apply Definition 1506.5. The zero-distance evidence in S is the only comparison row that can identify two displayed limit readings.

The carrier and finite-readback non-escape theorem rule out host equality, quotient equality, selected representatives, ambient completeness, and countable choice. Therefore every accepted comparison remains a local $\mathsf{SeparatedMetric}^{\uparrow}$ classifier comparison transported through H, C, P, N. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchReadback.MetricCompletion obligation separated comparison`

Theorem 1506.16 (MetricCompletion regular-Cauchy readback)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Any completion consumer that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row first chooses one visible Cauchy evidence branch, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F or the* $\mathsf{CauchyNet}^{\uparrow}$ *row D. Only after that branch choice may the consumer read R, and every such readback is replayed through H, C, P, N over the same metric source X.*

Proof. Project the carrier of Definition 1506.1. The only Cauchy evidence rows are F and D, and the only numerical readback row is R.

Apply the branch coverage and branch determinacy theorems, Definition 1506.9 and Definition 1506.7. Together they force every completion-facing read to select exactly one displayed branch before the finite readback row can be inspected.

Now apply the obligation branch-readback theorem Definition 1506.14. It places the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ tolerance row after the selected filter or net evidence.

The support rows do not alter the branch. The componentwise transport, replay, provenance, and local naming rows H, C, P, N preserve the same source metric, selected Cauchy evidence, and readback row. Thus no consumer reaches R before a visible branch choice. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RegularCauchyReadback.MetricCompletion regular cauchy readback`

Theorem 1506.17 (MetricCompletion separated-branch readback)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Every completion consumer that reaches separated comparison first reads the selected* $\mathsf{CauchyFilter}^{\uparrow}$ *branch F or* $\mathsf{CauchyNet}^{\uparrow}$ *branch D, then the finite readback row R, and only then the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row S. The separated comparison is therefore a branch-indexed local zero-distance classifier route, not host equality, quotient equality, selected representative equality, or ambient completeness.*

Proof. Start with the regular-Cauchy readback theorem above. It fixes the route to R as a route through exactly one displayed Cauchy evidence branch over the source metric row X.

Apply Definition 1506.15. It states that any comparison of displayed completion reads uses the separatedness row S together with the componentwise transport, continuation, provenance, and naming route.

The separated-limit uniqueness theorem, Definition 1506.5, identifies the content of S as local zero-distance classifier evidence. This comparison is downstream of the selected branch and readback rows, not an independent completion equality.

Finally use Definition 1506.8. Quotient equality, host equality, selected representatives, ambient complete spaces, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, so separated comparison cannot be reached through any route other than the displayed branch, readback, and S, H, C, P, N rows. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.SeparatedBranchReadback.MetricCompletion separated branch readback`

Theorem 1506.18 (MetricCompletion obligation uniform handoff)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet sees exactly the same displayed branch, finite readback row, separatedness row, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *route as the metric-completion packet itself. The handoff adds no quotient completion row, no branch conversion row, no selected limit, and no independent uniform-completion classifier.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchReadback.MetricCompletion obligation uniform handoff`

Proof. Use Definition 1506.13. The uniform consumer reads the displayed $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{CauchyNet}^{\uparrow}$ evidence, R, S, and the structural rows H, C, P, N.

The branch-readback obligation above fixes that the same branch precedes the same readback row. The separated-comparison obligation fixes that any comparison available to the uniform consumer is still routed through S rather than through host or quotient equality.

Finally Definition 1506.10 and Definition 1506.8 keep the handoff on the same source metric, readback, separatedness, transport, replay, provenance, and naming route. No additional uniform-completion data is introduced by the handoff. □

Theorem 1506.19 (MetricCompletion branch-conversion refusal)**.** *Let* $M = (X, F, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. Any completion-facing read that uses data from both the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch* F *and the* $\mathsf{CauchyNet}^{\uparrow}$ *branch* D *must display a branch-conversion row between those two branches. Since the carrier of Definition 1506.1 contains no such row, no accepted read of* M *may mix filter evidence and net evidence as one completion route.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchReadback.MetricCompletion branch conversion refusal`

Proof. Apply Definition 1506.7. The accepted packet selects the visible branch before a read reaches the readback row R or the separatedness row S.

Now apply Definition 1506.9. A consumer that reads F follows the filter handoff, while a consumer that reads D follows the net handoff. To combine the two as one route, the consumer would need an additional row witnessing conversion from one displayed branch to the other.

The carrier inventory in Definition 1506.1 lists only $X, F, D, R, S, H, C, P, N$. The structural rows transport, replay, source, and name the selected route; they do not add a conversion coordinate. Hence a mixed read has no projection from the accepted packet. □

Theorem 1506.20 (MetricCompletion uniform-seal factorization)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet factors through the selected* $\mathsf{CauchyFilter}^{\uparrow}$ *branch*

F or $\mathsf{CauchyNet}^{\uparrow}$ *branch D, the finite readback row R, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row S, the componentwise* hsame *row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *row N. No uniform-facing seal is available outside that selected branch and structural route.*

Proof. Start with Definition 1506.18. It gives the uniform consumer exactly the branch, readback, separatedness, transport, replay, provenance, and naming rows of the metric-completion packet.

Use Definition 1506.14 to place R after the selected Cauchy-evidence branch. Then use Definition 1506.15 to place every comparison through S and the structural rows H, C, P, N.

The branch-conversion refusal above prevents the uniform consumer from combining F and D through an absent conversion row. Thus the uniform seal factors through one selected branch together with R, S, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.UniformSealFactorization.MetricCompletion uniform seal factorization`

Theorem 1506.21 (MetricCompletion completion-consumer totality)**.** *Every current completion-facing consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet receives only the rows listed in the carrier*

$$X, F, D, R, S, H, C, P, N.$$

It receives no quotient-completion class, selected representative, countable-choice schedule, branch-conversion coordinate, open-cover compactness row, or $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CompletionConsumerTotality.MetricCompletion completion consumer totality`

Proof. Project the carrier of Definition 1506.1. The finite packet lists the metric source, two alternative Cauchy-evidence rows, one readback row, one separatedness row, and the transport, replay, provenance, and naming rows.

The obligation theorems above exhaust the possible consumer routes. Branch readback fixes how R is reached; separated comparison fixes how S is used; uniform handoff and uniform-seal factorization fix the completion-facing handoff; branch-conversion refusal rejects mixed branches without an explicit row.

Finally apply Definition 1506.8. The excluded quotient, representative, countable-choice, compactness, and ambient-completeness principles have no coordinate in the accepted tuple and cannot be recovered by the structural rows. □

Theorem 1506.22 (MetricCompletion carrier admission)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet, carrier admission is exactly projection of the finite rows*

$$X, F, D, R, S, H, C, P, N.$$

The admitted rows are the displayed $\mathsf{Met}^{\uparrow}$ *source X, the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch F or* $\mathsf{CauchyNet}^{\uparrow}$ *branch D, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row R, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row S, the componentwise* hsame *transport row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *row N. No carrier admission judgment for this packet has a coordinate for quotient completion equality, selected representatives, host equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CarrierAdmission.MetricCompletion carrier admission`

Proof. Project the carrier of Definition 1506.1. Its displayed tuple is exactly $M = (X, F, D, R, S, H, C, P, N)$.

The row inventory is already separated by the NameCert obligations of Definition 1506.3. The branch coverage theorem, Definition 1506.9, forces completion-facing reads to choose F or D before R and S can be inspected.

The finite-readback ledger non-escape theorem, Definition 1506.8, closes the negative side. Since every exported tolerance read, comparison read, and handoff read is exhausted by the displayed tuple, no excluded completion principle can be admitted as an additional carrier coordinate. □

Theorem 1506.23 (MetricCompletion classifier stability)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ and $M' = (X', F', D', R', S', H', C', P', N')$ be accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packets whose displayed rows are related componentwise by the* hsame *transport rows and replayed by the corresponding* Cont *rows. Then the* $\mathsf{MetricCompletion}^{\uparrow}$ *classifier preserves branch choice, finite readback, separated comparison, and completion handoff along that componentwise route.*

In particular, a classified replacement cannot change a filter branch into an unrelated net branch, replace R by an external tolerance oracle, compare endpoints outside S, or introduce a new $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row.*

Proof. Start with the classifier of Definition 1506.2. It reads the source metric, the chosen Cauchy branch, the finite readback row, the separatedness row, and the support rows as one displayed route.

Apply branch determinacy and branch coverage, Definition 1506.7 and Definition 1506.9. These results keep the branch position fixed as either F or D before any downstream read reaches R or S.

Next apply Definition 1506.14 and Definition 1506.15. The first keeps tolerance evidence at the transported readback row, and the second keeps endpoint comparison at the transported separatedness row.

Finally use Definition 1506.18. The $\mathsf{UniformCompletion}^{\uparrow}$ consumer sees the same displayed branch, readback, separatedness, transport, replay, provenance, and naming rows, so classifier transport preserves the handoff rather than adding an independent completion surface. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.ClassifierStability.MetricCompletion classifier stability`

Definition 1506.24 (MetricCompletion branch-interface scope)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet $M = (X, F, D, R, S, H, C, P, N)$, the branch-interface rows are the displayed source metric row X, exactly one Cauchy-evidence branch F or D, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row R, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row S, the componentwise* hsame *transport row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *row N. This scope is a row boundary: it names what filter and net consumers may read, and it does not add carrier/classifier transport beyond the accepted packet.*

Lean4 (definition) `BEDC.Derived.MetricCompletionUp.BranchInterfaceScope.MetricCompletionBranchInterfaceSco`

Theorem 1506.25 (MetricCompletion filter-branch scope)**.** *On the filter branch of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet, every completion-facing read consumes the rows in the order*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \text{ or } \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Equivalently, in the carrier notation it reads X, then F, then R, then S, and finally H, C, P, N. It has no route to a net branch, quotient completion row, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the branch-interface scope of Definition 1506.24. The filter case selects the displayed row F after the source metric row X.

Apply the branch-readback and separated-comparison obligations, Definition 1506.14 and Definition 1506.15. These place R after the chosen filter branch and place comparison at S together with H, C, P, N.

Finally use the filter handoff and finite-readback ledger non-escape theorems, Definition 1506.4 and Definition 1506.8. The selected route remains X, F, R, S, H, C, P, N, and no absent completion principle is introduced downstream. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchScope.MetricCompletion filter branch scope`

Theorem 1506.26 (MetricCompletion net-branch scope)**.** *On the net branch of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet, every completion-facing read consumes the rows in the order*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}\ \textit{or}\ \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Equivalently, in the carrier notation it reads X, then D, then R, then S, and finally H, C, P, N. It has no route to a filter branch, quotient completion row, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the branch-interface scope of Definition 1506.24. The net case selects the displayed row D after the source metric row X.

Apply the branch-readback and separated-comparison obligations, Definition 1506.14 and Definition 1506.15. These place R after the chosen net branch and place comparison at S together with H, C, P, N.

Finally use the net handoff and finite-readback ledger non-escape theorems, Definition 1506.6 and Definition 1506.8. The selected route remains X, D, R, S, H, C, P, N, and no absent completion principle is introduced downstream. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BranchScope.MetricCompletion net branch scope`

Theorem 1506.27 (MetricCompletion Cauchy-evidence handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet reaches separated comparison only after the exact Cauchy-evidence handoff*

$$X \longmapsto (F\ \textit{or}\ D) \longmapsto R \longmapsto S.$$

On the filter branch this is the $\mathsf{CauchyFilter}^{\uparrow}$ *route of Definition 1506.4; on the net branch this is the* $\mathsf{CauchyNet}^{\uparrow}$ *route of Definition 1506.6. The row R is the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback used before separated comparison, and the structural rows H, C, P, N only transport, replay, source, and name the same route.*

Proof. Use Definition 1506.9. A consumer that has not chosen the filter branch F or the net branch D has no route to readback, separated comparison, or completion handoff.

In the filter case, apply Definition 1506.4. The route is X to F, then to R, then to S, with the support rows preserving the same displayed evidence.

In the net case, apply Definition 1506.6. The route is X to D, then to R, then to S, again with only the support rows available downstream.

The finite-readback ledger non-escape theorem and the UniformCompletion handoff theorem, Definition 1506.8 and Definition 1506.13, prevent the consumer from replacing this sequence by quotient completion data, selected representatives, host equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CauchyEvidenceHandoff.MetricCompletion cauchy evidence handoff`

Theorem 1506.28 (Metric completion Cauchy-filter/net seal)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* MetricCompletion$^{\uparrow}$ *packet. Every accepted completion-facing seal exposes either* CauchyFilter$^{\uparrow}$ *evidence through F or* CauchyNet$^{\uparrow}$ *evidence through D over the same displayed metric source X, and then reads the finite tolerance row R, separatedness row S, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The seal does not quotient Cauchy names, select a representative completion point, or replace X by an ambient metric source.*

Proof. Project the carrier of Definition 1506.1. The only metric source is X, and the only Cauchy evidence rows are the filter branch F and the net branch D.

Use branch coverage and branch determinacy, Definition 1506.9 and Definition 1506.7. These force every completion-facing seal to choose the displayed filter branch or the displayed net branch before any read reaches R or S.

The local handoff theorems then identify the two allowed routes. Apply Definition 1506.4 in the filter case and Definition 1506.6 in the net case.

Finally use Definition 1506.8 and Definition 1506.19. The structural rows H, C, P, N preserve and name the same selected route, while quotient names, representative selection, and ambient metric replacement have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CauchyFilterNetSeal.MetricCompletion cauchy filter net seal`

Theorem 1506.29 (Metric completion separated-limit uniqueness boundary)**.** *For an accepted* MetricCompletion$^{\uparrow}$ *packet $M = (X, F, D, R, S, H, C, P, N)$, separatedness is the only uniqueness route exported to completion-facing consumers. Any identification of two displayed completion reads must pass through the* SeparatedMetric$^{\uparrow}$ *row S together with H, C, P, N, and no representative choice, quotient equality, host equality, or selected limit is exported by the packet.*

Proof. Start from the classifier of Definition 1506.2. It identifies reads only through the displayed metric source, selected Cauchy branch, finite readback, separatedness row, and structural rows.

Apply Definition 1506.5. The zero-distance evidence stored in S is the route by which two displayed completion readings may be identified.

The comparison cannot move to host equality or quotient equality. The finite-readback ledger non-escape theorem, Definition 1506.8, excludes quotient classes, selected limits, representative choice, countable choice, and ambient completeness from the exported rows.

Thus uniqueness remains a local separatedness boundary: S supplies the comparison, and H, C, P, N transport, replay, source, and name that same comparison without adding any representative selector. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.SeparatedLimitBoundary.MetricCompletion separated limit uniqueness boundary`

Theorem 1506.30 (Metric completion uniform-completion handoff)**.** *Every* UniformCompletion$^{\uparrow}$ *consumer of an accepted* MetricCompletion$^{\uparrow}$ *packet consumes only the displayed metric source, the selected* CauchyFilter$^{\uparrow}$ *or* CauchyNet$^{\uparrow}$ *row, the finite readback row, separatedness row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. In the carrier notation this is exactly*

$$X, (F \text{ or } D), R, S, H, C, P, N.$$

The handoff exports no quotient completion row, branch-conversion row, representative choice, host equality row, or independent uniform-completion classifier.

Proof. Use Definition 1506.13. It states that a uniform-completion consumer reads the same Cauchy evidence, finite readback, separatedness, transport, replay, provenance, and naming rows as the metric-completion packet.

Next apply Definition 1506.14. This places the selected branch before R, so the uniform consumer cannot obtain tolerance data without first using the displayed filter or net evidence over X.

Apply Definition 1506.15 and Definition 1506.20. They keep any comparison through S, H, C, P, N and factor the seal through one selected branch.

The refusal and non-escape boundaries complete the handoff. By Definition 1506.19 and Definition 1506.8, no absent branch-conversion row, quotient row, representative selector, host equality row, or independent uniform-completion classifier can be recovered downstream. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.UniformCompletionHandoffSurface.MetricCompletion uniform completion handoff surface`

Theorem 1506.31 (MetricCompletion Cauchy-filter carrier admission)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier whose completion route uses the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch. Then carrier admission for the filter route is exactly the displayed row chain*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto R \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow},$$

where R is the finite $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row named in Definition 1506.1. The admission route has no coordinate for* $\mathsf{CauchyNet}^{\uparrow}$ *conversion, quotient completion, selected representatives, selected limits, host equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CauchyFilterCarrierAdmission.MetricCompletion cauchyfilter carrier admission`

Proof. Project the carrier row by row. The filter-presented route reads the metric source X first and then the displayed $\mathsf{CauchyFilter}^{\uparrow}$ row F; the net row D remains an empty marker for this branch.

The numerical request is admitted only through R. Thus $\mathsf{RegSeqRat}^{\uparrow}$ windows or $\mathsf{Real}^{\uparrow}$ seal data are read as finite rows attached to the filter branch, not as selected limit representatives.

Separated comparison and uniform-completion handoff then use S and the existing replay surface C. Since the tuple has no further coordinate, the excluded net conversion, quotient, selector, host-equality, choice, and ambient-completeness data cannot be part of filter carrier admission. □

Theorem 1506.32 (MetricCompletion Cauchy-filter limit factorization)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet $M = (X, F, D, R, S, H, C, P, N)$ with displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *branch F, every completion-facing limit read factors through X, F, R, S, H, C, P, N before any* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer may inspect it. If a* $\mathsf{CauchyNet}^{\uparrow}$ *branch is also named elsewhere in the ambient theory, it is not read by this factorization unless it appears as the selected branch of the same packet.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.CauchyFilterLimitFactorization.MetricCompletion cauchyfilter limit factorization`

Proof. Start with the completion-facing request. The replay row C sends the request to the metric source X, then to the filter evidence F, and then to the finite readback row R.

The limit comparison is not selected externally. It is checked through the separatedness row S, which supplies only zero-distance classifier evidence over the displayed source metric and the chosen Cauchy-filter branch.

The final handoff to a uniform-completion consumer is therefore a repacking of the same rows under H, P, N. A separately named $\mathsf{CauchyNet}^{\uparrow}$ route is outside this branch unless it is the selected row of the packet, so no branch conversion or selected limit can be inferred. □

Theorem 1506.33 (MetricCompletion Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet factors through the displayed finite readback row R after the selected* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *branch and before the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row. Consequently a downstream* $\mathsf{UniformCompletion}^{\uparrow}$ *or L10 real-completion consumer cannot recover* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected representatives, selected limits, countable choice, host equality, or ambient complete metric space data from the packet.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RealSealNonescape.MetricCompletion real seal nonescape`

Proof. Inspect the carrier definition. The only numerical coordinate is R, and R is explicitly the finite $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback row used after a selected Cauchy branch.

The separatedness row S can compare displayed limit readings only after that finite readback has been opened. It supplies zero-distance classifier evidence, not a proof that the host real line is complete.

Uniform-completion and L10 real-completion consumers then replay the same route through H, C, P, N. Since quotient streams, representatives, selected limits, countable-choice schedules, host equality rows, and ambient complete metric spaces are absent from the tuple, the Real-seal read cannot escape to any of them. □

Theorem 1506.34 (MetricCompletion root carrier obligation)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet. The root carrier projection of M is exhausted by the displayed route*

$$\mathsf{Met}^{\uparrow} \longmapsto (F : \mathsf{CauchyFilter}^{\uparrow}) \text{ or } (D : \mathsf{CauchyNet}^{\uparrow}) \longmapsto R \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto H, C, P, N,$$

where R is the finite $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row attached to the selected branch. Thus every root consumer of M must expose the metric source X, one selected Cauchy branch, the finite readback row R, the separated comparison row S, and the structural rows H, C, P, N before it can read any completion-facing endpoint.*

Proof. Project the accepted carrier of Definition 1506.1. Its visible analytic source is X, and the only Cauchy evidence available to a consumer is the displayed filter row F or the displayed net row D.

Use branch coverage from Definition 1506.9. The packet selects one branch for the requested read, and the filter-net compatibility theorem Definition 1506.10 allows only the recorded compatibility rows to mediate between the two presentations.

The numerical endpoint then passes through R and the separated comparison row S. The finite readback compatibility of Definition 1506.8 keeps the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row attached to the selected branch.

Finally the transport, replay, provenance, and naming fields H, C, P, N repack the same carrier. Since there is no additional coordinate, a root consumer cannot read quotient completions, selected

representatives, choice schedules, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness from carrier admission. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligations.MetricCompletion root obligation carrier`

Theorem 1506.35 (MetricCompletion root classifier obligation)**.** *Let $M = (X, F, D, R, S, H, C, P, N)$ and $M' = (X', F', D', R', S', H', C', P', N')$ be accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packets. If $X, F, D, R, S, H, C, P, N$ and $X', F', D', R', S', H', C', P', N'$ are related componentwise by the displayed* hsame *rows and the replay rows* Cont *transport the same selected Cauchy branch, then the root classifier for* $\mathsf{MetricCompletion}^{\uparrow}$ *is stable between M and M'. The stability claim is only this componentwise replay; it does not identify quotient completions, selected representatives, host equality, open-cover compactness, or ambient complete metric spaces.*

Proof. Begin with the classifier of Definition 1506.2. It compares packets by reading the metric source, the selected Cauchy branch, the finite readback, the separated comparison, and the structural rows.

Apply carrier projection from Definition 1506.34. Componentwise hsame transport moves each visible row of M to the matching visible row of M' without changing the order in which the branch and readback rows are inspected.

The replay hypothesis supplies the Cont part of the comparison. It ensures that a request routed through F or D in one packet is routed through the matching branch in the other packet, using only the compatibility rows already displayed by the packets.

Thus the classifier is stable under the stated componentwise transport and replay. The proof has not introduced a quotient completion, representative selector, host equality row, open-cover compactness proof, or ambient complete metric space; those objects remain outside the classifier surface. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligations.MetricCompletion root obligation classifier`

Theorem 1506.36 (MetricCompletion root ledger nonescape)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet $M = (X, F, D, R, S, H, C, P, N)$, every root ledger read factors through the selected Cauchy branch, the finite readback row R, and the separated comparison row S. Consequently the packet exports no quotient completion ledger, selected representative ledger, choice ledger, open-cover compactness ledger, ambient complete-metric ledger, or* $\mathsf{Real}^{\uparrow}$ *completeness ledger.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligationLedger.MetricCompletion root obligation ledger`

Proof. Use the finite readback ledger nonescape theorem Definition 1506.8. It places every numerical ledger entry after the selected Cauchy branch and before the downstream separated or uniform-completion read.

Next use separated-limit uniqueness, Definition 1506.5 and Definition 1506.29. These results identify displayed zero-distance comparisons through S; they do not create a selected host representative.

The uniform handoff theorem Definition 1506.13 then exports only the same branch, readback, separatedness, transport, replay, provenance, and naming rows. Downstream consumers therefore see the ledger already present in M.

Since quotient completions, representative selectors, countable-choice schedules, open-cover compactness, ambient complete metric spaces, and $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier tuple, no root ledger read can escape to those objects. □

Theorem 1506.37 (MetricCompletion Cauchy-filter scope lock)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$ *whose selected branch is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F*, every root-unblock read of the filter branch is confined to* BHist *provenance, componentwise* hsame *transport, displayed* Cont *replay, the package row* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *ledger before it may cite chapter 333. The read exports no Cauchy-net conversion, quotient completion, selected representative, selected limit, host equality, countable-choice schedule, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.FilterScopeLock.MetricCompletion filter scope lock`

Proof. Project the accepted packet through Definition 1506.34. On the filter branch, the only Cauchy evidence exposed to a root consumer is F together with the history row carried by P, N.

Transport is componentwise. The hsame rows in H preserve the displayed metric source, the selected filter branch, the finite readback row R, and the separated comparison row S without adding a branch conversion.

Replay is likewise local. The Cont row C routes the same request through F and then through the finite readback and separatedness rows, after which the package and naming rows supply the ledger used by chapter 333.

Since the tuple contains no coordinate for a net conversion, quotient carrier, representative selector, selected limit, host equality row, countable-choice schedule, or ambient completeness witness, the filter branch remains locked to that finite scope. □

Theorem 1506.38 (MetricCompletion Cauchy-net scope lock)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$ *whose selected branch is the* $\mathsf{CauchyNet}^{\uparrow}$ *row* D*, every root-unblock read of the net branch is confined to* BHist *provenance, componentwise* hsame *transport, displayed* Cont *replay, the package row* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$ *ledger before it may cite chapter 589. The read exports no filter selector, quotient completion, selected representative, selected limit, host equality, countable-choice schedule, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.NetScopeLock.MetricCompletion net scope lock`

Proof. Start from the root classifier obligation Definition 1506.35. The net branch is compared by the displayed row D and by the same finite readback, separatedness, transport, replay, package, and naming rows used by the packet.

The hsame rows in H move the net presentation componentwise. They do not choose a filter, a subnet, a limit representative, or a host equality witness.

The Cont replay row C then routes the accepted request through D, R, and S before the ledger rows P, N are opened. This is the only route available to the citation of chapter 589.

Thus a root-unblock consumer can read the net branch only through the finite kernel surface already present in M. Filter selection, quotient completion, selected representatives, selected limits, countable-choice schedules, host equality, and ambient completeness remain outside the packet. □

Theorem 1506.39 (MetricCompletion Real-seal scope lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exported by an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet factors through the selected Cauchy branch, the finite readback row* R*, the separated comparison row* S*, and the structural rows* H, C, P, N *before it may cite chapter 301 or chapter 38. The handoff refuses quotient completion, quotient stream equality, selected representatives, selected limits, host equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1506.36. It places every root ledger read after the selected Cauchy branch and before any downstream completion-facing endpoint.

The finite readback row R is the only numerical coordinate. If R is a $\mathsf{RegSeqRat}^{\uparrow}$ row, the handoff cites chapter 301; if R is a $\mathsf{Real}^{\uparrow}$ seal row, the handoff cites chapter 38.

Separated comparison then passes through S, while H, C, P, N preserve transport, replay, provenance, and local naming. None of these rows changes the finite readback into a quotient carrier or a selected representative.

Consequently the Real-seal route is locked to the displayed branch and readback rows. Quotient completion, quotient stream equality, selected representatives, selected limits, host equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not exported. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.MetricCompletion real seal scope lock`

Theorem 1506.40 (MetricCompletion root carrier witness obligation)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$ *and any* BHist*-anchored root carrier request, the displayed witness is the finite row sequence consisting of the metric source* X*, the selected Cauchy branch, the finite readback row* R*, the separatedness row* S*, and the structural rows* H, C, P, N*. If the selected branch is the filter route, the witness reads* F *before* R*; if it is the net route, the witness reads* D *before* R*. No root carrier witness may consume a completion endpoint before this same route has exposed* R, S, H, C, P, N*.*

Proof. Start with carrier projection from Definition 1506.34. It already exhausts the accepted packet by X, one chosen Cauchy branch, R, S, H, C, P, N.

Use branch coverage from Definition 1506.9. The request selects exactly the displayed filter row F or the displayed net row D for the root read, so the witness cannot mix the two routes.

Finally apply finite-readback nonescape, Definition 1506.8. The readback row R remains downstream of the selected branch and upstream of separatedness and structural replay, giving the required BHist-anchored witness form. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligationCarrierWitness.MetricCompletion root obligation carrier witness`

Theorem 1506.41 (MetricCompletion root classifier witness obligation)**.** *Let* $M = (X, F, D, R, S, H, C, P, N)$ *and* $M' = (X', F', D', R', S', H', C', P', N')$ *be accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packets. A* BHist*-anchored root classifier witness between them consists of componentwise* hsame *rows for the metric source, the selected Cauchy branch, the finite readback row* R*, the separatedness row* S*, and the structural rows* H, C, P, N*, together with replay evidence that the same selected branch is read on both sides. Thus the classifier witness is branch-specific and cannot be replaced by quotient completion equality, selected representatives, or host metric equality.*

Proof. Begin with the root classifier obligation, Definition 1506.35. It states classifier stability using componentwise transport and replay for the displayed rows of the two packets.

The branch-specific part is supplied by branch coverage and filter-net compatibility. The selected Cauchy route is fixed before R is read, and compatibility can only mediate through recorded rows of the accepted packets.

The witness is therefore the finite transport data for the selected route plus R, S, H, C, P, N. Since the cited classifier theorem never introduces a quotient completion, representative selector, or host metric equality, the witness has no coordinate for those objects. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligationClassifierWitness.MetricCompletion root obligation classifier witness`

Theorem 1506.42 (MetricCompletion root ledger witness obligation)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$*, every* BHist*-anchored root ledger witness is the displayed ledger route through the selected Cauchy branch, the finite readback row* R*, the separatedness row* S*, and the structural rows* H, C, P, N*. The witness records whether the selected branch is* F *or* D*, records the finite readback row* R *attached to that branch, and records the separatedness row* S *before any uniform-completion or Real-facing consumer may use the ledger.*

Proof. Use the root ledger nonescape theorem Definition 1506.36. It places every root ledger read behind the selected branch, R, and S.

Refine the ledger route by finite-readback nonescape. The row R is not an ambient endpoint; it is the finite $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback attached to the displayed Cauchy branch.

Finally use carrier projection and branch coverage to repack the same rows as a witness. The structural rows H, C, P, N transport, replay, source, and name this ledger, while no additional coordinate supplies quotient completion ledgers, selected representatives, choice schedules, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.RootObligationLedgerWitness.MetricCompletion root obligation ledger witness`

Theorem 1506.43 (MetricCompletion source-separated scope)**.** *Let* $M = (X, F, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet that reaches a completion-facing consumer. The consumer first exposes the* $\mathsf{Met}^{\uparrow}$ *source row* X*, exactly one cofinal Cauchy branch, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *or the* $\mathsf{CauchyNet}^{\uparrow}$ *row* D*, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row* R*, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance uniqueness row* S*, and then the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff through* H, C, P, N*. Thus the source-separated scope of the packet is exactly the displayed route*

$$\mathsf{Met}^{\uparrow} \longmapsto (\mathsf{CauchyFilter}^{\uparrow} \textit{ or } \mathsf{CauchyNet}^{\uparrow}) \longmapsto (\mathsf{RegSeqRat}^{\uparrow} \textit{ or } \mathsf{Real}^{\uparrow}) \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow}.$$

This scope excludes quotient completion equality, selected representatives, countable choice, ambient completeness, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier of Definition 1506.1. Its visible source is the metric row X, and its only completion evidence rows are the displayed filter row F and net row D.

The NameCert obligation theorem, Definition 1506.3, keeps every accepted packet on the same carrier, classifier, stability, transport, replay, provenance, and naming surface. Branch coverage from Definition 1506.9 then forces a completion-facing consumer to choose exactly one of the two cofinal Cauchy routes before reading numerical data.

The finite readback ledger nonescape theorem, Definition 1506.8, places the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row after that selected branch and before any separated or uniform-completion read. The root obligation ledger, Definition 1506.36, repacks this same order at the root level.

It remains only to mark the boundary. Since the carrier has no quotient-equality coordinate, representative selector, choice schedule, ambient complete-space row, or $\mathsf{Real}^{\uparrow}$ completeness row, those principles cannot be opened by a completion-facing consumer. The consumer therefore reaches $\mathsf{UniformCompletion}^{\uparrow}$ only through X, the selected branch, R, S, and the structural rows H, C, P, N. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.SourceSeparatedScope.MetricCompletion source separated scope`

Theorem 1506.44 (MetricCompletion scoped dependency package)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$*, the scoped proof surface is bound by the existing carrier, classifier, Cauchy-filter handoff, Cauchy-net handoff, finite readback, separated-limit uniqueness, uniform-completion handoff, and root obligation rows. More precisely, every completion-facing consumer factors through the displayed route over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*, and through no quotient completion, selected representative, ambient complete metric space, open-cover compactness, countable-choice schedule, or host equality row.*

Proof. Carrier and classifier scope come from Definition 1506.1, Definition 1506.2, and Definition 1506.3. These fix the visible rows $X, F, D, R, S, H, C, P, N$ and require all local naming reads to pass through the same finite packet.

The Cauchy branch surface is then supplied by Definition 1506.4, Definition 1506.28, Definition 1506.6, Definition 1506.7, Definition 1506.9, and Definition 1506.10. Together these rows bind the filter and net presentations to the displayed branch evidence and prevent an unrecorded Cauchy presentation from entering the packet.

The endpoint and separation surface is supplied by Definition 1506.8, Definition 1506.5, and Definition 1506.29. These theorems place every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback behind the selected branch and keep zero-distance uniqueness inside the displayed $\mathsf{SeparatedMetric}^{\uparrow}$ row.

Finally, Definition 1506.13, Definition 1506.30, Definition 1506.34, Definition 1506.35, Definition 1506.36, and Definition 1506.43 repack the same data as the root and uniform-completion boundary. Since each cited row is a projection or replay of the displayed carrier, the scoped package contains exactly the named BEDC objects and none of the excluded ambient or choice principles. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.ScopedDependencyPackage.MetricCompletion scoped dependency package`

Theorem 1506.45 (MetricCompletion public export surface)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$*, the public interface exports exactly the displayed route through the* $\mathsf{Met}^{\uparrow}$ *source row* X*, one Cauchy branch* F *or* D*, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row* R*, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row* S*, the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. A public consumer may inspect this route, but it receives no quotient completion, selected representative, ambient complete metric space, open-cover compactness row, countable-choice schedule, branch-conversion row, host equality row, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the scoped dependency package of Definition 1506.44. It already binds every completion-facing consumer to the displayed carrier rows and excludes every ambient completion coordinate.

The public surface is therefore a projection of that same package, not a new carrier. It exposes the source row X, exactly one Cauchy branch F or D, the corresponding readback row R, separated comparison through S, and the uniform-completion handoff replayed through H, C, P, N.

Finally include the root BHist and structural rows as public provenance. They transport, replay, source, and name the route, while no carrier coordinate supplies quotient equality, representative choice, branch conversion, host equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.PublicExportSurface.MetricCompletion public export surface`

Definition 1506.46 (MetricCompletion scoped readback scope)**.** *For an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet* $M = (X, F, D, R, S, H, C, P, N)$*, the scoped readback scope is the displayed route*

$$\mathsf{Met}^{\uparrow} \longmapsto (\mathsf{CauchyFilter}^{\uparrow} \textit{ or } \mathsf{CauchyNet}^{\uparrow}) \longmapsto (\mathsf{RegSeqRat}^{\uparrow} \textit{ or } \mathsf{Real}^{\uparrow}) \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow}$$

together with the carrier rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *that transport, replay, source, and name that route. A read belongs to this scope exactly when it exposes the same metric source row* X*, exactly one of the Cauchy branch rows* F *or* D*, the corresponding readback row* R*, the separatedness row* S*, and the uniform-completion handoff through* H, C, P, N*.*

Lean4 (definition) `BEDC.Derived.MetricCompletionUp.ScopedReadbackScope.MetricCompletionScopedReadbackScope`

Theorem 1506.47 (MetricCompletion uniform source lock)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet must keep the same displayed* $\mathsf{Met}^{\uparrow}$ *source row and the same chosen Cauchy branch. If the consumer reads through the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch, all later finite readback, separatedness, transport, replay, provenance, and naming rows are read over* X, F, R, S, H, C, P, N*; if it reads through the* $\mathsf{CauchyNet}^{\uparrow}$ *branch, the corresponding rows are read over* X, D, R, S, H, C, P, N*. No uniform-completion read may switch between the two branches or replace* X *by an ambient metric source.*

Proof. Start with Definition 1506.46. A scoped read is admitted only after the displayed $\mathsf{Met}^{\uparrow}$ row X and exactly one Cauchy branch have been opened.

The branch is fixed by the existing coverage and compatibility rows. Theorems Definition 1506.9, Definition 1506.10, and Definition 1506.43 place finite readback after the selected branch and before separatedness or uniform completion.

Finally apply Definition 1506.44. Its package route carries the same $X, F, D, R, S, H, C, P, N$ rows through transport and replay, so a uniform-completion consumer has no coordinate from which to substitute a new metric source or cross from the chosen filter route to the net route. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.UniformSourceLock.MetricCompletion uniform source lock`

Theorem 1506.48 (MetricCompletion no ambient completion scope)**.** *No scoped read of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet can introduce a quotient completion, selected representative, ambient complete metric space, open-cover compactness row, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem. Every completion-facing read is already exhausted by the scoped readback route of Definition 1506.46 and the source lock of Definition 1506.47.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.NoAmbientCompletionScope.MetricCompletion no ambient completion scope`

Proof. Inspect the carrier of Definition 1506.1. Its visible coordinates are the metric source, filter branch, net branch, readback row, separatedness row, transport, continuation, provenance, and local name.

The scoped readback definition repacks exactly those coordinates as the route through $\mathsf{Met}^{\uparrow}$, a chosen Cauchy branch, finite readback, $\mathsf{SeparatedMetric}^{\uparrow}$, and $\mathsf{UniformCompletion}^{\uparrow}$. The source-lock theorem then prevents a consumer from replacing the displayed source or changing branches after the read has begun.

The excluded objects are not fields of the carrier and are not introduced by the cited package rows. Therefore quotient completions, representatives, ambient complete spaces, open-cover compactness, countable-choice data, and $\mathsf{Real}^{\uparrow}$ completeness remain outside the scoped MetricCompletion surface. □

Theorem 1506.49 (MetricCompletion bridge surface lock)**.** *Every bridge-facing consumer of an accepted* $\mathsf{MetricCompletion}^{\uparrow}$ *packet must preserve the same displayed* $\mathsf{Met}^{\uparrow}$ *source row, the chosen* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *branch, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row, the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff, and the structural* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The bridge surface may replay the public export route, but it may not replace the source, switch the Cauchy branch, introduce an ambient completion, or discharge readback and separatedness through any row outside the displayed packet.*

Proof. Begin with Definition 1506.45. It identifies the public interface as the route through the displayed $\mathsf{Met}^{\uparrow}$ source, one Cauchy branch, finite readback, separatedness, uniform-completion handoff, and structural carrier rows.

Use Definition 1506.46 to bind every readback to that same scoped route. The definition places $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback after the chosen branch and before the $\mathsf{SeparatedMetric}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ rows.

Apply Definition 1506.47. A bridge-facing replay therefore keeps the same source row and the same selected filter or net branch throughout the handoff.

Finally, Definition 1506.48 excludes quotient completions, selected representatives, ambient complete spaces, open-cover compactness, countable-choice schedules, and $\mathsf{Real}^{\uparrow}$ completeness. Hence the bridge surface is locked to the displayed MetricCompletion packet. □

Lean4 ✓ `BEDC.Derived.MetricCompletionUp.BridgeSurfaceLock.MetricCompletion bridge surface lock`

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1506.1, Definition 1506.2, Definition 1506.3, Definition 1506.44, Definition 1506.45, Definition 1506.46, Definition 1506.47, Definition 1506.48, and Definition 1506.49 bind the finite L10 metric-completion interface to the displayed Metric source, chosen Cauchy branch, readback, separatedness, uniform-completion, BHist, hsame, Cont, Pkg, and NameCert rows, and bridge the public MetricCompletion export through the locked acceptance schema.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletion}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.MetricCompletionUp.MetricCompletionUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This chapter does not close quotient completions, selected representatives, ambient complete metric spaces, open-cover compactness, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: No further theory-axis upgrade remains; later work may add bridge verification or external consumers without changing the closed MetricCompletion surface.

Constructive story: The construction starts from a displayed metric source, routes cofinal evidence through CauchyFilter or CauchyNet rows, reads finite RegSeqRat or Real tolerance data when requested, and uses SeparatedMetric uniqueness only as a local zero-distance classifier route.

Chapter 1507

A Concrete Naming Certificate for $\mathsf{ArchimedeanApproximation}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ArchimedeanApproximation}^{\uparrow}$ packet records the finite Archimedean approximation boundary used before a rational or dyadic scale computation may be sealed as a real-name observation. It sits over the natural-number bound rows of chapter 28, the rational source rows of chapter 37, the dyadic tolerance ledger of chapter 291, the finite name windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal real-name seal of chapter 38. The packet names approximation as displayed BEDC route data, not as quotient real equality, a selected host limit, countable choice, trichotomy, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1507.1 (ArchimedeanApproximation carrier)**.** *An* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (N, Q, D, \epsilon, S, R, E, H, C, P, M)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *bounding row that records the finite index or scale bound used by the approximation request.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *rational source row naming the displayed lower and upper rational bounds read at that scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that refines the rational bounds into a dyadic tolerance ledger.*
4. *ϵ is the displayed tolerance request, read only through D and the* $\mathsf{Nat}^{\uparrow}$ *bound row N.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the bound and tolerance named by N, D, ϵ.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same finite window S.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that exposes the approximation to a Real-facing consumer after the finite window and readback have been displayed.*
8. *H records componentwise* hsame *transport for the natural bound, rational source, dyadic tolerance, stream window, regular readback, real seal, continuation, provenance, and local naming rows.*
9. *C records the displayed* Cont *replay that opens the finite window, reads the rational and dyadic rows, extracts the regular rational readback, and hands it to the* $\mathsf{Real}^{\uparrow}$ *seal.*

10. *P is the* Pkg *provenance over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *M is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient real equality, selected representatives, host limits, countable choice, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationTasteGate single carrier alignment`

Theorem 1507.2 (ArchimedeanApproximation NameCert obligations)**.** *For every accepted* ArchimedeanApproxima *carrier $A = (N, Q, D, \epsilon, S, R, E, H, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Nat}^{\uparrow}$ *bound,* $\mathsf{Rat}^{\uparrow}$ *rational source,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local naming rows;*
2. *bound compatibility, stating that the requested finite approximation scale is read from the same N row that controls the tolerance request ϵ;*
3. *rational-bound exposure, stating that the lower and upper rational rows exported to the consumer are the displayed* $\mathsf{Rat}^{\uparrow}$ *data in Q;*
4. *dyadic tolerance exactness, stating that every tolerance comparison used by the packet is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger named by D;*
5. *window and readback compatibility, stating that S and R are the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows opened at the bound and tolerance already displayed by N, D, ϵ;*
6. *real-seal handoff, stating that the only Real-facing route is the row E after the displayed finite window and regular rational readback;*
7. *non-escape, stating that quotient real equality, selected host limits, countable choice, trichotomy, and ambient completeness are absent from the carrier.*

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier namecert obligations`

Proof. Project the carrier of Definition 1507.1. The only available coordinates are the natural bound, rational source, dyadic tolerance, finite stream window, regular rational readback, real seal, and the structural support rows.

Bound compatibility and rational-bound exposure are immediate from the rows N, Q, ϵ. The tolerance request is attached to the displayed natural bound, and the lower and upper rational readings are the $\mathsf{Rat}^{\uparrow}$ data named by Q rather than host rational choices outside the packet.

Dyadic tolerance exactness is the role of D. The finite window S can be opened only at the bound and tolerance already named by N, D, ϵ, and the readback R is the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ extraction from that same window.

The Real-facing consumer then sees only the seal row E transported and replayed by H and C. The provenance P and local naming row M name the same route and add no further coordinate, so the listed obligation rows exhaust the local $\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}$ surface. □

Theorem 1507.3 (ArchimedeanApproximation real-seal handoff)**.** *Every Real-facing read exported by an accepted* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Nat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, a consumer first reads the natural bound and rational source rows, then the dyadic tolerance row, then the finite stream window and regular rational readback, and only then the $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports no quotient real equality, selected host limit, countable-choice schedule, trichotomy, or ambient completeness principle.*

Proof. Start from an accepted carrier and project its Real-facing read. The row E is the only $\mathsf{Real}^{\uparrow}$ seal coordinate, so the read cannot begin from a host real or a quotient class.

Before E can be consumed, the continuation row C displays the bound, rational source, tolerance, window, and readback rows. Thus the route first passes through N and Q, then through D, then through S and R.

The transport row H preserves the same components, while P and M record only provenance and local naming. Since the carrier has no additional coordinate, every Real-facing approximation read factors through the stated finite route and cannot obtain any of the excluded principles. □

Theorem 1507.4 (ArchimedeanApproximation window obligations)**.** *For every accepted* ArchimedeanApproximatio *carrier*

$$A = (N, Q, D, \epsilon, S, R, E, H, C, P, M),$$

the $\mathsf{StreamName}^{\uparrow}$ *window row* S *opens only after the natural bound row* N*, dyadic tolerance row* D*, and tolerance request* ϵ *have been displayed. A consumer that reads* S *before those rows is not reading the accepted packet.*

Proof. Project the carrier of Definition 1507.1. The definition places S as the finite-window row opened at the bound and tolerance named by N, D, ϵ.

Use the NameCert obligations of Definition 1507.2. Their bound-compatibility and window-readback compatibility clauses require the same N, D, ϵ rows before S can be consumed.

The handoff theorem Definition 1507.3 then keeps every Real-facing read downstream of the same finite window. Thus a packet that opens S without first displaying N, D, ϵ leaves the accepted ArchimedeanApproximation surface. □

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier window obligations`

Theorem 1507.5 (ArchimedeanApproximation dyadic cofinal window)**.** *For every accepted* ArchimedeanApproxima *carrier*

$$A = (N, Q, D, \epsilon, S, R, E, H, C, P, M),$$

any later unary bound refining N *and any smaller displayed dyadic tolerance refining* D *open a* $\mathsf{StreamName}^{\uparrow}$ *window whose* $\mathsf{RegSeqRat}^{\uparrow}$ *readback remains on the same* $\mathsf{Real}^{\uparrow}$ *seal route.*

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier dyadic cofinal window`

Proof. Start from the carrier definition and the NameCert obligations. The rows N, D, ϵ control the window row S, and the obligation surface keeps the bound-compatibility, dyadic tolerance exactness, and window-readback compatibility rows in the same finite packet.

Apply Definition 1507.4. A later unary bound and a smaller dyadic tolerance refine the displayed gate for opening a StreamName window; they do not create a separate host approximation source.

The readback then uses the same R row named by Definition 1507.6, and the real-seal handoff of Definition 1507.3 keeps the resulting read downstream of E. Thus the cofinal window remains a refinement of the accepted $\mathsf{Nat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. □

Theorem 1507.6 (ArchimedeanApproximation dyadic readback)**.** *For every accepted* ArchimedeanApproximation$^{\uparrow}$ *carrier* $A = (N, Q, D, \epsilon, S, R, E, H, C, P, M)$*, rational bounds from the* Rat$^{\uparrow}$ *row* Q *become Real-facing only through the* DyadicRatCore$^{\uparrow}$ *row* D *and the* RegSeqRat$^{\uparrow}$ *readback row* R*. No consumer may expose the rational bounds directly as a* Real$^{\uparrow}$ *observation.*

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier dyadic readback`

Proof. Read the carrier definition. The rational source row Q is a displayed source of lower and upper rational bounds, while D records dyadic tolerance exactness and R records the regular rational readback from the finite window.

Apply the NameCert obligations. Rational-bound exposure, dyadic tolerance exactness, and window-readback compatibility are separate rows of the same certificate, so the rational data in Q must pass through D and R before the real seal row is available.

Finally use Definition 1507.3. The Real-facing route runs through DyadicRatCore$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ before Real$^{\uparrow}$, excluding any direct host read of rational bounds as real observations. □

Theorem 1507.7 (ArchimedeanApproximation real seal nonescape)**.** *For every accepted* ArchimedeanApproximatio *carrier* $A = (N, Q, D, \epsilon, S, R, E, H, C, P, M)$*, the* Real$^{\uparrow}$ *seal row* E *exports no quotient equality, selected host limit, countable choice, trichotomy, or ambient* Real$^{\uparrow}$ *completeness. The seal is only the terminal boundary of the displayed bound, dyadic, window, and readback route.*

Proof. The carrier definition lists the only coordinates available to a consumer: the natural bound, rational source, dyadic tolerance, tolerance request, StreamName window, RegSeqRat readback, Real seal, transport, continuation, provenance, and local naming rows.

The NameCert obligations identify non-escape as part of the local surface, and Definition 1507.3 fixes the route into E through the displayed finite rows.

Since no coordinate stores quotient equality, a selected host limit, a choice schedule, trichotomy, or completeness data, the seal row cannot export any of those principles. □

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier real seal nonescape`

Theorem 1507.8 (Dyadic upper ladder for Archimedean approximation)**.** *Every accepted* ArchimedeanApproximati *packet over* DyadicRatCore$^{\uparrow}$*,* Rat$^{\uparrow}$*,* Nat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *exposes a finite unary exponent ladder whose dyadic radius eventually lies below any displayed positive* Real$^{\uparrow}$ *tolerance row. The ladder is transported only through the displayed* hsame*,* Cont*, and* Pkg *rows of the same carrier, and it exports no trichotomy, no selected host limit, and no ambient choice of a real representative.*

Proof. Start from the carrier of Definition 1507.1 and the obligation rows of Definition 1507.2. The rows $N, D, \epsilon, S, R, E, H, C, P, M$ display the natural bound, dyadic tolerance ledger, positive tolerance request, finite window, regular readback, real seal, transport, replay, provenance, and local naming route.

Induct on the displayed unary ladder attached to the Nat$^{\uparrow}$ bound row. The base step reads the initial dyadic scale from D, and the successor step applies the dyadic scale monotonicity rows to replace the current radius by the next smaller dyadic radius while preserving the same DyadicRatCore$^{\uparrow}$ ledger.

The positive tolerance readback is then consumed through the StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ route already fixed by Definition 1507.5 and Definition 1507.6. Componentwise hsame transport, displayed Cont replay, and Pkg provenance keep the ladder inside the accepted packet, so no trichotomy, host limit selection, or external real representative is introduced. □

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier dyadic upper ladder`

Theorem 1507.9 (ArchimedeanApproximation kernel scope)**.** *The carrier of Definition 1507.1, the NameCert obligations, the real-seal handoff, the window obligations, the dyadic cofinal window, the dyadic readback, the seal nonescape theorem, and the dyadic upper ladder bind every accepted* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *packet to the displayed* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No accepted packet contains a row for quotient real equality, a selected host limit, countable choice, trichotomy, or ambient completeness.*

Proof. Start with the carrier and NameCert obligations, Definition 1507.1 and Definition 1507.2. They list the natural bound, rational source, dyadic tolerance, finite StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows as the whole accepted packet.

Next apply the real-seal handoff and window obligations, Definition 1507.3 and Definition 1507.4. These keep every Real-facing read downstream of the displayed $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ route.

The dyadic cofinal-window and dyadic readback theorems, Definition 1507.5 and Definition 1507.6, preserve the same finite route under later bounds and smaller dyadic tolerances.

Finally use seal nonescape and the dyadic upper ladder, Definition 1507.7 and Definition 1507.8. They keep the terminal $\mathsf{Real}^{\uparrow}$ read and the unary ladder inside the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, so none of the excluded host principles is available. □

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationCarrier kernel scope`

Theorem 1507.10 (ArchimedeanApproximation public finite export)**.** *Every accepted* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *packet exports its public approximation read only through the displayed route*

$$\mathsf{Nat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The public read may expose a natural bound, rational bounds, a dyadic tolerance ledger, a finite stream window, a regular rational readback, and a terminal real-name seal, but it cannot read quotient real equality, a selected host limit, countable choice, trichotomy, or ambient completeness outside that route.

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.PublicFiniteExport.ArchimedeanApproximationCarrier public finite export`

Proof. Start with the carrier of Definition 1507.1 and the NameCert obligations of Definition 1507.2. They list $N, Q, D, \epsilon, S, R, E, H, C, P, M$ as the whole accepted packet and require each public read to preserve the same local naming surface.

Apply the real-seal handoff of Definition 1507.3. A Real-facing consumer reaches E only after the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows have been displayed.

The dyadic cofinal window and dyadic readback theorems, Definition 1507.5 and Definition 1507.6, keep later bounds, smaller dyadic tolerances, rational bounds, finite windows, and regular readbacks on that same route. The seal nonescape theorem Definition 1507.7 prevents the terminal $\mathsf{Real}^{\uparrow}$ row from exporting any hidden real-equality or limit principle.

Finally use the dyadic upper ladder and kernel scope, Definition 1507.8 and Definition 1507.9. They keep the public approximation read inside the displayed hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, so the exported object is exactly the finite BEDC route named in the statement. □

Lean4 ✓ `BEDC.Derived.ArchimedeanApproximationUp.ArchimedeanApproximationPublicFiniteExport`

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanApproximation}^{\uparrow}$ packet is generated from a natural-number bound, rational bounding rows, a DyadicRatCore tolerance ledger, a StreamName finite window, a RegSeqRat readback, a RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1507.1, Definition 1507.2, Definition 1507.3, Definition 1507.4, Definition 1507.5, Definition 1507.6, Definition 1507.7, Definition 1507.8, and Definition 1507.9 close the carrier, NameCert obligation, real-seal handoff, window, dyadic cofinal-window, dyadic readback, seal-nonescape, dyadic upper-ladder, and kernel-scope surface for the displayed packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected host limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public export theorem for the same $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert packet.

Chapter 1508

A Concrete Naming Certificate for $\mathsf{BishopCompletionComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCompletionComparison}^{\uparrow}$ packet compares the displayed regular located Cauchy route with the completion-facing real-name seal as finite BEDC data. It sits after the regular located Cauchy surface of chapter 1454, the boundary packet of chapter 1455, the located-limit route of chapter 1420, the located-real enclosure of **??**, the real-name seal of chapter 38, the regular rational source of chapter 301, the stream-window source of chapter 126, and the dyadic arithmetic core of chapter 291. The chapter records the finite comparison route from regular located Cauchy data to the $\mathsf{Real}^{\uparrow}$ seal; it does not assert that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 1508.1 (BishopCompletionComparison carrier)**.** *A* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, B, L, E, T, H, K, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *source row, including its visible* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source,* $\mathsf{StreamName}^{\uparrow}$ *finite-window route, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*
2. *B is the* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *boundary row attached to the same regular located Cauchy source.*
3. *L is the* $\mathsf{LocatedLimit}^{\uparrow}$ *route read from the displayed boundary and regular located source rows.*
4. *E is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row exposed before the terminal real-name seal is inspected.*
5. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, B, L, E have been displayed.*
6. *H records componentwise* hsame *transport for the regular located source, boundary route, located-limit route, located-real enclosure, real seal, replay rows, provenance, and local naming row.*
7. *K records the displayed* Cont *replay from R to B, from B to L, from L to E, and from E to T.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{BishopLocatedComplet}$ $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, real trichotomy, countable choice, open-cover compactness, or a host-selected limit.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonTasteGate single carrier alignment`

Theorem 1508.2 (BishopCompletionComparison NameCert obligations)**.** *For the carrier of Definition 1508.1, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for* $C = (R, B, L, E, T, H, K, P, N)$*, regular located source exposure through* R*, boundary-route exposure through* B*, located-limit exposure through* L*, located-real enclosure exposure through* E*, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is tuple projection from the displayed packet C. The rows expose the regular located Cauchy source, Bishop boundary route, located-limit route, located-real enclosure, terminal real seal, transport, replay, provenance, and local name.

The analytic obligations are exactly the rows R, B, L, E, T. The source row R carries the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data used by the regular located Cauchy surface; the boundary row B keeps the same source visible before the located-limit and located-real rows are read.

The structural obligations are exactly H, K, P, N. They transport the same rows, replay the same finite route, record provenance for the named packets, and bind the local certificate without adding any coordinate outside the carrier. □

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonNameCertObligations`

Theorem 1508.3 (BishopCompletionComparison regular located route)**.** *Every accepted* $\mathsf{BishopCompletionCompar}$ *packet* $C = (R, B, L, E, T, H, K, P, N)$ *routes a completion-facing read through*

$$R \longmapsto B \longmapsto L \longmapsto E \longmapsto T.$$

The row R *supplies the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *source, including the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows;* B *supplies the* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *comparison boundary;* L *and* E *supply the* $\mathsf{LocatedLimit}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *rows before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier regular located route`

Proof. Project the accepted carrier. The only source row for regular located Cauchy data is R, and its regular rational, stream-window, and dyadic tolerance coordinates are present only as part of that row.

Now read the completion-facing side. The replay row K places B after R, then places L and E before the terminal seal T. Thus every such read factors through the displayed boundary and locatedness route.

Transport and provenance preserve the same factorization. The rows H and P identify the transported route as the same finite comparison packet, while N names the local surface for downstream consumers. □

Theorem 1508.4 (BishopCompletionComparison seal non-escape)**.** *No accepted* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *carrier exports data outside the tuple* $R, B, L, E, T, H, K, P, N$*. In particular, a* $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal cannot recover* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, real trichotomy, countable choice, open-cover compactness, or a host-selected limit from the packet.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier seal nonescape`

Proof. Inspect the carrier of Definition 1508.1. Its only analytic rows are the regular located source, boundary route, located-limit route, located-real enclosure, and terminal real seal.

Apply Definition 1508.2. Every local obligation is a projection of those rows or a structural transport, replay, provenance, or naming obligation for those rows.

Finally apply Definition 1508.3. Any terminal seal read first passes through R, B, L, E, so the finite comparison route is exhausted before the $\mathsf{Real}^{\uparrow}$ seal is reached. Since none of the excluded principles is a carrier coordinate, none can be exported by the packet. □

Theorem 1508.5 (BishopCompletionComparison Real route)**.** *Every accepted* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *carrier* $C = (R, B, L, E, T, H, K, P, N)$ *exposes the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the regular located Cauchy source row* R*, Bishop located completion boundary row* B*, located-limit route* L*, located-real enclosure* E*, componentwise transport* H*, replay row* K*, provenance row* P*, and local* $\mathsf{NameCert}$ *row* N *have all been read. The route refuses* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, trichotomy, countable choice, open-cover compactness, and host-selected limits.*

Proof. Project the carrier of Definition 1508.1. The terminal seal T is a displayed row of the same packet and is not available before the source, boundary, located-limit, and located-real rows have been exposed.

Apply Definition 1508.2. Its surface lists the source, boundary, located-limit, located-real, terminal seal, transport, replay, provenance, and local naming rows as the complete local obligation surface.

Use the regular located route of Definition 1508.3 and the non-escape theorem Definition 1508.4. Together they force any $\mathsf{Real}^{\uparrow}$ terminal read through R, B, L, E, T and exclude every principle not carried by the tuple. □

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier real route`

Theorem 1508.6 (BishopCompletionComparison regular seal)**.** *Every comparison between a Bishop located completion row and a regular Cauchy completion row accepted by* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedLimit}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *rows carried by* $C = (R, B, L, E, T, H, K, P, N)$*. The comparison exports no separate Cauchy quotient, selected limit, trichotomy, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier regular seal`

Proof. Start with the regular located route of Definition 1508.3. It exposes the regular located Cauchy source through the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows inside R, then routes the comparison through B, L, E before the terminal seal is visible.

Apply the Real route theorem, Definition 1508.5. It places every terminal $\mathsf{Real}^{\uparrow}$ read after the regular source, boundary, located-limit, located-real, transport, replay, provenance, and local naming rows.

Finally use the seal non-escape theorem Definition 1508.4. Since the carrier has no coordinate for the excluded quotient, choice, compactness, selected-limit, or completeness principles, the regular comparison reaches the Real seal only through the listed finite rows. □

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonRegularSeal`

Theorem 1508.7 (BishopCompletionComparison boundary transport)**.** *For every accepted* BishopCompletionComp *carrier* $C = (R, B, L, E, T, H, K, P, N)$*, componentwise* hsame *transport and displayed* Cont *replay preserve the route*

$$R \longmapsto B \longmapsto L \longmapsto E \longmapsto T$$

from the regular located Cauchy source through the Bishop located completion boundary to the terminal $\mathsf{Real}^{\uparrow}$ *seal. A consumer cannot bypass the boundary through* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, trichotomy, countable choice, open-cover compactness, or host-selected limits.*

Proof. Begin with the NameCert obligations of Definition 1508.2. They list H as the componentwise transport row and K as the replay row for the same regular source, boundary, located-limit, located-real, and terminal seal coordinates.

Apply the regular located route of Definition 1508.3. Its displayed order is $R \longmapsto B \longmapsto L \longmapsto E \longmapsto T$, so transport can only move the named rows componentwise and replay can only re-expose that route.

Finally use the seal non-escape theorem Definition 1508.4 together with the Real route of Definition 1508.5. Since the terminal seal is read only after the boundary and locatedness rows, none of the excluded completeness, quotient, trichotomy, choice, compactness, or host-limit principles is available as a bypass. □

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier boundary transport`

Theorem 1508.8 (BishopCompletionComparison located-filter comparison)**.** *Every accepted* BishopCompletionCor *carrier that receives a* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row routes that row through the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows used by the regular located route before any completion comparison is consumed. No quotient filter, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row may replace that route.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonUp.BishopCompletionComparisonCarrier located filter comparison`

Proof. Start with the carrier of Definition 1508.1. Its source row R is the only regular located Cauchy source, and that row already exposes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data consumed by the comparison route.

Apply the regular located route of Definition 1508.3 and the Real route of Definition 1508.5. Together they force a completion-facing read through the displayed source, boundary, located-limit, located-real, and terminal $\mathsf{Real}^{\uparrow}$ seal rows before the comparison is public.

Now use the regular seal theorem Definition 1508.6 and boundary transport theorem Definition 1508.7. A $\mathsf{LocatedCauchyFilter}^{\uparrow}$ row handed to the comparison surface is therefore compared only after the sibling route through chapter 1661, chapter 126, chapter 301, chapter 291, and chapter 38 has been displayed.

Finally apply the seal non-escape theorem Definition 1508.4. Since the carrier has no coordinate for quotient filters, selected limits, countable-choice schedules, or ambient completeness, none of those rows can replace the located-filter route. □

Theorem 1508.9 (BishopCompletionComparison public L10 route)**.** *Every completion-facing comparison read accepted by* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *factors through* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$*,* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$*,* $\mathsf{LocatedCauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,*

and the terminal $\mathsf{Real}^{\uparrow}$ *seal before any public comparison boundary is exported. The exported boundary is therefore the displayed finite L10 route*

$$R \longmapsto B \longmapsto L \longmapsto E \longmapsto T$$

together with the located-filter comparison handoff, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a quotient completion, a selected limit, trichotomy, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 1508.2. They expose the carrier rows $R, B, L, E, T, H, K, P, N$ as the whole local obligation surface.

Apply the regular located route of Definition 1508.3. It places the $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ source before the boundary row and keeps the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data inside the displayed source route.

Next apply the Real route of Definition 1508.5 and the regular seal theorem Definition 1508.6. These force the terminal $\mathsf{Real}^{\uparrow}$ read to occur only after the source, boundary, located-limit, located-real, transport, replay, provenance, and local naming rows have been exposed.

Now use the boundary transport theorem Definition 1508.7. It preserves the same route under componentwise hsame transport and displayed Cont replay, so the boundary cannot be bypassed by a transported seal read.

Finally use the located-filter comparison theorem Definition 1508.8 and the seal non-escape theorem Definition 1508.4. The $\mathsf{LocatedCauchyFilter}^{\uparrow}$ handoff is consumed through the same finite rows, and none of the excluded quotient, selection, choice, compactness, trichotomy, or completeness principles is a carrier coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionComparison}^{\uparrow}$ packet is generated from a regular located Cauchy source row, a Bishop located completion boundary row, a located-limit row, a located-real enclosure row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionComparison}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1508.9 binds the public L10 comparison route through $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, BishopLocatedCompletionB $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any comparison boundary is exported.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of Cauchy names, real trichotomy, countable choice, open-cover compactness, host-selected limits, Lean verification, or bridge checking.

Upgrade path: A checked Lean theorem for Definition 1508.9 upgrades the verification axis without changing the paper closure scope.

Chapter 1509

A Concrete Naming Certificate for $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ packet records the constructive Cauchy convergence criterion as finite BEDC route data. It sits between the finite stream schedule of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38, the modulus surface of chapter 292, and the limit-seal route of chapter 386. The certificate names the finite rows that make a convergence read admissible; it is not host completeness, quotient streams, selected limits, trichotomy, or open-cover compactness.

Definition 1509.1 (Cauchy convergence criterion carrier)**.** *A* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite windows are the only sequence observations visible to the carrier.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning each dyadic tolerance request a displayed finite threshold for the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic scales, rational comparisons, and exhaustion budget used by the criterion.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled windows under the threshold and tolerance data M, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, M, D, R have been displayed and the local convergence criterion has been admitted.*
6. *H records componentwise* hsame *transport for the stream schedule, modulus, dyadic ledger, regular-rational handoff, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each tolerance request through S, M, D, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It contains no coordinate for host completeness, quotient-stream equality, a selected host limit, trichotomy, open-cover compactness, or an unbounded stream read.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionTasteGate single carrier alignment`

Theorem 1509.2 (Cauchy convergence criterion NameCert obligations)**.** *For every accepted* CauchyConvergenceCri *carrier $G = (S, M, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceCriterion}^{\uparrow}}$ *surface consists exactly of the following six obligation rows:*

1. *carrier admission for the displayed stream schedule, Cauchy modulus, dyadic tolerance ledger, regular-rational handoff, Real seal, transport, continuation, provenance, and local name;*
2. *finite-window classification, requiring every sequence read to pass through the* $\mathsf{StreamName}^{\uparrow}$ *schedule S;*
3. *modulus stability, requiring the threshold row M to be preserved by the componentwise* hsame *transports in H and replayed by C for the same tolerance requests;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the regular-rational row R to be read only after the scheduled windows, modulus thresholds, and dyadic tolerance ledger have been displayed;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the seal row E to remain downstream of S, M, D, R and the stored structural rows;*
6. *ledger exhaustion, requiring every accepted tolerance request to be accounted for by the dyadic ledger D and the provenance row P before any convergence-facing consumer can read the seal.*

No obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionNameCertObligations`
↪ variant `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier namecert obligations`

Proof. Project the carrier of Definition 1509.1. Its visible coordinates are exactly the stream schedule, modulus, dyadic ledger, regular-rational handoff, Real seal, transport, continuation, provenance, and local naming rows.

The finite-window classifier is forced by the first coordinate. A sequence read has no source except the displayed $\mathsf{StreamName}^{\uparrow}$ schedule S, and the continuation row can replay only the windows attached to that schedule.

Modulus stability and ledger exhaustion are read next. The threshold row M and the dyadic ledger D answer the same tolerance requests, and the transport row H preserves those answers before the handoff R is available.

The Real-facing rows are downstream. The regular-rational handoff R is admitted only from S, M, D, and the seal row E is consumed only after that handoff. Since the carrier has no coordinate for host completeness, quotient streams, selected limits, trichotomy, open-cover compactness, or an unbounded stream read, the six listed rows exhaust the local NameCert surface. □

Theorem 1509.3 (Cauchy convergence criterion Real seal handoff)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$*-facing convergence read of a* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier $G = (S, M, D, R, E, H, C, P, N)$ factors through the displayed finite route*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E$$

together with the stored hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. Before reaching the* $\mathsf{Real}^{\uparrow}$ *seal, the read is compatible with the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary and exports no host completeness theorem, quotient stream, selected limit, trichotomy row, open-cover compactness row, or detached seal.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier real seal handoff`

Proof. Start with an accepted Real-facing convergence read. Carrier admission gives only the finite schedule S as sequence data, so the read first factors through the displayed stream windows.

The tolerance part of the route is then forced. The modulus row M supplies thresholds for the requests, while the dyadic ledger D records the scales and comparisons consumed at those thresholds. The continuation row C replays this same request path.

Next pass to regular-rational data and the seal. The row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ handoff in the carrier, and the $\mathsf{Real}^{\uparrow}$ seal row E is downstream of R. The transport and provenance rows H and P preserve the same packet, while the local name N records the route as a $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ certificate.

The route has no extra coordinate after E. Thus compatibility with the $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary is witnessed by the same finite handoff, and the read cannot export host completeness, quotient streams, selected limits, trichotomy, open-cover compactness, or a detached seal. □

Theorem 1509.4 (Cauchy convergence criterion limit-seal determinacy)**.** *Let* $G = (S, M, D, R, E, H, C, P, N)$ *and* $G' = (S, M, D, R, E', H, C, P, N)$ *be accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carriers sharing the same displayed stream schedule, Cauchy modulus, dyadic ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise transport, continuation replay, provenance, and local* NameCert *rows. If their Real-facing convergence reads are compatible with the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary over the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, then the two reads determine the same seal route.*

The comparison cannot introduce a detached seal, quotient stream, selected host limit, trichotomy row, open-cover compactness row, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier limit seal determinacy`

Proof. Apply Definition 1509.3 to each Real-facing convergence read. Both reads are forced through the displayed finite route

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E$$

or through the corresponding notational endpoint E' for the second carrier, with the same transport, continuation, provenance, and local naming rows.

The shared $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary now supplies the seal comparison. By Definition 386.23, once the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal boundary, hsame transport, Cont replay, Pkg provenance, and NameCert rows agree, there is no second seal route available to a completion or $\mathsf{Real}^{\uparrow}$ consumer.

Finally return to the non-escape clauses in the handoff theorem. The carrier has no coordinate for a detached seal, quotient stream, selected host limit, trichotomy row, open-cover compactness row, or ambient completeness theorem, so the identified $\mathsf{CauchyLimitSeal}^{\uparrow}$ route is determined entirely by the displayed finite packet. □

Theorem 1509.5 (Cauchy convergence criterion NullSequence factorization)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing convergence read of G whose comparison row is a zero-difference read factors through a displayed* $\mathsf{NullSequence}^{\uparrow}$ *packet before the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary may consume it.*

The displayed $\mathsf{NullSequence}^{\uparrow}$ *packet uses the same* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{StreamName}^{\uparrow}$ *window schedule S,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row M,* $\mathsf{Real}^{\uparrow}$ *seal row E, and provenance rows H, C, P, N already carried by G. No second stream representative, quotient stream, host limit, trichotomy row, choice principle, open-cover compactness object, or ambient completeness coordinate is introduced by this zero-difference handoff.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier nullsequence factorization`

Proof. Project the accepted carrier G. The coordinates S, M, D, R give the finite tolerance-window route: stream observations are read only through S, tolerance requests are bounded by M, dyadic scales and comparisons are recorded by D, and the regular-rational comparison row is R.

Now impose the zero-difference condition on the comparison read. By Definition 380.6, the tolerance request must pass through the displayed dyadic tolerance row, observation window, and threshold row before any $\mathsf{Real}^{\uparrow}$ seal read. In the present carrier these rows are exactly D, S, M, with R as the displayed difference row.

Apply Definition 380.7. It makes the $\mathsf{NullSequence}^{\uparrow}$ packet the finite consumer boundary for the $\mathsf{Real}^{\uparrow}$ equality read, so the seal row E is reached only through the same difference, tolerance, window, threshold, transport, continuation, package, and local certificate rows.

Finally return to the remaining coordinates of G. The rows H, C, P, N record component-wise transport, continuation replay, provenance, and local naming for the same packet, while the $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary can consume only the finite handoff already displayed. Since the carrier has no coordinate for a quotient stream, host limit, trichotomy, choice, open-cover compactness, or ambient completeness theorem, the zero-difference read factors through $\mathsf{NullSequence}^{\uparrow}$ and exports nothing beyond that route. □

Theorem 1509.6 (Cauchy convergence criterion source-triad exhaustion)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing read of G factors through the displayed source triad*

$$S, M, D, R$$

before the $\mathsf{Real}^{\uparrow}$ *seal row E is available.*

The read has no bypass through quotient streams, host completeness, selected limits, trichotomy, or open-cover compactness. In particular, every convergence-facing consumer sees the stream schedule, modulus threshold row, dyadic tolerance ledger, and regular-rational handoff before it can consume a seal boundary.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier source triad exhaustion`

Proof. Project the carrier in Definition 1509.1. The only sequence observations are the finite windows named by S, the only tolerance thresholds are carried by M, the only scale and comparison ledger is D, and the only regular-rational handoff is R.

Apply Definition 1509.2. Its finite-window classification, modulus stability, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, Real-seal nonescape, and ledger-exhaustion rows require the consumer to traverse S, M, D, R before any convergence-facing seal read.

For a $\mathsf{Real}^{\uparrow}$ consumer, Definition 1509.3 identifies the displayed route from the stream schedule through the threshold, ledger, and handoff rows to E. For a $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer, Definition 1509.4 reads the same boundary data and admits no second seal route.

The final exclusion is structural. The carrier definition contains no coordinate for quotient streams, host completeness, selected limits, trichotomy, or open-cover compactness, and Definition 1509.5 keeps zero-difference reads inside the same finite packet. Hence every accepted read is exhausted by the displayed source triad before E. □

Theorem 1509.7 (Cauchy convergence criterion window-threshold coverage)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Every finite* $\mathsf{StreamName}^{\uparrow}$ *window consumed by the convergence criterion has a matching* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold in M and a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in D in the same packet. Thus no unbounded stream read is accepted by the local classifier route.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionDyadicRoute determinacy`

Proof. Start from a finite window read admitted by the local classifier. By Definition 1509.1, the window can only come from the displayed $\mathsf{StreamName}^{\uparrow}$ schedule S.

The threshold and tolerance data are then forced by the same carrier projection. The row M assigns the relevant $\mathsf{CauchyModulus}^{\uparrow}$ threshold for the tolerance request, while D records the dyadic scale, rational comparison, and exhaustion budget consumed by that threshold.

Apply Definition 1509.2. Finite-window classification keeps the read on S, modulus stability preserves the threshold row under H and C, and ledger exhaustion accounts for the request in D and P before the handoff R or seal row E can be consumed.

The handoff and seal results do not add a stream source. By Definition 1509.3 and Definition 1509.5, downstream $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and zero-difference consumers reuse the same S, M, D rows. Since the carrier has no unbounded stream coordinate, the classifier accepts only covered finite windows. □

Theorem 1509.8 (Cauchy convergence criterion tail-diameter scope)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Every tail-diameter request consumed by a convergence-facing read factors through the same finite route*

$$S \longmapsto M \longmapsto D \longmapsto R$$

before the $\mathsf{Real}^{\uparrow}$ *seal row E is available. The request is therefore scoped by the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{CauchyModulus}^{\uparrow}$ *thresholds,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff of chapter 126, chapter 301, chapter 291, chapter 38, and chapter 386; it does not introduce a second tail classifier, detached limit seal, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier tail diameter scope`

Proof. Project the accepted carrier. By Definition 1509.1, the only stream observations are the finite windows in S, the only thresholds are in M, the only tolerance ledger is D, and the only regular handoff is R.

Apply Definition 1509.7. A tail-diameter request must be covered by a window and a matching threshold in the same packet, so the request cannot leave S, M, D before the handoff row is formed.

Now use Definition 1509.6 and Definition 1509.3. These force every convergence-facing read through S, M, D, R before E, while Definition 1509.4 keeps the $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer on the same finite boundary. □

Theorem 1509.9 (Cauchy convergence criterion scoped closure)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing, or zero-difference convergence read of G is scoped exactly by the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{Real}^{\uparrow}$ *seal E,* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N.*

Consequently such a read has no coordinate outside

$$S, M, D, R, E, H, C, P, N$$

and cannot introduce quotient streams, selected host limits, detached limit seals, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier scoped closure`

Proof. Start with the source rows. The source-triad exhaustion theorem, Definition 1509.6, forces every $\mathsf{Real}^{\uparrow}$- or $\mathsf{CauchyLimitSeal}^{\uparrow}$-facing read through S, M, D, R before E is visible.

The window and tail requirements stay on the same route. By Definition 1509.7, every finite stream window has its matching threshold and dyadic ledger inside the carrier, and by Definition 1509.8, every tail-diameter request passes through S, M, D, R before the seal.

Zero-difference reads add no second source. The null-sequence scope theorem, Definition 1509.10, keeps comparison reads inside the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ route.

Finally read the structural rows. The carrier definition supplies only H, C, P, N as transport, replay, provenance, and local naming data for this route. Since the listed theorems exhaust all Real-facing, limit-seal-facing, and zero-difference reads, the displayed rows $S, M, D, R, E, H, C, P, N$ are exactly the scope of the convergence criterion packet. □

Theorem 1509.10 (Cauchy convergence criterion null-sequence scope)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. If a convergence-facing comparison is a zero-difference read, then the read uses the existing* $\mathsf{NullSequence}^{\uparrow}$ *factorization route over $S, M, D, R, E, H, C, P, N$ and not a second stream representative. In particular, the zero-difference consumer remains inside the finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route recorded by the carrier.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier null sequence scope`

Proof. Start from the zero-difference comparison. The carrier has one stream schedule S and one regular-rational comparison row R, so there is no separate stream representative available for the comparison.

Apply Definition 1509.5. The zero-difference read factors through the displayed $\mathsf{NullSequence}^{\uparrow}$ packet using the same difference row R, tolerance ledger D, stream schedule S, threshold row M, Real seal row E, and structural rows H, C, P, N.

Finally combine Definition 1509.7 with Definition 1509.4. The finite window-threshold ledger and the limit-seal boundary are already fixed by the carrier, so the null-sequence route cannot introduce quotient streams, selected host limits, or a second pre-seal representation. □

Theorem 1509.11 (Cauchy convergence criterion regular-seal handoff)**.** *Let $G = (S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. The* $\mathsf{RegSeqRat}^{\uparrow}$ *row R is the unique pre-seal route available to any* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of G: every such consumer first reads the* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{CauchyModulus}^{\uparrow}$ *thresholds M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, and then R, before it can consume the* $\mathsf{Real}^{\uparrow}$ *seal row E. The route is preserved by H, C, P, N and contains no quotient-stream equality, selected host limit, or ambient completeness principle.*

Proof. Project the consumer-facing rows of G. The regular-rational handoff coordinate is exactly R, and the seal row E is downstream of it by Definition 1509.1.

Apply Definition 1509.6. Every $\mathsf{Real}^{\uparrow}$- or $\mathsf{CauchyLimitSeal}^{\uparrow}$-facing read must pass through the displayed source triad S, M, D, R before any seal row is visible.

The uniqueness claim follows from Definition 1509.4. Once the displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal boundary, transport, continuation, provenance, and name rows agree, no second seal route remains for the consumer. The structural rows H, C, P, N only preserve and name this route. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier regular seal handoff`

Theorem 1509.12 (Cauchy convergence criterion regular-tail coverage)**.** *Every accepted* $\mathsf{CauchyConvergenceCriteri}$ *packet $G = (S, M, D, R, E, H, C, P, N)$ whose finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{CauchyModulus}^{\uparrow}$ *row pass the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold exposes a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail handoff and a* $\mathsf{Real}^{\uparrow}$ *seal through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Concretely, each covered tolerance request first reads the windows in S, then the matching threshold in M, then the dyadic tolerance ledger D, then the regular tail row R, and only then the seal row E.*

The coverage route exports no quotient stream, selected tail representative, detached limit seal, host completeness theorem, trichotomy row, or open-cover compactness object.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier regular tail coverage`

Proof. Project the carrier of Definition 1509.1. The rows $S, M, D, R, E, H, C, P, N$ are the only visible rows of the accepted packet, so every tolerance request begins inside the same BHist packet and the same structural provenance.

Apply Definition 1509.7. The finite $\mathsf{StreamName}^{\uparrow}$ window consumed by the request has a matching $\mathsf{CauchyModulus}^{\uparrow}$ threshold in M and a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row in D, so the request cannot read an unbounded stream or an unrecorded threshold.

Next use Definition 1509.11. Once the covered threshold has passed through S, M, D, the row R is the unique pre-seal $\mathsf{RegSeqRat}^{\uparrow}$ route available to the $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer.

Finally combine Definition 1509.5 with Definition 1509.17. Zero-difference comparisons remain inside the same null-sequence factorization, and compatible boundary reads determine the same classifier route through H, C, P, N. Hence the covered packet exposes the regular tail handoff and the Real seal through the same finite rows, with none of the excluded host-side data in scope. □

Theorem 1509.13 (Cauchy convergence criterion cofinal-modulus extraction)**.** *Every accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier $G = (S, M, D, R, E, H, C, P, N)$ determines a cofinal finite*

modulus route for convergence-facing reads. Any later tolerance request is first reduced to a displayed $\mathsf{StreamName}^{\uparrow}$ *window in* S*, then to the matching* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold in* M*, then to the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and then to the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed.*

The route exports no quotient stream, selected host limit, trichotomy branch, open-cover compactness object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier cofinal modulus extraction`

Proof. Start with a later tolerance request. By Definition 1509.7, any accepted finite window is a displayed $\mathsf{StreamName}^{\uparrow}$ row in S with a matching $\mathsf{CauchyModulus}^{\uparrow}$ threshold in M and a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row in D.

Next apply Definition 1509.8. Tail-diameter data cannot leave the displayed route; they pass through S, M, D, R before the terminal seal row is available.

Use Definition 1509.11. The row R is the unique pre-seal $\mathsf{RegSeqRat}^{\uparrow}$ handoff for the $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer, and the structural rows H, C, P, N preserve that handoff.

Finally apply Definition 1509.12. It identifies the covered tolerance request with the same regular tail and Real seal route. Since the carrier has no coordinate for quotient streams, selected host limits, trichotomy, open-cover compactness, or ambient completeness, the cofinal modulus route exports none of them. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CofinalModulusExtraction.CauchyConvergenceCriterionCa cofinal modulus extraction`

Theorem 1509.14 (Cauchy convergence criterion scoped readback strengthening)**.** *Let* $G = (S, M, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing,* $\mathsf{NullSequence}^{\uparrow}$*-facing, or regular-tail consumer of* G *reads the same finite scope*

$$S, M, D, R, E, H, C, P, N.$$

Thus the convergence criterion exposes no quotient stream, selected host limit, detached seal, trichotomy row, open-cover compactness row, or ambient completeness coordinate to any of these consumers.

Proof. First read the Real and limit-seal consumers. The source-triad exhaustion theorem and the Real seal handoff theorem force such consumers through S, M, D, R before E, while the limit-seal determinacy theorem keeps the $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary on the same displayed rows.

Next read the window and tail data. The window-threshold coverage theorem puts each finite $\mathsf{StreamName}^{\uparrow}$ window together with its threshold and dyadic ledger inside S, M, D, and the tail-diameter scope theorem sends every tail-diameter request through S, M, D, R before the seal row.

For zero-difference and regular-tail consumers, use the null-sequence scope theorem, the regular-seal handoff theorem, and the regular-tail coverage theorem. These results keep $\mathsf{NullSequence}^{\uparrow}$ factorization and regular-tail handoff inside the same S, M, D, R, E route.

Finally project the structural rows of the accepted carrier. The only remaining coordinates are hsame transport H, Cont replay C, Pkg provenance P, and the local $\mathsf{NameCert}$ row N, so every listed consumer reads exactly the displayed scope and none of the excluded host-side data. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier scoped readback strengthening`

Theorem 1509.15 (Cauchy convergence criterion Specker boundary)**.** *Let* $G = (S, M, D, R, E, H, C, P, N)$ *be an accepted* CauchyConvergenceCriterion$^{\uparrow}$ *packet read through an accepted* SpeckerSequence$^{\uparrow}$ *carrier surface. The read exposes only finite* StreamName$^{\uparrow}$ *windows,* CauchyModulus$^{\uparrow}$ *threshold rows,* DyadicRatCore$^{\uparrow}$ *tolerance rows, the* RegSeqRat$^{\uparrow}$ *handoff, the* Real$^{\uparrow}$ *seal, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows shared by the two packets.*

Consequently the criterion cannot yield a located supremum, ambient Real completeness, quotient stream, or selected host limit from the Specker read. Such a consumer must supply an additional located-modulus row outside the displayed CauchyConvergenceCriterion$^{\uparrow}$ *and* SpeckerSequence$^{\uparrow}$ *packets.*

Proof. First apply Definition 1509.6. Any Real$^{\uparrow}$- or CauchyLimitSeal$^{\uparrow}$-facing read of G is forced through the source triad S, M, D, R before the seal row E is visible.

Next use Definition 1509.12. The covered tolerance request exposes only the scheduled windows, matching threshold, dyadic ledger, regular tail row, seal row, and the structural rows H, C, P, N.

Now read the same route through the Specker carrier surface. By Definition 1406.2, Definition 1406.12, and Definition 1406.10, the SpeckerSequence$^{\uparrow}$ packet supplies a finite regular-source and seal route but no located supremum coordinate, selected limit, quotient stream, countable-choice selector, trichotomy branch, or ambient completeness theorem.

The remaining located-supremum claim therefore has no row to read. A downstream consumer that needs located convergence must add an external located-modulus row; it cannot recover that row from the displayed Cauchy criterion and Specker packets. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier specker boundary`

Theorem 1509.16 (Cauchy convergence criterion located-modulus frontier)**.** *Let* $G = (S, M, D, R, E, H, C, P, N)$ *be an accepted* CauchyConvergenceCriterion$^{\uparrow}$ *carrier. Any downstream consumer claiming located convergence from* G *must display an additional* LocatedReal$^{\uparrow}$ *or located-modulus row outside the carrier. The stored* CauchyModulus$^{\uparrow}$ *thresholds,* DyadicRatCore$^{\uparrow}$ *ledger,* SpeckerSequence$^{\uparrow}$ *boundary read,* StreamName$^{\uparrow}$ *schedule,* RegSeqRat$^{\uparrow}$ *handoff, and* Real$^{\uparrow}$ *seal do not produce such a row.*

Proof. First apply Definition 1509.2. The accepted packet exposes exactly the carrier rows $S, M, D, R, E, H, C, P, N$ and the listed stability, exactness, handoff, transport, replay, provenance, and local naming obligations.

Next use Definition 1509.6. Every Real$^{\uparrow}$- or CauchyLimitSeal$^{\uparrow}$-facing read passes through the source triad S, M, D, R before the seal row is available, so the only tolerance data visible before the seal are the displayed CauchyModulus$^{\uparrow}$ thresholds and DyadicRatCore$^{\uparrow}$ ledger.

Now apply Definition 1509.15. Reading the same carrier through the SpeckerSequence$^{\uparrow}$ surface still exposes only finite stream windows, threshold rows, dyadic tolerance rows, regular rational handoff, terminal seal, and the structural rows; it does not expose a located supremum, selected host limit, quotient stream, or ambient completeness coordinate.

Thus a located-convergence consumer has no carrier row from which to read locatedness. It must add a separate LocatedReal$^{\uparrow}$ or located-modulus row, and that row lies outside the displayed CauchyConvergenceCriterion$^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier located modulus frontier`

Theorem 1509.17 (Cauchy convergence criterion ledger-classifier exactness)**.** *Let*

$$G = (S, M, D, R, E, H, C, P, N)$$

and

$$G' = (S, M, D, R, E', H, C, P, N)$$

be accepted CauchyConvergenceCriterion$^{\uparrow}$ *carriers with the same displayed* StreamName$^{\uparrow}$ *schedule,* CauchyModulus$^{\uparrow}$ *thresholds,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff, componentwise transport, continuation replay, provenance, and local name rows. If their* Real$^{\uparrow}$ *and* CauchyLimitSeal$^{\uparrow}$ *boundary reads are compatible, then the two carriers determine the same local classifier route.*

Proof. Project both carriers. The displayed classifier data agree on S, M, D, R, H, C, P, N, so their finite windows, threshold assignments, dyadic tolerance rows, regular-rational handoff, transports, replays, provenance, and local names are the same.

Apply Definition 1509.6. Any Real$^{\uparrow}$- or CauchyLimitSeal$^{\uparrow}$-facing read from either carrier must pass through the same source triad S, M, D, R before reaching its seal row.

Next use Definition 1509.7. The shared ledger covers exactly the stream windows accepted by the classifier, so there is no residual unbounded stream read that could distinguish the two carriers.

The compatible boundary reads identify the remaining endpoint. By Definition 1509.4, compatible CauchyLimitSeal$^{\uparrow}$ boundaries over the same displayed schedule, handoff, dyadic ledger, seal boundary, transport, continuation, provenance, and name rows determine the same seal route. The Real handoff theorem supplies the corresponding Real$^{\uparrow}$ route, and the NullSequence factorization theorem keeps zero-difference comparisons inside the same packet. Therefore the accepted carriers determine the same local classifier route. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier ledger classifier exactness`

Theorem 1509.18 (Cauchy convergence criterion obligation closure upgrade)**.** *For every accepted* CauchyConvergenceCriterion$^{\uparrow}$ *carrier* $G = (S, M, D, R, E, H, C, P, N)$*, the carrier admission, finite-window classification, modulus stability,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal nonescape, and ledger exhaustion rows listed in Definition 1509.2 form the full obligation surface of the chapter. Every convergence-facing read must pass through the displayed* StreamName$^{\uparrow}$ *schedule,* CauchyModulus$^{\uparrow}$ *threshold row,* DyadicRatCore$^{\uparrow}$ *ledger,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row, with no quotient stream, selected host limit, ambient completeness, trichotomy, or open-cover compactness coordinate.*

Proof. Apply Definition 1509.2. It enumerates the six obligation rows and states that no obligation is stored outside the displayed carrier coordinates.

The Real-facing side is controlled by Definition 1509.3. It forces every seal read through $S, M, D, R, E, H, C, P, N$ and refuses a detached Real endpoint.

The boundary comparison is controlled by Definition 1509.4. Compatible reads over the same displayed schedule, handoff, dyadic ledger, seal boundary, transport, replay, provenance, and naming rows determine the same seal route.

Zero-difference and source coverage are supplied by Definition 1509.5 and Definition 1509.6. The former keeps comparison reads inside the same finite packet, and the latter exhausts every Real- or limit-seal-facing read by S, M, D, R before E.

Together these theorems account for carrier admission, window coverage, threshold stability, regular handoff, Real-seal nonescape, and ledger exhaustion. Since the carrier has no additional coordinate, the chapter reaches obligation closure exactly over the displayed packet. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier obligation closure upgrade`

Theorem 1509.19 (Cauchy convergence criterion regular-tail window)**.** *For every accepted* CauchyConvergenceCrit *carrier $G = (S, M, D, R, E, H, C, P, N)$, the first criterion read opens the regular-tail window only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R. In particular, every tail-diameter request must expose the dyadic modulus rows M, D before the regular rational row R or the terminal seal row E can be consumed.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier regular tail window`

Proof. Project the carrier rows. A criterion read has no stream observation outside S, no threshold source outside M, and no tolerance ledger outside D.

Apply Definition 1509.7. Each finite window accepted by the classifier has its matching threshold and dyadic tolerance row in the same packet, so the regular-tail request is already inside S, M, D before any handoff is read.

Now use Definition 1509.8. Tail-diameter data pass through S, M, D, R before E is available. The structural rows H, C, P, N preserve and name that route, so the first criterion read opens exactly the displayed regular-tail window and dyadic modulus rows. □

Theorem 1509.20 (Cauchy convergence criterion Real seal route)**.** *For every accepted* CauchyConvergenceCriterion *carrier $G = (S, M, D, R, E, H, C, P, N)$, the terminal* $\mathsf{Real}^{\uparrow}$ *seal is available only after the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*, and* $\mathsf{NullSequence}^{\uparrow}$ *rows used by the criterion have been displayed. The seal read therefore factors through the source schedule, dyadic tolerance ledger, modulus threshold, regular rational handoff, zero-difference comparison route when present, and the structural rows H, C, P, N before it reaches E.*

Proof. Start with the source and modulus rows. By Definition 1509.6, every Real-facing read must pass through S, M, D, R before the seal row E is visible.

The dyadic and regular parts remain displayed. Definition 1509.19 forces the first regular-tail read through the $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{CauchyModulus}^{\uparrow}$ threshold, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, so the seal cannot bypass those rows.

For zero-difference comparisons, apply Definition 1509.5. The $\mathsf{NullSequence}^{\uparrow}$ route uses the same $S, M, D, R, E, H, C, P, N$ packet before any $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary consumes the comparison. Finally Definition 1509.3 identifies E as the downstream $\mathsf{Real}^{\uparrow}$ seal, with no detached endpoint or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier real seal route`

Theorem 1509.21 (Cauchy convergence criterion scope window)**.** *For every accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier $G = (S, M, D, R, E, H, C, P, N)$, the convergence criterion's window-threshold and tail-diameter reads are scoped by the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{NullSequence}^{\uparrow}$ *zero-difference factorization, and* $\mathsf{Real}^{\uparrow}$ *seal row E. A consumer must traverse*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E$$

with H, C, P, N before it can read a convergence boundary.

Proof. Project the carrier rows. The only windows are named by S, the only threshold row is M, the only dyadic tolerance ledger is D, and the only regular-rational handoff is R.

Apply Definition 1509.7 and Definition 1509.8. These theorems force every finite window and tail-diameter request through S, M, D, R before the seal row E is available.

Zero-difference and seal reads remain on the same route. By Definition 1509.5, any zero-difference comparison factors through the displayed $\mathsf{NullSequence}^{\uparrow}$ packet; by Definition 1509.3, the $\mathsf{Real}^{\uparrow}$ consumer can only read the downstream seal row. The structural rows H, C, P, N preserve and name that scope. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier scope window`

Theorem 1509.22 (Cauchy convergence criterion kernel-dependency scope)**.** *Every exported read from an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *carrier depends only on* BHist, hsame, *displayed* Cont *replay,* Pkg *provenance, the local* $\mathsf{NameCert}$ *row, and the listed L10 dependencies* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$. *It does not depend on host limits, quotient equality, trichotomy, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier definition exposes exactly $S, M, D, R, E, H, C, P, N$. Thus the kernel rows available to a consumer are the history packet, componentwise equality transport, continuation replay, provenance, and local naming row attached to those displayed dependencies.

The obligation theorem and the source-triad exhaustion theorem account for carrier admission, finite-window classification, threshold stability, regular handoff, ledger exhaustion, and the pre-seal route. The null-sequence factorization and limit-seal determinacy theorems account for zero-difference and boundary comparisons without adding a new coordinate.

Finally read the exclusions from the carrier surface. No row names a host limit, quotient equality, trichotomy branch, countable-choice selector, open-cover compactness object, or ambient completeness principle. Hence every exported criterion read is scoped by the stated kernel and L10 dependency rows. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier kernel dependency scope`

Theorem 1509.23 (Cauchy convergence criterion modulus-tail lock)**.** *Every accepted convergence-facing read whose null-difference row is certified must pass through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{NullSequence}^{\uparrow}$ *factorization, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before it may be consumed as a* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *criterion. The route admits no selected limits, quotient stream equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the window-threshold coverage row. It binds each finite $\mathsf{StreamName}^{\uparrow}$ window to the matching $\mathsf{CauchyModulus}^{\uparrow}$ threshold and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, so a convergence-facing request cannot reach the regular handoff before the modulus and dyadic rows have been displayed.

Next use null-sequence factorization. A certified null-difference row is accepted only as a $\mathsf{NullSequence}^{\uparrow}$ route over the same displayed window, threshold, dyadic tolerance, and regular-rational handoff rows.

Finally apply the regular seal handoff and the kernel dependency scope. The terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after the displayed $\mathsf{RegSeqRat}^{\uparrow}$ handoff and structural rows have replayed the same packet, and the kernel scope has no coordinate for selected limits, quotient stream equality, trichotomy, open-cover compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionCarrier modulus tail lock`

Theorem 1509.24 (Cauchy convergence criterion scoped dependency package)**.** *Every accepted* CauchyConvergenceCriterion$^{\uparrow}$ *consumer factors through the displayed dependency package consisting of* StreamName$^{\uparrow}$ *windows,* CauchyModulus$^{\uparrow}$ *thresholds,* DyadicRatCore$^{\uparrow}$ *tolerance ledgers,* RegSeqRat$^{\uparrow}$ *handoff,* CauchyLimitSeal$^{\uparrow}$ *boundary rows,* NullSequence$^{\uparrow}$ *zero-difference packages, the terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The package contains no ambient completeness principle, quotient-stream equality, selected host limit, trichotomy branch, open-cover compactness argument, or external limit oracle.*

Proof. Project the carrier $G = (S, M, D, R, E, H, C, P, N)$. The finite stream windows are stored in S, the threshold and modulus data in M, the dyadic tolerance ledger in D, and the regular-rational handoff in R.

Apply Definition 1509.7, Definition 1509.17, and Definition 1509.19. These rows force every window, threshold, tolerance, and regular-tail read to remain inside the displayed S, M, D, R package before the terminal seal is available.

Next read the boundary comparisons. By Definition 1509.4 and Definition 1509.5, any CauchyLimitSeal$^{\uparrow}$ or NullSequence$^{\uparrow}$ consumption is a downstream route over the same displayed windows, thresholds, dyadic ledgers, and handoff rows.

Finally use Definition 1509.20 and Definition 1509.22. The Real$^{\uparrow}$ seal and the structural rows H, C, P, N preserve and name precisely this dependency package. Since the carrier has no coordinate for ambient completeness, quotient-stream equality, selected host limits, trichotomy, open-cover compactness, or an external limit oracle, every accepted consumer is scoped by the stated route. □

Closure status for NameCert$_{\text{CauchyConvergenceCriterion}^{\uparrow}}$**.**

Constructive story: A CauchyConvergenceCriterion$^{\uparrow}$ packet is generated from a finite StreamName$^{\uparrow}$ schedule, a CauchyModulus$^{\uparrow}$ threshold row, a DyadicRatCore$^{\uparrow}$ tolerance ledger, a RegSeqRat$^{\uparrow}$ handoff, a Real$^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyConvergenceCriterion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1509.1, Definition 1509.2, Definition 1509.3, Definition 1509.4, Definition 1509.5, Definition 1509.6, Definition 1509.7, Definition 1509.17, and Definition 1509.24 expose the public dependency package from StreamName windows through Cauchy modulus and dyadic ledger rows to the RegSeqRat handoff, CauchyLimitSeal route, NullSequence zero-difference package, and Real seal.

Formal verification: FormalStatus(NameCert$_{\text{CauchyConvergenceCriterion}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.CauchyConvergenceCriterionUp.CauchyConvergenceCriterionNameCertObligations`

Bridge status: paperBridge

Not claimed: This chapter does not close ambient completeness, quotient-stream equality, selected host limits, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Only a future standard bridge check can raise the independent formal bridge status for the same public StreamName, CauchyModulus, DyadicRatCore, RegSeqRat, Real seal, transport, replay, provenance, and local NameCert packet.

Chapter 1510

A Concrete Naming Certificate for $\mathsf{FormalBall}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Vickers-style formal-ball presentations, the $\mathsf{FormalBall}^{\uparrow}$ packet records a radius-indexed observation interface for constructive completion. It sits between the metric carrier of chapter 57, the dyadic radius ledger of chapter 291, the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the real-name seal of chapter 38, and the uniform-completion boundary of chapter 1473. The packet gives completion consumers a finite formal-ball window without quotienting Cauchy names, selecting limits, using countable choice, invoking open-cover compactness, or assuming ambient completeness.

Definition 1510.1 (FormalBall carrier)**.** *A* $\mathsf{FormalBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, R, D, W, H, C, P, N)$$

with the following visible rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, distance witness surface, and finite observation histories.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *radius-name row read as a positive rational tolerance through finite requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger recording radius refinement, dyadic addition, and the strict comparison budget attached to R.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose entries display the selected center observations and requested radii before any completion handoff.*
5. *H records componentwise* hsame *transport for the metric source, radius row, dyadic ledger, finite window, replay row, provenance row, and local naming row.*
6. *C records the displayed* Cont *replay from metric observations to radius refinements, window reads,* $\mathsf{Real}^{\uparrow}$ *tolerance seals, and the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff boundary.*
7. *P is the* Pkg *provenance over* $\mathsf{FormalBall}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, countable choice, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallTasteGate single carrier alignment`

Theorem 1510.2 (FormalBall NameCert obligations)**.** *For the carrier of Definition 1510.1, the local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *surface consists exactly of carrier admission for* $B = (M, R, D, W, H, C, P, N)$*, metric source exposure through* M*, radius-name exposure through* R*, dyadic refinement exposure through* D*, finite-window exposure through* W*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Every completion-facing read of an accepted carrier must pass through the displayed route

$$M \longmapsto R \longmapsto D \longmapsto W \longmapsto H, C, P, N.$$

No such read exports quotient completion equality, a chosen Cauchy representative, a selected limit, countable choice, open-cover compactness, or ambient completeness.

Proof. Carrier admission is tuple projection from Definition 1510.1. The tuple displays the metric source, radius name, dyadic ledger, finite window, transport, replay, provenance, and local name.

The analytic obligations are exactly M, R, D, W. The metric row supplies point and distance reads, the radius row supplies the requested rational scale, the dyadic ledger records the refinement budget, and the stream window exposes the center observations available at that scale.

The structural obligations are exactly H, C, P, N. They transport the same rows, replay the same finite route, record package provenance, and bind the local certificate. Since the carrier contains no quotient, selected representative, selected limit, countable-choice schedule, compactness principle, or ambient-completeness coordinate, none can be exported by the NameCert surface. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier namecert obligations`

Theorem 1510.3 (FormalBall radius refinement)**.** *Let* $B = (M, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. A refinement request from radius* r *to a displayed smaller radius* s *is admissible only when the dyadic ledger* D *records the comparison and the replay row* C *reads the corresponding finite center window* W *over the same metric source* M*.*

The refined formal ball is therefore a smaller window inside the same packet. It is not a second metric, not a quotient of centers, not a selected Cauchy representative, and not an appeal to ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallRadiusRefinement`
↪ variant `BEDC.Derived.FormalBallUp.FormalBallCarrier radius refinement`

Proof. Project the accepted packet and read the metric source M. Any center comparison used by the refinement is interpreted through the point classifier and distance rows already displayed there.

Next read the radius row R and the dyadic ledger D. The ledger is the only coordinate that records the comparison between r and s, together with the finite arithmetic budget needed to keep the smaller radius inside the requested tolerance.

Finally replay the finite window through W and C. The transport row H preserves the same metric, radius, dyadic, and window rows, while P and N record provenance and naming. Thus refinement narrows an existing displayed formal-ball window and introduces no extra metric, quotient, representative choice, selected limit, or completeness principle. □

Theorem 1510.4 (FormalBall radius refinement chain)**.** *Let* $B = (M, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. For any finite displayed chain of radius refinements*

$$r_0 \geq r_1 \geq \cdots \geq r_k,$$

whose comparisons are all recorded in the same dyadic ledger D and replayed through the same row C, every formal-ball window reached along the chain is read over the same metric source M and the same finite stream-window row W.

The chain therefore refines only the displayed radius budget of the accepted packet. It does not identify quotient-completion classes, choose Cauchy representatives, select limits, use countable choice, invoke open-cover compactness, or assume ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier radius refinement chain`

Proof. For the empty chain there is no new refinement step. The accepted packet already exposes the metric source M, the radius row R, the dyadic ledger D, the stream-window row W, and the replay row C through Definition 1510.1.

For a nonempty chain, apply Definition 1510.3 to the first displayed comparison. The theorem keeps the smaller formal-ball window inside the same accepted packet, with its comparison recorded by D and its finite center read through W and C over M.

Iterate the same argument over the remaining displayed comparisons. The transport row H carries the metric, radius, dyadic, window, and replay rows componentwise at each step, while P and N only record provenance and local naming for the same packet.

No step introduces a field for quotient-completion equality, a selected Cauchy representative, a selected limit, a countable-choice schedule, an open-cover compactness principle, or an ambient complete space. Hence the whole finite chain preserves the same finite formal-ball window interface. □

Theorem 1510.5 (FormalBall completion-window handoff)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier* $B = (M, R, D, W, H, C, P, N)$ *receives only the finite window route through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{UniformCompletion}^{\uparrow}$ *rows recorded by B. The handoff exposes radius-indexed formal balls as finite observation data before any completion boundary is read.*

Consequently the handoff can support constructive completion arguments that use formal balls as observable neighborhoods, but it does not close quotient completion, selected limits, countable choice, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier completion window handoff`

Proof. Begin with the metric source and radius data. The rows M and R fix the center-observation surface and the requested radius scale before any completion-facing route is available.

Read the dyadic and stream windows next. The row D records the arithmetic budget for the radius, and W records the finite center windows inspected at that budget. Any $\mathsf{Real}^{\uparrow}$ tolerance seal reached by the consumer is read only through these rows.

Now pass to the completion boundary through C. The replay route carries the same finite formal-ball data to the $\mathsf{UniformCompletion}^{\uparrow}$ handoff, while H, P, N preserve transport, provenance, and local naming.

The carrier fields are exhausted by this route. Since no field stores quotient equality, a selected limit, a countable-choice schedule, an open-cover compactness principle, or an ambient complete space, the completion-window handoff exports none of those principles. □

Theorem 1510.6 (FormalBall center-radius admission)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier exposes its* $\mathsf{Met}^{\uparrow}$ *center row,* $\mathsf{RegSeqRat}^{\uparrow}$ *radius row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger, and* $\mathsf{StreamName}^{\uparrow}$

finite window before the local $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *row is consumed. The admission route is a* BHist *route over*

$$M, R, D, W, H, C, P, N,$$

and no consumer may read the formal ball as an accepted packet while omitting any one of M, R, D, W.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier center radius admission`

Proof. Project the carrier of Definition 1510.1. Its first four analytic coordinates are exactly the metric source M, radius row R, dyadic ledger D, and finite window W.

The local naming row N appears only after the structural rows H, C, P. Thus an accepted read must first display the center source, radius name, comparison ledger, and window route, and only then consume the local certificate.

Since the tuple has no alternate center or radius coordinate, a consumer that drops any of M, R, D, W has no accepted BHist route to the same $\mathsf{FormalBall}^{\uparrow}$ packet. □

Theorem 1510.7 (FormalBall formal-order monotonicity)**.** *Let* $B = (M, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. Any radius refinement or formal-order shrinkage of* B *can only pass through the displayed dyadic ledger* D *and the replay row* C*. It cannot introduce quotient completion equality, selected limits, countable choice, open-cover compactness, or ambient completeness as evidence for the shrinkage.*

Proof. Read the accepted carrier and isolate the rows that can mention radii. The radius row is R, and the comparison data for shrinking that radius is recorded only in D.

Replay through C preserves the same metric source and finite window while reading the smaller radius through the displayed ledger. The transport row H keeps this shrinkage componentwise inside the same packet, and P, N only source and name the route.

The remaining forbidden principles are absent by row exhaustion. There is no field for quotient completion equality, selected limits, countable choice, open-cover compactness, or ambient completeness, so none can be used to justify formal-order monotonicity. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier formal order monotonicity`

Definition 1510.8 (FormalBall rounded-filter boundary)**.** *For an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier* $B = (M, R, D, W, H, C, P, N)$*, the rounded-filter boundary row is the finite row*

$$\partial_{\mathrm{rf}}(B) = (M, R, D, W, C, H, P, N)$$

read after the metric source, radius row, dyadic refinement ledger, finite center-window row, replay row, componentwise transport, provenance, and local naming have all been displayed. The boundary records only rounded formal-ball windows generated by the same carrier; it does not contain quotient completion equality, selected Cauchy representatives, countable-choice schedules, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter boundary certificate`

Theorem 1510.9 (FormalBall completion dependency scope)**.** *Every completion-facing read of an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier* $B = (M, R, D, W, H, C, P, N)$ *factors through the displayed rows* M, R, D, W, H, C, P, N *and through the named* $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{UniformCompletion}^{\uparrow}$ *surfaces. The read may consume the rounded-filter boundary of Definition 1510.8, but it cannot bypass the carrier rows or replace them by a quotient completion principle.*

Proof. Start with carrier projection and the NameCert obligations. Theorem 1510.2 exposes the metric source, radius name, dyadic ledger, finite window, transport, replay, provenance, and local name as the only carrier rows available to a completion-facing consumer.

Next apply the radius-refinement chain. Theorem 1510.4 keeps every smaller-radius window inside the same dyadic ledger D, stream window W, and replay row C over the same source M.

Finally apply formal-order monotonicity. Theorem 1510.7 prevents a shrinkage read from introducing quotient completion equality, selected representatives, countable choice, compactness, or ambient completeness. Therefore the completion dependency scope is exactly the named finite route through $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{UniformCompletion}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier completion dependency scope`

Theorem 1510.10 (FormalBall public window export)**.** *Every public* $\mathsf{FormalBall}^{\uparrow}$ *consumer receives exactly the displayed route*

$$M, R, D, W, H, C, P, N$$

before any $\mathsf{UniformCompletion}^{\uparrow}$ *handoff or* $\mathsf{Real}^{\uparrow}$ *tolerance seal is read. The exported window is the metric source, radius row, dyadic ledger, finite stream window, componentwise transport, replay, provenance, and local NameCert surface of the accepted carrier.*

Proof. Begin with the NameCert obligations and center-radius admission. They expose M, R, D, W as the analytic prefix of every accepted formal-ball read.

Next apply the radius-refinement chain and completion-window handoff. Radius comparisons remain in D, finite center observations remain in W, and the route to $\mathsf{Real}^{\uparrow}$ or $\mathsf{UniformCompletion}^{\uparrow}$ is replayed through C over the same packet.

Finally attach H, P, N. These rows transport, source, and name the public window, so the consumer receives exactly M, R, D, W, H, C, P, N before any completion or tolerance seal is consumed. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier public window export`

Theorem 1510.11 (FormalBall radius ledger exhaustion)**.** *Every radius shrinkage, formal-order comparison, and completion-window read from an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier is exhausted by the radius row R, dyadic ledger D, finite window W, and replay row C, together with the fixed source, transport, provenance, and local name in M, H, P, N. The route exports no quotient completion, selected limit, countable choice, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier radius ledger exhaustion`

Proof. Read the radius-refinement chain. It keeps every shrinkage inside the displayed radius row and the dyadic comparison ledger.

Apply formal-order monotonicity and completion dependency scope. Formal-order comparisons and completion-window reads are replayed through W, C over the same metric source rather than through a quotient completion or external complete space.

The remaining structural rows H, P, N preserve the same packet. Since the accepted carrier has no coordinate for selected limits, countable choice, open-cover compactness, quotient completion, or ambient completeness, the radius ledger exhausts the handoff. □

Theorem 1510.12 (FormalBall rounded-filter non-escape)**.** *For an accepted* FormalBall$^{\uparrow}$ *carrier, a rounded-filter read exposes no quotient completion equality, no selected Cauchy representative, no countable-choice schedule, no open-cover compactness argument, and no ambient completeness principle. It exposes only the finite boundary row* $\partial_{\mathrm{rf}}(B)$ *and the rows from which that boundary is projected.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter nonescape`

Proof. Project the rounded-filter boundary of Definition 1510.8. Its entries are M, R, D, W, C, H, P, N, all inherited from the accepted carrier.

Use the NameCert obligations and the radius-refinement chain. The first theorem exhausts the accepted packet by the displayed carrier rows, and the second keeps every rounded refinement inside D, W, C over the same metric source.

The formal-order monotonicity theorem supplies the final exclusion. Since every shrinkage remains inside the displayed dyadic and replay rows, the rounded-filter read has no coordinate from which to expose quotient equality, selected representatives, countable choice, compactness, or ambient completeness. □

Theorem 1510.13 (FormalBall Cauchy-filter handoff)**.** *Every* CauchyFilter$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer that reads an accepted* FormalBall$^{\uparrow}$ *packet must factor through the displayed* Met$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows. The handoff exports formal balls only as finite center-radius windows in the accepted* BHist *packet, not as quotient completions or selected limits.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier cauchy filter handoff`

Proof. Begin with the analytic rows. The metric source M supplies the center surface, R supplies the regular rational radius, D supplies the dyadic comparison ledger, and W supplies the finite center-window observations.

The Real-facing tolerance seal is reached only through the replay row C, which reads the same M, R, D, W data before any completion-facing consumer can inspect the handoff. Componentwise transport is carried by H.

Finally P and N record provenance and local naming for this route. Therefore a CauchyFilter$^{\uparrow}$ or UniformCompletion$^{\uparrow}$ consumer receives exactly the displayed finite formal-ball packet and no quotient-completion equality, chosen Cauchy representative, selected limit, countable-choice schedule, compactness principle, or ambient complete space. □

Theorem 1510.14 (FormalBall rounded-filter Cauchy-filter boundary)**.** *Every* CauchyFilter$^{\uparrow}$ *consumer of the rounded-filter boundary of an accepted* FormalBall$^{\uparrow}$ *packet must first read the same rows*

$$M, R, D, W, C, H, P, N$$

displayed by $\partial_{\mathrm{rf}}(B)$ *in Definition 1510.8. Equivalently, a filter-limit boundary may be consumed only after the metric source, radius row, dyadic refinement ledger, finite center window, replay row, componentwise transport, provenance, and local NameCert row of the accepted packet have been displayed. The route exports no quotient completion, selected limit, countable-choice schedule, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter cauchyfilter boundary`

Proof. Start from the rounded-filter boundary definition. The boundary row is exactly the projection $\partial_{\mathrm{rf}}(B) = (M, R, D, W, C, H, P, N)$, so a consumer of that boundary already sits inside the displayed accepted carrier.

Apply rounded-filter non-escape and rounded-filter admission. The non-escape theorem excludes quotient completion, selected representatives, choice schedules, compactness, and ambient completeness from the rounded-filter read, while admission forces the completion-facing or Cauchy-facing route to display M, R, D, W, C, H, P, N before the boundary is consumed.

Finally apply the Cauchy-filter handoff. It attaches every $\mathsf{CauchyFilter}^{\uparrow}$ consumer to the same metric, dyadic, regular-rational, finite-window, real-seal, transport, replay, provenance, and local naming rows. Thus a filter-limit boundary cannot be read before those rows, and cannot export any of the excluded completion or compactness data. □

Theorem 1510.15 (FormalBall located-radius window)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *located-radius completion read must display the* $\mathsf{Met}^{\uparrow}$ *source* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *radius row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, and the* Cont *replay row* C *before any* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff is consumed. The read is therefore a finite located-radius window in the carrier* $B = (M, R, D, W, H, C, P, N)$*, not a quotient completion, selected limit, countable-choice schedule, open-cover compactness argument, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier located radius window`

Proof. Project the carrier of Definition 1510.1. The located-radius data available to a completion-facing consumer is exactly M, R, D, W together with transport, replay, provenance, and naming rows.

Apply the radius-refinement chain of Definition 1510.4. It keeps every displayed radius comparison inside the dyadic ledger D and the replayed finite window W, C over the same metric source M.

Finally apply the completion-window handoff of Definition 1510.5 and the Cauchy-filter handoff of Definition 1510.13. These handoffs force $\mathsf{UniformCompletion}^{\uparrow}$ and $\mathsf{CauchyFilter}^{\uparrow}$ consumers to read the finite center-radius packet before the completion boundary, so no quotient completion, selected limit, choice schedule, compactness principle, or ambient completeness row can enter. □

Theorem 1510.16 (FormalBall rounded-filter admission)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer admitted through an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier must display the* $\mathsf{Met}^{\uparrow}$ *source* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *radius row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, and the* Cont *replay row* C *before reading a rounded-filter boundary. The admitted route also preserves componentwise transport, formal-order monotonicity, provenance, and local naming through* H, P, N*.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter admission`

Proof. Start with the NameCert obligations of Definition 1510.2. They make carrier admission, metric exposure, radius exposure, dyadic refinement, finite-window exposure, transport, replay, provenance, and naming part of one packet.

Use the radius-refinement route of Definition 1510.4 and the monotonicity boundary of Definition 1510.7. They force every rounded shrinkage to remain inside the dyadic ledger D and replay row C over the same source M and window W.

Finally apply the completion-window and Cauchy-filter handoffs, Definition 1510.5 and Definition 1510.13. A completion-facing consumer therefore reads the rounded-filter boundary only

after the displayed finite rows M, R, D, W, C, H, P, N, and receives no quotient completion, selected representative, choice schedule, compactness principle, or ambient completeness row. □

Theorem 1510.17 (FormalBall rounded-filter stability)**.** *Let $B = (M, R, D, W, H, C, P, N)$ be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. Any rounded-filter read admitted by Definition 1510.16 remains stable under componentwise* hsame *transport of the metric source M,* $\mathsf{RegSeqRat}^{\uparrow}$ *radius row R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{StreamName}^{\uparrow}$ *finite window W, and* Cont *replay row C. The transported read is again the rounded-filter boundary of Definition 1510.8 for the same displayed packet route.*

The stability route refuses quotient completion equality, selected limits, countable choice, open-cover compactness, and ambient completeness as evidence for the transported rounded-filter read.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter stability`

Proof. Start with the boundary definition. The rounded-filter row of Definition 1510.8 is projected from the displayed rows M, R, D, W, C, H, P, N, so every component available for transport is already named in the accepted packet.

Apply rounded-filter admission, Definition 1510.16. It forces any completion-facing consumer to read M, R, D, W, C before the rounded-filter boundary, with H, P, N preserving transport, provenance, and naming.

Finally apply directed radius transport, Definition 1510.19. Componentwise hsame transport keeps radius refinements inside the same dyadic ledger D and replay row C over the transported metric and window rows. Since the carrier contains no quotient equality, selected limit, choice schedule, compactness principle, or ambient complete-space coordinate, none can justify or alter the transported rounded-filter read. □

Theorem 1510.18 (FormalBall carrier admission)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *packet must display the metric source M, radius row R, dyadic comparison ledger D, and finite center-window row W before the local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *row N is read. Thus the admitted carrier route has the visible analytic prefix*

$$M, R, D, W$$

inside the BHist *packet, and no completion consumer may treat N as naming a formal ball without first reading those four rows.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier admission`

Proof. Project the accepted carrier of Definition 1510.1. Its displayed tuple is $B = (M, R, D, W, H, C, P, N)$, so the analytic rows M, R, D, W occur before the structural transport, replay, provenance, and naming rows.

Apply Definition 1510.2. The local NameCert surface names carrier admission only for the same displayed route and records no alternate entry point into N.

The completion handoff theorems then keep every $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{CauchyFilter}^{\uparrow}$ consumer downstream of that prefix. Hence an accepted packet must expose M, R, D, W before N can be consumed as the local name. □

Theorem 1510.19 (FormalBall directed radius transport)**.** *Let $B = (M, R, D, W, H, C, P, N)$ be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. If a displayed radius refinement is preserved componentwise by the* hsame *row H, then the transported refinement is still read through the same dyadic ledger D and replay row C. In particular, radius refinements cannot be transported by quotient completion equality, selected representatives, countable choice, open-cover compactness, or an ambient complete-space principle.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier directed radius transport`

Proof. Start with a displayed refinement. By Definition 1510.3, the comparison from the larger radius to the smaller one is recorded in D, and the corresponding center-window read is replayed through C over the same metric source.

Now apply the componentwise transport row H from the carrier. It transports the metric source, radius row, dyadic ledger, finite window, replay row, provenance row, and local naming row together; it does not supply an independent equality of completions or a selected representative.

The transported route therefore has the same radius-comparison evidence in D and the same replay evidence in C. Since Definition 1510.13 exhausts the consumer-facing fields by the displayed packet rows, no forbidden completion or compactness coordinate can justify the refinement. □

Theorem 1510.20 (FormalBall rounded ideal handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier reads only the rounded finite center-radius route generated by the metric source M, radius row R, dyadic ledger D, finite window W, componentwise transport H, replay row C, provenance row P, and local naming row N. The handoff exposes rounded formal-ball data, not quotient limits, selected Cauchy representatives, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded ideal handoff`

Proof. First read the carrier-admission route of Definition 1510.18. It forces every consumer to expose M, R, D, W before the local naming row can certify the packet.

Next use Definition 1510.4 and Definition 1510.19. Finite radius shrinkage remains inside the displayed dyadic ledger and replay route, while componentwise transport preserves the same center-radius packet.

Finally apply Definition 1510.5 and Definition 1510.13. These handoff statements exhaust the $\mathsf{CauchyFilter}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ reads by the finite rows M, R, D, W, H, C, P, N, so the exported rounded ideal interface contains no quotient limit, selected representative, choice schedule, compactness principle, or ambient completeness row. □

Theorem 1510.21 (FormalBall rounded-basis comparison)**.** *Let $B = (M, R, D, W, H, C, P, N)$ be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. Any consumer comparing a formal-ball rounded basis must display the center source M, radius row R, dyadic refinement ledger D, finite center-window row W, componentwise* hsame *transport H, and displayed* Cont *replay C before it reads the local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *row. The comparison is therefore a row-level comparison of finite center-radius windows, not quotient equality of balls, a selected limit, countable choice, open-cover compactness, or ambient completion.*

Proof. Project the accepted carrier. The rows M, R, D, W display the metric center surface, the regular rational radius, the dyadic refinement budget, and the finite observation window.

Rounded-basis comparison can only shrink or compare those displayed radii through D and replay the corresponding center windows through C. Componentwise transport through H preserves the same source, radius, dyadic, and window rows.

The local name and provenance rows P, N do not add analytic data. Hence the comparison remains a finite formal-ball basis comparison and cannot become quotient equality of balls, a selected limit, a choice schedule, an open-cover compactness argument, or an ambient-completion principle. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded basis comparison`

Theorem 1510.22 (FormalBall Cauchy-net admission)**.** *Every* $\mathsf{CauchyNet}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *admission route that consumes an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier must read the center-radius rows* M, R*, the rounded refinement ledger* D*, the finite window* W*, and the replay row* C *before admitting Cauchy evidence to a completion-facing packet. The admitted Cauchy data is attached to the displayed* BHist *route*

$$M, R, D, W, H, C, P, N$$

and not to a quotient of formal balls or a selected representative.

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier cauchy net admission`

Proof. Begin with carrier admission. By Definition 1510.18, every consumer must expose M, R, D, W before the local NameCert row is read.

Use the rounded ideal handoff. The Cauchy-facing route reads rounded finite center-radius data through D, W, C over the same metric source and radius row, and H transports that data componentwise.

The admission row is therefore downstream of the finite packet. Since the carrier has no coordinate for quotient-ball equality, selected Cauchy representatives, selected limits, countable choice, open-cover compactness, or ambient completeness, neither a Cauchy net nor a Cauchy filter can obtain such evidence from the formal-ball packet. □

Theorem 1510.23 (FormalBall uniform-completion route)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier factors through the displayed rounded-basis and Cauchy-admission rows before reading any completion handoff. The route first exposes* M, R, D, W*, then transports and replays the finite window through* H, C*, then records provenance and local naming through* P, N*; it does not quotient formal balls, select limits, use countable choice, or appeal to ambient completeness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier uniform completion route`

Proof. First apply the rounded-basis comparison. It fixes the center source, radius row, dyadic refinement ledger, and finite window as the visible formal-ball basis data.

Next apply Cauchy-net admission. Completion-facing Cauchy evidence is admitted only after the finite rounded basis route is displayed and replayed through C with componentwise transport H.

Finally use the existing completion-window and rounded-ideal handoffs. They send exactly the rows M, R, D, W, H, C, P, N to uniform or metric completion consumers, so the route has no place for quotient formal-ball equality, selected limits, countable choice, open-cover compactness, or an ambient complete-space assumption. □

Theorem 1510.24 (FormalBall filter-basis route)**.** *Every* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier must first read the center-radius rows* M, R*, the rounded refinement ledger* D*, the finite center window* W*, and the replay row* C*. The basis row is therefore admitted only after the rounded-basis comparison and Cauchy-net admission surface have been exposed; it cannot be consumed as a detached filter basis, a quotient of balls, a selected Cauchy representative, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier filter basis route`

Proof. Start with Definition 1510.21. It fixes the center source, radius row, refinement ledger, finite window, transport, and replay rows as the only basis-facing data.

Apply Definition 1510.22. Any Cauchy-facing basis read is downstream of the displayed route M, R, D, W, H, C, P, N, so the basis cannot enter as an external filter object.

Finally use Definition 1510.23. Completion consumers receive the basis only through the same formal-ball packet, with no row for quotient equality, selected representatives, choice schedules, or ambient completeness. □

Theorem 1510.25 (FormalBall radius-order handoff)**.** *Every* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *comparison handed off by an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier is read through the center-radius rows* M, R*, the rounded refinement ledger* D*, and the replayed window* W, C *before any* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer may inspect it. The comparison is a finite radius-order row inside the same packet, not a host order on quotient balls or a selected completion representative.*

Proof. Apply Definition 1510.4. The radius comparison is recorded in the dyadic ledger D and is tied to the same center-radius route.

Use Definition 1510.19. Componentwise hsame transport preserves the comparison together with M, R, W, C, P, N rather than replacing it by a quotient-level order.

The completion route of Definition 1510.23 then forces every completion-facing consumer to read this radius-order handoff before it reads the terminal completion surface. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier radius order handoff`

Theorem 1510.26 (FormalBall completion-basis nonescape)**.** *Let* $B = (M, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier. Any* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer that uses* B *must first read the center-radius rows, the* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *comparison row encoded by* D*, and the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row encoded by the rounded Cauchy admission route. The consumer cannot bypass those rows to a quotient completion, selected limit, open-cover compactness proof, countable choice principle, or ambient complete-space witness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier completion basis nonescape`

Proof. First combine the filter-basis route with the radius-order handoff. The basis read is downstream of M, R, D, W, H, C, P, N, and the radius comparison is stored in D over the same center-radius rows.

Next apply the rounded ideal and Cauchy-net admission theorems. They attach all completion-facing Cauchy evidence to the displayed finite packet and replay it through C.

Finally apply the uniform-completion route. Since that route exposes no coordinate beyond M, R, D, W, H, C, P, N, the completion consumer cannot escape to quotient equality, selected limits, compactness, choice, or ambient completeness. □

Theorem 1510.27 (FormalBall rounded-filter admission package)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier* $B = (M, R, D, W, H, C, P, N)$ *whose center-radius row, directed radius transport row, rounded ideal handoff row, filter-basis route row, radius-order handoff row, and completion-basis nonescape row are displayed admits the rounded-filter package read by completion consumers. The package passes through* BHist, hsame, Cont, Pkg, NameCert, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$*, and* $\mathsf{UniformCompletion}^{\uparrow}$*, and exports no quotient Cauchy name, selected limit, countable-choice schedule, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier rounded filter admission package`

Proof. Project the carrier of Definition 1510.1. The analytic prefix M, R, D, W is visible by Definition 1510.18, so the center-radius read starts from a displayed $\mathsf{Met}^{\uparrow}$ source, a regular rational radius, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and a finite window.

Apply directed radius transport and the rounded ideal handoff. Theorems 1510.19 and 1510.20 keep radius shrinkage inside the same dyadic ledger, componentwise hsame transport, and replay row C.

Next read the Cauchy-facing basis rows. Theorems 1510.22 and 1510.24 attach $\mathsf{CauchyNet}^{\uparrow}$ and $\mathsf{CauchyFilterBasis}^{\uparrow}$ evidence to the displayed packet rather than to an external quotient or representative.

Finally apply the radius-order handoff and completion-basis nonescape, Definition 1510.25 and Definition 1510.26. These rows exhaust the completion-facing package by M, R, D, W, H, C, P, N, so the admitted rounded-filter package exports no quotient Cauchy name, selected limit, countable choice, or ambient completeness. □

Theorem 1510.28 (FormalBall completion obligation triad)**.** *Let $B = (M, R, D, W, H, C, P, N)$ be an accepted $\mathsf{FormalBall}^{\uparrow}$ carrier. A completion-facing read of B is admitted only when the center-radius row M, R, the $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ comparison row encoded by D, and the $\mathsf{CauchyFilterBasis}^{\uparrow}$ basis route through W, H, C are all displayed before any $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer reads the packet. The three rows form one finite BEDC route through M, R, D, W, H, C, P, N and do not introduce a quotient Cauchy name, selected limit, countable-choice schedule, open-cover compactness theorem, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier completion obligation triad`

Proof. First project the rounded-filter package of Definition 1510.27. It exposes the center-radius source, dyadic refinement ledger, finite window, transport, replay, provenance, and local name before any completion handoff is available.

Next apply the radius-order handoff, Definition 1510.25. The comparison read is stored in the same dyadic row D over M, R and is replayed with W, C rather than with a quotient order on formal balls.

Finally use completion-basis nonescape, Definition 1510.26. It forces the Cauchy-filter basis row and completion consumer to remain on M, R, D, W, H, C, P, N. Thus the center-radius row, radius-order comparison, and Cauchy basis route are a single finite obligation triad, with no selected limit, quotient name, choice schedule, compactness principle, or ambient completeness coordinate. □

Theorem 1510.29 (FormalBall radius-order scope package)**.** *Let $B = (M, R, D, W, H, C, P, N)$ be an accepted $\mathsf{FormalBall}^{\uparrow}$ carrier. Its radius-order scope package consists of the center-radius source M, R, the $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ comparison row stored in D, the $\mathsf{MetricClosedBall}^{\uparrow}$ boundary read available from the same center and radius window, the $\mathsf{DyadicRatCore}^{\uparrow}$ refinement ledger, and the terminal $\mathsf{Real}^{\uparrow}$ tolerance rows replayed by C. A completion-facing consumer may inspect a radius-order comparison only through this package; it cannot replace the package by a host order on balls, quotient equality of completions, a selected center representative, or an ambient complete-space witness.*

Proof. Project the accepted carrier. The center and radius rows are M, R, the dyadic comparison ledger is D, and the finite window and replay rows are W, C.

Use the radius-order handoff, Definition 1510.25. It places every $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ comparison inside the same dyadic row D and ties the comparison to the center-radius route rather than to a quotient order.

Now read the metric closed-ball boundary and real tolerance rows through the same center, radius, window, and replay data. Componentwise transport through H and provenance through P, N preserve that package, so the completion consumer receives only the displayed L10 dependency surface. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier radius order scope package`

Theorem 1510.30 (FormalBall Cauchy filter-basis triad)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier that is consumed by a completion-facing route must expose three Cauchy-facing rows before the completion handoff: a rounded-filter route over the displayed center-radius packet, a* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row read through the same finite windows, and a* $\mathsf{CauchyNet}^{\uparrow}$ *basis row with the same dyadic tolerance ledger. The triad is attached to* M, R, D, W, H, C, P, N *and does not introduce detached filters, quotient Cauchy names, selected limits, countable-choice schedules, or ambient completeness.*

Proof. Start with the rounded ideal handoff, Definition 1510.20. It forces the rounded-filter route to read the finite center-radius data M, R, D, W, H, C, P, N.

Apply Cauchy-net admission and the filter-basis route. Theorems 1510.22 and 1510.24 attach $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, and basis evidence to the same rounded formal-ball packet before any completion row is consumed.

Finally use the completion obligation triad. The completion-facing read sees the rounded-filter, filter-basis, and net-basis data as one finite L10 surface, with no coordinate for detached filters, quotient names, selected limits, choice schedules, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier cauchy filter basis triad`

Theorem 1510.31 (FormalBall uniform-completion ledger exhaustion)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff from an accepted* $\mathsf{FormalBall}^{\uparrow}$ *carrier is exhausted by radius refinement, finite-window replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *row. Equivalently, the handoff consumes only* M, R, D, W, H, C, P, N *together with the local radius-order, Cauchy-filter, Cauchy-net,* $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *tolerance rows already displayed by the packet. It exports no quotient completion equality, selected representative, countable-choice schedule, open-cover compactness, or ambient complete-space assumption.*

Proof. Begin with the uniform-completion route, Definition 1510.23. That route already factors the completion consumer through M, R, D, W, H, C, P, N before any completion handoff is read.

Next add the L10 dependency rows. The radius-order scope package supplies the radius comparison, metric closed-ball boundary, dyadic ledger, and real tolerance seal, while the Cauchy filter-basis triad supplies the rounded-filter, $\mathsf{CauchyFilter}^{\uparrow}$, and $\mathsf{CauchyNet}^{\uparrow}$ basis data.

It remains to account for structural stability. Radius refinement is recorded in D, finite windows are replayed through W, C, componentwise hsame transport is carried by H, and provenance and local naming are exactly P, N.

Thus the displayed ledger is exhausted by the accepted packet itself. Since no field remains for quotient completion equality, selected representatives, countable choice, open-cover compactness, or ambient completeness, the $\mathsf{UniformCompletion}^{\uparrow}$ handoff cannot export those objects. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier uniform completion ledger exhaustion`

Theorem 1510.32 (FormalBall obligation-closure export)**.** *An accepted* $\mathsf{FormalBall}^{\uparrow}$ *packet exports an obligation-closure surface exactly when its carrier admission, radius refinement, rounded-filter*

boundary, Cauchy-filter handoff, radius-order handoff, completion-basis nonescape, and uniform-completion route all factor through the same finite rows

$$M, R, D, W, H, C, P, N.$$

The exported surface is the shared row-ordering of Definition 1510.18, Definition 1510.4, Definition 1510.16, Definition 1510.13, Definition 1510.25, Definition 1510.26, and Definition 1510.23; it contains no quotient Cauchy name, selected limit, countable-choice schedule, open-cover compactness row, or ambient completeness witness.

Proof. Project carrier admission through Definition 1510.18. It places every accepted read on the displayed formal-ball rows M, R, D, W, H, C, P, N before local naming is consumed.

Next read the radius route. The radius-refinement chain and directed transport theorems keep every shrinkage and comparison inside the dyadic ledger D, replay row C, and the same center-window data.

Now attach the rounded-filter and Cauchy-facing boundaries. The rounded-filter admission theorem and the Cauchy-filter handoff theorem force filter consumers to read the same finite packet before any completion-facing row is available.

Finally apply the radius-order handoff, completion-basis nonescape, and uniform-completion route. These theorems order the remaining completion consumers over the same rows, so the packet exports one obligation surface precisely when all listed routes factor through that row list. □

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier obligation closure export`

Theorem 1510.33 (FormalBall public completion-interface export)**.** *Every accepted* $\mathsf{FormalBall}^{\uparrow}$ *packet exports a public completion-facing interface exactly through* $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{FormalBall}^{\uparrow}}$ *rows. A* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer may read the center-radius packet, dyadic radius order, finite stream windows, regular rational tolerance route, and real tolerance seal, but it cannot read quotient completion equality, selected limits, countable choice, open-cover compactness, or ambient completeness from the FormalBall surface.*

Lean4 ✓ `BEDC.Derived.FormalBallUp.FormalBallCarrier public completion interface export`

Proof. Start with the obligation-closure export. Theorem 1510.32 places carrier admission, radius refinement, rounded-filter boundary, Cauchy-filter handoff, radius-order handoff, completion-basis nonescape, and uniform-completion routing on the same rows M, R, D, W, H, C, P, N.

Next read the radius-order scope package. It exposes the metric source, dyadic radius ledger, regular rational tolerance route, stream-window readback, and real tolerance seal without adding an external completion object.

Attach the Cauchy filter-basis triad and the uniform-completion ledger exhaustion theorem. Theorems 1510.30 and 1510.31 show that $\mathsf{CauchyFilter}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ consumers receive only those displayed rows, transported by hsame, replayed by Cont, and sealed by Pkg and the local $\mathsf{NameCert}$ row.

Thus the public completion-facing interface is the listed finite BEDC surface. Since every completion consumer is already routed through that surface, no quotient completion equality, selected limit, countable-choice schedule, open-cover compactness proof, or ambient completeness witness remains available. □

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBall}\uparrow}$.

Constructive story: A $\mathsf{FormalBall}^{\uparrow}$ packet is generated from a displayed MetricSpaceUp source, a RegSeqRat radius row, a DyadicRatCore refinement ledger, a StreamName finite-window row, componentwise hsame transport, displayed Cont replay toward RealUp tolerance seals and UniformCompletionUp handoff, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalBall}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1510.1, Definition 1510.2, the radius-order scope package, the metric and dyadic-radius rows, the Cauchy filter-basis triad, the completion-basis nonescape row, the uniform-completion ledger exhaustion theorem, and the public completion-interface export bind the completed finite formal-ball observation surface for constructive completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalBall}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Mature closure requires an explicit standard-bridge schema tying the public completion-interface export to the accepted bridge rows while retaining the same finite packet inventory.

Chapter 1511

A Concrete Naming Certificate for $\mathsf{CauchyRealPresentation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRealPresentation}^{\uparrow}$ packet records the plain Cauchy-real presentation surface used before any completion-facing seal is consumed. It sits over the dyadic arithmetic row of chapter 291, the finite stream-window row of chapter 126, the regular rational readback row of chapter 301, and the terminal real seal of chapter 38. It is the presentation face adjacent to the Cauchy sequence space of chapter 406, the located Bishop-real route of chapter 343, and the phase exit certificate of chapter 1327.

Definition 1511.1 (CauchyRealPresentation carrier)**.** *A* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose entries are the only visible Cauchy-name observations.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic scales, comparison budget, and rational arithmetic used by the presentation.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in S under the tolerance data in D.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed route through S, D, R has been admitted.*
5. *H records componentwise* hsame *transport for the stream-window, dyadic-tolerance, regular-rational readback, real-seal, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from each finite window and tolerance request through S, D, R, E and then through the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyRealPresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealPresentation}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient stream equality, a selected representative, host real equality, countable choice, or ambient completeness.

Theorem 1511.2 (CauchyRealPresentation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *carrier* $Q = (S, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealPresentation}^{\uparrow}}$ *surface consists exactly of the following seven obligation rows:*

1. *carrier admission for the displayed stream-window, dyadic-tolerance, regular-rational readback, real-seal, transport, continuation, provenance, and local naming rows;*
2. *classifier transport by common finite windows, requiring any comparison of accepted carriers to inspect only matching windows of* S *preserved by* H *and replayed by* C*;*
3. *dyadic tolerance exactness, requiring each tolerance request to be accounted for by the row* D *before readback is available;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring* R *to be read only downstream of the displayed windows and dyadic tolerance data;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring* E *to remain terminal with respect to the route* S, D, R *and the structural rows;*
6. *provenance, requiring the package row* P *to name the same presentation packet and dependency rows;*
7. *local naming, requiring the row* N *to bind the accepted packet as a* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *certificate.*

No obligation is stored outside these rows.

Proof. Carrier admission is tuple projection from Definition 1511.1. The tuple displays exactly the stream-window, dyadic-tolerance, regular-rational readback, real-seal, transport, replay, provenance, and local name.

The analytic obligations are forced by S, D, R, E. Finite-window classification reads S, dyadic tolerance exactness reads D, regular-rational readback reads R, and the terminal seal reads E only after those rows have been displayed.

The structural obligations are forced by H, C, P, N. Transport and replay preserve the same finite windows and tolerance requests, provenance records the same dependency rows, and the local name binds the accepted packet. Since the carrier has no coordinate beyond these rows, the listed obligations exhaust the local NameCert surface. □

Theorem 1511.3 (CauchyRealPresentation Real seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *carrier* $Q = (S, D, R, E, H, C, P, N)$ *factors through the displayed finite route*

$$S \longmapsto D \longmapsto R \longmapsto E$$

together with the stored hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. The factorization exports no quotient stream, selected representative, host real equality, countable choice, or ambient completeness principle.*

Proof. Start with an accepted Real-facing read. Carrier admission exposes the finite stream-window row S as the only source of Cauchy-name observations.

The tolerance and readback rows then determine the route. The dyadic ledger D records the scale and comparison budget for the request, and the row R is the only regular-rational readback available from those displayed windows and tolerances.

The read reaches the real boundary only through E. The rows H and C transport and replay the same finite route, while P and N record provenance and local naming. The carrier fields are

exhausted by these rows, so the factorization cannot export quotient streams, selected representatives, host real equality, countable choice, or ambient completeness. □

Theorem 1511.4 (CauchyRealPresentation phase-exit handoff)**.** *An accepted* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *carrier supplies the Cauchy-presentation face consumed by* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *only through the four local L10 records* S, D, R, E*: finite stream windows, dyadic tolerance rows, regular-rational readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff may be transported, replayed, packaged, and locally named by* H, C, P, N*, but it does not add quotient stream equality, a selected representative, host real equality, countable choice, or ambient completeness.*

Proof. Project the accepted packet and read the four L10 records in order. The stream row S supplies finite windows, the dyadic row D supplies tolerance arithmetic, the readback row R supplies regular rational data, and the seal row E is terminal.

Now pass to the phase-exit consumer. The continuation row can replay only this same route, and the transport row can preserve only its displayed components. The package and local naming rows record the same accepted carrier.

Thus $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ receives a Cauchy-presentation face through S, D, R, E and no additional analytic principle. The excluded quotient, representative, host equality, choice, and completeness data are absent from the carrier itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealPresentation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRealPresentation}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealPresentation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1511.1, Definition 1511.2, Definition 1511.3, and Definition 1511.4 seed the finite Cauchy-real presentation surface used by the real-completion phase exit.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealPresentation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport by common finite windows, dyadic tolerance exactness, RegSeqRat readback, RealUp seal nonescape, provenance, and local naming for the same displayed packet.

Chapter 1512

A Concrete Naming Certificate for $\mathsf{CompletionEmbedding}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the Bourbaki treatment of completion by separated metric envelopes, the $\mathsf{CompletionEmbedding}^{\uparrow}$ packet names the dense isometric embedding surface of completion as finite BEDC data. It sits after the metric-completion surface of chapter 1506, the displayed isometry route of chapter 439, and the regular Cauchy dense embedding boundary of chapter 1453. The packet binds those sibling surfaces before any downstream consumer treats a source point, regular Cauchy name, or Real seal as a point of a completed host space.

Definition 1512.1 (CompletionEmbedding carrier)**.** *A* $\mathsf{CompletionEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, D, I, R, S, A, L, C, P, N)$$

with the following visible rows:

1. *X is the source metric row whose point classifier and distance witnesses are the domain of the embedding.*
2. *Y is the completion target row, read through the finite* $\mathsf{MetricCompletion}^{\uparrow}$ *surface rather than through an ambient complete metric space.*
3. *D is the dense image row recording that every displayed completion-facing tolerance request is met by a source-side image window.*
4. *I is the isometry row, read through* $\mathsf{IsometricEmbedding}^{\uparrow}$ *distance reflection and not through host function equality.*
5. *R is the regular-Cauchy source row supplying the finite rational or regular source names used to approach target reads.*
6. *S is the Hausdorff separated boundary row, comparing two target reads only through displayed zero-distance classifier evidence.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by the regular Cauchy and distance-reflection routes.*
8. *L records componentwise* hsame *transport for the source metric, completion target, dense image, isometry, regular-Cauchy source, Hausdorff boundary, Real seal, continuation, provenance, and local naming rows.*

9. *C records the displayed* Cont *replay through $X, Y, D, I, R, S, A, L, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completions, selected representatives, host equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingTasteGate single carrier alignment`

Theorem 1512.2 (CompletionEmbedding NameCert obligations)**.** *For an accepted* $\mathsf{CompletionEmbedding}^{\uparrow}$ *carrier $E = (X, Y, D, I, R, S, A, L, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionEmbedding}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed source metric, completion target, dense image, isometry, regular-Cauchy source, Hausdorff separated boundary, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *dense-image coverage, requiring each completion-facing tolerance request in Y to route through the image row D and a regular-Cauchy source read in R;*
3. *isometric reflection, requiring each source-target distance comparison to pass through I and then through the* $\mathsf{Real}^{\uparrow}$ *seal row A;*
4. *Hausdorff separated comparison, requiring any identification of two target reads to pass through S after the dense and isometric rows have been displayed;*
5. *ledger non-escape, stating that no quotient completion, selected representative, host equality, countable-choice schedule, or ambient completeness theorem is exported by the packet.*

Proof. Carrier admission is projection from Definition 1512.1. The tuple lists the source, target, dense-image, isometry, regular-Cauchy, Hausdorff, Real-seal, transport, replay, provenance, and naming rows.

Dense-image coverage reads a completion-facing tolerance request in Y through D before a target read is accepted. The row R supplies the finite regular-Cauchy source data used by that image window.

Isometric reflection is then read through I and A. The isometry row preserves the source distance route, while the Real seal row records the displayed distance comparison consumed by later completion readers.

Hausdorff separated comparison is local to S. The continuation row C replays the already displayed dense and isometric route before S compares target reads, and the package row P and naming row N record that no excluded completion or choice principle is available. □

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier namecert obligations`

Theorem 1512.3 (CompletionEmbedding dense isometric handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionEmbedding}^{\uparrow}$ *packet factors through the finite route*

$$X \longmapsto R \longmapsto D \longmapsto I \longmapsto A \longmapsto Y \longmapsto S \longmapsto (L, C, P, N).$$

Thus the consumer receives a dense source image and a distance-reflecting route into the completion target, not a quotient-completion point, not a selected representative, not host equality, and not an ambient completeness principle.

Proof. Start with the source metric row X and the regular-Cauchy row R. These two rows provide the displayed source-side data from which the completion-facing image can be read.

The dense image row D is the next route component. A consumer cannot read a target point from Y before the dense source image has been displayed through D.

The isometry row I and Real seal row A then attach distance preservation to that image. The target row Y is reached only after this dense isometric route has been recorded.

Finally the Hausdorff row S compares target reads through separated zero-distance evidence, while L, C, P, N transport, replay, source, and name the same packet. Since the route has no field for quotient classes, selected representatives, host equality, countable choice, or ambient completeness, the handoff exports only the displayed dense isometric surface. □

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier dense isometric handoff`

Theorem 1512.4 (CompletionEmbedding Real seal non-escape)**.** *For every accepted* $\mathsf{CompletionEmbedding}^{\uparrow}$ *packet* $E = (X, Y, D, I, R, S, A, L, C, P, N)$*, each* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by* E *factors through the regular-Cauchy source row* R*, the dense image row* D*, the isometry row* I*, and the Hausdorff separated boundary row* S*. The Real seal cannot be used as a detached completed point, quotient-class representative, host equality witness, countable-choice selection, or ambient completeness witness.*

Proof. Read the Real seal coordinate A from the carrier. It is listed after the regular-Cauchy source row, dense image row, isometry row, and Hausdorff separated boundary row, so the packet exposes it only as part of that displayed route.

Apply the NameCert obligations of Definition 1512.2. Dense-image coverage places R and D before any completion-facing read, isometric reflection places I before the Real distance comparison, and separated comparison places S around target-read identification.

The replay and provenance rows C and P record no second Real route. Transport by L preserves the same fields componentwise, and the local naming row N names exactly this packet.

Therefore any exported $\mathsf{Real}^{\uparrow}$ read remains inside $R, D, I, S, A, L, C, P, N$. The excluded detached point, quotient representative, host equality, choice schedule, and ambient completeness data have no coordinate from which a consumer could read them. □

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier real seal nonescape`

Theorem 1512.5 (CompletionEmbedding source-density reflection)**.** *For every accepted* $\mathsf{CompletionEmbedding}^{\uparrow}$ *packet* $E = (X, Y, D, I, R, S, A, L, C, P, N)$*, any completion-target read that the packet classifies back to a source-side approximation factors through the regular-Cauchy source row* R*, dense image row* D*, isometry row* I*,* $\mathsf{Real}^{\uparrow}$ *seal row* A*, and Hausdorff separated boundary row* S*. The resulting comparison is a local classifier reflection recorded by* L, C, P, N*, not host equality, quotient equality, selected representatives, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier source density reflection`

Proof. Begin with the accepted carrier and its NameCert obligations. The dense-image coverage obligation requires a completion-facing tolerance read in Y to pass first through the source-side regular-Cauchy data in R and the dense image window in D.

Use the dense isometric handoff of Definition 1512.3 to extend that source-density route through I and A. The isometry row supplies the distance-reflecting comparison, and the $\mathsf{Real}^{\uparrow}$ seal records the displayed real-valued boundary consumed by completion readers.

The Real-seal non-escape theorem, Definition 1512.4, keeps that comparison inside the same finite route. The separated boundary row S is therefore the only target-read comparison surface available after the dense and isometric rows have been replayed.

Finally, L, C, P, N transport, replay, source, and name the reflected classifier route. Since the carrier has no coordinate for host equality, quotient equality, selected representatives, countable choice, or ambient completeness, the source-density read exports only the local reflection described above. □

Theorem 1512.6 (CompletionEmbedding obligation closure package)**.** *The carrier of Definition 1512.1, the NameCert obligations of Definition 1512.2, the dense-isometric handoff of Definition 1512.3, the Real-seal non-escape boundary of Definition 1512.4, and the source-density reflection of Definition 1512.5 jointly form the* obligation *package for* $\mathsf{CompletionEmbedding}^{\uparrow}$ *over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The package keeps the existing exclusions: it exports no quotient completion, selected representative, host equality, countable-choice schedule, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier obligation closure package`

Proof. First take carrier admission from Definition 1512.1. The displayed rows are exactly the source metric, completion target, dense image, isometry, regular-Cauchy source, Hausdorff separated boundary, Real seal, componentwise transport, continuation replay, provenance, and local naming data.

Next apply Definition 1512.2. It turns those rows into the local NameCert surface: dense-image coverage, isometric reflection, Hausdorff separated comparison, and ledger non-escape are all obligations on the same finite packet.

The public route is supplied by Definition 1512.3. It sends every completion-facing consumer through $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any target read is accepted.

Finally combine Definition 1512.4 with Definition 1512.5. The first keeps Real-facing reads inside the same route, and the second reflects target reads back to the source-density classifier. The excluded quotient, selected-representative, host-equality, choice, and ambient-completeness data therefore remain absent throughout the obligation package. □

Theorem 1512.7 (CompletionEmbedding public interface)**.** *The public* $\mathsf{CompletionEmbedding}^{\uparrow}$ *interface for downstream completion consumers is the package consisting of the carrier of Definition 1512.1, the NameCert obligations of Definition 1512.2, the dense isometric handoff of Definition 1512.3, the Real seal non-escape theorem of Definition 1512.4, the source-density reflection of Definition 1512.5, and the obligation closure package of Definition 1512.6.*

Every public consumer must read $\mathsf{CompletionEmbedding}^{\uparrow}$ *over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *through that package. The interface exports dense source coverage, distance reflection, source-density reflection, and Real-seal non-escape, but exports no quotient completion, selected representative, host equality, countable-choice schedule, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier public interface`

Proof. Project the accepted public consumer request through Definition 1512.1. The only displayed source rows are the source metric, completion target, dense image, isometry, regular-Cauchy source, Hausdorff boundary, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1512.2. The NameCert surface admits exactly those rows and records dense-image coverage, isometric reflection, Hausdorff separated comparison, and ledger non-escape.

Use Definition 1512.3 for the public handoff. It routes completion consumers through the dense source image and distance-reflecting embedding before a target read is accepted.

The Real-facing and source-facing public boundaries are supplied by Definition 1512.4 and Definition 1512.5. These theorems keep Real seal reads and target-source reflections inside the same finite route.

Finally package the route with Definition 1512.6. Since every cited row belongs to that package and the excluded data have no carrier coordinate, the named package is the public $\mathsf{CompletionEmbedding}^{\uparrow}$ interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionEmbedding}^{\uparrow}$ packet is generated from a source metric row, a completion target row, a dense image row, an isometry row, a regular-Cauchy source row, a Hausdorff separated boundary row, a Real seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionEmbedding}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1512.7, Definition 1512.3, Definition 1512.5, and Definition 1512.6 give the mature paper treatment of the dense isometric completion-embedding interface over $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionEmbedding}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CompletionEmbeddingUp.CompletionEmbeddingCarrier\_public\_interface`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host equality, countable choice, or ambient completeness.

Upgrade path: Bridge checking remains separate from the mature paper treatment displayed here.

Chapter 1513

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ packet records the finite regular-Cauchy completion surface needed when a real-name consumer wants both separatedness and uniqueness in the same displayed route. It reads the regular source of chapter 301, the finite-window schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the metric-completion handoff of chapter 1506, the zero-distance classifier route of chapter 1411, the completion uniqueness ledger of chapter 1463, and the regular universal-property surface of chapter 1425.

The packet is a local L10 bridge. It names the rows by which regular Cauchy names enter a completion-facing metric route, get compared through separated zero-distance evidence, and then feed the uniqueness ledger. It does not turn regular names into quotient streams or assert completeness of an ambient host real line.

Definition 1513.1 (RegularCauchyCompletionSeparated carrier)**.** *A* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, D, R, M, Z, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose accepted histories are regular rational Cauchy names.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect those regular names at bounded precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the windows of W.*
4. *R is the regular-name comparison row, read through the existing regular Cauchy comparison surface and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that exposes completion-facing Cauchy evidence without quotienting the source names.*
6. *Z is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance and separation row used to identify displayed limit readings inside the metric classifier.*
7. *U is the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *ledger comparing completion-facing presentations over the same regular source, window schedule, tolerance ledger, comparison row, metric handoff, and separatedness row.*

8. *H records componentwise* hsame *transports for S, W, D, R, M, Z, U and the naming support rows.*
9. *C records the displayed* Cont *replay from regular names to windows, tolerances, comparison, metric completion, separated zero-distance evidence, and uniqueness ledger.*
10. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}}$ *row.*

The carrier stores no quotient stream, no selected host limit, no host real equality coordinate, no countable-choice selector, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, no open-cover compactness principle, and no trichotomy row.*

Theorem 1513.2 (RegularCauchyCompletionSeparated NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *carrier $Q = (S, W, D, R, M, Z, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCo}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed regular source, finite windows, dyadic tolerance ledger, regular comparison row, metric-completion handoff, separatedness row, completion uniqueness ledger, transports, replay routes, provenance, and local naming row;*
2. *classifier stability under the componentwise* hsame *transports H and the replay routes C;*
3. *regular-source compatibility, requiring completion consumers to read S, W, D, R before the metric handoff M;*
4. *separatedness compatibility, requiring any identification of displayed completion readings to pass through the zero-distance row Z;*
5. *uniqueness-ledger exactness, requiring comparison of two completion-facing presentations to be exhausted by the ledger U over the same displayed route.*

Proof. Carrier admission is projection from Definition 1513.1. The tuple displays the regular source, stream windows, dyadic tolerances, regular comparison row, metric-completion handoff, separatedness row, uniqueness ledger, and the structural support rows.

Classifier stability is componentwise. The transports in H move each displayed coordinate without changing the order of dependency, and the continuation row C replays the same route after transport.

The remaining obligations are sibling handoffs. The regular-source compatibility clause reads through S, W, D, R before M; the separatedness clause reads through Z after the metric-completion handoff; and the uniqueness exactness clause reads through U only after the same finite route has been projected.

No carrier coordinate contains quotient streams, selected host limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, or trichotomy. The listed obligations therefore exhaust the local NameCert surface. □

Theorem 1513.3 (Regular separated completion route)**.** *Let $Q = (S, W, D, R, M, Z, U, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *packet. Every separated comparison exported by Q factors through the route*

$$S, \quad W, \quad D, \quad R, \quad M, \quad Z.$$

Thus a completion-facing consumer identifies two displayed readings only by projecting the regular source, scheduled windows, tolerance ledger, comparison row, metric-completion handoff, and zero-distance separation row. The conclusion is classifier equivalence inside the displayed separated metric surface, not equality of quotient streams or equality in a host real line.

Proof. Project the accepted carrier. The first four rows S, W, D, R keep the comparison attached to a regular Cauchy name inspected through finite windows and dyadic tolerances.

Read the metric-completion handoff only after those rows have been fixed. The handoff M supplies completion-facing evidence over the displayed regular route, so a consumer cannot replace it by a selected host limit.

Apply the separatedness row Z to the displayed zero-distance reading. The replay row C exposes exactly this route, and the transport row H moves it componentwise without adding a host equality coordinate.

Since the packet carries no quotient stream, host real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness field, every separated comparison is the displayed finite route. □

Theorem 1513.4 (Regular separated uniqueness ledger)**.** *For accepted packets $Q = (S, W, D, R, M, Z, U, H, C, P, N$ and $Q' = (S, W, D, R, M, Z, U', H', C', P, N')$ over the same regular source, window schedule, tolerance ledger, comparison row, metric-completion handoff, separatedness row, and provenance, any comparison between their completion-facing exports is exhausted by the uniqueness ledgers U and U' together with their displayed transport and replay rows.*

Proof. Start from the shared coordinates S, W, D, R, M, Z, P. They fix the regular Cauchy source, the finite windows, the dyadic tolerance ledger, the comparison row, the metric-completion handoff, the separatedness row, and the provenance surface for both packets.

The remaining comparison data are U, H, C, N and U', H', C', N'. The ledgers U and U' compare completion-facing presentations over the same shared route, while H, H' and C, C' display the permitted transports and replays.

No further field remains from which a consumer could read quotient-stream equality, a selected host limit, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, or trichotomy. The uniqueness judgement is therefore exactly the local ledger over the displayed regular separated completion route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1513.1, Definition 1513.2, Definition 1513.3, and Definition 1513.4 seed the regular Cauchy completion route with separatedness and uniqueness rows over a finite L10 packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, host real equality, selected host limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, trichotomy, or a standard bridge.

Upgrade path: A later verification route can encode the carrier and prove carrier admission, classifier stability, separation routing, and uniqueness-ledger exactness for the same displayed packet.

Constructive story: A $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ packet is generated from a regular rational Cauchy source, StreamName windows, a DyadicRatCore tolerance ledger, a regular-name comparison row, a MetricCompletion handoff, a SeparatedMetric zero-distance row, a CompletionUniqueness ledger, componentwise transports, replay routes, provenance, and a local NameCert row.

Chapter 1514

A Concrete Naming Certificate for $\mathsf{ApartnessSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ApartnessSpace}^{\uparrow}$ packet records the constructive neighbour relation needed between located positive-gap evidence and separated metric recognition. It reads the finite gap handoff of chapter 1380 and exposes the zero-distance boundary consumed by chapter 1411. The packet is an interface for positive apartness over displayed carriers; it is not a source of trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1514.1 (ApartnessSpace carrier)**.** *An* $\mathsf{ApartnessSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, L, G, T, C_0, C_1, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying carried-object row, including the local point classifier used by the packet.*
2. *L is the* $\mathsf{LocatedApartness}^{\uparrow}$ *source row that supplies two located observations, a shared finite window, and the displayed positive-gap evidence.*
3. *G is the positive-gap evidence row read from L as a finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap ledger attached to the two observations of X.*
4. *T is the apartness transport row stating that the positive-gap ledger is stable under componentwise transport of the two observations and their shared finite window.*
5. *C_0 is the classifier-exclusion row: if G is displayed between two observations, the local point classifier of X does not identify them.*
6. *C_1 is the zero-distance boundary row exported to* $\mathsf{SeparatedMetric}^{\uparrow}$*: any consumer that has only a displayed zero-distance route must pass through the separated-metric classifier boundary before it can identify observations.*
7. *H stores componentwise* hsame *transport for the carried-object row, the located-apartness source row, the positive-gap evidence, both classifier boundary rows, the continuation row, the provenance row, and the local naming row.*
8. *C stores the* Cont *replay from finite located observations to positive-gap evidence, from positive-gap evidence to classifier exclusion, and from zero-distance readings to the separated-metric boundary.*

9. *P is the* Pkg *provenance over* LocatedApartness$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{ApartnessSpace}^{\uparrow}}$ *row.*

The carrier records apartness as displayed positive-gap evidence over finite histories. It carries no trichotomy row, no quotient real equality, no host inequality, no selected limit, no open-cover compactness principle, and no Real$^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceTasteGate single carrier alignment`

Definition 1514.2 (ApartnessSpace classifier)**.** *The classifier of an accepted* ApartnessSpace$^{\uparrow}$ *packet relates two carried observations a, b as apart when the packet displays a finite route*

$$a, b \longmapsto L(a, b) \longmapsto G(a, b) \longmapsto C_0(a, b).$$

The first step reads the two observations through the LocatedApartness$^{\uparrow}$ *source row, the second step extracts the positive* DyadicRatCore$^{\uparrow}$ *gap row, and the last step records classifier exclusion inside the carried-object surface X. Transport of this classifier is componentwise: if a, b, the shared window, and $G(a, b)$ are moved by the stored* hsame *rows, then the replayed* Cont *path produces the transported positive-gap evidence and the transported classifier-exclusion row.*

The classifier is local positive information. It does not decide every pair of observations, does not turn apartness into host inequality, and does not form a quotient equality surface for constructive reals.

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceClassifier positive gap exactness`

Theorem 1514.3 (ApartnessSpace NameCert obligations)**.** *For an accepted* ApartnessSpace$^{\uparrow}$ *carrier $A = (X, L, G, T, C_0, C_1, H, C, P, N)$, the local* NameCert$_{\text{ApartnessSpace}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the carried-object row, the* LocatedApartness$^{\uparrow}$ *source row, the positive-gap evidence row, the apartness transport row, the two classifier boundary rows, componentwise transport, continuation replay, package provenance, and local naming row;*

2. *classifier stability, stating that transported observations and transported finite windows replay the same positive-gap route and the same classifier-exclusion row;*

3. *positive-gap exactness, stating that every apartness assertion exported by the packet factors through the displayed finite G row read from L;*

4. *separated-metric boundary compatibility, stating that zero-distance consumers use only the displayed C_1 route into* SeparatedMetric$^{\uparrow}$ *and do not identify observations by host equality;*

5. *ledger visibility, stating that the packet exports no trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, or* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier namecert obligations`

Proof. Carrier admission is the finite tuple of Definition 1514.1. Each row named in the obligation list is visible in A, and the packet has no coordinate from which an excluded classical or completion principle could be read.

Classifier stability follows from the paired transport and replay rows. The hsame fields move the two observations, their shared finite window, the located-apartness source, the positive-gap

row, and the classifier boundary rows componentwise. The Cont row then replays the same finite route after transport.

Positive-gap exactness is the defining use of G. An apartness assertion exported by the packet must pass through L and then through the displayed positive dyadic gap row before it reaches the classifier-exclusion row C_0.

For zero-distance consumers, the only exported boundary is C_1. That row points toward the separated-metric classifier route, so it does not create host equality, quotient equality, or a total comparison principle inside the apartness-space packet. □

Theorem 1514.4 (ApartnessSpace located positive-gap route)**.** *Let A be an accepted* ApartnessSpace$^{\uparrow}$ *packet and let a, b be two carried observations of its object row X. If the* LocatedApartness$^{\uparrow}$ *row L displays a shared finite window for a, b and the positive* DyadicRatCore$^{\uparrow}$ *gap row $G(a, b)$ on that window, then A exports a constructive apartness route*

$$a, b \longmapsto L(a, b) \longmapsto G(a, b) \longmapsto C_0(a, b)$$

inside the local point classifier of X. The route is positive-gap evidence; it is not a proof of trichotomy, quotient real inequality, host inequality, a selected limiting comparison, open-cover compactness, or Real$^{\uparrow}$ *completeness.*

Proof. Read a and b through the located-apartness source row L. This exposes the two located observations, their shared finite window, and the finite endpoint data used by the positive-gap ledger.

Attach the displayed $G(a, b)$ row to that common window. By Definition 1514.1, G is already a row of the accepted packet and is transported componentwise with the two observations.

Replay the continuation route from $G(a, b)$ to the classifier-exclusion row $C_0(a, b)$. The resulting apartness route is therefore a finite BHist calculation inside the packet.

The final boundary is an inventory statement. Since the carrier has no row for trichotomy, quotient equality, host inequality, selected limits, open-cover compactness, or Real$^{\uparrow}$ completeness, none of those principles can be read from this positive-gap route. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier located positive gap route`

Theorem 1514.5 (ApartnessSpace positive-gap transport)**.** *Let A be an accepted* ApartnessSpace$^{\uparrow}$ *packet, and let a, b, a', b' be carried observations of its object row X. Suppose the two observations a, b, their transported observations a', b', the shared finite window, and the positive dyadic gap row are related componentwise by the displayed* hsame *transport of Definition 1514.1. Then the same route*

$$L \longmapsto G \longmapsto C_0$$

replays through Cont *for a', b'. The transported route is still positive apartness evidence only; it does not introduce trichotomy, host inequality, quotient real inequality, selected limits, open-cover compactness, or* Real$^{\uparrow}$ *completeness.*

Proof. Start from the located positive-gap route of Definition 1514.4. That theorem reads the two observations, their shared located window, and the positive DyadicRatCore$^{\uparrow}$ gap row before reaching C_0.

Now apply the carrier inventory of Definition 1514.1 and the classifier surface of Definition 1514.2. The hsame row transports exactly the displayed observations, window, and gap row, while the Cont row replays the same finite continuation from L to G and then to C_0.

The replay has no additional carrier coordinate. Therefore the transported positive-gap evidence remains a local apartness route and cannot become a comparison principle, quotient real inequality, selected limit, compactness principle, or real-completeness theorem. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier positive gap transport`

Theorem 1514.6 (ApartnessSpace classifier stability)**.** *Let A be an accepted* ApartnessSpace$^{\uparrow}$ *packet. If two observations, their shared finite window, and the displayed positive-gap row are transported componentwise by the* hsame *rows of Definition 1514.1, then the transported route preserves classifier exclusion through the same local C_0 row. In particular, the transported located positive-gap evidence remains apartness evidence and cannot be reread as trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or* Real$^{\uparrow}$ *completeness.*

Proof. Start with the transported positive-gap route of Definition 1514.5. That route carries the two observations, their shared finite window, and the positive DyadicRatCore$^{\uparrow}$ gap row through the same $L \longmapsto G \longmapsto C_0$ spine.

Now read the classifier definition in Definition 1514.2. The final row is classifier exclusion inside the carried-object surface X, so componentwise transport preserves exclusion by replaying the displayed Cont path rather than by adding a new comparison principle.

The carrier inventory has no coordinate for trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or Real$^{\uparrow}$ completeness. Thus the transported classifier route remains exactly the positive apartness route named by C_0. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier classifier stability`

Theorem 1514.7 (ApartnessSpace transport and replay boundary)**.** *For an accepted* ApartnessSpace$^{\uparrow}$ *packet,* hsame *transport followed by displayed* Cont *replay preserves the finite route through $X, L, G, T, C_0, C_1, H, C,$ and cannot create trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or* Real$^{\uparrow}$ *completeness. Any consumer claiming one of those endpoints has left the displayed apartness-space carrier.*

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier transport and replay`

Proof. Project the carrier of Definition 1514.1. The transport row H moves only the displayed carried-object, located-apartness, positive-gap, classifier-boundary, continuation, provenance, and local naming rows.

Replay is then bounded by C. It sends finite located observations to the positive-gap row, then to classifier exclusion, and sends zero-distance readings only toward the separated-metric boundary row C_1.

Since neither H nor C contains a decision, equality, selected-limit, compactness, or completeness coordinate, replay cannot supply any of the listed endpoints. Such a claim would require data absent from the accepted packet. □

Theorem 1514.8 (ApartnessSpace scoped separated positive-gap route)**.** *Every accepted* ApartnessSpace$^{\uparrow}$ *consumer that exports separated-metric nonidentification must first display the* LocatedApartness$^{\uparrow}$ *source row, the* DyadicRatCore$^{\uparrow}$ *positive-gap ledger, the classifier-exclusion row, and the* SeparatedMetric$^{\uparrow}$ *boundary row before any separation conclusion is read. The route is the one named by Definition 1514.1, Definition 1514.2, Definition 1514.4, Definition 1514.5, and Definition 1514.7; it does not export trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1514.1. A separated nonidentification read has access only to the displayed carried object, the located-apartness source row L, the positive-gap row G, the separated-metric boundary row C_1, and the transport and replay rows already listed in the carrier.

Use Definition 1514.4 to force any positive separation claim through the $\mathsf{LocatedApartness}^{\uparrow}$ source row and the $\mathsf{DyadicRatCore}^{\uparrow}$ positive-gap ledger. Then apply Definition 1514.5 to keep the same ledger under componentwise hsame transport.

The classifier surface is fixed by Definition 1514.2. It reads exclusion only after the positive-gap ledger has been displayed, and the zero-distance boundary can enter only through the $\mathsf{SeparatedMetric}^{\uparrow}$ row already present in the carrier.

Finally apply Definition 1514.7. Replay cannot create trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, because none of those objects is a carrier row. The separated conclusion is therefore consumed only through the displayed positive-gap and separated-metric route. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier scoped separated positive gap route`

Theorem 1514.9 (ApartnessSpace NameCert obligation package)**.** *The paper-side obligation surface for* $\mathsf{ApartnessSpace}^{\uparrow}$ *is the package consisting of carrier admission, positive-gap exactness, separated-metric boundary compatibility, classifier stability, transport, replay, provenance, and local naming:*

$$X, L, G, T, C_0, C_1, H, C, P, N,\ \mathsf{NameCert}_{\mathsf{ApartnessSpace}^{\uparrow}}.$$

This package records exactly the finite positive-gap classifier route of the chapter and does not export trichotomy, host inequality, quotient real equality, selected limits, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier namecert obligation package`

Proof. Carrier admission is supplied by Definition 1514.1. Positive-gap exactness is the route through Definition 1514.4 and Definition 1514.5.

The separated-metric boundary is supplied by Definition 1514.11, while classifier stability is supplied by Definition 1514.6. These results keep the positive route through C_0 and the zero-distance route through C_1 distinct.

Finally apply the transport-and-replay boundary above. The provenance row P and local naming row N name the same finite packet, so the obligation surface is exhausted by the displayed carrier fields and no excluded endpoint is available to a consumer. □

Theorem 1514.10 (ApartnessSpace zero-distance nonescape)**.** *Any zero-distance consumer of an accepted* $\mathsf{ApartnessSpace}^{\uparrow}$ *packet must pass through the displayed* C_1 *separated-metric boundary of Definition 1514.11. In particular, absence of a positive gap cannot be combined inside the packet with equality, quotient real equality, selected limits, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the packet through Definition 1514.1. The only zero-distance-facing row is C_1, and it is exposed as a boundary toward the separated-metric consumer, not as a host equality row.

Apply Definition 1514.11. That boundary separates the positive-gap route through C_0 from the zero-distance route through C_1 and keeps both routes inside the finite carrier.

Finally compare with the positive-gap route of Definition 1514.4. A missing positive gap is not a row of equality evidence, and the packet contains no quotient real equality, selected-limit, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness coordinate. The zero-distance consumer therefore cannot escape the displayed C_1 boundary. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier zero distance nonescape`

Theorem 1514.11 (ApartnessSpace separated-metric zero-distance boundary)**.** *Every* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{ApartnessSpace}^{\uparrow}$ *packet can use the packet only through the displayed boundary*

$$\mathsf{LocatedApartness}^{\uparrow},\ \mathsf{ApartnessSpace}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow}.$$

Concretely, a positive-gap row may yield classifier exclusion through C_0*, while a zero-distance reading may be passed to* $\mathsf{SeparatedMetric}^{\uparrow}$ *through* C_1*. The packet does not allow a consumer to combine the two directions into trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier inventory in Definition 1514.1 gives the full consumer surface. A positive-gap consumer reads L, G, and C_0; a zero-distance consumer reads C_1 and then passes to the separated-metric classifier boundary.

The hsame and Cont rows preserve this order under transport. They move finite observation rows and replay finite routes, but they do not add a decision row comparing every pair of observations.

Thus the separated-metric boundary is one-way data flow from the apartness packet to the metric classifier consumer. No quotient equality, host inequality, selected limit, compactness principle, or real-completeness theorem is a field of A, so no local NameCert obligation can export such data. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier separatedmetric zero distance boundary`

Theorem 1514.12 (ApartnessSpace mature route induction)**.** *Every public consumer of an accepted* $\mathsf{ApartnessSpace}^{\uparrow}$ *packet*

$$A = (X, L, G, T, C_0, C_1, H, C, P, N)$$

is handled by induction over the displayed consumer route. Positive-gap consumers factor through L, G, C_0*; zero-distance consumers factor through* C_1 *and the* $\mathsf{SeparatedMetric}^{\uparrow}$ *boundary; transport and replay consumers factor through* H, C*; provenance and naming consumers factor through* P, N*. These are the only consumer cases supplied by the packet, and none of them exports trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the consumer route exposed by Definition 1514.1. The carrier rows split the public reads into positive-gap, zero-distance, transport/replay, and provenance/name cases.

1. In the positive-gap case, apply Definition 1514.4. The read begins at the $\mathsf{LocatedApartness}^{\uparrow}$ source row L, displays the positive $\mathsf{DyadicRatCore}^{\uparrow}$ gap row G, and reaches classifier exclusion only through C_0.

2. In the transported positive-gap case, apply Definition 1514.5 and Definition 1514.8. These theorems keep the same L, G, C_0 spine under componentwise hsame transport and force separated-metric consumers to display the boundary row before a separation conclusion is read.

3. In the zero-distance case, apply Definition 1514.10 and Definition 1514.11. The consumer can only pass through C_1 toward $\mathsf{SeparatedMetric}^{\uparrow}$; it cannot turn absence of a positive gap into equality or a total comparison principle.

It remains to account for structural consumers. The rows H and C transport and replay only the displayed finite route, while P and N package and name that same route. Since no row of A contains trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, the induction exhausts the public consumer surface and refuses those endpoints. □

Lean4 ✓ `BEDC.Derived.ApartnessSpaceUp.ApartnessSpaceCarrier mature route induction`

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ApartnessSpace}^{\uparrow}$ packet is generated from a carried-object row, a $\mathsf{LocatedApartness}^{\uparrow}$ source row, one positive dyadic gap ledger, apartness transport, classifier-exclusion and separated-metric boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessSpace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1514.1, Definition 1514.2, Definition 1514.4, Definition 1514.8, Definition 1514.10, Definition 1514.11, and Definition 1514.12 close the carrier/classifier scope, located positive-gap route, scoped separated positive-gap route, zero-distance nonescape, separated-metric zero-distance boundary, and mature route induction as the bridge-facing surface for constructive apartness-space use.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, host inequality, selected limits, open-cover compactness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: No further theory-axis upgrade remains; Lean verification and bridge checking remain separate.

Chapter 1515

A Concrete Naming Certificate for $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley-style metric completion, the SequentiallyCompleteMe packet records the L10 sequence-completeness interface as finite Cauchy-sequence data over a displayed metric source. It sits between the metric carrier of chapter 57, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the limit-witness boundary of chapter 128, and the completion route of chapter 1506. The packet gives later real-completion consumers a traditional sequence-completeness bridge without quotienting Cauchy names, selecting representatives, using countable choice, invoking open-cover compactness, assuming ambient completeness, or asserting that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 1515.1 (SequentiallyCompleteMetric carrier)**.** *A* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, S, M, L, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, including the admitted point classifier, distance witness surface, and finite metric observation histories.*
2. *S is the regular Cauchy sequence row, read through* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readbacks over the same metric source.*
3. *M is the displayed modulus row assigning each positive tolerance request a finite late-index threshold.*
4. *L is the displayed limit row, carried as an admitted point history of X before any completion-facing consumer can read it.*
5. *D is the distance-bound ledger whose rows display, for every requested tolerance and every sufficiently late sequence window, the metric-distance witness from the sequence value to L and the rational comparison below that tolerance.*
6. *H records componentwise* hsame *transport for the metric source, Cauchy-sequence rows, modulus, displayed limit, distance-bound ledger, replay row, provenance row, and local naming row.*
7. *C records the displayed* Cont *replay from source metric admission to stream-window reads, regular rational readbacks, modulus thresholds, late-distance bounds, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness handoff.*

8. *P is the* Pkg *provenance over* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricUp`

Theorem 1515.2 (SequentiallyCompleteMetric NameCert obligations)**.** *For an accepted* SequentiallyCompleteMetr *carrier $Q = (X, S, M, L, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed metric source, regular Cauchy sequence row, modulus, displayed limit, late-distance ledger, componentwise transport, continuation replay, provenance, and local naming;*

2. *classifier stability, requiring any accepted replacement of Q to transport X, S, M, L, D componentwise by H before the local classifier identifies the two packets;*

3. *sequence convergence, requiring each tolerance request to read a threshold from M and then a late-distance row from D witnessing convergence of the displayed sequence S to the displayed limit L inside X;*

4. $\mathsf{CompleteMetric}^{\uparrow}$ *handoff, requiring the same rows S, M, L, D to supply the limit-witness surface consumed by chapter 128;*

5. *ledger non-escape, stating that no quotient completion, selected representative, countable-choice schedule, open-cover compactness principle, ambient-completeness witness, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricPacket semantic name certificate`

Proof. Carrier admission is projection from Definition 1515.1. The tuple exposes the metric source, sequence row, modulus, limit row, distance-bound ledger, transport, replay, provenance, and local name as visible rows.

Classifier stability is componentwise. A comparison of two accepted packets first transports the metric source, stream windows, regular rational readbacks, modulus thresholds, displayed limits, and distance-bound rows by H; only after that transport can the local classifier identify the two packets.

Sequence convergence is the content of M and D. For each tolerance request, the modulus row supplies a late threshold, and the distance-bound ledger supplies the metric-distance witness from every displayed late sequence value to L together with the rational comparison below the requested tolerance.

The complete-metric handoff consumes the same convergence rows rather than a second completion object. The replay row C presents S, M, L, D to the $\mathsf{CompleteMetric}^{\uparrow}$ limit-witness boundary, while P and N record that the route is sourced and named by the same finite packet.

The rows of Q are exhausted by this route. Since none of them stores quotient equality, a selected representative, a countable-choice schedule, an open-cover compactness principle, an ambient complete space, or a $\mathsf{Real}^{\uparrow}$ completeness theorem, the ledger non-escape clause follows. □

Theorem 1515.3 (SequentiallyCompleteMetric complete-metric handoff)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. If the source metric X, the stream rows S, the modulus row M, the displayed limit L, and all late-distance bounds D are displayed, then Q supplies the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness surface for that regular Cauchy sequence over X.*

The handoff is the finite route

$$X \longmapsto S \longmapsto M \longmapsto L \longmapsto D \longmapsto H, C, P, N.$$

It exports sequence completeness only as a displayed limit-witness packet for the given regular Cauchy data, not as quotient completion, representative selection, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompleteMetricHandoff`

Proof. Start with the accepted carrier and project the metric source X. The point classifier and metric-distance witnesses used by the handoff are read from this source row, so the limit-witness surface is over the same metric carrier.

Next read the sequence and modulus rows. The row S supplies the finite stream windows and regular rational readbacks of the Cauchy sequence, while M supplies the threshold requested by each tolerance.

Now read the proposed limit and late-distance ledger. The row L is already an admitted point history of X, and D records the metric-distance witness from each sufficiently late displayed sequence value to L together with the required rational comparison.

Finally replay the route through C and attach H, P, N. These rows transport, source, and name exactly the data required by the $\mathsf{CompleteMetric}^{\uparrow}$ limit-witness boundary of Definition 128.2. Because the route has no further coordinate, the handoff cannot export quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.4 (SequentiallyCompleteMetric classifier transport)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ and $Q' = (X', S', M', L', D', H', C', P', N')$ be accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carriers. If the transport rows identify X with X', S with S', M with M', L with L', D with D', C with C', P with P', and N with N' componentwise by* hsame*, then the sequence-completeness read exposed by Q is the same read exposed by Q'. The comparison is made only through the displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, modulus, distance-ledger, replay, provenance, and local naming rows.*

Proof. Project the carrier definition for both packets. The local classifier has no coordinate beyond $X, S, M, L, D, H, C, P, N$, so a comparison can inspect only those rows.

Use the transport row componentwise. The source metric, stream windows, rational readbacks, modulus thresholds, displayed limit, and late-distance ledger are carried by hsame before any convergence read is compared.

The replay and provenance rows preserve the same route to the $\mathsf{CompleteMetric}^{\uparrow}$ handoff. Since no quotient completion, representative-selection, choice, open-cover, ambient-completeness, or $\mathsf{Real}^{\uparrow}$ completeness coordinate is present, the transported classifier read is exactly the same sequence-completeness surface. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricClassifierTransport`

Theorem 1515.5 (SequentiallyCompleteMetric Cauchy-sequence obligation)**.** *Every accepted* $\mathsf{SequentiallyComplete}$ *packet $Q = (X, S, M, L, D, H, C, P, N)$ must display the* $\mathsf{Met}^{\uparrow}$ *source X, the* $\mathsf{StreamName}^{\uparrow}$ *windows*

in S, the RegSeqRat$^{\uparrow}$ *readback of those windows, and the modulus threshold row M before any sequence-completeness read can be consumed. The read then reaches the displayed limit row L and late-distance ledger D only through the same* BHist, hsame, Cont, Pkg, *and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCauchySequenceObligation`

Proof. Project the carrier definition for Q. The sequence row S is meaningful only over the displayed metric source X, and its finite windows are the only sequence observations present in the packet.

Read the rational and threshold rows next. The RegSeqRat$^{\uparrow}$ readback attached to S supplies the rational window data, while M supplies the late threshold requested by the sequence-completeness consumer.

Only after those rows are displayed can the consumer read L and D. The rows H, C, P, N transport, replay, source, and name this same route, so no sequence-completeness read bypasses the metric source, stream windows, rational readback, or modulus threshold. □

Theorem 1515.6 (SequentiallyCompleteMetric limit-stability obligation)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ and $Q' = (X', S', M', L', D', H', C', P', N')$ be accepted* SequentiallyCompleteMetric$^{\uparrow}$ *packets. If the displayed transport identifies X, S, M, L, D, C, P, N with $X', S', M', L', D', C', P', N'$ componentwise by* hsame*, then the limit read exposed by Q is the same limit read exposed by Q'. In particular,* hsame *transport preserves the displayed limit row and the late-distance ledger before any* CompleteMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer can compare the packets.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitStabilityObligation`

Proof. Start with the classifier-transport theorem. It confines comparison of accepted packets to the displayed metric source, stream-window, regular-readback, modulus, distance-ledger, replay, provenance, and local naming rows.

Use the componentwise transport hypotheses. The displayed limit rows L and L' are compared only after the common metric source, sequence windows, and modulus thresholds have been transported, and the late-distance ledgers D and D' carry the corresponding distance comparisons.

Replay through C, P, N and C', P', N'. Since neither carrier contains a quotient-completion equality, selected representative, ambient completeness witness, or independent completed carrier, the transported limit read is exactly the same finite limit-stability surface. □

Theorem 1515.7 (SequentiallyCompleteMetric separated uniqueness boundary)**.** *For an accepted* SequentiallyCompleteMetric$^{\uparrow}$ *carrier $Q = (X, S, M, L, D, H, C, P, N)$, separated uniqueness is only a boundary condition on displayed limit reads. Any uniqueness consumer must first read the* Met$^{\uparrow}$ *classifier in X, the common* StreamName$^{\uparrow}$ *windows and* RegSeqRat$^{\uparrow}$ *readback of S, the modulus row M, the displayed limit row L, and the late-distance ledger D. The packet exports neither quotient completion nor completeness of* Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSeparatedUniquenessBoundary`

Proof. Project the rows of Q. The source metric classifier in X is the only equality-facing surface available to a separated uniqueness consumer, and the sequence data are displayed only through S and its regular rational readback.

Read the convergence rows. The modulus row M supplies the late threshold, while L and D provide the displayed limit and the finite distance comparisons used at the separation boundary.

The structural rows H, C, P, N preserve this finite route without adding a completed quotient carrier or a real-completeness theorem. Therefore separated uniqueness can be consumed only as a boundary condition on the displayed rows, not as quotient completion or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.8 (SequentiallyCompleteMetric late-bound coverage)**.** *Every tolerance request made to an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$ *factors first through the modulus row* M *and then through the distance-bound ledger* D *before any* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff is available. Thus a completion-facing consumer receives late convergence data only as a displayed threshold and a displayed metric-distance comparison inside* X*.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLateBoundCoverage`

Proof. Begin with a tolerance request. The carrier definition stores tolerance handling in M, so the request first reads a finite late-index threshold rather than a chosen subsequence or a countable schedule.

Next read the distance-bound ledger. The row D records the metric-distance witness from each sufficiently late displayed sequence value in S to the displayed limit L, together with the rational comparison below the requested tolerance.

Only after those rows are exposed can the route replay through C toward Definition 1515.3. The handoff therefore consumes M and D as late-bound evidence and cannot bypass them through quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.9 (SequentiallyCompleteMetric finite-modulus induction coverage)**.** *Let* $Q = (X, S, M, L, D, H, C, P, N)$ *be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier, and let* ρ *be a finite late-distance request history addressed to the completion-facing read of* Q*. Every accepted late-distance read in* ρ *factors by induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows in* S *and the modulus row* M*: the base read inspects the first admitted window, the successor read advances only through the displayed threshold selected by* M *and the corresponding distance-bound entry in* D*, and the resulting read is replayed through* H, C, P, N *before any* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer may use it. The route introduces no quotient completion, representative selection, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or independent completed carrier.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricFiniteModulusInductionCover`

Proof. Project the carrier rows. The Cauchy-sequence obligation of Definition 1515.5 exposes only the source metric X, the displayed stream windows S, the regular rational readback, the modulus row M, the displayed limit L, and the late-distance ledger D before a completion-facing read is available.

Induct on the finite displayed request history ρ. In the base case, the first accepted read has only the first admitted $\mathsf{StreamName}^{\uparrow}$ window and the carrier rows projected above. Thus it is already routed through S and M before any distance comparison can be consumed.

For the successor step, apply the induction hypothesis to the earlier displayed windows. The next request can advance only by reading the threshold supplied by M and then the matching distance-bound entry in D; this is exactly the late-bound coverage route of Definition 1515.8. Replay through H, C, P, N preserves the same finite route for the $\mathsf{CompleteMetric}^{\uparrow}$ handoff.

Finally apply the nonescape boundary of Definition 1515.10. Since the carrier contains no coordinate for quotient completion, representative selection, countable choice, open-cover compactness, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, or an independent completed carrier, the induction covers only the displayed finite modulus route. □

Theorem 1515.10 (SequentiallyCompleteMetric ledger nonescape)**.** *For every accepted* SequentiallyCompleteMetri *carrier* $Q = (X, S, M, L, D, H, C, P, N)$*, the local ledger cannot export quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or any assertion that* $\mathsf{Real}^{\uparrow}$ *is complete. Any consumer asking for those claims is returned to the displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, modulus, late-bound, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLedgerNonescape`

Proof. Inspect the tuple Q. Its rows name a metric source, regular Cauchy sequence data, a modulus, a displayed limit, a late-distance ledger, transport, replay, provenance, and a local NameCert row.

Apply the NameCert obligation theorem. Its ledger non-escape clause states that the local surface contains no row for quotient equality, representative selection, countable-choice schedules, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

The complete-metric handoff adds no extra coordinate. It only exposes the same displayed convergence route to $\mathsf{CompleteMetric}^{\uparrow}$, so every forbidden request remains outside the carrier and outside the consumer-facing handoff. □

Theorem 1515.11 (SequentiallyCompleteMetric root limit witness)**.** *Let* $Q = (X, S, M, L, D, H, C, P, N)$ *be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. The root limit witness exported by* Q *is exactly the displayed limit row* L *together with the late-distance ledger* D *over the* $\mathsf{Met}^{\uparrow}$ *source* X*, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of* S*, the modulus row* M*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The witness is finite carrier data and does not assert that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootLimitWitness`

Proof. Project the carrier Q. The only limit coordinate is L, and it is admitted as a point history of the source metric X before any completion-facing handoff can inspect it.

The ledger D attaches L to the stream and rational readback rows. For each displayed tolerance request, M gives the late threshold, while S and its $\mathsf{RegSeqRat}^{\uparrow}$ reads provide the finite sequence windows whose distances to L are recorded in D.

The rows H, C, P, N transport, replay, source, and name the same finite limit witness. Since no row of Q stores ambient real completeness or a completed real carrier, the root witness remains a displayed sequence-completeness packet over X. □

Theorem 1515.12 (SequentiallyCompleteMetric root modulus coverage)**.** *For every accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$*, each root tolerance request is covered by the modulus row* M *before the late-distance ledger* D *can be consumed. The coverage factors through the* $\mathsf{Met}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff,* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer boundary,* BHist *rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootModulusCoverage`

Proof. Start with a tolerance request at the root sequence-completeness interface. The carrier places all threshold data in M, so the request first reads the displayed modulus rather than a host choice function or an infinite schedule.

After the threshold is displayed, S supplies the finite stream windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback, and D supplies the metric-distance comparison from the corresponding late values to L inside X. Thus the late-bound coverage is a finite BHist route.

The replay row C exposes this same coverage to the $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ boundaries, while H, P, N preserve the route under transport, provenance, and naming. No step requires or exports $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.13 (SequentiallyCompleteMetric source-first tail read)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Every accepted tail-read packet that is later consumed as a displayed limit read must expose the* $\mathsf{Met}^{\uparrow}$ *source row X, the* $\mathsf{StreamName}^{\uparrow}$ *windows in S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to those windows, and the modulus row M before any displayed limit row L or late-distance ledger D is read. Thus a completion-facing tail read is source-first: it cannot begin from a free-standing limit, a quotient-completion class, or a selected representative.*

Proof. Project the carrier of Definition 1515.1. The only metric source is X, the only sequence observations are the windows in S, and the regular rational readback attached to those observations is part of the same finite sequence row.

Apply root modulus coverage from Definition 1515.12. A tolerance request cannot inspect late-distance data until the modulus row M has supplied its displayed threshold, so the tail read already contains X, S and the $\mathsf{RegSeqRat}^{\uparrow}$ readback before D is available.

Now use root nonescape from Definition 1515.21 and the complete-metric handoff of Definition 1515.3. The handoff sends the same source-first rows to the $\mathsf{CompleteMetric}^{\uparrow}$ boundary, and the nonescape clause blocks any route that would start from a quotient class, representative selector, or independent limit row. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSourceFirstTailRead`

Theorem 1515.14 (SequentiallyCompleteMetric tail induction)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Any finite induction over completion-facing tails of the displayed sequence must keep the* $\mathsf{Met}^{\uparrow}$ *source X, the* $\mathsf{StreamName}^{\uparrow}$ *tail windows in S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of those windows, the modulus row M, the displayed limit row L, and the late-distance ledger D on the same route. The base tail reads X, S, M before L, D, and each successor tail may extend only the displayed window and late-distance rows before replay through H, C, P, N.*

Proof. Use the source-first tail read. The base tail cannot enter through L or D alone, so it first exposes the metric source, StreamName windows, regular rational readback, and modulus row.

For the successor tail, append one displayed window request to S. The regular rational readback remains the handoff from the window to the tolerance ledger, and the modulus row still supplies the threshold before the new late-distance entry in D is visible.

Project the carrier rows H, C, P, N at the end of the induction step. They transport, replay, source, and name the same finite route, so tail induction cannot introduce quotient completion, selected representatives, countable choice, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricTailInduction`

Theorem 1515.15 (SequentiallyCompleteMetric limit ledger coverage)**.** *For an accepted* SequentiallyCompleteMetr *carrier $Q = (X, S, M, L, D, H, C, P, N)$, every tolerance request that reaches the displayed limit ledger must first read the modulus row M and the late-distance ledger D over the* $\mathsf{Met}^{\uparrow}$ *source X and the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *sequence rows. Only after this coverage is displayed may the request be handed to* $\mathsf{CompleteMetric}^{\uparrow}$*; no tolerance request reaches that handoff through an unrecorded limit, quotient-completion class, selected representative, or host Cauchy schedule.*

Proof. Start from root modulus coverage. It requires each tolerance request to obtain its threshold from M before any late-distance comparison is consumed.

Apply the source-first tail read and tail induction. Together they keep the sequence windows and regular rational readback upstream of the late-distance ledger for the base tail and for every successor tail.

Finally use the complete-metric handoff. The $\mathsf{CompleteMetric}^{\uparrow}$ boundary receives only the already covered route $X, S, M, L, D, H, C, P, N$, so the handoff has no separate entry for unrecorded limits, quotient classes, selected representatives, host schedules, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitLedgerCoverage`

Theorem 1515.16 (SequentiallyCompleteMetric completion-consumer route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier receives only the displayed sequence-completeness packet*

$$X, S, M, L, D, H, C, P, N.$$

The consumer must read the source-first tail route, the tail-induction route, and the limit-ledger coverage route before it can use the $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It receives no second completion carrier, quotient equality, selected representative, countable-choice schedule, ambient complete space, or proof that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionConsumerRoute`

Proof. Begin with the source-first tail route. It confines every completion-facing read to the metric source, sequence windows, regular rational readback, and modulus row before limit data are inspected.

Next use tail induction and limit-ledger coverage. These results ensure that finite tail refinement and every tolerance request keep the late-distance ledger attached to the same displayed carrier rows.

Apply the complete-metric handoff and root nonescape. The handoff exposes the packet to $\mathsf{CompleteMetric}^{\uparrow}$, while nonescape refuses all coordinates for an independent completion carrier, quotient equality, representative selection, countable choice, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. The $\mathsf{MetricCompletion}^{\uparrow}$ consumer therefore receives exactly the displayed packet. □

Theorem 1515.17 (SequentiallyCompleteMetric displayed-limit uniqueness)**.** *Let* $Q = (X, S, M, L, D, H, C, P, N)$ *be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. If two displayed limit reads for the same* BHist *source pass through the same* $\mathsf{Met}^{\uparrow}$ *row* X*,* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *sequence row* S*, modulus row* M*, late-distance ledger* D*, componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *row* P*, and local* $\mathsf{NameCert}$ *row* N*, then the uniqueness route is confined to the displayed limit row* L *and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It cannot compare limits through quotient completion, selected representatives, countable choice, or a hidden ambient complete metric.*

Proof. Project the carrier and keep both limit reads inside the same packet Q. The source metric, stream windows, regular rational readback, modulus, late-distance ledger, transport, replay, package provenance, and local naming rows are shared before any uniqueness comparison is made.

Apply the completion-consumer route. It forces every completion-facing read to pass through the displayed $\mathsf{Met}^{\uparrow}/\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{CompleteMetric}^{\uparrow}$ route and refuses an independent completion carrier.

The comparison therefore has only the displayed limit row L and the late-distance ledger D available. The structural rows H, C, P, N preserve that route, so uniqueness is a displayed-limit claim rather than an equality imported from an ambient completion. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricDisplayedLimitUniqueness`

Theorem 1515.18 (SequentiallyCompleteMetric Cauchy tail stability)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. Any cofinal tail replacement of the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *sequence row S that preserves the displayed* BHist *source X, the modulus row M, the late-distance ledger D, componentwise* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N remains on the same* $\mathsf{Met}^{\uparrow}$ *to* $\mathsf{CompleteMetric}^{\uparrow}$ *route. The replacement may refine tail windows, but it may not introduce a second limit carrier, quotient-completion equality, selected representative, or* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCauchyTailStability`

Proof. Read the tail replacement as a finite refinement of S. The regular rational readback remains attached to the same $\mathsf{Met}^{\uparrow}$ source X, and the modulus row M still supplies the displayed thresholds for the late-distance ledger D.

Use the tail-induction and completion-consumer routes. Tail induction keeps the refined windows in the same carrier, while the completion-consumer theorem admits downstream reads only after the displayed route through $X, S, M, L, D, H, C, P, N$ is visible.

Transport and replay through H, C, P, N preserve the packet after the tail refinement. Hence the cofinal tail stays on the $\mathsf{Met}^{\uparrow}/\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{CompleteMetric}^{\uparrow}$ path and cannot export an external completion object or ambient real completeness. □

Theorem 1515.19 (SequentiallyCompleteMetric completion-boundary refusal)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. A completion-boundary consumer that does not display the* BHist *source X, the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *sequence row S, the modulus row M, the displayed limit row L, the late-distance ledger D, componentwise* hsame *row H,* Cont *replay row C,* Pkg *row P, and local* NameCert *row N is refused by the* $\mathsf{Met}^{\uparrow}$ *to* $\mathsf{CompleteMetric}^{\uparrow}$ *route. The boundary exports no Real completeness theorem, countable-choice schedule, quotient completion, selected representative, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionBoundaryRefusal`

Proof. Start from root nonescape. A root-facing consumer is confined to the displayed metric, sequence, completion, history, transport, replay, package, and naming rows of Q.

Apply the completion-consumer route. The $\mathsf{CompleteMetric}^{\uparrow}$ handoff is available only after the source-first tail route, tail induction route, and limit-ledger coverage route have all been displayed.

If any row of $X, S, M, L, D, H, C, P, N$ is absent, the consumer no longer has the packet required by the handoff. The boundary therefore refuses the request rather than supplying Real completeness, countable choice, quotient completion, selected representatives, or open-cover compactness. □

Theorem 1515.20 (SequentiallyCompleteMetric limit ledger nonescape)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. The limit ledger formed by L, D, H, C, P, N cannot export quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or any assertion that* $\mathsf{Real}^{\uparrow}$ *is complete. Every such request is returned to the carrier rows of Definition 1515.1, the source-first read of Definition 1515.13, the root nonescape boundary of Definition 1515.21, and the complete-metric handoff of Definition 1515.3.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitLedgerNonescape`

Proof. Read the ledger coordinates. The displayed limit row L is an admitted point history of the metric source, while D records late-distance comparisons from the sequence windows to that point; the remaining rows H, C, P, N only transport, replay, source, and name the same packet.

Use the source-first tail-read theorem. It forces every completion-facing read of L and D to pass through X, S with its $\mathsf{RegSeqRat}^{\uparrow}$ readback and through the modulus row M before the limit ledger is consumed.

Apply root nonescape and the complete-metric handoff. Those two results identify the downstream completion read with the same finite rows and refuse all coordinates for quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.21 (SequentiallyCompleteMetric root nonescape)**.** *Every root-facing consumer of an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$ *is confined to the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of* Q*. In particular, the root route cannot escape to quotient completion equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootNonescape`

Proof. Inspect the root route exposed by the carrier. A consumer can read the metric source X, the stream row S, the modulus M, the displayed limit L, the late-distance ledger D, and the structural rows H, C, P, N.

Apply the complete-metric handoff and late-bound coverage theorems. They show that completion-facing reads pass through the same finite modulus and distance-ledger rows before reaching the $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ boundary.

There is no coordinate in Q for quotient completion equality, selected representatives, choice schedules, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. Hence every root-facing request for those claims remains outside the local NameCert surface. □

Theorem 1515.22 (SequentiallyCompleteMetric Real refusal boundary)**.** *An accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$ *supplies a displayed limit witness for a regular Cauchy sequence over its metric source* X*, but it cannot be consumed as completeness of* $\mathsf{Real}^{\uparrow}$ *or as ambient metric completeness unless an additional Real-specific completion carrier is displayed. The available route is the finite sequence-completeness surface through* $X, S, M, L, D, H, C, P, N$ *and not a global completeness theorem.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRealRefusalBoundary`

Proof. Start with the local NameCert obligations of Definition 1515.2. They admit the metric source, regular Cauchy sequence row, modulus, displayed limit, late-distance ledger, transport, replay, provenance, and local naming rows, and their ledger non-escape clause refuses ambient completeness and $\mathsf{Real}^{\uparrow}$ completeness.

Apply the complete-metric handoff of Definition 1515.3. It sends the same rows X, S, M, L, D to the $\mathsf{CompleteMetric}^{\uparrow}$ limit-witness surface for that sequence, without creating an independent complete carrier or Real-specific completion row.

Apply the root limit witness and root nonescape theorems. The witness is exactly the displayed limit row L with late-distance data over X, while every root-facing consumer remains confined to

$\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Consequently the carrier supplies sequence completeness only for the displayed Cauchy data. A consumer that asks for completeness of $\mathsf{Real}^{\uparrow}$ or ambient metric completeness must display a separate Real-specific completion carrier; it cannot obtain that claim from Q. □

Theorem 1515.23 (SequentiallyCompleteMetric root Cauchy limit existence)**.** *Let $Q = (X, S, M, L, D, H, C, P, N$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Any root consumer asserting Cauchy limit existence for the displayed sequence must obtain the claim by reading the* $\mathsf{Met}^{\uparrow}$ *source X, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in S, the modulus row M, the displayed limit row L, and the late-distance ledger D through the same* BHist, hsame, Cont, Pkg, *and* NameCert *route. The existence read may then be handed to* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *consumers, but it refuses quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, and completeness of* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootCauchyLimitExistence`

Proof. Project the tuple Q. The only available source for a limit-existence read is the displayed metric row X together with the sequence, modulus, limit, and late-distance rows S, M, L, D.

Read the Cauchy data before the limit. The stream windows and regular rational readback in S expose the observed sequence, while M supplies the threshold demanded by a tolerance request.

Now read L and D. The displayed limit row gives the candidate point inside X, and the late-distance ledger records the finite convergence comparison needed by the root consumer.

Finally replay the same rows through H, C, P, N. This makes the handoff visible to $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ without adding any quotient class, chosen representative, choice schedule, open-cover compactness object, ambient complete carrier, or $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Theorem 1515.24 (SequentiallyCompleteMetric root modulus-limit factorization)**.** *For an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier $Q = (X, S, M, L, D, H, C, P, N)$, every root read that combines a modulus with a displayed limit factors through*

$$X, S, M \longmapsto L, D \longmapsto H, C, P, N.$$

The factorization first fixes the $\mathsf{Met}^{\uparrow}$ *source, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *sequence row, and the modulus threshold row; only then may a consumer compare the displayed limit through the late-distance ledger and replay the result through* BHist, hsame, Cont, Pkg, *and* NameCert. *The factorization exports no quotient completion, selected representative, countable-choice schedule, open-cover compactness principle, ambient completeness row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with a modulus-limit request. The carrier places metric admission in X, sequence observations in S, and threshold data in M, so these rows form the first stage of the read.

The displayed limit cannot be inspected earlier. It is meaningful only after the metric source and Cauchy tail threshold have been fixed, because the ledger D compares late sequence values with L inside X.

The structural rows then preserve the factorization. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming all act on the same rows rather than constructing a second completion object.

Since the route has no coordinate for quotient equality, representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, each such request remains outside the root factorization. □

Lean4 ✓ BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootModulusLimitFactorizati

Theorem 1515.25 (SequentiallyCompleteMetric root completion consumer interface)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet* $Q = (X, S, M, L, D, H, C, P, N)$ *is confined to the displayed interface*

$$\mathsf{Met}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

as instantiated by the rows of Q*. The consumer may read sequence-completeness evidence only through* $X, S, M, L, D, H, C, P, N$*, and must refuse quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, and completeness of* $\mathsf{Real}^{\uparrow}$ *unless a separate carrier displays those data.*

Proof. Start with a completion-facing consumer. The carrier inventory exposes exactly the metric source, sequence row, modulus, displayed limit, late-distance ledger, transport, replay, provenance, and local name.

Apply the root Cauchy limit existence theorem. It forces the consumer to read X, S, M, L, D before any limit-existence handoff is visible.

Apply the root modulus-limit factorization. It keeps the threshold and limit comparison in the displayed order, so the completion consumer receives a finite sequence-completeness surface rather than a detached completed object.

The remaining rows H, C, P, N merely transport, replay, source, and name that interface. Therefore every request for quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness is refused unless supplied by another displayed carrier. □

Lean4 ✓ BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRootCompletionConsumerInter

Theorem 1515.26 (SequentiallyCompleteMetric regular Cauchy limit coverage)**.** *Let* $Q = (X, S, M, L, D, H, C, P,$ *be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Every regular Cauchy limit read exposed at the root must display the* $\mathsf{Met}^{\uparrow}$ *source row* X*, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in* S*, the modulus row* M*, the displayed limit row* L*, the late-distance ledger* D*, the ambient* BHist *packet, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N *before any* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer may use the read. The coverage refuses quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, and completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRegularCauchyLimitCoverage

Proof. Project the carrier. The source metric and sequence data are exactly X and S, with the regular rational readback attached to the displayed $\mathsf{StreamName}^{\uparrow}$ windows.

Read the convergence rows next. The modulus M supplies the late threshold, while L and D provide the displayed limit and the metric-distance comparisons used by the root consumer.

Finally replay through H, C, P, N. These rows keep the same finite BHist route available to $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ consumers, and no carrier coordinate supplies quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1515.27 (SequentiallyCompleteMetric limit ledger stability)**.** *For accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packets* $Q = (X, S, M, L, D, H, C, P, N)$ *and* $Q' = (X', S', M', L', D', H', C', P', N')$*, any comparison of their limit ledgers must transport the* $\mathsf{Met}^{\uparrow}$ *source rows,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$

sequence rows, modulus rows, displayed limits, late-distance ledgers, BHist *histories,* Cont *replay rows,* Pkg *provenance rows, and local* NameCert *rows componentwise by* hsame*. The resulting* CompleteMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *read is stable only through those displayed rows and refuses quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, and completeness of* Real$^{\uparrow}$*.*

Proof. Start with the two carrier inventories. Each packet exposes only its metric source, sequence row, modulus, displayed limit, late-distance ledger, transport, replay, provenance, and local name.

Use componentwise hsame transport before comparing limit ledgers. The metric source, finite stream windows, regular rational readback, thresholds, displayed limits, and late-distance rows must move together.

The replay and provenance rows then preserve the transported route for CompleteMetric$^{\uparrow}$ and MetricCompletion$^{\uparrow}$ consumers. Since neither packet contains quotient-completion equality, selected representatives, countable-choice schedules, open-cover compactness, ambient completeness, or Real$^{\uparrow}$ completeness, stability is confined to the displayed ledger rows. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitLedgerStability`

Theorem 1515.28 (SequentiallyCompleteMetric completion consumer nonescape)**.** *Every* CompleteMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer of an accepted* SequentiallyCompleteMetric$^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$ *must read the displayed* Met$^{\uparrow}$ *source* X*,* StreamName$^{\uparrow}$ *windows and* RegSeqRat$^{\uparrow}$ *readback* S*, modulus row* M*, limit row* L*, late-distance ledger* D*, finite* BHist *history,* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. No completion consumer can escape from that route to quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of* Real$^{\uparrow}$*.*

Proof. Inspect the completion-facing entry points of the carrier. The only rows available to a CompleteMetric$^{\uparrow}$ or MetricCompletion$^{\uparrow}$ consumer are $X, S, M, L, D, H, C, P, N$.

Apply regular Cauchy limit coverage. It forces the consumer to read the metric source, finite sequence windows, regular rational readback, modulus, limit, and late-distance data before using a limit claim.

Apply limit ledger stability for transported reads. The same rows remain the only stable comparison surface, so a consumer has no route to quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or Real$^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionConsumerNonescape`

Theorem 1515.29 (SequentiallyCompleteMetric Cauchy-filter bridge)**.** *Let* $Q = (X, S, M, L, D, H, C, P, N)$ *be an accepted* SequentiallyCompleteMetric$^{\uparrow}$ *carrier. Every Cauchy-filter consumer of* Q *must read the metric source row* X*, the finite sequence-window row* S*, the modulus row* M*, the displayed limit row* L*, and the late-distance ledger* D *before it can export a filter-facing convergence observation. The bridge is therefore the finite read*

$$X, S, M, L, D \longmapsto H, C, P, N$$

and not a host filter object, quotient completion equality, selected representative, or countable-choice schedule.

Proof. Project the carrier rows of Q. A Cauchy-filter consumer has no entry point except the displayed metric source, finite sequence windows, modulus, limit row, and late-distance ledger.

The late-bound route supplies the filter basis. The row M gives the threshold for each tolerance, while S and D display the late sequence windows and the metric comparisons to L inside X.

Replay the same rows through H, C, P, N. Since the carrier has no coordinate for a host filter, quotient completion equality, selected representative, or countable-choice schedule, the Cauchy-filter bridge consumes only the finite late-bound and limit rows already exposed by Q. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCauchyFilterBridge`

Theorem 1515.30 (SequentiallyCompleteMetric completion route)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer that reads sequence-completeness data from Q factors through the same displayed rows $X, S, M, L, D, H, C, P, N$ named by Definition 1515.21. In particular, the completion route consumes finite late thresholds and displayed limit evidence; it does not manufacture an independent completed carrier, quotient completion class, representative selector, countable-choice sequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start from a completion-facing request. The root non-escape theorem confines such a request to the metric source, stream-window, regular-readback, modulus, displayed-limit, late-ledger, replay, provenance, and local naming rows of Q.

Read the analytic rows in order. The metric source X fixes the distance surface, S supplies the finite sequence windows, M supplies the late threshold, and L, D supply the displayed limit and its distance ledger.

The structural rows H, C, P, N then present this finite surface to $\mathsf{MetricCompletion}^{\uparrow}$. Because the same carrier exposes no independent completed carrier, quotient class, selected representative, countable-choice sequence, or $\mathsf{Real}^{\uparrow}$ completeness theorem, the completion route is exactly the finite route above. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionRoute`

Theorem 1515.31 (SequentiallyCompleteMetric separated-limit uniqueness boundary)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Any separated-limit consumer comparing two displayed limits for the sequence row S must read the source classifier of X, the common finite windows S, the modulus row M, the displayed limit row L, and the late-distance ledger D before using uniqueness. Thus separated-limit uniqueness is bounded by the finite rows already exposed by Q and cannot be sourced from host point equality, quotient completion equality, selected representatives, or ambient completeness.*

Proof. Project the consumer-facing comparison through the carrier. The only source classifier available is the one displayed by X, and the only convergence evidence available is carried by S, M, L, D.

The common finite windows and modulus force both sides of the comparison to use the same late-bound route. The ledger D records the distance comparisons to the displayed limit row L inside the source metric, so separated-limit use is already bounded by the packet.

Transport and replay through H, C, P, N preserve that boundary. Since Q contains no host point equality, quotient completion equality, selected representative, or ambient completeness coordinate, no separated-limit consumer can bypass the finite rows named above. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitUniquenessBoundary`

Theorem 1515.32 (SequentiallyCompleteMetric limit-modulus induction)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier, and let ρ be any finite tolerance-request history addressed to the sequence-completeness surface of Q. Every initial segment of ρ factors through the displayed route*

$$M \longmapsto S \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto D \longmapsto L$$

inside the same BHist *packet before the* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary can read a limit claim. Thus each finite request path reaches the displayed limit row L only through the modulus row M, the stream-window row S, the regular rational readback of S, the late-distance ledger D, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitModulusInduction`

Proof. Project the carrier rows of Q. The tolerance interface has only the displayed modulus row M, the stream row S, the readback route through $\mathsf{RegSeqRat}^{\uparrow}$, the displayed limit L, and the late-distance ledger D available for convergence data.

Induct on the finite request history ρ. For the empty history, there is no consumer-facing limit read, so the factorization is the trivial carrier projection through M, S, L, D, H, C, P, N.

For the successor history, apply the induction hypothesis to the preceding requests. The next tolerance is replayed through Cont by first reading a threshold from M, then reading the corresponding stream windows from S and their regular rational data, and then reading the late-distance row in D which compares the displayed sequence values to L inside X.

The rows H, P, N transport, source, and name exactly this replay. Since the carrier exposes no quotient equality, selected representative, choice schedule, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, every finite request path remains inside BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data. □

Theorem 1515.33 (SequentiallyCompleteMetric completion-consumer factorization)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet $Q = (X, S, M, L, D, H, C, P, N)$ factors through the same visible surface S, M, L, D, H, C, P, N together with the source metric row X. In particular, the consumer reads sequence completeness only as finite stream windows, regular rational readback, a displayed modulus, a displayed limit, late-distance bounds, componentwise transport, continuation replay, provenance, and local naming; it cannot read quotient-completion equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or an independent complete carrier.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionConsumerFactoriza`

Proof. Start from a completion-facing request. The carrier definition gives the consumer no entry point except the named rows $X, S, M, L, D, H, C, P, N$.

The $\mathsf{CompleteMetric}^{\uparrow}$ handoff reads S, M, L, D as its limit-witness surface over X. The $\mathsf{MetricCompletion}^{\uparrow}$ boundary receives the same route through C, with H preserving componentwise transport and P, N preserving provenance and local naming.

No second surface is present. Since quotient completion, representative selection, countable-choice schedules, open-cover compactness, ambient completeness, and independent completed carriers are absent from Q, every completion consumer factors through the displayed finite route. □

Theorem 1515.34 (SequentiallyCompleteMetric choice-free uniqueness boundary)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ and $Q' = (X, S, M, L', D', H', C', P', N')$ be accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$

packets with the same displayed source metric row X, stream row S, and modulus row M. If D and D' satisfy the same late-distance requests under the same classifier rows, then any consumer-facing comparison between the displayed limits L and L' is identified only through the source $\mathsf{Met}^{\uparrow}$ *classifier and the transported sequence-completeness rows. It is not identified by host equality, selected representatives, quotient completion, or choice of a preferred limit name.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricChoiceFreeUniquenessBoundar`

Proof. Project both packets. Their shared source, stream, and modulus rows force every convergence comparison to begin with the same $\mathsf{Met}^{\uparrow}$ classifier, the same $\mathsf{StreamName}^{\uparrow}$ windows, and the same $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the hypothesis on the late-distance ledgers. For each displayed tolerance request, D and D' provide the same kind of late comparison from the same sequence row to the displayed limit rows L and L' inside the source metric classifier.

The comparison is then transported only by the visible hsame rows and replayed only by Cont. Because neither packet contains host equality of points, selected representatives, quotient-completion equality, or a choice operator choosing one limit name, the consumer-facing uniqueness boundary is exactly the source metric classifier together with the displayed finite convergence rows. □

Theorem 1515.35 (SequentiallyCompleteMetric separation obligations)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier, and let ρ be a finite* BHist *request history addressed to a separation comparison at the completion boundary. Before the comparison can be consumed, the request must display the source* $\mathsf{Met}^{\uparrow}$ *classifier in X, the* $\mathsf{StreamName}^{\uparrow}$ *windows in S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of those windows, the late-distance ledger D, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff, the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. No separation read may be sourced from quotient-completion equality, selected representatives, host equality of points, or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSeparationObligations`

Proof. Start with the complete-metric handoff and late-bound coverage routes already displayed for Q. They force any completion-facing comparison to read the source metric classifier, stream windows, regular readback, displayed modulus, and late-distance bounds before a limit comparison is available.

Next apply the ledger nonescape theorem. It excludes quotient-completion equality, selected representatives, host equality, and ambient completeness from the carrier coordinates, so a separation request has no alternate source.

Finally replay the comparison through H, C, P, N. These rows transport, continue, source, and name the same finite BHist history, so the separation obligation surface is exactly the visible packet rows. □

Theorem 1515.36 (SequentiallyCompleteMetric tail stability)**.** *For an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier $Q = (X, S, M, L, D, H, C, P, N)$, every finite tail replacement of a request history that preserves the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and late-distance entries in D preserves the completion-facing limit route through* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$*. The preserved route remains transported by* hsame*, replayed by* Cont*, sourced by* Pkg*, and named by* NameCert *inside the same carrier.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricTailStability`

Proof. Use limit-modulus induction on the finite request history. The base case is the empty tail, where the visible carrier rows are unchanged.

For a successor tail, the preserved $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback give the same displayed tolerance data. The late-distance ledger D then supplies the same comparison from the sequence row to L inside the source metric classifier.

The complete-metric handoff and completion-consumer factorization identify the downstream read with the same displayed route. The rows H, C, P, N preserve the transported, replayed, sourced, and named packet, so tail replacement does not create a new completion surface. □

Theorem 1515.37 (SequentiallyCompleteMetric completion-route exhaustion)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *request served by an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet* $Q = (X, S, M, L, D, H, C, P,$ *is exhausted by the rows* $X, S, M, L, D, H, C, P, N$ *together with finite* BHist *histories,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. In particular, after the carrier displays the complete-metric handoff, late-bound coverage, ledger nonescape, limit-modulus induction, and completion-consumer factorization routes, no remaining completion request can demand quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or an independent completed carrier.*

Proof. Collect the existing local routes. Complete-metric handoff supplies the limit-witness surface, late-bound coverage forces tolerance reads through M, S, D, L, and ledger nonescape removes the excluded host objects from the carrier.

Use limit-modulus induction to cover arbitrary finite BHist request histories. Each initial segment reaches the displayed limit only through the same stream-window, regular-readback, and late-distance rows.

Finally apply completion-consumer factorization. A $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives no entry point beyond $X, S, M, L, D, H, C, P, N$, so the displayed finite routes exhaust the completion-facing obligation surface. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionRouteExhaustion`

Definition 1515.38 (SequentiallyCompleteMetric finite Cauchy window)**.** *For an accepted* SequentiallyCompleteMe *carrier* $Q = (X, S, M, L, D, H, C, P, N)$*, a finite Cauchy-window obligation package is the displayed tuple*

$$\Omega_Q = (X, S, R, M, L, D, H, C, P, N)$$

where X *is the metric source row of Definition 1515.2,* S *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to those windows,* M *is the modulus threshold row,* L *is the displayed limit row,* D *is the late-distance ledger, and* H, C, P, N *are the transport, replay, provenance, and local naming rows. The package contains no quotient-completion equality, selected representative, countable-choice schedule, ambient-completeness witness, independent completed carrier, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 (definition) `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricFiniteCauchyWindow`

Theorem 1515.39 (SequentiallyCompleteMetric Cauchy-window obligation)**.** *For an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$*, every finite Cauchy-window obligation package* $\Omega_Q = (X, S, R, M, L, D, H, C, P, N)$ *must display the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows reached from* D*, the ambient* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$ *row before any completion-facing consumer can read the window.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCauchyWindowObligation`

Proof. Project the package Ω_Q from Definition 1515.38. Its displayed rows already contain $S, R, M, L, D, H, C, P, N$ over the same metric source X.

Read the analytic front of the package first. The finite $\mathsf{StreamName}^{\uparrow}$ windows S and their $\mathsf{RegSeqRat}^{\uparrow}$ readback R expose the inspected sequence data, while M, L, D bind the requested tolerance, displayed point row, and late-distance comparisons.

The support rows then close the obligation surface. The BHist carrier records the finite packet, H transports it by hsame, C replays it by Cont, P sources it through Pkg, and N names it by the local $\mathsf{NameCert}$ row. No further completion object is read by this package. □

Theorem 1515.40 (SequentiallyCompleteMetric RegSeqRat handoff)**.** *In the notation of Definition 1515.38, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *is the unique handoff surface from the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S *to the late-distance ledger* D *and the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows. The handoff is recorded inside the same* BHist *packet and is transported, replayed, sourced, and named only by* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRegSeqRatHandoff`

Proof. Start with the window rows S of Ω_Q. They are finite $\mathsf{StreamName}^{\uparrow}$ observations over the metric source X, so a consumer can read only the displayed windows before the rational handoff appears.

The row R is the regular rational readback attached to those same windows. It is therefore the row that connects the source-window data to the tolerance, point, and late-distance rows M, L, D before any $\mathsf{Real}^{\uparrow}$-facing seal is available.

Finally inspect H, C, P, N. These rows do not add another readback surface; they transport the same handoff by hsame, replay it by Cont, source it by Pkg, and name it by the local $\mathsf{NameCert}$ row. □

Theorem 1515.41 (SequentiallyCompleteMetric Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal-facing read produced from a finite Cauchy-window obligation package* $\Omega_Q = (X, S, R, M, L, D, H, C, P, N)$ *is confined to the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the late-distance ledger* D*, the* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The seal-facing read exports no host completion equality, representative choice, countable-choice schedule, ambient-completeness witness, or independent completed carrier.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRealSealNonescape`

Proof. Read the package order. The $\mathsf{Real}^{\uparrow}$-facing boundary can be reached only after S and R have displayed the finite stream windows and regular rational data, and after M, L, D have displayed the tolerance and late-distance rows.

Apply the Cauchy-window obligation and the RegSeqRat handoff above. Together they force every seal-facing request through the same finite BHist packet and the same rows S, R, D, H, C, P, N.

There is no remaining coordinate in Ω_Q for host completion equality, representative choice, choice schedules, ambient completeness, or an independent completed carrier. Hence the $\mathsf{Real}^{\uparrow}$ seal-facing read cannot escape the displayed finite route. □

Theorem 1515.42 (SequentiallyCompleteMetric limit readback package)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* SequentiallyCompleteMetric$^{\uparrow}$ *carrier, and let $\Omega_Q = (X, S, R, M, L, D, H, C, P, N)$ be its finite Cauchy-window obligation package. The rows of Ω_Q expose the completion-facing limit readback by first reading the metric source X, then the finite StreamName windows S and their* RegSeqRat$^{\uparrow}$ *readbacks R, then the modulus threshold M, displayed limit L, and late-distance ledger D. The readback is the same route named by Definition 1515.32 and exhausted by Definition 1515.37; it does not pass through quotient completion or a selected representative.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitReadbackPackage`

Proof. Start with the finite package of Definition 1515.38. Its first row is the metric source X, so every distance comparison is read inside the same source admitted by Definition 1515.2.

Read the sequence surface next. The windows S and the regular rational readback R supply exactly the finite stream data used by the induction route of Definition 1515.32.

Now read the modulus threshold, limit row, and late-distance ledger. The rows M, L, D give the displayed threshold, the displayed point, and the finite distance comparisons, so the limit readback is already present before any completion-facing consumer asks for it.

Finally replay through H, C, P, N and apply Definition 1515.37. Since the exhausted route has no quotient-completion, representative-selection, choice, ambient-completeness, independent completed-carrier, or Real$^{\uparrow}$ completeness coordinate, the package exposes only the finite limit readback. □

Theorem 1515.43 (SequentiallyCompleteMetric completion handoff obligations)**.** *Every* CompleteMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer of an accepted* SequentiallyCompleteMetric$^{\uparrow}$ *carrier $Q = (X, S, M, L, D, H, C, P, N)$ must read the finite Cauchy-window obligation package of Definition 1515.38 before using the handoff. In particular, the consumer must read the same metric source row, finite StreamName windows, RegSeqRat readbacks, modulus threshold, displayed limit row, late-distance ledger, transport, replay, provenance, and local naming rows named by Definition 1515.33 and Definition 1515.37.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionHandoffObligatio`

Proof. Project the completion-facing request. By Definition 1515.3, the CompleteMetric$^{\uparrow}$ boundary receives its limit witness from X, S, M, L, D rather than from an independent completion object.

Apply completion-consumer factorization from Definition 1515.33. A MetricCompletion$^{\uparrow}$ consumer has the same entry point, so it must read $X, S, M, L, D, H, C, P, N$ before using the completion route.

Insert the finite package Ω_Q from Definition 1515.38. Its RegSeqRat readback row R records the rational window data already consumed by the limit-modulus induction of Definition 1515.32.

The limit readback theorem Definition 1515.42 then supplies the displayed limit row and late-distance ledger to both consumers. Since Definition 1515.37 exhausts all completion requests through the same rows, no consumer can bypass the package through quotient completion, representative selection, countable choice, open-cover compactness, ambient completeness, or Real$^{\uparrow}$ completeness. □

Theorem 1515.44 (SequentiallyCompleteMetric regular limit extraction)**.** *For an accepted* SequentiallyCompleteM *carrier $Q = (X, S, M, L, D, H, C, P, N)$, the finite Cauchy-window package $\Omega_Q = (X, S, R, M, L, D, H, C, P, N)$ extracts the displayed limit row L and late-distance ledger D before any* CompleteMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer can read a completion-facing witness. The extraction is the route of Definition 1515.38, the modulus induction of Definition 1515.32, and the readback package of Definition 1515.42.*

Proof. Project Ω_Q from the finite Cauchy-window definition. Its rows list the source metric, stream-window data, regular rational readback, modulus threshold, displayed limit, late-distance ledger, and structural transport before any consumer-facing handoff is considered.

Apply the limit-modulus induction. The induction forces each tolerance request to pass through M, then through the $\mathsf{StreamName}^{\uparrow}$ windows S and $\mathsf{RegSeqRat}^{\uparrow}$ readback R, before the displayed limit row L and ledger D are available.

Finally apply the limit readback package. It identifies L and D as the already displayed completion-facing witness, so a $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives the limit data only after the finite package has exposed those rows. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRegularLimitExtraction`

Theorem 1515.45 (SequentiallyCompleteMetric MetricCompletion consumer admission)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier factors through the same* $\mathsf{Met}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CompleteMetric}^{\uparrow}$ *limit boundary,* BHist *packet,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$ *rows as the finite Cauchy-window package. No consumer obtains a second completion carrier or a separate representative-selection surface.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricMetricCompletionConsumerAdm`

Proof. Start with the consumer admission point. By completion handoff obligations, the consumer must read the finite package of Definition 1515.38 before using any completion-facing witness.

Read the analytic rows of that package. The metric source is X, the finite sequence surface is S, the rational readback is R, and the limit boundary is supplied through M, L, D toward $\mathsf{CompleteMetric}^{\uparrow}$.

Read the structural rows next. The same BHist packet, hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row carry the route into the $\mathsf{MetricCompletion}^{\uparrow}$ request. Because the consumer has no other entry point in the carrier, the admission factors through exactly those rows. □

Theorem 1515.46 (SequentiallyCompleteMetric Real route boundary)**.** *The* $\mathsf{Real}^{\uparrow}$*-facing route exposed by an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the late-distance ledger, the finite seal-facing boundary, and the local* $\mathsf{NameCert}$ *rows of the same package. It exports no quotient completion, selected representative, countable choice, ambient completeness, or assertion that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRealRouteBoundary`

Proof. Read the route in package order. The finite $\mathsf{StreamName}^{\uparrow}$ windows are displayed first, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is the only rational handoff from those windows toward the late-distance ledger.

Apply the Real-seal nonescape theorem. The seal-facing read is confined to S, R, D, H, C, P, N inside the same BHist packet, with hsame transport, Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserving the package boundary.

There is no coordinate in the carrier for quotient completion, selected representatives, countable-choice schedules, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$. Therefore the Real-facing route ends at the displayed readback-and-seal boundary rather than at any host completion principle. □

Theorem 1515.47 (SequentiallyCompleteMetric display route)**.** *Every accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet exposes its root sequence-completeness surface in the order*

$$X, S, R, M, L, D, H, C, P, N.$$

Here X is the metric source, S is the $\mathsf{StreamName}^{\uparrow}$ *window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to that row, M is the displayed modulus, L is the displayed limit, D is the late-distance ledger, H is componentwise* hsame *transport, C is* Cont *replay, P is* Pkg *provenance, and N is the local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricDisplayRoute`

Proof. Project the carrier of Definition 1515.1 and the finite Cauchy-window package of Definition 1515.38. The carrier supplies $X, S, M, L, D, H, C, P, N$, and the package displays the regular rational readback row R between the stream windows and the modulus.

Apply the completion handoff obligations of Definition 1515.43. They require every completion-facing consumer to read the metric source, finite stream windows, regular rational readback, modulus threshold, displayed limit row, late-distance ledger, transport, replay, provenance, and local naming rows before using the handoff.

Finally compose with regular limit extraction from Definition 1515.44. The extraction reaches L and D only after X, S, R, M have been displayed, and the route is then replayed through H, C, P, N. □

Theorem 1515.48 (SequentiallyCompleteMetric limit nonescape)**.** *For an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier, the displayed limit row L cannot be replaced by quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness. Any limit-facing read is confined to the displayed metric source, stream windows, regular rational readback, modulus, late-distance ledger, transport, replay, provenance, and local naming rows.*

Proof. Start with the ledger nonescape theorem Definition 1515.10. It states that the carrier has no row for quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Use the limit readback package of Definition 1515.42. The displayed limit row is read together with the late-distance ledger through the same finite Cauchy-window package, so the limit witness remains a row of the accepted packet.

The Real route boundary of Definition 1515.46 gives the final exclusion. Even when a consumer asks for a $\mathsf{Real}^{\uparrow}$-facing route, it reaches only the displayed readback-and-seal boundary, not a completeness theorem for $\mathsf{Real}^{\uparrow}$ or an ambient completion object. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricLimitNonescape`

Theorem 1515.49 (SequentiallyCompleteMetric RegSeqRat source route)**.** *Every sequence-completeness consumer reaches the late-distance ledger D only after the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows have been displayed over the same metric source. The route is source-first: it reads X, then S and R, then the modulus M, and only then the displayed limit row L and late-distance ledger D.*

Proof. Project the finite Cauchy-window package. Its sequence surface is not a free stream: the windows S and regular rational readback R are displayed over the metric source row X before any modulus or limit row is available.

Apply the Cauchy-sequence obligation of Definition 1515.5. It forces the source metric, stream windows, rational readback, and modulus threshold to be exposed before a sequence-completeness read can consume L or D.

Now use source-first tail read from Definition 1515.13. A tail read later consumed as a displayed limit read cannot begin from a free-standing limit, quotient-completion class, or selected representative, so every path to the late-distance ledger passes through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ first. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricRegSeqRatSourceRoute`

Theorem 1515.50 (SequentiallyCompleteMetric window-limit extraction)**.** *Every accepted* SequentiallyCompleteM *packet extracts its displayed limit row from finite* BHist *windows before any completion-facing consumer may use the packet. The extraction route reads the metric source row, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the modulus row, and the* $\mathsf{Real}^{\uparrow}$ *seal-facing late-distance row through the same* hsame *transports and* Cont *replays, and only then admits the resulting boundary to a* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricWindowLimitExtraction`

Proof. Start from the display route of Definition 1515.47. It orders the rows as $X, S, R, M, L, D, H, C, P, N$, so the limit row L is never available before the finite stream windows and regular rational readback rows.

Apply regular limit extraction and the Real route boundary. The $\mathsf{RegSeqRat}^{\uparrow}$ source rows provide the rational tolerance readback, while the $\mathsf{Real}^{\uparrow}$ seal is reached only through the late-distance ledger D inside the same packet.

Finally use the completion handoff obligations. A $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives the extracted limit boundary only after hsame transport and Cont replay have preserved the displayed finite-window route; quotient completion, selected representatives, countable choice, and ambient Real completeness remain outside the carrier. □

Theorem 1515.51 (SequentiallyCompleteMetric tail cofinality)**.** *For every accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier, tail replacement by a cofinal finite window preserves the same completion-facing obligation surface. The replacement may change only the displayed* BHist *window inspected by the* $\mathsf{StreamName}^{\uparrow}$ *row; it must keep the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, modulus row,* $\mathsf{Real}^{\uparrow}$ *seal-facing ledger,* hsame *transport,* Cont *replay, provenance, and local* NameCert *rows on the same route before a* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer is admitted.*

Proof. Use source-first tail read from Definition 1515.13. A tail read cannot enter through a free-standing limit, so it must first display the metric source together with the finite stream windows and regular rational readback.

Apply the RegSeqRat source route above. The cofinal tail keeps the same R row as the rational source for the modulus and the late-distance ledger, so the $\mathsf{Real}^{\uparrow}$ seal-facing boundary is transported rather than regenerated.

The completion-consumer factorization then admits the same $\mathsf{MetricCompletion}^{\uparrow}$ consumer route. Since H, C, P, N preserve only the displayed packet, the cofinal tail cannot introduce quotient completion, selected representatives, countable choice, ambient completeness, or an independent completed carrier. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricTailCofinality`

Theorem 1515.52 (SequentiallyCompleteMetric completion consumer admission)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet must first display the finite* BHist *window-limit extraction and tail-cofinality routes over the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows. The admitted consumer sees the* $\mathsf{Real}^{\uparrow}$ *seal only as the terminal readback of the late-distance ledger, with* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *preserving the packet; it does not receive quotient completion, selected representatives, countable choice, open-cover compactness, ambient Real completeness, or a proof that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Begin with completion-consumer factorization. It identifies the consumer entry point with the displayed rows of the $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ carrier and refuses any independent completion object.

Attach window-limit extraction. The consumer must read the finite BHist windows, the $\mathsf{StreamName}^{\uparrow}$ route, the $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the modulus, and the $\mathsf{Real}^{\uparrow}$ seal-facing ledger before the displayed limit row can be used.

Attach tail cofinality. Cofinal tail replacement preserves the same source rows and structural replay, so admission to $\mathsf{MetricCompletion}^{\uparrow}$ is stable under finite-window refinement but still confined to the packet. The refusal clauses of the nonescape and Real boundary theorems exclude quotient completion, selected representatives, countable choice, open-cover compactness, ambient Real completeness, and $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionConsumer`

Theorem 1515.53 (SequentiallyCompleteMetric tail fusion)**.** *Let* $Q = (X, S, M, L, D, H, C, P, N)$ *and* $Q' = (X, S, M', L', D', H', C', P', N')$ *be accepted late-bound* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *ledgers sharing the same* $\mathsf{StreamName}^{\uparrow}$ *row and* $\mathsf{RegSeqRat}^{\uparrow}$ *tail schedule. If both ledgers are admitted by the displayed* $\mathsf{Met}^{\uparrow}$ *classifier, then their tail reads fuse through the modulus rows, late-distance ledgers, componentwise transports, replay rows, package provenance, and local NameCert rows before any* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff is available.*

Proof. Start from the shared source route. By Definition 1515.12, each tolerance request must pass through the displayed X, S rows and the same regular tail read before it reaches M, D or M', D'.

Apply Definition 1515.52. A completion-facing consumer is admitted only after the finite window-limit route and tail-cofinality route have been displayed through the same source rows.

Finally use Definition 1515.3. The $\mathsf{CompleteMetric}^{\uparrow}$ boundary receives its limit witness only after the source-first package has already replayed through H, C, P, N and H', C', P', N', so the two late-bound ledgers fuse at the displayed tail route before any handoff can read them. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricTailFusion`

Theorem 1515.54 (SequentiallyCompleteMetric displayed-limit uniqueness route)**.** *For an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier* $Q = (X, S, M, L, D, H, C, P, N)$*, separated uniqueness of the displayed limit is routed only through the metric source* X*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the modulus row* M*, the displayed limit row* L*, the late-distance ledger* D*, and the* $\mathsf{Met}^{\uparrow}$ *classifier. It is not routed through quotient completion, selected representatives, countable choice, ambient completion, or a host equality of completed points.*

Proof. Read uniqueness inside the displayed carrier. The source row X supplies the $\mathsf{Met}^{\uparrow}$ classifier, while S, M, L, D give the finite sequence, modulus, candidate limit, and late-distance evidence inspected by separatedness.

Apply Definition 1515.34. It already confines uniqueness to the displayed metric and sequence rows and refuses quotient completion, selected representatives, countable choice, and ambient completion.

The route is then preserved by the carrier boundary of Definition 1515.12. A uniqueness comparison may tighten the tolerance through M and D, but it cannot skip from L to an external completed-point equality. □

Lean4 ✓ `BEDC.Derived.Sequentially CompleteMetricUp.SequentiallyCompleteMetricDisplayedLimitUniquenessRou`

Theorem 1515.55 (SequentiallyCompleteMetric completion-factorization ledger)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier factors through the finite ledger route*

$$X \to S \to M \to L \to D \to H, C, P, N.$$

The consumer therefore receives the metric source, stream windows, modulus, displayed limit, late-distance ledger, transport, replay, provenance, and local naming rows as the complete visible route, not as an ambient completion object.

Proof. First project the carrier and the display route. The rows $X, S, M, L, D, H, C, P, N$ are the only rows available for sequence completeness, and the finite $\mathsf{StreamName}^{\uparrow}$ windows must be read before the limit-facing ledger is consumed.

Use Definition 1515.33 and Definition 1515.52. These results identify the $\mathsf{MetricCompletion}^{\uparrow}$ entry point with the displayed packet and require the window-limit and tail-cofinality routes before the consumer is admitted.

For a $\mathsf{CompleteMetric}^{\uparrow}$ consumer, apply Definition 1515.3. The handoff receives the same X, S, M, L, D rows and then the structural H, C, P, N replay. Thus every completion-facing read factors through the finite ledger route and imports no quotient completion, selected representative, countable choice, or independent completed carrier. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricCompletionFactorizationLedg`

Theorem 1515.56 (SequentiallyCompleteMetric source-first subsequence read)**.** *Let* $Q = (X, S, M, L, D, H, C, P,$ *be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Every subsequence, tail, or cofinal-window consumer that is later used by a* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff must first expose the* $\mathsf{Met}^{\uparrow}$ *source row* X*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback attached to those windows, the modulus row* M*, the displayed limit row* L*, and the late-distance ledger* D*. The handoff cannot begin from quotient completion, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or an independent completed-point carrier.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSourceFirstSubsequenceRead`

Proof. Start with the source-first tail read of Definition 1515.13. It forces every completion-facing tail packet to expose the metric source, finite stream windows, regular rational readback, and modulus row before any displayed limit or late-distance row can be inspected.

Pass from tails to subsequences by tail induction. The base tail has the displayed route X, S, M before L, D, and the successor step preserves the same source rows while tightening only the late-window request. Apply the limit-ledger coverage of Definition 1515.15; the displayed limit row and late-distance ledger are therefore read after the regular-source route rather than as free completion data.

Finally use the completion-factorization ledger of Definition 1515.55. Any $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives $X, S, M, L, D, H, C, P, N$ as the visible route, so quotient

completion, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and independent completed carriers remain outside the handoff. □

Theorem 1515.57 (Sequentially complete metric source-first subsequence readback)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. Every source-first subsequence read that is later inspected by a completion-facing consumer must replay through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before the consumer may inspect the subsequence. The replay exports no selected subsequence, countable-choice schedule, quotient limit, host equality proof, or ambient Real completeness theorem.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSourceFirstSubsequenceReadb`

Proof. Project the packet rows. The source-first subsequence read of Definition 1515.56 already places the metric source X, stream windows S, regular rational readback, modulus row M, displayed limit row L, and late-distance ledger D before a completion handoff.

Replay the displayed route through the completion-facing rows. The completion-factorization ledger sends the same $X, S, M, L, D, H, C, P, N$ packet to $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$, while the StreamName, RegSeqRat, and Real rows remain the finite readback corridor through which the subsequence is observed.

The structural rows H, C, P, N transport, replay, source, and name the same data. Because no selected subsequence, countable-choice function, quotient limit, host equality proof, or ambient completeness row appears in the carrier, the completion-facing consumer cannot inspect the subsequence outside the displayed readback route. □

Theorem 1515.58 (Sequentially complete metric source-first completion nonescape)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *packet. Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of the source-first subsequence route must read the displayed rows $X, S, M, L, D, H, C, P, N$ together with the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readback rows before it can inspect subsequence data. The consumer cannot replace that route by quotient completion, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricSourceFirstSubsequenceCompl`

Proof. Apply the source-first subsequence read of Definition 1515.56. It exposes the metric source X, stream-window row S, regular rational readback, modulus row M, displayed limit row L, and late-distance ledger D before any completion handoff.

Then apply the source-first subsequence readback theorem, Definition 1515.57. Its replay keeps $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ on the visible route and exports no selected subsequence, quotient limit, countable-choice schedule, or ambient Real completeness theorem.

Finally attach the structural rows H, C, P, N. They transport, replay, source, and name the same packet, so every completion-facing consumer remains inside $X, S, M, L, D, H, C, P, N$ and the displayed readback rows. □

Theorem 1515.59 (SequentiallyCompleteMetric tail source exhaustion)**.** *Let $Q = (X, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier. Every completion-facing tail read is exhausted by the displayed source route through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows: the read must expose the metric source X, stream windows S, regular rational readback attached to S, modulus row M, displayed limit row L, late-distance ledger D,*

transport H, replay C, provenance P, and local naming N before any completion consumer is admitted. No further quotient completion, selected representative, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or independent completed-point carrier is exported.*

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricTailSourceExhaustion`

Proof. Start from the source-first subsequence read of Definition 1515.56. It already forces subsequence, tail, and cofinal-window consumers through X, S, M, L, D before either a $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ handoff can inspect the packet.

Next attach the display route and regular readback rows. By Definition 1515.47, the source route is ordered through the metric source, stream windows, regular rational readback, modulus, limit, late-distance ledger, transport, replay, provenance, and local naming rows.

Finally use Definition 1515.55. A completion-facing consumer receives exactly this finite ledger route, so the tail read is exhausted at the displayed $\mathsf{CompleteMetric}^{\uparrow}$ boundary and cannot export quotient completion, selected representatives, countable choice, ambient Real completeness, or an independent completed carrier. □

Theorem 1515.60 (SequentiallyCompleteMetric mature consumer boundary)**.** *Every mature consumer of an accepted* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *carrier factors through* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *the finite* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$ *rows before it may read a displayed limit. The consumer boundary has no route through quotient completion, selected representatives, countable choice, ambient completion, or a host equality of completed points.*

Proof. Start with the completion handoff and its obligations. By Definition 1515.3 and Definition 1515.43, a $\mathsf{CompleteMetric}^{\uparrow}$ request receives its limit witness only after the carrier has displayed the metric source, stream windows, modulus, limit row, late-distance ledger, and structural replay rows.

Now route the $\mathsf{MetricCompletion}^{\uparrow}$ side through the consumer theorems. The completion-consumer route, factorization theorem, and completion-factorization ledger force the same finite package through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before any completion-facing consumer is admitted.

Finally apply regular limit extraction and the nonescape ledger. The displayed limit row is extracted from the finite Cauchy-window package, while the ledger refuses quotient completion, selected representatives, countable choice, ambient completeness, and host completed-point equality. Thus every mature consumer reaches the displayed limit only through the named BEDC rows. □

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteMetricUp.SequentiallyCompleteMetricMatureConsumerBoundary`

Closure status for $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ packet is generated from a displayed $\mathsf{Met}^{\uparrow}$ source, a regular Cauchy sequence read through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows, a modulus, a displayed limit point, late-distance bound rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1515.3, Definition 1515.16, Definition 1515.11, Definition 1515.10, Definition 1515.43, and Definition 1515.60 bind the SequentiallyCompleteMetric carrier as a mature complete-metric and MetricCompletion consumer surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentiallyCompleteMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or any assertion that $\mathsf{Real}^{\uparrow}$ is complete.

Upgrade path: The remaining work is formal-axis verification and bridge checking for the mature consumer boundary.

Chapter 1516

A Concrete Naming Certificate for $\mathsf{RegularCauchyBounded}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyBounded}^{\uparrow}$ packet records boundedness of a regular Cauchy name by finite dyadic ledgers and displayed window reads. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ carrier of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291, the finite-window equivalence boundary of chapter 1404, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the bounded sequence consumer surface of chapter 1415. The certificate stores a usable finite bound ledger for one regular name; it does not identify quotient streams or select a limiting real.

Definition 1516.1 (Regular Cauchy bounded carrier)**.** *A* $\mathsf{RegularCauchyBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, W, D, E, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *request schedule used to inspect the name.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and radius ledger attached to the inspected requests.*
4. *E is the optional* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *comparison row used when the same bound is transported across an equivalent regular name.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-name, stream-window, dyadic-ledger, and equivalence rows have been displayed.*
6. *L is the finite bound ledger, consisting of a displayed dyadic center-radius window and a finite verification row saying that every inspected request in W is contained in that window after the tolerance data in D are applied.*
7. *H stores componentwise* hsame *transport for the source name, request schedule, dyadic ledger, comparison row, real seal, bound ledger, continuations, provenance, and local naming row.*
8. *C stores displayed* Cont *replay from the regular name to stream requests, from stream requests to dyadic tolerance rows, from the tolerance rows to the bound ledger, and from the bound ledger to the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBounded}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBounded}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, W, D, E, R, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, real trichotomy, countable choice, host real order completeness, or Dedekind-cut construction.

Theorem 1516.2 (Finite bound ledger for regular Cauchy names)**.** *Every accepted* $\mathsf{RegularCauchyBounded}^{\uparrow}$ *carrier exposes boundedness through the finite route*

$$Q \longmapsto W \longmapsto D \longmapsto L$$

together with E, R, H, C, P, N. Thus a consumer can read a dyadic center-radius bound for the inspected regular Cauchy name without importing quotient stream equality, selected limits, real trichotomy, countable choice, host order completeness, or a Dedekind-cut construction.

Proof. Project the carrier of Definition 1516.1. The source row Q is inspected only through the displayed request schedule W, and each request in W is measured against the dyadic tolerance ledger D.

Read the bound ledger L next. Its center-radius row and verification row are finite data over the displayed requests, so boundedness is certified by the visible regular-name windows rather than by an ambient completeness or choice principle.

The optional equivalence row E transports the same bound shape across a displayed $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ comparison, while R records only the later real seal reached after the ledger is already present. The rows H, C, P, N preserve, replay, source, and name this route. Since the carrier lists no quotient stream equality, selected limit, trichotomy branch, countable-choice selector, host order-completeness row, or Dedekind-cut coordinate, the finite bound ledger exhausts the boundedness surface. □

Theorem 1516.3 (Real window readback from a bounded regular name)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{BoundedRealSequence}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyBounded}^{\uparrow}$ *packet must read the bound through the displayed regular Cauchy source, stream request schedule, dyadic tolerance ledger, and finite bound ledger before it reaches the stored real seal. The exported readback is exactly*

$$Q, W, D, L, E, R, H, C, P, N,$$

with no quotient stream equality, selected limit, trichotomy, countable choice, host completeness, or Dedekind-cut construction.

Proof. Begin with a seal-facing read. By Definition 1516.1, the real seal row R is downstream from Q, W, D, E, L, so the consumer must first inspect the regular rational source, the finite stream requests, the dyadic tolerances, and the bound ledger.

Apply Definition 1516.2. It identifies L as the finite center-radius boundedness surface and keeps the route attached to the same displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

A $\mathsf{BoundedRealSequence}^{\uparrow}$ consumer may reuse this bounded regular name as one inspected sequence value, but it receives only the same finite route and the stored real seal. No additional coordinate in the carrier can supply quotient stream equality, a selected limiting real, real trichotomy, countable choice, host completeness, or a Dedekind-cut construction. □

Falsifiable prediction: Every $\mathsf{Real}^{\uparrow}$ read from a $\mathsf{RegularCauchyBounded}^{\uparrow}$ packet factors through a finite regular-name request schedule, a dyadic tolerance ledger, and a displayed center-radius bound ledger before the real seal is consumed.

Independence witness: regseqrat, streamname, dyadicratcore, regularcauchyequivalence, real, boundedrealsequence: $\mathsf{RegularCauchyBounded}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one regular Cauchy source, request windows, dyadic tolerances, an optional equivalence transport row, a real seal, a finite bound ledger, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBounded}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName request windows, DyadicRatCore tolerance data, an optional RegularCauchyEquivalence transport row, a RealUp seal, a finite center-radius bound ledger, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1516.1, Definition 1516.2, and Definition 1516.3 bind the finite boundedness ledger for one regular Cauchy name and its real-window readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBounded}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general completeness, selected limits, quotient stream equality, trichotomy, Dedekind-cut construction, countable choice, host real order completeness, or Lean verification.

Upgrade path: Lean closure requires carrier admission, finite bound ledger preservation, real-window readback, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyBoundedUp.

Chapter 1517

A Concrete Naming Certificate for $\mathsf{RealNameClassifier}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealNameClassifier}^{\uparrow}$ packet records equality inspection for two regular Cauchy real names as a finite tolerance classifier rather than as host equality of completed objects. It sits over the regular-name source of chapter 371, the regular rational rows of chapter 301, the common finite-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later $\mathsf{Real}^{\uparrow}$, metric, and algebra chapters a named classifier surface for regular Cauchy names without quotienting Cauchy classes, selecting limits, or importing trichotomy.

Definition 1517.1 (RealNameClassifier source packet)**.** *A* $\mathsf{RealNameClassifier}^{\uparrow}$ *source packet is a finite* BHist *record*

$$C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N)$$

with the following displayed rows:

1. *A and B are the two source* $\mathsf{RegularCauchyName}^{\uparrow}$ *rows whose equality is being inspected.*
2. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposing the same finite precision requests to both sources.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows read from the two sources along W.*
4. *T is the finite tolerance classifier row, recording that every inspected precision request is discharged by a dyadic comparison between the corresponding observations of A and B.*
5. *R_A and R_B are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the two regular Cauchy names.*
6. *H records componentwise* hsame *transport for the two source names, common stream windows, dyadic tolerance rows, readback rows, classifier row, package provenance, seal row, and local naming row.*
7. *K records the displayed* Cont *replay from A, B through W, D_A, D_B, T, R_A, R_B.*
8. *P is the* Pkg *provenance over* $\mathsf{RealNameClassifier}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tolerance classifier and both regular rational readbacks have been exposed.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}$ *row.*

The packet has no coordinate for quotient Cauchy classes, host sequence equality, selected limits, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealNameClassifierUp.RealNameClassifierSourcePacketRows`

Theorem 1517.2 (RealNameClassifier tolerance obligation)**.** *For an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet* $C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N)$*, every classifier query factors through the common window* W*, the two dyadic tolerance rows* D_A, D_B*, and the finite tolerance classifier row* T *before either regular rational readback or terminal real seal is consumed.*

Proof. Project the accepted packet. The only precision schedule visible to both regular Cauchy names is the shared $\mathsf{StreamName}^{\uparrow}$ row W, so a classifier query has no independent observation route for A or B.

The dyadic tolerance rows D_A and D_B are read from W. The classifier row T records the finite comparison of these two displayed dyadic observations at the requested precisions.

The readback rows R_A, R_B and the seal row S are downstream of this finite comparison. Hence every equality-facing consumer first consumes the common window and dyadic tolerance data, then the tolerance classifier, and only afterward reads regular rational or real-facing rows. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierSource tolerance obligation`

Theorem 1517.3 (RealNameClassifier reflexive window)**.** *Let* $C = (A, A, W, D_A, D_A, T, R_A, R_A, H, K, P, S, N)$ *be an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet whose two displayed source rows are the same* $\mathsf{RegularCauchyName}^{\uparrow}$ *row and whose classifier query is read through the same* $\mathsf{StreamName}^{\uparrow}$ *window. Then the* $A \sim A$ *read is admitted by the reflexive classifier route through the existing* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no quotient equality of Cauchy names, selected limit, host sequence equality, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierReflexiveWindow`

Proof. Project the accepted packet. Since both source entries are the same row A and both observation requests use the same window W, the displayed source routes agree componentwise before any classifier row is consumed.

Apply the tolerance obligation of Definition 1517.2. The classifier query must pass through W, D_A, D_A, T before the regular rational readback or terminal seal can be inspected, so the reflexive read has no independent equality oracle.

The two readback rows are the same $\mathsf{RegSeqRat}^{\uparrow}$ row attached to A. Transport by H and replay by K therefore preserve the displayed source, tolerance, classifier, and readback rows without changing the packet surface.

Finally apply the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. The $\mathsf{Real}^{\uparrow}$ seal is reached only after the finite reflexive route has been displayed, and every consumed row is already accounted for by the carrier ledger. □

Theorem 1517.4 (RealNameClassifier common-window symmetry)**.** *Let* $C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K,$ *be an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet. Swapping the two* $\mathsf{RegularCauchyName}^{\uparrow}$ *rows* A, B*, swapping* D_A, D_B*, and swapping* R_A, R_B *preserves the same local* $\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}$ *surface whenever the common* $\mathsf{StreamName}^{\uparrow}$ *window* W *and finite tolerance classifier row* T *are unchanged. The swapped packet exports no new equality oracle, selected limit, quotient completion, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierCommonWindowSymmetry`

Proof. Project the source packet of Definition 1517.1. The only shared observation route for the two regular Cauchy names is the common window W, and the only classifier row is T.

Use the tolerance obligation of Definition 1517.2. It forces both source directions through W, D_A, D_B, T before either readback row or the terminal seal can be consumed, so exchanging the two sides changes only the row order inside the displayed pair.

Apply refinement stability and the seal boundary, Definition 1517.10 and Definition 1517.11. Transport and replay preserve the same finite classifier surface, and the terminal seal still lacks coordinates for quotient equality, selected limits, external equality oracles, and completeness. □

Theorem 1517.5 (RealNameClassifier Cauchy-completion handoff)**.** *Let $C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K,$ be an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet. Every* $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *completion-facing consumer that reads equality-classifier data from C can read it only through the common* $\mathsf{StreamName}^{\uparrow}$ *window W, the dyadic rows D_A, D_B, the finite classifier row T, the readbacks R_A, R_B, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal S, transported and replayed by H, K, P, N. The handoff exports no quotient Cauchy class, selected limit, host equality of real names, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierCauchyCompletionHandoff`
↪ variant `BEDC.Derived.RealNameClassifierUp.RealNameClassifierCommonWindowCauchyCompletionHandoff`

Proof. Start with the tolerance obligation of Definition 1517.2. It forces every classifier query to pass through W, D_A, D_B, T before either readback row or the terminal seal is consumed.

Apply common-window symmetry, Definition 1517.4. Completion-facing consumers may exchange the two source names only by swapping the displayed dyadic and readback rows while keeping the same common window and classifier row.

Finally use the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. The seal is reached after the finite classifier route, and the ledger contains no coordinate for quotient Cauchy classes, selected limits, host equality, countable choice, or Real completeness. Hence a completion consumer receives exactly the common-window handoff described above. □

Theorem 1517.6 (RealNameClassifier common-window transitivity)**.** *Let $C_{AB} = (A, B, W, D_A, D_B, T_{AB}, R_A, R_B,$ and $C_{BC} = (B, C, W, D'_B, D_C, T_{BC}, R'_B, R_C, H_{BC}, K_{BC}, P_{BC}, S_{BC}, N_{BC})$ be accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packets. If both packets inspect $A \sim B$ and $B \sim C$ through the same common* $\mathsf{StreamName}^{\uparrow}$ *window W, and the two middle-source rows D_B, D'_B, R_B, R'_B are compatible by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback transports, then the composed $A \sim C$ classifier read is admitted through W, the transported rows D_A, D_C, R_A, R_C, the componentwise* hsame *transport through B, and the same* $\mathsf{Real}^{\uparrow}$ *seal boundary. The composed read exports no quotient equality of Cauchy names, selected limits, host sequence equality, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierCommonWindowTransitivity`

Proof. Project the two accepted packets. The hypotheses identify their observation route as the single common window W, so the $A \sim B$ and $B \sim C$ classifier reads cannot use independent precision schedules.

Apply the tolerance obligation of Definition 1517.2 to both packets. The first read exposes $W, D_A, D_B, T_{AB}, R_A, R_B$ before reaching its seal, and the second read exposes $W, D'_B, D_C, T_{BC}, R'_B, R_C$ before reaching its seal.

Use the displayed compatibility of D_B, D'_B and R_B, R'_B to transport the middle source componentwise through the two hsame rows. This composes the dyadic tolerance checks along the shared B row and leaves the endpoint rows D_A, D_C, R_A, R_C on the same window W.

Finally invoke ledger exhaustion and the seal boundary, Definition 1517.12 and Definition 1517.11. They account for every row consumed by the composed classifier read and rule out any escape through quotient equality, selected limits, host equality, choice, trichotomy, or completeness. □

Theorem 1517.7 (RealNameClassifier shared-window equivalence)**.** *For accepted* RealNameClassifier$^{\uparrow}$ *packets over the same* StreamName$^{\uparrow}$ *window, the tolerance obligation, common-window symmetry, and common-window transitivity assemble an equivalence-style classifier route on the displayed* RegularCauchyName$^{\uparrow}$ *rows. The route uses only* RegularCauchyName$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, the terminal* Real$^{\uparrow}$ *seal,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already present in the packets. It exports no quotient equality, selected limit, host sequence equality, trichotomy, countable choice, or* Real$^{\uparrow}$ *completeness.*

Proof. Start with the tolerance obligation of Definition 1517.2. It forces every classifier read through the shared window, dyadic tolerance rows, finite classifier row, regular rational readbacks, and terminal seal before any equality-facing consumer receives the packet.

Symmetry is supplied by Definition 1517.4. Swapping the two source names changes only the displayed side order, because the same window, classifier row, readback rows, transport, replay, provenance, and local naming surface remain in place.

Transitivity is supplied by Definition 1517.6. When two adjacent accepted reads use the same window and compatible middle rows, the middle source is transported through the displayed hsame entries and the endpoint classifier read remains on that window.

Finally apply the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. These theorems account for every consumed row and prevent the equivalence-style route from becoming quotient equality, selected limits, host sequence equality, trichotomy, choice, or Real completeness. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierSharedWindowEquivalence`

Theorem 1517.8 (RealNameClassifier finite window coverage)**.** *Every accepted* RealNameClassifier$^{\uparrow}$ *classifier route assembled from the reflexive window route, common-window symmetry route, and common-window transitivity route consumes exactly one displayed* StreamName$^{\uparrow}$ *window W, the two* DyadicRatCore$^{\uparrow}$ *tolerance rows attached to that window, and the two* RegSeqRat$^{\uparrow}$ *readback rows before reaching the terminal* Real$^{\uparrow}$ *seal. The route may reuse the displayed window through componentwise* hsame *transport and* Cont *replay, but it may not introduce a second precision schedule, an external equality oracle, or a completion principle outside the carrier rows of Definition 1517.1.*

Proof. Start with the tolerance obligation of Definition 1517.2. It forces every classifier query to expose the common window W, the two dyadic tolerance rows, and the finite classifier row before any readback or seal row can be consumed.

For reflexive reads, use Definition 1517.3. The two source entries are the same displayed row, so the single window is reused rather than copied into a second schedule.

For exchanged and composed reads, use Definition 1517.4 and Definition 1517.6. Symmetry swaps the endpoint rows while leaving W fixed, and transitivity transports the middle source through compatible dyadic and regular readback rows on the same window.

Finally apply the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. They place the $\mathsf{Real}^{\uparrow}$ seal after the displayed window, tolerance, classifier, readback, transport, replay, provenance, and naming rows, and they leave no coordinate for a second window, external equality oracle, quotient completion, selected limit, trichotomy, choice, or Real completeness. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierWindowCoverage`

Theorem 1517.9 (RealNameClassifier window trichotomy refusal)**.** *Every accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *read over a common* $\mathsf{StreamName}^{\uparrow}$ *window exports only tolerance comparison, regular-rational readback, transport, replay, provenance, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows for the two displayed real names. Consequently the classifier cannot decide a constructive trichotomy row for those names: no accepted read supplies a row deciding equality, strict left order, or strict right order as an exhaustive alternative.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierWindowTrichotomyRefusal`

Proof. Apply the tolerance obligation of Definition 1517.2. A classifier read must first pass through the common window, the two dyadic tolerance rows, and the finite tolerance classifier row; this produces only bounded comparison data on the inspected window.

The shared-window equivalence route of Definition 1517.7 then assembles reflexive, symmetric, and transitive classifier behavior from the same displayed rows. It does not add an order row or a decision row beyond the tolerance classifier.

Finally use the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. The terminal seal is reached only after the displayed tolerance, readback, transport, replay, provenance, and naming rows have been consumed, and the ledger has no coordinate for trichotomy. Hence no constructive trichotomy witness can be exported from the accepted classifier packet. □

Theorem 1517.10 (RealNameClassifier refinement stability)**.** *Let* $C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N$ *be an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet. If a downstream consumer refines the common window* W *by a displayed* $\mathsf{StreamName}^{\uparrow}$ *transport and replays the two dyadic rows through* H *and* K*, then the resulting classifier read is the same local* $\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}$ *surface. The refinement changes only the finite observation window, not the two source names, dyadic tolerance obligation, regular rational readbacks, package provenance, or terminal seal boundary.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierRefinementStability`

Proof. Start with the displayed refinement of W. The transport row H identifies the refined window with the original common schedule in the componentwise hsame sense recorded by the packet.

Replay by K carries both dyadic rows through the same refinement. Thus the comparison row T is read after transporting D_A and D_B along a single common route, not by changing one source independently of the other.

The remaining rows R_A, R_B, P, S, N are attached to the same transported packet. The local naming surface is therefore stable under the displayed refinement, because no new source coordinate or external equality principle is introduced. □

Theorem 1517.11 (RealNameClassifier Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet reaches the seal row* S *only after the two* $\mathsf{RegularCauchyName}^{\uparrow}$ *source rows, the common* $\mathsf{StreamName}^{\uparrow}$ *window, the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the tolerance classifier row, and the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows have been displayed. The seal exports no*

quotient equality of Cauchy names, host sequence equality, selected limit, countable-choice schedule, trichotomy witness, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the carrier of Definition 1517.1. The terminal seal row S appears after the source rows, common finite window, dyadic tolerance rows, tolerance classifier, regular rational readbacks, transport, replay, and provenance rows.

Apply Definition 1517.2. A seal-facing consumer cannot bypass W, D_A, D_B, T, because those rows are the only route by which the classifier query is discharged.

The carrier contains no coordinate for any of the excluded principles. Consequently the $\mathsf{Real}^{\uparrow}$ seal is only a boundary row for the displayed finite classifier packet, not a source of quotient equality, host equality, choice, trichotomy, selected limits, or completeness. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierSealBoundary`

Theorem 1517.12 (RealNameClassifier ledger exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}$ *ledger for Definition 1517.1 is exhausted by carrier admission for* $A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N$*, common-window tolerance comparison, refinement transport, regular rational readback exposure, package provenance, terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, and local naming. No additional equality oracle or completion principle is available to a consumer of the packet.*

Proof. Carrier admission supplies exactly the displayed tuple. The analytic rows are the two regular Cauchy sources, the common window, the two dyadic tolerance rows, the classifier row, the regular rational readbacks, and the terminal real seal.

The structural rows are H, K, P, N. They transport, replay, source, and name the same finite packet, so their obligations do not add a hidden quotient or host-level equality coordinate.

The tolerance obligation and refinement stability theorems account for the classifier-facing reads. The seal-boundary theorem accounts for the real-facing reads. These routes cover every row in the ledger, and the carrier explicitly omits the excluded equality, choice, trichotomy, selected-limit, and completeness principles. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierLedgerExhaustion`

Theorem 1517.13 (RealNameClassifier obligation closure route)**.** *The source packet of Definition 1517.1, together with the tolerance obligation, reflexive window route, common-window symmetry, common-window transitivity, shared-window equivalence, finite window coverage, trichotomy refusal, refinement stability, seal boundary, and ledger exhaustion, assembles the full obligation surface for* $\mathsf{RealNameClassifier}^{\uparrow}$ *over* $\mathsf{RegularCauchyName}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The assembled route closes the finite classifier obligations for equality inspection of two regular Cauchy real names while excluding quotient Cauchy classes, host sequence equality, selected limits, countable choice, trichotomy, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierObligationClosureRoute`

Proof. The carrier is fixed by Definition 1517.1. Its rows are exactly the two regular Cauchy sources, the common stream window, two dyadic tolerance rows, the finite classifier row, two regular rational readbacks, componentwise transport, continuation replay, package provenance, the terminal real seal, and local naming.

The first classifier-facing obligations are supplied by Definition 1517.2, Definition 1517.3, Definition 1517.4, and Definition 1517.6. These results account for tolerance comparison, reflexive

reuse of the common window, exchange of the two sources, and compatible composition through a shared middle source.

The remaining classifier-facing obligations are supplied by Definition 1517.7, Definition 1517.8, and Definition 1517.9. They account for equivalence-style reuse on the displayed window, finite window coverage, and refusal of a trichotomy row.

The boundary obligations are supplied by Definition 1517.10, Definition 1517.11, and Definition 1517.12. They show that refinement only transports the same finite route, that the $\mathsf{Real}^{\uparrow}$ seal is reached after the displayed classifier data, and that no ledger coordinate remains for a hidden equality oracle or completion principle.

Combining these rows gives the named obligation surface for $\mathsf{RealNameClassifier}^{\uparrow}$. Since every cited row is internal to the displayed packet, the route still excludes quotient Cauchy classes, host sequence equality, selected limits, countable choice, trichotomy, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1517.14 (RealNameClassifier scoped kernel route)**.** *The obligation closure route of Definition 1517.13 is scoped exactly by the displayed packet rows*

$$A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N$$

and by the primitives BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Any accepted equality-inspection consumer of* $\mathsf{RealNameClassifier}^{\uparrow}$ *must consume the tolerance obligation, finite window coverage, refinement stability, seal boundary, and ledger exhaustion through those rows before it reads the local classifier surface. The route exports no quotient Cauchy class, host sequence equality, selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierScopedKernelRoute`

Proof. Start with the source packet of Definition 1517.1. Its carrier rows are precisely $A, B, W, D_A, D_B, T, R_A, R_B, H$ and its structural primitives are the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Apply the tolerance obligation and finite window coverage, Definition 1517.2 and Definition 1517.8. They force every classifier read through the common $\mathsf{StreamName}^{\uparrow}$ window, the two $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, the finite classifier row, and the two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks before any real-facing seal is inspected.

Next use refinement stability, Definition 1517.10. Refining the observation window changes only the displayed window route and transported dyadic rows, so the same componentwise transport, replay, provenance, and local naming rows remain in force.

Finally use the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. The $\mathsf{Real}^{\uparrow}$ seal is reached only after the finite classifier data has been displayed, and the ledger contains no coordinate beyond the rows listed above. Thus the scoped route is exactly the displayed kernel surface and no excluded completion or equality principle is exported. □

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierScopeRoute`

Theorem 1517.15 (Real name classifier refinement scope factorization)**.** *Every accepted* $\mathsf{RealNameClassifier}^{\uparrow}$ *refinement read factors through the common finite-window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D_A, D_B*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R_A, R_B*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S *before exposing a classifier decision. The factorization is scoped by the sibling surfaces of chapter 371, chapter 291, chapter 126, chapter 301, and chapter 38, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of Definition 1517.1. It uses no quotient real, host equality, selected representative, trichotomy, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierRefinementScopeFactorization`

Proof. Project the carrier of Definition 1517.1. A refinement read begins with the same displayed rows $A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N$ as the original classifier packet.

Apply refinement stability, Definition 1517.10. The refined observation changes only the displayed window route and the transported dyadic rows; it does not introduce a second source, a host equality test, or a new decision coordinate.

Next compose the readback and seal obligations. The tolerance obligation, read through chapter 291 and chapter 126, forces the classifier through W, D_A, D_B, T; the regular rational rows are the readback surface of chapter 301; and the terminal seal is the $\mathsf{Real}^{\uparrow}$ boundary of chapter 38.

The source names remain the regular Cauchy rows supplied by chapter 371. Componentwise transport through H, replay through K, provenance through P, and local naming through N preserve the same finite route, so the classifier decision is exposed only after the common window, dyadic ledger, readback rows, and terminal seal have been displayed.

No carrier coordinate supplies quotient real equality, host equality, a selected representative, trichotomy, or ambient completeness. The refinement read therefore factors through the stated finite scope rather than through any external real-number principle. □

Theorem 1517.16 (RealNameClassifier kernel-scope determinacy)**.** *Let*

$$C = (A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N)$$

and

$$C' = (A', B', W, D'_A, D'_B, T', R'_A, R'_B, H', K', P', S', N')$$

be accepted $\mathsf{RealNameClassifier}^{\uparrow}$ *reads whose classifier queries use the same common* $\mathsf{StreamName}^{\uparrow}$ *window* W*. Suppose the dyadic tolerance rows* D_A, D_B, D'_A, D'_B *are matched at the displayed precision requests, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_A, R_B, R'_A, R'_B *are matched by componentwise* hsame *transport, the two* Cont *replays* K, K' *follow the same window route, the* Pkg *provenance rows* P, P' *source the same classifier packet surface, and the* $\mathsf{Real}^{\uparrow}$ *seals* S, S' *are reached after the same finite tolerance and readback rows. Then* C *and* C' *expose the same classifier decision route inside the* $\mathsf{RealNameClassifier}^{\uparrow}$ *kernel scope. The route cannot branch through quotient Cauchy classes, host sequence equality, selected representatives, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierKernelScopeDeterminacy`

Proof. Apply the tolerance obligation of Definition 1517.2. Both accepted reads must pass through the shared window W, the displayed dyadic tolerance rows, and the finite classifier row before any readback or seal row is visible.

Use finite window coverage, Definition 1517.8. Since the window is common and the dyadic rows are matched at the displayed precision requests, neither read can introduce a second precision schedule or an external equality oracle.

Next apply refinement stability, Definition 1517.10. The componentwise hsame matches on R_A, R_B, R'_A, R'_B and the Cont replays K, K' transport the same regular readback surface through the same window route.

The seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12, account for the Real seals, provenance rows, and local names. The seals are downstream of the finite classifier data, and the ledger has no coordinate for quotient Cauchy classes, host sequence equality, selected representatives, trichotomy, or completeness.

Finally apply the refinement scope factorization of Definition 1517.15. With the same common window, matched tolerance rows, matched regular readbacks, transported replay, shared provenance surface, and downstream Real seal, both accepted reads expose the same classifier decision route inside the displayed kernel scope. □

Theorem 1517.17 (RealNameClassifier refined-window synchronization)**.** *Let*

$$C_0 = (A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N)$$

be an accepted $\mathsf{RealNameClassifier}^{\uparrow}$ *read, and let* C_1, C_2 *be two accepted refinement reads whose classifier queries refine the same base* $\mathsf{StreamName}^{\uparrow}$ *window* W*. Suppose both refinements transport the displayed dyadic rows through the same componentwise* hsame *rows, replay the same window route through* Cont*, match the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows before opening the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and keep the* Pkg *provenance and local* NameCert *row on the carrier surface of* C_0*. Then* C_1 *and* C_2 *expose one synchronized classifier route through the matching* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and terminal* $\mathsf{Real}^{\uparrow}$ *rows. The synchronized route exports no quotient Cauchy class, host sequence equality, selected representative, trichotomy, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierRefinedWindowSynchronization`

Proof. Start with the tolerance obligation and finite window coverage, Definition 1517.2 and Definition 1517.8. Both refinements must consume the base window W, the transported dyadic tolerance rows, the finite classifier row, and the regular rational readbacks before any seal-facing row is visible.

Apply refinement stability, Definition 1517.10. Since the two reads transport their dyadic rows by the same hsame rows and replay the same window route through Cont, the refinements change only the finite observation window and not the source names, classifier row, provenance, or local naming surface.

Use the seal boundary and ledger exhaustion, Definition 1517.11 and Definition 1517.12. The terminal $\mathsf{Real}^{\uparrow}$ row is downstream of the displayed dyadic and $\mathsf{RegSeqRat}^{\uparrow}$ rows, and the ledger has no coordinate for quotient Cauchy classes, host equality, selected representatives, trichotomy, or completeness.

Finally apply kernel-scope determinacy, Definition 1517.16. With the same base window, transported dyadic rows, matched readbacks, common replay, shared provenance, and downstream seal, the two refinement reads determine the same synchronized classifier route inside the $\mathsf{RealNameClassifier}^{\uparrow}$ kernel scope. □

Theorem 1517.18 (RealNameClassifier bridge route)**.** *The public classifier surface of Definition 1517.15 bridges the concrete* $\mathsf{RealNameClassifier}^{\uparrow}$ *packet to the abstract real-name equality-inspection interface through the displayed* $\mathsf{RegularCauchyName}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route exposes the common-window classifier and terminal seal as public packet data, without quotient equality, selected limits, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealNameClassifierUp.RealNameClassifierBridgeRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1517.14 and Definition 1517.15 make the finite classifier packet mature as a paper-side route over $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, the displayed packet rows $A, B, W, D_A, D_B, T, R_A, R_B, H, K, P, S, N$, and the primitives BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealNameClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host sequence equality, selected limits, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The paper-side route is mature; Lean verification and bridge checking for the same finite classifier packet remain unclaimed.

Constructive story: A $\mathsf{RealNameClassifier}^{\uparrow}$ packet is generated from two RegularCauchyName source rows, one common StreamName window, two DyadicRatCore tolerance rows, a finite tolerance classifier, two RegSeqRat readbacks, componentwise transport, continuation replay, package provenance, a RealUp seal, and local naming.

Chapter 1518

A Concrete Naming Certificate for $\mathsf{FastCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FastCauchySubsequence}^{\uparrow}$ packet records the finite extraction route from inspected Cauchy-modulus data to a fast regular subsequence. It reads the modulus surface of chapter 292, the fast-rate route of chapter 323, the selector ledger of chapter 405, the regular subsequence handoff of chapter 381, the regular rational readback of chapter 301, and the real-name seal of chapter 38.

The bridge is a local L10 NameCert object. It turns displayed Cauchy-modulus inspections into a cofinal fast subsequence route, then hands that route to the existing regular-subsequence and regular-rational surfaces without importing host subsequence equality, arbitrary countable choice, quotient Cauchy classes, selected limits, trichotomy, or real completeness.

Definition 1518.1 (FastCauchySubsequence carrier)**.** *A* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, M, Q, F, R, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *or Cauchy-name row whose windows are inspected before any subsequence is read;*
2. *M is the accepted* $\mathsf{CauchyModulus}^{\uparrow}$ *row recording the inspected modulus bounds for S;*
3. *Q is the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row, including the finite monotone-cofinal ledger used to choose later windows;*
4. *F is the* $\mathsf{FastCauchy}^{\uparrow}$ *fast-rate row obtained from the inspected modulus data along Q;*
5. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row that repacks the selected fast windows as a regular subsequence surface;*
6. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row determined by the same selected windows, radius data, and fast-rate ledger;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R and W have been projected;*
8. *H records componentwise* hsame *transports for S, M, Q, F, R, W, E and the naming support rows;*
9. *C records the displayed* Cont *replay from source windows to modulus inspection, cofinal selection, fast-rate routing, regular-subsequence handoff, regular rational readback, and real seal;*

10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares two carriers only through these displayed rows and stores no host subsequence equality, arbitrary countable-choice functional, quotient Cauchy class, selected limit, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 (definition) `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceUp`

Theorem 1518.2 (FastCauchySubsequence NameCert obligations)**.** *For an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source row, modulus row, selector row, fast-rate row, regular-subsequence row, regular rational readback, real seal, transports, replay routes, provenance, and local naming row;*
2. *modulus coverage, requiring every selected window used by the downstream route to be covered by the inspected bounds in M;*
3. *cofinal selector admission for Q, including the displayed monotone-cofinal ledger and the absence of a host-level choice selector;*
4. *fast-rate exactness, requiring F to be read from the modulus coverage row along the selected cofinal windows;*
5. *regular-subsequence window handoff, requiring R to consume the selected windows and transported dyadic radius data exposed by Q and F;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring W to be obtained from the same selected regular windows and not from an independent rational sequence;*
7. $\mathsf{Real}^{\uparrow}$ *seal delivery, requiring E to be reached only after R and W have been projected;*
8. hsame *transport through H for the source, modulus, selector, fast-rate, regular-subsequence, readback, seal, and support rows;*
9. Cont *replay through C for the same dependency route;*
10. Pkg *provenance through P over the cited sibling certificates and BEDC support rows;*
11. *local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *admission through N.*

No obligation row exports host subsequence equality, arbitrary countable choice, quotient Cauchy classes, selected limits, trichotomy, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The tuple displays exactly the source, inspected modulus, cofinal selector, fast-rate row, regular-subsequence handoff, regular rational readback, real seal, transports, replay routes, provenance, and local naming row.

Use the modulus and selector rows first. The row M supplies only inspected Cauchy-modulus bounds, and Q supplies only a finite monotone-cofinal selection ledger. Thus selected downstream windows must be covered by displayed modulus data rather than by a host-level choice functional.

Next use the fast-rate and regular-subsequence rows. The row F reads the chosen windows through the modulus coverage route, and R repacks exactly those windows and their transported dyadic radius data as a $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff.

Finally read the regular rational and real-facing rows. The row W is tied to the same selected windows, while E is placed after R and W in the carrier. The transport, replay, package, and local naming rows preserve that order componentwise, and the carrier has no remaining coordinate for host equality, countable choice, quotient classes, selected limits, trichotomy, or completeness. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceNamecertObligations`

Theorem 1518.3 (FastCauchySubsequence regular route)**.** *Every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet factors any* $\mathsf{Real}^{\uparrow}$*-facing read through the inspected modulus row, cofinal selector row, fast-rate row,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the* $\mathsf{Real}^{\uparrow}$ *seal is exposed. In the notation of Definition 1518.1, every such read follows*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad E$$

with the displayed hsame*,* Cont*,* Pkg*, and local* NameCert *provenance.*

Proof. Begin with the carrier order. The real seal row E occurs only after the source row S, the inspected modulus row M, the cofinal selector row Q, the fast-rate row F, the regular-subsequence row R, and the regular rational row W.

Apply the NameCert obligations of Definition 1518.2. They force modulus coverage before selection, selector admission before fast-rate readback, fast-rate exactness before the regular-subsequence handoff, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback before any real-facing seal is consumed.

The rows H, C, P, and N carry the same dependency order under transport, replay, provenance, and local naming. Since no carrier coordinate stores host subsequence equality, arbitrary countable choice, quotient Cauchy classes, selected limits, trichotomy, or real completeness, every $\mathsf{Real}^{\uparrow}$-facing read factors through the displayed route. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegularRoute`

Theorem 1518.4 (FastCauchySubsequence modulus-selector coherence)**.** *For an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *row* Q *determine the same selected* $\mathsf{StreamName}^{\uparrow}$ *windows before either the fast-rate row* F *or the regular-subsequence handoff row* R *is read. Thus the selected windows used downstream are fixed by the displayed modulus-selector pair and not by host subsequence equality or a countable-choice selector.*

Proof. Project the carrier of Definition 1518.1. The only rows available before F and R are the source row S, the inspected modulus row M, and the cofinal selector row Q.

Apply the NameCert obligations of Definition 1518.2. They require modulus coverage before selection and selector admission before fast-rate readback, so the windows chosen by Q must be windows whose bounds are already displayed in M.

The regular route theorem, Definition 1518.3, then prevents any later row from changing that selection before F or R is consumed. Since the carrier has no coordinate for host subsequence equality or countable choice, coherence is exactly the displayed M, Q agreement. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceModulusSelectorCoherence`

Theorem 1518.5 (FastCauchySubsequence selector-window coverage)**.** *Every selected window in an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *is covered by the displayed cofinal selector* Q *together with the dyadic and fast-rate ledger read through* M *and* F*. The coverage route exposes only the finite selector ledger, inspected modulus data, fast-rate row, regular-subsequence handoff, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback; it does not import an independent subsequence function.*

Proof. Start with the selected windows named by Q. By carrier admission, these windows are rows of the finite packet and are read from the source row S rather than from an external selector.

Use Definition 1518.4. It binds the selected windows to the same inspected modulus row M before the fast-rate row F and the handoff row R are visible.

Apply the regular route theorem, Definition 1518.3. The route from Q to W passes through F and R, so each selected window is covered by the displayed cofinal selector, dyadic radius data carried in the fast-rate ledger, and regular rational readback. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSelectorWindowCoverage`

Theorem 1518.6 (FastCauchySubsequence selected-window induction)**.** *For every accepted* FastCauchySubsequenc *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the finite list of selected windows is determined by the displayed rows* M, Q, F, R, W*. More precisely, induction over the selected-window rows exposed by* Q *reads each step through*

$$M \longmapsto Q \longmapsto F \longmapsto R \longmapsto W,$$

with S, H, C, P, N *only transporting and naming the route. No induction step may branch on host subsequence equality, an independent selector function, countable choice, quotient Cauchy classes, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSelectedWindowInduction`

Proof. Project the selected windows named by Q. The carrier exposes them as a finite BHist ledger, so the induction is ordinary finite row induction over the displayed selector entries.

At the base row, Definition 1518.4 binds the selected source window to the inspected modulus row M. The fast-rate data F, regular-subsequence handoff R, and regular rational readback W then read the same window by Definition 1518.5.

For the successor row, repeat the same projection on the next displayed selector entry. Since the carrier has no coordinate for host subsequence equality, countable choice, quotient Cauchy classes, selected limits, or ambient completeness, the step can only reuse the displayed M, Q, F, R, W route. □

Theorem 1518.7 (FastCauchySubsequence tail-choice refusal)**.** *Let* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *be an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier. Any tail-choice claim made by a downstream consumer is accepted only when it is read from the finite selector windows already covered by* M, Q, F, R, W*. A claim whose witness is a host subsequence functional, a countable-choice schedule, quotient equality of Cauchy representatives, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness has no row in the carrier and is therefore not a* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *read.*

Proof. Start with selector-window coverage. It makes every selected window pass through the cofinal selector Q, inspected modulus data M, fast-rate row F, regular-subsequence handoff R, and $\mathsf{RegSeqRat}^{\uparrow}$ readback W.

A tail-choice claim must therefore name one of those finite rows. If it names an external functional or a countable schedule instead, there is no carrier coordinate that can be transported by H, replayed by C, sourced by P, or named by N.

The refusal is stable under finite-window induction from Definition 1518.6. Each additional selected window is another displayed M, Q, F, R, W row, not an opportunity to import host equality, quotient classes, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailChoiceRefusal`

Theorem 1518.8 (FastCauchySubsequence Real-seal nonescape induction)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, finite induction over the selected-window ledger preserves the Real-seal boundary. At every selected window, any route that reaches the terminal seal row* E *has already consumed the displayed rows*

$$M, \quad Q, \quad F, \quad R, \quad W.$$

Thus Real-facing reads cannot escape through host subsequence equality, countable choice, quotient Cauchy classes, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness at any finite induction stage.*

Proof. Use Definition 1518.6 as the induction spine. The base selected window is read through M, Q, F, R, W before any Real-facing consumer can ask for E.

For the successor window, apply the same finite row projection. Selector-window coverage keeps the new window inside the fast-rate ledger and regular-subsequence handoff before the regular rational readback W is public.

The Real-facing conclusion follows from Definition 1518.7. Since no induction stage carries a host selector, quotient Cauchy class, selected limit, trichotomy witness, or completeness coordinate, the terminal seal cannot expose any such data. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealNonescapeInduction`

Theorem 1518.9 (Fast Cauchy subsequence tail normal form)**.** *Every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet has a tail normal form whose selector is exposed only after the packet has factored through the displayed* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *rows. For a carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the normal-form read is*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad E, \quad H, \quad C, \quad P, \quad N.$$

The exposed tail selector is therefore the cofinal finite-window row Q *read through inspected modulus bounds, dyadic radius support, fast-rate evidence, regular-subsequence handoff, regular rational readback, source windows, and the terminal Real seal, not an independent subsequence function or a countable-choice object.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequence tail normal form`

Proof. Project the carrier of Definition 1518.1. The source windows S and inspected modulus row M are the first rows available to a tail request.

Read the cofinal index next. The selector row Q supplies the finite monotone-cofinal ledger, and by Definition 1518.4 its windows are already tied to the inspected modulus data in M.

Read the dyadic radius and fast-rate information through F. The provenance row records $\mathsf{DyadicRatCore}^{\uparrow}$ support, and Definition 1518.5 keeps the selected windows inside the displayed fast-rate ledger.

Finally pass through the regular-Cauchy and Real-facing rows. The handoff R, readback W, and seal E are read in order by Definition 1518.3, while H, C, P, N transport, replay, source, and name the same route. Thus the tail selector appears only in the displayed normal form and cannot be replaced by a host subsequence or choice functional. □

Theorem 1518.10 (FastCauchySubsequence RealUp tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing tail read of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet factors through the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row, cofinal finite-window selector,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger,* $\mathsf{FastCauchy}^{\uparrow}$ *rate evidence,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *source windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. For a carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the handoff route is*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad E.$$

The structural rows H, C, P, N *transport, replay, source, and name this same route, so the tail read exposes no quotient Cauchy class, selected limit, independent subsequence function, countable-choice selector, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealUpTailHandoff`

Proof. Begin with the regular route of Definition 1518.3. It places every $\mathsf{Real}^{\uparrow}$-facing read downstream of the source row, inspected modulus, cofinal selector, fast-rate evidence, regular-subsequence handoff, and regular rational readback.

Use Definition 1518.4 to bind the selector to the inspected modulus windows. Then apply Definition 1518.5; the selected windows remain inside the displayed dyadic radius and fast-rate ledger before the handoff row R is read.

Finally apply Definition 1518.9. It records the same ordered read $S, M, Q, F, R, W, E, H, C, P, N$, so the Real-facing seal is reached only by the finite tail route and not by an external subsequence or choice object. □

Theorem 1518.11 (FastCauchySubsequence Real-seal selector boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet must pass through the modulus row* M*, cofinal selector row* Q*, fast-rate row* F*, regular-subsequence row* R*, and regular rational readback row* W *before the seal row* E *is visible. The seal boundary is therefore the displayed route*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad E$$

inside the packet $A = (S, M, Q, F, R, W, E, H, C, P, N)$*.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealSelectorBoundary`

Proof. Begin with Definition 1518.3. It already places every $\mathsf{Real}^{\uparrow}$-facing read downstream of S, M, Q, F, R, W and before the terminal row E.

Use Definition 1518.4 to bind the first two active rows of the boundary. The seal consumer cannot replace the displayed M, Q window selection by host subsequence equality or a countable-choice selector.

Then use Definition 1518.5. It forces the selected windows through the fast-rate ledger, regular-subsequence handoff, and $\mathsf{RegSeqRat}^{\uparrow}$ readback before E is consumed. The structural rows H, C, P, N transport and name this route without adding another seal path. □

Definition 1518.12 (FastCauchySubsequence source surface)**.** *The* source surface *of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *is the finite* BHist *route*

$$\Theta_A = (S, M, Q, F, R, W, E, H, C, P, N)$$

read in the following order: source windows S*, inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *bounds* M*,* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector rows* Q*,* $\mathsf{FastCauchy}^{\uparrow}$ *rate rows* F*,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff rows* R*,* $\mathsf{RegSeqRat}^{\uparrow}$

readback rows W, terminal $\mathsf{Real}^{\uparrow}$ *seal rows E, and structural support H, C, P, N. Every Real-facing read of the source surface must pass through all six analytic rows M, Q, F, R, W, E after the source row S and before public data is named by N.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSourceSurface`

Theorem 1518.13 (FastCauchySubsequence cofinal-window obligation)**.** *For every accepted* $\mathsf{FastCauchySubsequen}$ *carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$, every cofinal window accepted by the source surface is a finite* BHist *row whose readback passes through the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M,* $\mathsf{CofinalSubsequence}^{\uparrow}$ *row Q,* $\mathsf{FastCauchy}^{\uparrow}$ *row F,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row R,* $\mathsf{RegSeqRat}^{\uparrow}$ *row W, and terminal* $\mathsf{Real}^{\uparrow}$ *row E. The obligation rejects any route that reads a Real-facing comparison from Q alone, from an independent subsequence function, or from a host-level choice selector.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalWindowObligation`

Proof. Project the source surface of Definition 1518.12. The carrier displays S, M, Q, F, R, W, E before the support rows, so a cofinal window entering through Q is still tied to source access and inspected modulus data.

Use Definition 1518.4 for the front of the route. It binds selector admission to the inspected modulus row, preventing a consumer from replacing M, Q by an external selector.

Apply Definition 1518.3 and Definition 1518.11 for the downstream route. They force the selected window through F, R, W, E before any Real-facing public read is exposed, while H, C, P, N only transport, replay, source, and name the same finite rows. □

Theorem 1518.14 (FastCauchySubsequence Real seal nonescape)**.** *Let $A = (S, M, Q, F, R, W, E, H, C, P, N)$ be an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier. No Real-facing read can escape the source surface before consuming the Cauchy-modulus, cofinal-selector, fast-rate, regular-subsequence, regular-rational, and Real-seal rows M, Q, F, R, W, E. In particular, a consumer that reaches E still receives only the finite route named by $S, M, Q, F, R, W, E, H, C, P, N$, not a selected limit, quotient Cauchy class, host real equality, trichotomy, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealNonescape`

Proof. Start with the Real-seal selector boundary. It places the seal row E behind M, Q, F, R, W and denies a direct path from the selector row to a Real-facing observation.

Use the cofinal-window obligation above for every selected finite window. Each such window remains a BHist row in the source surface and is read through the displayed CauchyModulus, CofinalSubsequence, FastCauchy, RegularCauchySubsequence, RegSeqRat, and Real rows.

Finally apply the NameCert obligations of Definition 1518.2. The support rows H, C, P, N preserve componentwise transport, replay, provenance, and local naming only for the displayed finite route, so the forbidden host-level data has no coordinate through which it could escape. □

Theorem 1518.15 (FastCauchySubsequence formal target ledger)**.** *Any later Lean target for* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *must encode the same displayed carrier rows used in this chapter: inspected source windows S, the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *row Q, the* $\mathsf{FastCauchy}^{\uparrow}$ *rate row F, the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback W, the* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *row N. The target may prove only obligations over these rows and must not encode quotient stream equality, selected limits, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness as hidden support.*

Proof. Start with the carrier definition. It lists exactly the displayed source windows, CauchyModulus, CofinalSubsequence, FastCauchy, RegularCauchySubsequence, RegSeqRat, Real seal, transport, replay, provenance, and local NameCert rows.

Apply the local obligation theorems in order. The NameCert obligations, regular route, modulus-selector coherence, selected-window induction, cofinal-window obligation, and Real-seal nonescape theorem all consume the same rows and never introduce a second carrier.

The formal target therefore has no room for quotient stream equality, selected limits, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness. Any such field would be outside $S, M, Q, F, R, W, E, H, C, P, N$ and would not be the chapter's finite BHist ledger. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceFormalTargetLedger`

Theorem 1518.16 (FastCauchySubsequence cofinal tail obligation)**.** *Let $A = (S, M, Q, F, R, W, E, H, C, P, N)$ be an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier. Before any downstream consumer may read the* $\mathsf{FastCauchy}^{\uparrow}$ *row F, the cofinal selector row Q must expose, for every inspected modulus threshold in M, a finite tail window whose selector index lies beyond that threshold and whose source window is still covered by M. The obligation is a row-order condition inside $S, M, Q, F, R, W, E, H, C, P, N$; it is not supplied by a host subsequence function, countable choice, quotient Cauchy equality, selected limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalTailObligation`

Proof. Project the carrier and inspect the rows before F. The available analytic rows are the source windows S, the inspected modulus row M, and the cofinal selector row Q.

Use Definition 1518.5. Every selected window is already a finite row covered by the displayed selector, inspected modulus data, and fast-rate ledger, so a downstream fast-Cauchy read cannot invent a later selector outside the packet.

For each inspected threshold in M, exhaust the finite row order of Q until the first displayed selector row beyond that threshold is reached. Cofinality is read as the presence of that later row in the selector ledger, and coverage is read back through M.

Only after this tail window has been displayed may F consume it as fast-rate evidence. The structural rows H, C, P, N transport, replay, source, and name the same tail route, while the carrier lacks every refused host-level coordinate. □

Theorem 1518.17 (FastCauchySubsequence RegSeqRat and Real route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{CauchyModulus}^{\uparrow},\quad \mathsf{CofinalSubsequence}^{\uparrow},\quad \mathsf{FastCauchy}^{\uparrow},\quad \mathsf{RegularCauchySubsequence}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRat}$$

In carrier notation, the consumer reads M, Q, F, R, W, E with dyadic radius support recorded in the provenance row P before the terminal seal is available, and it reads no independent rational sequence, quotient Cauchy class, selected limit, host subsequence equality, countable-choice selector, trichotomy, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegSeqRatRealRoute`

Proof. Begin with the regular route of Definition 1518.3. It already places every Real-facing read downstream of the inspected modulus row M, cofinal selector row Q, fast-rate row F, regular-subsequence handoff R, and regular rational readback W.

Use the cofinal tail obligation above to expose the tail window before F is consumed. The selector row therefore supplies a later covered window for every inspected modulus threshold, rather than delegating the choice to an external subsequence.

Next apply Definition 1518.5. The selected window carries the dyadic radius support named in P, passes through the fast-rate row F, and is repacked by R before the $\mathsf{RegSeqRat}^{\uparrow}$ row W can be read.

Finally the terminal row E seals the same route as a $\mathsf{Real}^{\uparrow}$ read. Transport through H, replay through C, provenance through P, and local naming through N preserve the route and do not add any of the refused host-level data. □

Theorem 1518.18 (FastCauchySubsequence bridge scope)**.** *The bridge-facing public route of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet is exhausted by the displayed* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows, together with componentwise transport, replay, provenance, and local* NameCert *rows. No bridge-facing read can enter through host subsequence equality, a countable-choice selector, a quotient Cauchy class, a selected limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the regular route of Definition 1518.3. It orders every public read through the inspected modulus row, cofinal selector row, fast-rate row, regular-subsequence handoff, regular rational readback, and terminal real seal.

Use the cofinal tail obligation of Definition 1518.16 and the selector-window coverage of Definition 1518.5. These theorems keep the selected windows inside the displayed modulus and selector ledgers before the fast-rate and regular-subsequence rows are consumed.

Finally apply the RegSeqRat and Real route of Definition 1518.17. The dyadic support, regular rational readback, and real seal are read through the same finite packet, while H, C, P, N only transport, replay, source, and name the route. Since none of the displayed rows stores host equality, countable choice, quotient classes, selected limits, trichotomy, or ambient completeness, those endpoints cannot enter the bridge-facing read. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1518.1, Definition 1518.2, Definition 1518.3, Definition 1518.16, Definition 1518.17, and Definition 1518.18 bind the bridge-facing FastCauchySubsequence route through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceNamecertObligations`

Bridge status: none

Not claimed: This chapter does not claim host subsequence equality, arbitrary countable choice, quotient Cauchy classes, selected limits, trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: The finite fast-Cauchy subsequence route is mature on the paper axis; remaining work is limited to Lean-side cleanliness and bridge synchronization when a standard bridge theorem is supplied.

Constructive story: A $\mathsf{FastCauchySubsequence}^{\uparrow}$ packet is generated from inspected source windows, a CauchyModulus row, a CofinalSubsequence selector, a FastCauchy rate row, a RegularCauchySubsequence handoff, a RegSeqRat readback, a RealUp seal, componentwise transports, replay routes, provenance, and a local NameCert row.

Definition 1518.19 (FastCauchySubsequence selection surface)**.** *The* selection surface *of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *is the finite* BHist *subpacket*

$$\Sigma_A = (M, Q, F, W, H, C, P, N)$$

whose rows expose:

1. *the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *bounds in* M*;*

2. *the finite cofinal-window ledger in Q, with each displayed window tied to a source window of S;*
3. *the* FastCauchy$^{\uparrow}$ *rate row in F read from those same inspected windows;*
4. *the* RegSeqRat$^{\uparrow}$ *readback row W reached through the selected regular windows;*
5. *the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows carried by H, C, P, N.*

The surface has no coordinate for an infinite subsequence object, a choice functional, host stream equality, or a selected limit.

Lean4 (definition) `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSelectionSurface`
Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSelectionSurface namecert window`

Theorem 1518.20 (FastCauchySubsequence cofinal finite window)**.** *For every accepted* FastCauchySubsequence$^{\uparrow}$ *carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$ and every displayed target precision row consumed by the fast-rate route, the selection surface Σ_A contains a finite cofinal window row in Q whose source window is covered by the inspected* CauchyModulus$^{\uparrow}$ *data in M and whose transported radius data is read by F. The witness is a finite* BHist *row carried through H, C, P, N, not an infinite selected subsequence and not an appeal to countable choice.*

Proof. Project the selection surface of Definition 1518.19. The target precision row can be consumed only by the displayed fast-rate row F, and F is listed downstream of the modulus row M and cofinal-window ledger Q.

Use the NameCert obligations of Definition 1518.2. They require modulus coverage for every selected downstream window and require selector admission before the fast-rate readback is exposed.

The row Q is finite carrier data: it records a displayed monotone-cofinal ledger of windows rather than a host selector. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve that finite witness as the only available cofinal-window row. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalWindowCertificate`

Theorem 1518.21 (FastCauchySubsequence window nonescape)**.** *For every accepted* FastCauchySubsequence$^{\uparrow}$ *carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$, every selected window used by the packet is read first through the source row S, inspected* CauchyModulus$^{\uparrow}$ *row M, and cofinal selector row Q before the fast-rate row F, regular-subsequence handoff R, regular rational readback W, and terminal seal E are available. The support rows H, C, P, N transport, replay, source, and name that same finite-window route.*

Proof. Project the carrier of Definition 1518.1. Its selected-window data begins at S, M, Q, while F, R, W, E are downstream consumer rows.

Use the NameCert obligations of Definition 1518.2. They require modulus coverage before selection and selector admission before fast-rate readback, so no selected window can be consumed outside the displayed S, M, Q front.

Finally apply the regular route theorem, Definition 1518.3. The rows F, R, W, E read the same inspected windows in order, and H, C, P, N preserve the route without adding an independent selector, selected limit, or choice functional. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceWindowNonescape`

Theorem 1518.22 (FastCauchySubsequence tail-modulus lock)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, every downstream tail or window consumed by* F, R, W, E *is already covered by the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and the cofinal selector row* Q*. Thus the finite tail witness used by the fast-rate ledger, regular-subsequence handoff, regular rational readback, and terminal seal is locked to the inspected modulus-selector pair; no independent tail selector, host subsequence functional, or countable-choice functional can enter the route.*

Proof. Begin with modulus-selector coherence, Definition 1518.4. It binds the selected windows read by Q to the inspected modulus row M before the downstream rows F and R are consumed.

Next apply selector-window coverage, Definition 1518.5. That coverage carries each selected finite window from M, Q through the same fast-rate and regular-subsequence route used by F, R, W, E.

Finally use window nonescape, Definition 1518.21. Since every selected window must pass through S, M, Q before the downstream rows are available, the route has no coordinate for an independent tail selector or countable-choice functional. □

Theorem 1518.23 (FastCauchySubsequence tail-comparison extraction)**.** *For every accepted* FastCauchySubsequen *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, any two downstream tail comparisons consumed by* F, R, W, E *are answered by a displayed later cofinal window in* Q *whose source is covered by* S *and* M*, whose fast-rate row is read by* F*, and whose regular readback passes through* R, W *before the terminal seal* E*. Thus the comparison used by the L10* $\mathsf{Real}^{\uparrow}$ *completion route is extracted from the finite cofinal-window ledger and not from an independent tail selector, quotient stream equality, selected limit, or countable-choice functional.*

Proof. Start with the cofinal finite-window theorem, Definition 1518.20. It supplies a finite row in Q for the requested precision, and that row is already tied to source access in S and inspected modulus data in M.

Apply the tail-modulus lock above. The two tail comparisons consumed downstream cannot leave the displayed M, Q pair, because F, R, W, E read only windows covered by that inspected modulus-selector route.

Use cofinal $\mathsf{RegSeqRat}^{\uparrow}$ coverage and the modulus regular handoff, Definition 1518.24 and Definition 1518.25. They route the selected later window through F, then R, W, and only then to E.

The structural rows H, C, P, N transport, replay, source, and name the same finite witness. Since the carrier has no coordinate for an independent tail selector, quotient stream equality, selected limit, or countable-choice functional, the extracted comparison is exactly the displayed cofinal-window comparison used by the L10 Real completion route. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailComparisonExtraction`

Theorem 1518.24 (FastCauchySubsequence cofinal RegSeqRat coverage)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, each cofinal selected window that reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *reaches it only through the fast-rate row* F*, regular-subsequence handoff* R*, and regular rational readback row* W*. The route keeps the source and modulus rows* S, M, Q *visible and uses* H, C, P, N *only as structural support.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalRegSeqRatCoverage`

Proof. Begin with the cofinal finite-window theorem above. It gives each precision request a finite window in Q already covered by inspected data in M and source access in S.

Use the regular route theorem. It places every $\mathsf{RegSeqRat}^{\uparrow}$ readback behind F, R, W, so a cofinal selected window cannot jump from Q directly to a rational sequence or a terminal seal.

The NameCert obligations close the coverage claim. They force fast-rate exactness before the regular-subsequence handoff and the regular rational readback before any Real-facing row, while H, C, P, N transport and name the same finite route. □

Theorem 1518.25 (FastCauchySubsequence modulus regular handoff)**.** *For every accepted* FastCauchySubsequenc *carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$, the inspected modulus row M and regular-subsequence handoff R form one route to the* $\mathsf{Real}^{\uparrow}$ *seal:*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad E, \quad H, \quad C, \quad P, \quad N.$$

Thus the modulus witness, cofinal selector, fast-rate evidence, regular-subsequence handoff, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback are consumed as one finite package before the terminal seal is visible.*

Proof. Project A and read the displayed carrier order. The modulus row M is not separate from the selector row Q or the handoff row R; it is the inspected source of the selected windows later consumed by F, R, W.

Apply Definition 1518.2 and Definition 1518.3. Together they order modulus coverage, selector admission, fast-rate exactness, regular-subsequence handoff, regular rational readback, and terminal Real sealing along one route.

Finally use the existing source and structural support rows S, H, C, P, N. They preserve the same route under source access, componentwise transport, displayed replay, provenance, and local naming, so the handoff cannot be split into an external subsequence, quotient stream, selected limit, or countable-choice datum. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceModulusRegularHandoff`

Theorem 1518.26 (FastCauchySubsequence regular readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier factors through the selection surface*

$$\Sigma_A = (M, Q, F, W, H, C, P, N).$$

In particular, W reads the same cofinal finite windows certified by Q, the same inspected modulus bounds certified by M, and the same fast-rate ledger certified by F before any $\mathsf{Real}^{\uparrow}$ *seal E is visible. The readback exports no independent rational stream, no selected infinite subsequence, and no quotient Cauchy-class representative.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegularReadback`

Proof. Begin with Definition 1518.3. It places every real-facing route through M, Q, F, R, W before E.

Now restrict attention to the $\mathsf{RegSeqRat}^{\uparrow}$ row W. By Definition 1518.19, the rows available to W inside the selection surface are exactly the inspected modulus row M, the cofinal finite-window ledger Q, the fast-rate row F, and the structural rows H, C, P, N.

Apply Definition 1518.20 to each displayed precision read. The cofinal witness is already a finite BHist window row transported through the same support rows, so the regular rational readback cannot be replaced by an independent stream, a choice-selected subsequence, or a quotient Cauchy representative. □

Theorem 1518.27 (FastCauchySubsequence selector regularity pullback)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row* R *pulls its regularity witness back to the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row* Q *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* W *is read. The pullback is the displayed route*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad H, \quad C, \quad P, \quad N,$$

and it exports no selected limit, quotient stream equality, host real equality, or countable-choice selector.

Proof. Project the selection surface Σ_A of Definition 1518.19. The only selector-facing rows available to the regular handoff are M, Q, F, W, H, C, P, N, with R sitting in the carrier as the regular-subsequence handoff from those rows.

Use the modulus-selector coherence theorem, Definition 1518.4. It fixes the selected windows by the displayed M, Q pair before either the fast-rate row F or the regular-subsequence handoff R can be consumed.

Apply Definition 1518.26. The $\mathsf{RegSeqRat}^{\uparrow}$ row W reads the same finite cofinal windows and inspected modulus bounds, so the regularity witness in R is pulled back to the finite selector surface rather than to an independent stream or a selected limit. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSelectorRegularityPullback`

Theorem 1518.28 (FastCauchySubsequence cofinal readback non-escape)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the cofinal readback route from the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *row* Q *to the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* W *remains inside*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad H, \quad C, \quad P, \quad N.$$

It may feed $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{CofinalSubsequence}^{\uparrow}$*,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers through the displayed rows, but it cannot escape as a selected limit, quotient stream equality, host real equality, arbitrary countable choice, or an independent rational stream.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalReadbackNonescape`

Proof. Begin with the cofinal finite-window theorem, Definition 1518.20. Each precision request receives a finite window row in Q covered by the inspected modulus row M and transported by H, C, P, N.

Next apply the selector-window coverage theorem, Definition 1518.5. The route from Q to the regular rational readback passes through F and R, so W cannot be read from a separate stream or a host-level subsequence object.

Finally use the Real-seal selector boundary of Definition 1518.11. The $\mathsf{Real}^{\uparrow}$ seal E is visible only after M, Q, F, R, W, and the carrier has no coordinate for selected limits, quotient stream equality, host real equality, countable choice, or an independent rational sequence. □

Theorem 1518.29 (FastCauchySubsequence effective Cauchy consumer)**.** *Any effective-Cauchy or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *must consume the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M*, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row* Q*, the fast-rate row* F*, the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff* R*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* W *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed. The consumer receives finite evidence for an effective Cauchy route from* $\mathsf{StreamName}^{\uparrow}$ *windows to regular rational readback; it receives no selected limit, quotient stream equality, host real equality, or countable-choice functional.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceEffectiveCauchyConsumer`

Proof. Start with the regular route theorem, Definition 1518.3. It forces every real-facing read through S, M, Q, F, R, W before the seal E.

Use selector regularity pullback, Definition 1518.27. The regular handoff R is not an independent regular subsequence; it is pulled back to the inspected modulus and cofinal selector rows.

Now apply cofinal readback non-escape, Definition 1518.28. The readback route remains inside $M, Q, F, R, W, H, C, P, N$, so an effective-Cauchy consumer gets finite displayed evidence and cannot replace it by a selected limit, quotient stream equality, host real equality, or countable choice. □

Theorem 1518.30 (FastCauchySubsequence source carrier obligation)**.** *For every accepted* $\mathsf{FastCauchySubsequence}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the source carrier obligation binds the displayed source row* S *to inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *data* M *and* $\mathsf{FastCauchy}^{\uparrow}$ *rate data* F *before any cofinal readback is exported. The obligation is witnessed inside the finite* BHist *route*

$$S, \quad M, \quad Q, \quad F, \quad H, \quad C, \quad P, \quad N,$$

where H *supplies componentwise* hsame *transport,* C *supplies displayed* Cont *replay,* P *supplies provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *support, and* N *supplies the local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSourceCarrier`

Proof. Project the carrier of Definition 1518.1. The only source-facing rows available before regular readback are S, M, Q, F and the support rows H, C, P, N.

Use the NameCert obligations and modulus-selector coherence. They bind each selected source window to inspected Cauchy-modulus data in M before the fast-rate row F can be consumed.

The support rows preserve the same finite route: hsame transport is componentwise through H, Cont replay is displayed by C, provenance is recorded by P, and local naming is recorded by N. Since the carrier has no selected-limit or countable-choice coordinate, the source obligation is exactly the displayed BHist route. □

Theorem 1518.31 (FastCauchySubsequence root obligation)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the root obligation surface is the complete finite route over the inspected source row* S*,* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M*,* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row* Q*,* $\mathsf{FastCauchy}^{\uparrow}$ *rate row* F*,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row* R*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* W*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{FastCauchySubsequence}^{\uparrow}}$ *row* N*. Every downstream effective-Cauchy, regular-rational, or real-facing consumer must read this surface before using the packet; no coordinate exports a selected limit, quotient Cauchy class, host real equality, arbitrary countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRootObligation`

Proof. Begin with the source carrier theorem, Definition 1518.30. It binds S, M, Q, F, H, C, P, N as the source-facing route before any cofinal readback is exported.

Add the regular readback obligation, Definition 1518.41. It forces R and W to consume the same displayed selector and fast-rate rows rather than an independent subsequence or rational stream.

Finally apply the Real-seal handoff and Real seal theorems, Definition 1518.35 and Definition 1518.42. They place the terminal seal E after S, M, Q, F, R, W and keep H, C, P, N as structural support. Since the carrier lists no escape coordinate, the displayed rows exhaust the root obligation surface. □

Theorem 1518.32 (FastCauchySubsequence modulus-selector obligation)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *and every selector window read by a downstream consumer, the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *covers that window before* $\mathsf{FastCauchy}^{\uparrow}$ *rate data,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff data, or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback data are consumed. The selector row* Q *therefore acts only as a finite cofinal-window ledger attached to* M*; it is not a countable-choice functional, a host subsequence object, or a quotient Cauchy representative.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceModulusSelectorObligation`

Proof. Start with modulus-selector coherence, Definition 1518.4. It identifies each selector window with inspected modulus data already present in M.

Use selector-window coverage and modulus-threshold extraction, Definition 1518.5 and Definition 1518.36. These keep every selected window and every threshold request inside S, M, Q, H, C, P, N before the regular route is read.

Now apply selector regularity pullback and cofinal readback non-escape. The regular-subsequence handoff R and readback row W consume the same M, Q, F route, so no later consumer can reinterpret Q as an external choice selector or as an independent rational stream. □

Theorem 1518.33 (FastCauchySubsequence Real-seal obligation)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed only after the inspected modulus row* M*, selector row* Q*, fast-rate row* F*, regular-subsequence handoff row* R*, and regular rational readback row* W *have all been displayed. The seal is a terminal row of the finite selector route; it does not supply a selected limit, quotient stream equality, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealObligation`

Proof. Read the Real-seal selector boundary, Definition 1518.11. It already prevents a real-facing consumer from reaching E before M, Q, F, R, W.

Use the effective Cauchy consumer theorem and the Real-seal handoff obligation. Together they keep every effective-Cauchy or real-facing read downstream of the inspected modulus, cofinal selector, fast-rate, regular-subsequence, and readback rows.

Finally apply the root obligation above. The structural rows H, C, P, N preserve and name the same route, while the carrier has no coordinate for selected limits, quotient classes, choice functionals, host equality, trichotomy, or completeness. Thus the Real seal is exposed only as the terminal row of the displayed route. □

Theorem 1518.34 (FastCauchySubsequence cofinal tail stability)**.** *Let* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *be an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier. If a finite tail-window comparison preserves the inspected* S, M, Q, F *rows by* hsame*, then every cofinal selector read used by* R *and* W *remains in the same displayed tail route*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad H, \quad C, \quad P, \quad N.$$

Thus selector stability is a finite tail-window fact over $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, not a host subsequence equality and not a countable-choice principle.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalTailStability`

Proof. Start from the finite tail-window comparison. The hypothesis says that the inspected source, modulus, selector, and fast-rate rows are preserved by hsame before the regular handoff is read.

Apply selector-window coverage and selector regularity pullback. These force the selected cofinal windows used by R and W to be the same windows certified by M, Q, F, with the dyadic and stream-window support carried through the displayed route.

Finally use cofinal readback non-escape. The $\mathsf{RegSeqRat}^{\uparrow}$ readback cannot leave $M, Q, F, R, W, H, C, P, N$, and the carrier has no coordinate for host subsequence equality or countable choice. Stability is therefore the finite hsame-tail statement over the displayed rows. □

Theorem 1518.35 (FastCauchySubsequence Real-seal handoff obligation)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal handoff from an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier consumes only the displayed finite selector route*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad E, \quad H, \quad C, \quad P, \quad N.$$

The route opens $\mathsf{StreamName}^{\uparrow}$ *windows, inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius support,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the seal E; it does not claim a selected limit, quotient stream equality, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealHandoff`

Proof. Begin with the effective Cauchy consumer theorem above. It places every effective-Cauchy or real-facing consumer downstream of M, Q, F, R, W before E is exposed.

Use source carrier obligation and cofinal tail stability. The first binds the source to inspected modulus and fast-rate rows, while the second keeps the cofinal selector route inside the same finite tail-window package.

The terminal row E is therefore reached only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback W and the structural rows H, C, P, N preserve the displayed route. Since no carrier row stores a selected limit, quotient stream equality, host real equality, choice functional, or completeness principle, the $\mathsf{Real}^{\uparrow}$ handoff consumes only that finite route. □

Theorem 1518.36 (FastCauchySubsequence modulus-threshold extraction)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *and every downstream precision request visible to the packet, the threshold row used by the cofinal selector is extracted from the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row M before the selector row Q is consumed. Thus an effective consumer can cite the finite route*

$$S, \quad M, \quad Q, \quad H, \quad C, \quad P, \quad N$$

as displayed modulus-threshold evidence, without appealing to a selected subsequence, quotient Cauchy class, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceModulusThresholdExtraction`

Proof. Project the carrier and the NameCert obligations. The row M is listed before Q, and the obligations require modulus coverage for every selected downstream window before selector admission is read.

Use the regular route and modulus-selector coherence. They identify the windows consumed by Q with windows already covered by the inspected bounds in M, while H, C, P, N preserve the same finite source replay and local naming route.

The Real-seal handoff theorem keeps all real-facing consumption downstream of M, Q, F, R, W. Hence the threshold needed by an effective consumer is exported from M before Q and never from an ambient choice functional or a completed real object. □

Theorem 1518.37 (FastCauchySubsequence cofinal selector strict growth)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *row* Q *exposes a finite strict-growth ledger for the selected windows used by* F, R*, and* W*. Each later selected window is certified as a strictly later inspected source window, and the ledger is cofinal in the precision requests visible to the packet.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalSelectorStrictGrowth`

Proof. Begin with the cofinal finite-window theorem. It supplies a finite selector row in Q for each precision request and binds that row to the inspected bounds in M.

Apply selector-window coverage and cofinal tail stability. Coverage prevents Q from skipping outside the displayed modulus data, and tail stability records that later selector reads stay in the same hsame-preserved finite route.

The regular-subsequence handoff R and regular rational readback W consume only those selected windows. Therefore strict selector growth and cofinality are exported as finite data in Q, not as host subsequence equality or countable choice. □

Theorem 1518.38 (FastCauchySubsequence dyadic tail budget)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the fast-rate row* F *exposes the dyadic tail budget used by downstream regular consumers through* $\mathsf{DyadicRatCore}^{\uparrow}$ *support before the regular-subsequence handoff* R *and the readback row* W *are consumed. The visible budget route is*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad H, \quad C, \quad P, \quad N.$$

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceDyadicTailBudget`

Proof. Use the NameCert obligations for fast-rate exactness. They force F to be read from the modulus coverage row along the selected cofinal windows supplied by Q.

Next apply the selector regularity pullback. The handoff R repacks the same selected windows and transported dyadic radius data rather than introducing an independent regular subsequence.

Finally use cofinal readback non-escape. The $\mathsf{RegSeqRat}^{\uparrow}$ row W reads the same dyadic and selector route through M, Q, F, R, H, C, P, N, so the tail budget remains visible to effective consumers as $\mathsf{DyadicRatCore}^{\uparrow}$ data. □

Theorem 1518.39 (FastCauchySubsequence source replay exhaustion)**.** *For every accepted* FastCauchySubsequenc *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the structural rows* S, H, C, P, N *exhaust the source replay needed by any effective Cauchy consumer. Every read from source windows to modulus inspection, selector growth, fast-rate routing, regular-subsequence handoff, regular rational readback, and the terminal seal factors through these displayed rows.*

Proof. Start with the source carrier obligation. It binds the displayed source row S to the inspected modulus and fast-rate rows before any cofinal readback can be exported.

Use H, C, P, N in their carrier order. The row H supplies componentwise hsame transport, C supplies displayed Cont replay, P records provenance over $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ support, and N records the local NameCert row.

The Real-seal handoff theorem places all real-facing consumption after the same replay route. Since the carrier has no coordinate for a selected limit, quotient Cauchy class, countable-choice functional, or real completeness proof, S, H, C, P, N exhaust the source replay surface. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSourceReplayExhaustion`

Theorem 1518.40 (FastCauchySubsequence effective consumer export)**.** *Every effective-Cauchy, regular-rational, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier may export exactly the finite consumer package*

$$M, \quad Q, \quad F, \quad R, \quad W, \quad E.$$

The package gives inspected modulus thresholds, strict cofinal selector growth, dyadic fast-rate budgets, regular-subsequence handoff, regular rational readback, and the terminal real-name seal; it does not export selected subsequences, quotient Cauchy classes, countable-choice functionals, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Combine modulus-threshold extraction with cofinal selector strict growth. These two facts give the finite M, Q front of the package consumed by effective Cauchy sequence routes.

Add the dyadic tail-budget theorem. It supplies the F, R, W readback surface over $\mathsf{DyadicRatCore}^{\uparrow}$ and regular rational data, with no independent stream or selected limit.

Use source replay exhaustion only to justify that the package has already passed through the displayed source support. The exported consumer interface is therefore M, Q, F, R, W, E; the structural rows certify the route but do not enlarge it with choice, quotient equality, or completeness data. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceEffectiveConsumerExport`

The downstream explicit-modulus sequence route of chapter 1705 may consume $\mathsf{FastCauchySubsequence}^{\uparrow}$ when it needs finite fast-subsequence evidence: the inspected modulus data M and cofinal selector rows Q become the effective Cauchy sequence witness after the fast-rate and regular-subsequence handoff rows are displayed. The same relationship also feeds rate-realization consumers through the visible F, R, W route, without selecting a limit and without invoking countable choice.

Theorem 1518.41 (FastCauchySubsequence regular readback obligation)**.** *Every accepted* FastCauchySubsequence *packet exposes the inspected modulus row* M*, cofinal selector row* Q*, fast-rate row* F*, regular-subsequence row* R*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* W*, and the source* $\mathsf{StreamName}^{\uparrow}$ *window rows before any* $\mathsf{Real}^{\uparrow}$*, effective-Cauchy, or regular-rational consumer may read it. The obligation is the finite route*

$$S, \quad M, \quad Q, \quad F, \quad R, \quad W, \quad H, \quad C, \quad P, \quad N,$$

not an independent subsequence, quotient Cauchy class, selected limit, or countable-choice functional.

Proof. Project the accepted carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$. The carrier order displays the source windows, inspected modulus data, selector ledger, fast-rate row, regular-subsequence handoff, regular rational readback, and structural support rows before the real seal row can be consumed.

Use the NameCert obligations to bind the early route. Modulus coverage is read through M, selector admission through Q, and fast-rate exactness through F; no later consumer can introduce an unseen selector or an independent rational stream.

The regular-subsequence and readback rows then consume the same finite route. The handoff row R repacks the selected windows, and W reads those windows as regular rational data, while H, C, P, N only transport, replay, source, and name the displayed package. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegularReadbackObligation`

Theorem 1518.42 (FastCauchySubsequence Real seal)**.** *For an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal is reached only after the finite route through inspected modulus data, cofinal selection, fast-rate evidence, regular-subsequence handoff, regular rational readback, source-window support, componentwise transport, displayed replay, provenance, and local naming has been displayed. Thus any Real-facing read factors through the same root obligation surface before the seal row* E *is visible.*

Proof. Begin with the Real-seal selector boundary. It already places every $\mathsf{Real}^{\uparrow}$ seal consumer downstream of M, Q, F, R, W.

Add the source and structural rows from the carrier. The source row S supplies the inspected windows, while H, C, P, N preserve the route under componentwise transport, replay, provenance, and local naming.

Apply the regular readback obligation above. It identifies the complete root surface that a Real-facing read must traverse, so the seal cannot be reached by quotient stream equality, selected limits, arbitrary countable choice, host real equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSeal`

Theorem 1518.43 (FastCauchySubsequence Phase Real and Completion exit route)**.** *Every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *consumer that exports a Phase Real and Completion exit read must factor through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow},$$

together with the displayed cofinal-selector and modulus rows of the carrier. More precisely, the exit read first consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget in* F*, the* $\mathsf{StreamName}^{\uparrow}$ *source-window schedule in* S*, the cofinal selector row* Q*, the inspected modulus row* M*, the regular readback row* W*, the regular-subsequence handoff* R*, and the terminal seal* E *before it may be used by a Real or Completion downstream packet. It cannot pass through quotient streams, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequencePhaseRealCompletionExitRoute`

Proof. Start from the Real seal theorem Definition 1518.42. It places every Real-facing read after the inspected modulus data, cofinal selection, fast-rate evidence, regular-subsequence handoff, regular rational readback, source-window support, transport, replay, provenance, and local naming rows.

Read the dyadic and selector components next. The dyadic tail budget theorem Definition 1518.38 exposes the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget through F, R, W, while the cofinal selector strict-growth theorem Definition 1518.37 keeps the selected windows inside the displayed $\mathsf{StreamName}^{\uparrow}$ source schedule and the inspected modulus row M.

Apply the effective consumer export theorem Definition 1518.40. It identifies the consumer-visible package as M, Q, F, R, W, E, with structural support from S, H, C, P, N and without an independent rational stream.

Thus a Phase Real and Completion exit read has already traversed the finite dyadic tolerance budget, source-window schedule, regular rational readback, and terminal Real seal before it is exported. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those routes can supply the exit. □

Theorem 1518.44 (FastCauchySubsequence choice-free completion window)**.** *Every completion-facing window served by an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *factors through* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any completion or Real seal is read. The window is therefore the finite BEDC route*

$$S \to M \to Q \to F \to R \to W \to E \to H, C, P, N$$

and not a quotient stream, selected limit, countable-choice functional, host subsequence equality, or ambient completeness row.

Proof. Begin with the regular route and selector-window coverage theorems. They force each selected window through the inspected modulus row M, cofinal selector row Q, fast-rate row F, regular-subsequence handoff R, and $\mathsf{RegSeqRat}^{\uparrow}$ readback W.

Next apply the Real-seal boundary and Phase Real and Completion exit route. These place the terminal row E after the regular rational readback and before any Real or completion-facing export.

Finally use the root obligation surface. The support rows H, C, P, N transport, replay, source, and name the same finite route, while the carrier has no coordinate for quotient streams, selected limits, countable choice, host equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceChoiceFreeCompletionWindow`

Theorem 1518.45 (FastCauchySubsequence cofinal selector totality)**.** *For every displayed precision request made of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$, *the cofinal selector ledger* Q *supplies a finite source window whose readback is covered by* M, F, R, W, E. *This totality is a finite* BHist *coverage claim over the selected ledger and does not use host countable choice, an infinite subsequence object, or a selected real limit.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalSelectorTotality`

Proof. Use the selector-window coverage theorem for the requested precision. It reads the selected finite window from Q together with the inspected modulus row M and the fast-rate row F.

The cofinal selector strict-growth and dyadic tail-budget theorems keep the selected window inside the displayed source schedule S and the dyadic tolerance budget used by F, R, W.

Apply the effective consumer export theorem and the Real-seal obligation. They identify the consumer-visible package as M, Q, F, R, W, E with structural support from S, H, C, P, N, so the requested precision is served by a finite ledger row rather than by countable choice. □

Theorem 1518.46 (FastCauchySubsequence RegSeqRat completion handoff)**.** *Every completion-facing rational readback exported by an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier passes through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* W *reached from* M, Q, F, R. *The handoff*

$$\mathsf{CauchyModulus}^{\uparrow},\ \mathsf{CofinalSubsequence}^{\uparrow},\ \mathsf{FastCauchy}^{\uparrow},\ \mathsf{RegularCauchySubsequence}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

is the only completion-facing rational readback route named by the carrier, and it exports no independent rational stream, quotient Cauchy representative, selected subsequence, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegSeqRatCompletionHandoff`

Proof. First read the regular readback and regular-subsequence pullback theorems. They identify W as the $\mathsf{RegSeqRat}^{\uparrow}$ row obtained from the same inspected modulus, cofinal selector, fast-rate, and regular-subsequence handoff data.

Next use cofinal readback non-escape. It prevents the selector row Q from bypassing F, R, W or from exporting an independent rational stream.

Finally compose with the Real-seal handoff obligation and Phase Real and Completion exit route. Since the terminal seal is reached only after W, every completion-facing rational readback uses that regular rational row and no separate quotient, choice, selected-limit, or completeness coordinate. □

Theorem 1518.47 (FastCauchySubsequence tail extraction obligations)**.** *Every tail extracted from an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *is a finite route from source windows through* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. The extraction reads the source schedule* S*, inspected modulus row* M*, cofinal selector ledger* Q*, fast-rate row* F*, regular-subsequence handoff* R*, regular rational readback* W*, terminal seal* E*, and structural rows* H, C, P, N*; it exports no host tail object, selected infinite subsequence, quotient stream equality, countable-choice functional, selected limit, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailExtractionObligations`

Proof. Project the source surface and selection surface. Definitions 1518.12 and 1518.19 expose the finite source windows, inspected modulus data, cofinal selector rows, fast-rate evidence, and support rows before any regular rational readback is consumed.

Use cofinal finite windows and dyadic tail budget. Theorems 1518.20, 1518.34, and 1518.38 keep each extracted tail inside the displayed BHist, hsame, and $\mathsf{DyadicRatCore}^{\uparrow}$ route.

Finally apply the regular readback obligation and the RegSeqRat completion handoff. They place the extracted tail through R, W, E before any Real or Completion consumer reads it, so the refused host subsequence, quotient, choice, selected-limit, and completeness objects have no carrier coordinate. □

Theorem 1518.48 (FastCauchySubsequence synchronized finite-window routing)**.** *Every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet synchronizes its finite source windows with the inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *row,* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *window route, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and support rows* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The synchronized route exposes no countable-choice selector, selected limit, quotient Cauchy representative, host subsequence equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSynchronizedWindow`

Proof. Project the accepted carrier $A = (S, M, Q, F, R, W, E, H, C, P, N)$. The source windows S are read beside the modulus row M, cofinal selector Q, fast-rate row F, regular-subsequence handoff R, regular rational readback W, and Real seal E.

Apply the cofinal window, dyadic tail budget, and tail extraction obligations. These results keep every visible tail inside the same finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ route.

The synchronized window is therefore a displayed finite route from source inspection to W and then E. Since the carrier has no coordinate for countable choice, selected limits, quotient representatives, host subsequence equality, or completeness, none of those objects is exported. □

Theorem 1518.49 (FastCauchySubsequence tail-selector coverage)**.** *The cofinal tail selector of an accepted* FastCauchySubsequence$^{\uparrow}$ *packet is covered exactly by finite* CofinalSubsequence$^{\uparrow}$ *windows tied to the same* CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. A downstream consumer can read only those covered tail windows and cannot extract a countable-choice functional, selected infinite subsequence, selected limit, quotient stream equality, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailSelectorCoverage`

Proof. Start with the selection surface and cofinal readback non-escape theorems. They bind the selector row Q to displayed finite windows and prevent it from bypassing the fast-rate, regular-subsequence, and regular rational rows.

Use the tail extraction obligations to cover each consumed tail. The extracted data pass through M, Q, F, R, W, E with StreamName$^{\uparrow}$ windows, DyadicRatCore$^{\uparrow}$ budgets, and the structural H, C, P, N rows.

Thus the selector coverage is finite and carrier-internal. It records which inspected windows are available to downstream consumers, but it does not supply a host function choosing infinitely many indices, a selected limit, quotient equality, or Real completeness. □

Theorem 1518.50 (FastCauchySubsequence Real-seal factorization)**.** *Every* Real$^{\uparrow}$ *seal exported by an accepted* FastCauchySubsequence$^{\uparrow}$ *packet factors through the displayed* CauchyModulus$^{\uparrow}$, CofinalSubsequence$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows before reaching the terminal seal E. The factorization exposes only the finite regular rational route and exports no selected limit, quotient real equality, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealSealFactorization`

Proof. Read the RegSeqRat completion handoff and RegSeqRat tail readback theorems. They identify W as the regular rational row reached from the inspected modulus, cofinal selector, fast-rate, and regular-subsequence data.

Next apply the Phase Real and Completion exit route together with tail extraction obligations. These force every Real-facing read to pass through the same M, Q, F, R, W, E corridor with dyadic budgets, stream windows, transport, replay, provenance, and local naming.

The terminal seal E is therefore factored through W and its finite support rows. No accepted packet contains a selected limit, quotient real equality, countable-choice selector, host real equality, or ambient completeness coordinate from which a consumer could bypass that factorization. □

Theorem 1518.51 (FastCauchySubsequence cofinal fast-rate scope)**.** *For every accepted* FastCauchySubsequence$^{\uparrow}$ *carrier, the scoped route from the cofinal selector row Q to the fast-rate ledger F is generated by the inspected source windows, the* CauchyModulus$^{\uparrow}$ *row M, the* DyadicRatCore$^{\uparrow}$ *tail budget, and the structural H, C, P, N rows. It supplies only the finite fast-rate ledger consumed by R, W, E and supplies no host subsequence equality, countable-choice schedule, quotient Cauchy representative, selected limit, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalFastRateScope`

Proof. Begin with modulus-selector coherence and selector-window coverage. They bind the cofinal selector Q to the same inspected source windows and modulus row M before the fast-rate row F is read.

Next use the cofinal selector strict-growth theorem. The strict-growth ledger is a finite row of selected windows visible to the carrier, not a host subsequence function or a countable-choice schedule.

Close with the dyadic tail budget and effective consumer export theorems. They show that the fast-rate ledger reaches downstream consumers only through F, R, W, E with H, C, P, N as support, so the scoped route contains no extra equality, quotient, selected-limit, or completeness coordinate. □

Theorem 1518.52 (FastCauchySubsequence RegSeqRat tail readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback consumed by Real-and-Completion routes from an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet is read through the same* M, Q, F, R, W, E *route named by the carrier. The readback uses the displayed source windows, cofinal selector, dyadic tail budget, fast-rate row, regular-subsequence handoff, regular rational row, terminal Real seal, transport, replay, provenance, and local naming rows; it does not introduce an independent rational stream, a selected subsequence, quotient Cauchy equality, host real equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegSeqRatTailReadback`

Proof. Start with the regular readback theorem and selector regularity pullback. They identify the $\mathsf{RegSeqRat}^{\uparrow}$ row W as the readback obtained from the inspected modulus row M, selector row Q, fast-rate row F, and regular-subsequence handoff R.

Use cofinal readback non-escape and tail extraction obligations. The cofinal selector cannot bypass F, R, W, and each tail remains inside the same finite route over source windows, dyadic support, transport, replay, provenance, and local naming.

Finally apply the Phase Real and Completion exit route. Since E is reached only after W, every Real-and-Completion tail readback consumes the displayed $\mathsf{RegSeqRat}^{\uparrow}$ row and no independent stream, selected subsequence, quotient, host equality, choice, or completeness row. □

Theorem 1518.53 (FastCauchySubsequence modulus selector tail extraction)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row* Q *determine the selected tail windows before the* $\mathsf{FastCauchy}^{\uparrow}$ *rate row* F *and the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row* R *are read. Each tail window is a finite* BHist *row read through* S, M, Q, H, C, P, N *and then handed to the fast-rate ledger; it is not an external subsequence function, a countable-choice schedule, or a selected limit.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceModulusSelectorTailExtraction`

Proof. Start with the modulus-selector coherence and selector-window coverage theorems. They bind every selected window in Q to inspected modulus data in M before any downstream fast-rate or regular-subsequence row is visible.

Use modulus-threshold extraction and cofinal tail stability. The precision request is first read from M, then served by a finite cofinal window in Q, with source replay and componentwise transport carried by S, H, C, P, N.

Only after this finite tail window is fixed can the route enter F and R. Since the carrier contains no coordinate for a host subsequence function, countable-choice schedule, quotient class, or selected limit, the selected tail is exactly the displayed modulus-selector row. □

Theorem 1518.54 (FastCauchySubsequence regular subsequence handoff totality)**.** *Every selected fast tail in an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier is handed to* $\mathsf{RegularCauchySubsequence}^{\uparrow}$

and $\mathsf{RegSeqRat}^{\uparrow}$ *through the same dyadic radius ledger. In the carrier notation* $A = (S, M, Q, F, R, W, E, H, C, P, N$ *the handoff reads*

$$M, \quad Q, \quad F, \quad R, \quad W$$

with the $\mathsf{DyadicRatCore}^{\uparrow}$ *budget displayed by* F *and preserved by* H, C, P, N*. No regular-subsequence or regular-rational consumer may replace that ledger by an independent rational stream, a selected subsequence, quotient Cauchy equality, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegularSubsequenceHandoffTotality`

Proof. Apply the dyadic tail budget theorem. It places the finite radius budget in the fast-rate row F after the inspected modulus and cofinal selector rows have been read.

Next use selector regularity pullback and the regular readback obligation. The $\mathsf{RegularCauchySubsequence}^{\uparrow}$ row R repacks the same selected windows and transported dyadic radii, and the $\mathsf{RegSeqRat}^{\uparrow}$ row W reads that same package rather than a separate rational sequence.

Finally apply the RegSeqRat completion handoff and RegSeqRat tail readback theorems. They keep every completion-facing rational read on the route through M, Q, F, R, W, E with structural support H, C, P, N, excluding independent streams, selected subsequences, quotient equality, host equality, and completeness. □

Theorem 1518.55 (FastCauchySubsequence seal boundary exhaustion)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier is exhausted by the displayed route*

$$S, M, Q, F, R, W, E, H, C, P, N.$$

Every Real-facing or completion-facing read must consume the source window, inspected modulus, cofinal selector, fast-rate ledger, regular-subsequence handoff, regular rational readback, terminal seal, transport, replay, provenance, and local naming rows in that route. The packet exports no quotient class, selected limit, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the Real-seal factorization and Real seal theorem. They place the terminal row E after the inspected modulus, cofinal selector, fast-rate ledger, regular-subsequence handoff, and regular rational readback.

Use the synchronized finite-window routing theorem to restore the source and support rows. It keeps S, H, C, P, N visible as the route moves from selected windows to regular readback and then to the terminal seal.

Finally combine the Phase Real and Completion exit route with cofinal readback non-escape. These results exhaust every Real-facing or completion-facing endpoint by the same finite carrier rows and leave no coordinate from which a quotient class, selected limit, choice schedule, trichotomy row, or completeness theorem could be exported. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceSealBoundaryExhaustion`

Theorem 1518.56 (FastCauchySubsequence uniform tail window)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the fast-rate selector supplies a uniform tail window for every* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row consumed by* W*. The window is read from the displayed route*

$$S, M, Q, F, R, W, H, C, P, N$$

with $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data visible through* M *and* F*; no later Real or Completion consumer may replace it by a host subsequence, quotient Cauchy class, selected limit, or countable-choice schedule.*

Proof. Read the cofinal fast-rate scope theorem. It generates the route from the selector row Q to the fast-rate ledger F using the inspected source windows, modulus row, dyadic tail budget, and structural rows.

Use the regular subsequence handoff totality theorem. The same dyadic radius ledger passes through R and then W, so each tolerance row seen by $\mathsf{RegSeqRat}^{\uparrow}$ is served by the previously displayed fast tail.

The uniformity is therefore carrier-internal: all tolerance requests use the same finite selector surface $S, M, Q, F, R, W, H, C, P, N$. The refused host subsequence, quotient, selected-limit, and choice objects have no coordinate in that surface. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceUniformTailWindow`

Theorem 1518.57 (FastCauchySubsequence cofinal modulus consumption)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier, the cofinal modulus row is consumed before any fast-rate, regular-subsequence, regular-rational, or Real-seal row can be exported. The consumption is a finite* BHist *handoff from* M *and* Q *through* F, R, W, E, H, C, P, N*, and it does not use countable choice, an external subsequence functional, or an infinite choice sequence.*

Proof. Start with modulus-threshold extraction. Each downstream precision request first reads the inspected $\mathsf{CauchyModulus}^{\uparrow}$ row M and only then enters the cofinal selector row Q.

Apply the modulus selector tail extraction theorem. It fixes the selected tail as a finite BHist row carried by S, M, Q, H, C, P, N before F and R are read.

Finally use the RegSeqRat tail readback and seal boundary exhaustion theorems. They carry the already consumed modulus row through W and E, so no countable-choice functional or infinite selection object is introduced. □

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalModulusConsumption`

Theorem 1518.58 (FastCauchySubsequence Real-completion tail readback route)**.** *Every Real-completion consumer of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier reads the cofinal fast tail through the displayed route*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqR}$

For $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, the source-window row* S*, inspected modulus row* M*, cofinal selector row* Q*, fast-rate row* F*, regular-subsequence handoff* R*, regular rational readback* W*, dyadic tail budget, and terminal seal row* E *are all displayed before any completion-facing read is named. The route exports no quotient Cauchy class, selected limit, countable-choice selector, trichotomy row, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealCompletionTailReadbackRoute`

Proof. Start with the modulus selector tail extraction theorem. It fixes the selected tail window from the source row S, inspected modulus row M, and cofinal selector row Q before the fast-rate or regular-subsequence rows are consumed.

Use the dyadic tail budget and regular subsequence handoff totality theorems. They carry the selected tail through the $\mathsf{DyadicRatCore}^{\uparrow}$ budget in F, the regular-subsequence handoff R, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row W without introducing an independent rational stream.

Finally apply seal boundary exhaustion and Real-name nonescape. The terminal seal E is reached only after the same finite route has been displayed, while H, C, P, N transport, replay,

source, and name that route. Since no carrier coordinate stores quotient Cauchy classes, selected limits, countable choice, trichotomy, host equality, or completeness, a Real-completion consumer can read only this finite tail-readback route. □

Theorem 1518.59 (FastCauchySubsequence Real-name nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *name row exported by an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *packet receives only the displayed regular-readback route*

$$S, M, Q, F, R, W, E, H, C, P, N.$$

The row refuses selected limits, quotient Cauchy classes, host real equality, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRealNameNonescape`

Proof. Begin with Real-seal factorization. It places the terminal seal E after the inspected modulus, cofinal selector, fast-rate ledger, regular-subsequence handoff, and $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the uniform tail window theorem above to identify the regular readback received by W as the same finite tail route selected by M, Q, F, R. The support rows H, C, P, N preserve that route by componentwise transport, replay, provenance, and local naming.

The Real-name row therefore sees only the displayed regular-readback route. Since no accepted carrier contains a coordinate for selected limits, quotient Cauchy classes, host real equality, trichotomy, countable choice, or ambient completeness, the row cannot escape to those objects. □

Theorem 1518.60 (FastCauchySubsequence tail regularity)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, a cofinal fast-subsequence tail that preserves the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row* R *remains a* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible tail before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. The compatibility is witnessed by the same* BHist *tail window,* hsame *transport row,* Cont *replay,* Pkg *provenance, and local* NameCert *row used by* W*; it exports no selected limit, quotient stream equality, countable-choice selector, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailRegularity`

Proof. Start with the displayed carrier route $S, M, Q, F, R, W, E, H, C, P, N$. The source window S, modulus row M, cofinal selector row Q, and fast-rate row F determine the tail window before any regular rational readback is available.

Use regular subsequence handoff totality. It shows that the selected fast tail reaches R with the same dyadic radius ledger that was exposed by M and F, so the regular-subsequence row cannot replace the tail by an independent rational stream.

Now read the RegSeqRat tail readback theorem. The row W consumes the transported tail produced by R, and the structural rows H, C, P, N keep the source window, modulus, selector, and regular-subsequence data attached to the same finite packet.

Only after this $\mathsf{RegSeqRat}^{\uparrow}$-compatible row is displayed may the route enter E. Since the carrier has no coordinate for selected limits, quotient stream equality, countable choice, or ambient completeness, tail regularity is exhausted before Real-seal consumption. □

Theorem 1518.61 (FastCauchySubsequence cofinal regular window)**.** *For every accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier, the cofinal selector rows and* $\mathsf{StreamName}^{\uparrow}$ *windows expose the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers. In the carrier notation* $A = (S, M, Q, F, R, W, E, H, C, P, N)$*, a downstream consumer reads the displayed budget through*

$$S, M, Q, F, R, W, E, H, C, P, N$$

and cannot insert a separate dyadic tolerance, quotient rational stream, host subsequence equality, selected limit, or countable-choice schedule.

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceCofinalRegularWindow`

Proof. Read the synchronized finite-window routing theorem. It binds the $\mathsf{StreamName}^{\uparrow}$ windows in S to the inspected modulus row M, cofinal selector row Q, fast-rate row F, regular-subsequence handoff R, and regular rational readback W.

Apply the dyadic tail budget and uniform tail window theorems. The $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data visible to the selector is the same budget carried into F and then through R to W.

The terminal Real route is now fixed. Seal boundary exhaustion places E after the displayed regular rational row and keeps H, C, P, N as the transport, replay, provenance, and local naming support.

Thus $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers receive one displayed tolerance budget. The refused separate dyadic tolerance, quotient stream, host subsequence equality, selected-limit, and choice-schedule objects have no carrier coordinate. □

Theorem 1518.62 (FastCauchySubsequence tail Real-seal cofinality)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing fast-Cauchy subsequence tail read of an accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carrier* $A = (S, M, Q, F, R, W, E, H, C, P, N)$ *exposes, in order, the cofinal selector row* Q*, the inspected modulus row* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carried by* F, R*, and the terminal Real seal row* E*. The route may transport, replay, source, and name the same finite window through* H, C, P, N*, but it exports no separate cofinal selector, quotient stream equality, selected limit, countable-choice schedule, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceTailRealSealCofinality`

Proof. Project the carrier route for a Real-facing tail read. The stream window S is fixed first, and the cofinal selector row Q can be interpreted only against the inspected modulus row M.

Use Definition 1518.61. It identifies the selector window and the displayed tolerance budget as the same finite window consumed by the regular-subsequence handoff R and the $\mathsf{RegSeqRat}^{\uparrow}$ readback W.

The DyadicRatCore tolerance data is therefore already attached to the tail before E is read. The Real seal can certify only that displayed route, while H, C, P, N preserve it as transport, replay, provenance, and local naming.

Since the carrier contains no coordinate for an independent selector, quotient stream equality, selected limits, countable-choice schedules, or ambient Real completeness, the Real-facing read cannot escape the cofinal window. □

Theorem 1518.63 (FastCauchySubsequence RegSeqRat tail transport)**.** *For accepted* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *carriers with componentwise* hsame *transport on the cofinal window rows, the transported tail preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *route before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read. Concretely, transport of* S, M, Q, F, R, W *along* H *carries the same cofinal selector, inspected modulus, fast-rate ledger, regular-subsequence handoff, regular rational readback, and DyadicRatCore tolerance budget into the transported packet; only then may the Real seal row be consumed.*

Lean4 ✓ `BEDC.Derived.FastCauchySubsequenceUp.FastCauchySubsequenceRegSeqRatTailTransport`

Proof. Begin with componentwise transport through H. It identifies the source window S, inspected modulus M, cofinal selector Q, fast-rate ledger F, regular-subsequence row R, and regular rational readback W before any terminal Real data is compared.

Apply the tail regularity theorem and the cofinal regular-window theorem. The transported rows preserve the same BHist tail window and the same DyadicRatCore tolerance budget through R and into W.

The Real-name nonescape theorem then applies after the transported RegSeqRat route has been read. The seal row E is terminal, so it cannot replace the transported tail by a quotient stream, selected limit, countable-choice schedule, or ambient Real-completeness witness. □

Chapter 1519

A Concrete Naming Certificate for $\mathsf{MetricSubspace}^{\uparrow}$

Following Kelley and Bishop–Bridges metric-space practice, the $\mathsf{MetricSubspace}^{\uparrow}$ packet records the standard subspace metric as a finite BEDC NameCert carrier. It sits between the parent metric surface of chapter 57, the topology surface of chapter 88, the ball rows of chapter 1450 and chapter 1451, and the numerical rows of chapter 38 and chapter 37. The packet gives compact-subspace, closed-ball, completion, and topology consumers a displayed carrier for restricting distance to admitted points, without importing host subsets, quotient equality, ambient choice, or a second metric law.

Definition 1519.1 (MetricSubspace carrier)**.** *A* $\mathsf{MetricSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, A, D, H, C, P, N)$$

with the following visible rows:

1. *X is the parent* $\mathsf{Met}^{\uparrow}$ *row, including its point classifier, distance witness, metric-law ledger, and finite observation histories.*
2. *A is the displayed subset or admission-predicate row. A point is available to the subspace packet only when the parent point classifier of X and the admission row A both accept it.*
3. *D is the inherited distance ledger. It contains no independent distance value; each subspace distance read is the parent distance row of X applied to two admitted points.*
4. *H records componentwise* hsame *transport for the parent metric row, admission row, inherited distance ledger, restricted replay row, provenance row, and local naming row.*
5. *C records the displayed* Cont *route replaying point admission, subset membership, parent-distance evaluation, restricted metric-law transport, and downstream ball or topology handoff.*
6. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{MetricClosedBall}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricSubspace}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host subset equality, quotient membership, an independently chosen distance, an ambient open-cover principle, countable choice, or a replacement topology.

Lean4 ✓ `BEDC.Derived.MetricSubspaceUp.MetricSubspaceTasteGate single carrier alignment`

Theorem 1519.2 (MetricSubspace NameCert obligations)**.** *For an accepted* $\mathsf{MetricSubspace}^{\uparrow}$ *carrier* $S = (X, A, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricSubspace}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the parent metric row, displayed admission row, inherited distance ledger, componentwise transport, restricted replay, provenance row, and local naming row;*
2. *subset-membership stability, requiring classifier transport by* H *to preserve the admission row* A *before any distance read is exposed;*
3. *inherited-distance restriction, requiring every subspace distance query to be a parent* $\mathsf{Met}^{\uparrow}$ *distance query on two points already admitted by* A*;*
4. *restricted metric-law transport, requiring symmetry, zero-distance, triangle, and rational or real comparison reads to be replayed only along the parent metric-law ledger named by* X *and transported by* H*;*
5. *ledger non-escape, stating that the packet exports no host subset equality, quotient membership, independent distance, ambient choice principle, open-cover principle, or replacement topology.*

Proof. Carrier admission is projection from Definition 1519.1. The tuple lists the parent metric row, admission predicate row, inherited distance ledger, transport, replay, provenance, and local naming rows.

Subset-membership stability is local to A and H. Transport first aligns the parent point classifier and admission row, so a downstream consumer cannot read a subspace point without replaying both admissions.

Inherited-distance restriction is the role of D and C. Every distance request is routed through two admitted points and then through the parent distance witness of X; no separate distance coordinate is present.

Restricted metric-law transport is inherited from the metric-law ledger of X. The replay row C uses the same parent symmetry, zero-distance, triangle, and numerical comparison rows after the admission checks have been performed.

The provenance row P and naming row N record exactly the dependencies available to the packet. Since the carrier has no coordinate outside X, A, D, H, C, P, N, the excluded host, quotient, choice, open-cover, and replacement-topology principles cannot be exported. □

Theorem 1519.3 (MetricSubspace distance restriction)**.** *Let* $S = (X, A, D, H, C, P, N)$ *be an accepted* $\mathsf{MetricSubspace}^{\uparrow}$ *carrier. If two displayed reads* x *and* y *pass the parent point classifier of* X *and the admission row* A*, then the subspace distance row between* x *and* y *is exactly the parent* $\mathsf{Met}^{\uparrow}$ *distance row read through* D *and replayed by* C*.*

Consequently every ball, closed-ball, completion, or topology consumer of S *factors through admitted endpoints before it can consume a distance comparison:*

$$(x, y) \longmapsto A(x), A(y) \longmapsto D_X(x, y) \longmapsto C, H, P, N.$$

The route is not a quotient of subsets, not host equality, and not a second metric carried beside X*.*

Proof. Project the accepted carrier. The only point rows visible to the subspace packet are parent points of X that also pass the admission row A.

For admitted x and y, the inherited ledger D reads the parent distance witness from X. The replay row C records this read after the two admission checks, so the subspace distance has no value other than the displayed parent distance.

The rows H, P, N transport and name the same finite route. Thus any ball, closed-ball, completion, or topology consumer receives a distance comparison only after admission of both endpoints and parent-distance evaluation, while quotient, host-equality, and independent-metric data remain absent from the carrier. □

Theorem 1519.4 (MetricSubspace closed complete inheritance)**.** *Let $S = (X, A, D, H, C, P, N)$ be an accepted* $\mathsf{MetricSubspace}^{\uparrow}$ *carrier. Suppose the parent metric row X carries a* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness route for a regular* $\mathsf{StreamName}^{\uparrow}$ *Cauchy stream, every displayed observation of the stream passes the admission row A, and the admission row A is closed under the parent limit witness.*

Then the same stream has a subspace $\mathsf{CompleteMetric}^{\uparrow}$ *limit witness with the same limit row. Every convergence read in the subspace factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow X, A, D, H, C, P, N \longrightarrow \mathsf{CompleteMetric}^{\uparrow},$$

and each late-distance comparison is the parent metric comparison identified by Definition 1519.3. The inherited witness exports no quotient subset, selected host equality, replacement limit row, or ambient completeness coordinate beyond the displayed parent $\mathsf{CompleteMetric}^{\uparrow}$ *route.*

Proof. Project the accepted carrier. The stream observations visible to the subspace packet are parent observations of X together with admission proofs from A, and the distance row available to them is the inherited row D replayed by C.

Apply the parent $\mathsf{CompleteMetric}^{\uparrow}$ route on X to the same regular $\mathsf{StreamName}^{\uparrow}$ Cauchy stream. This produces the parent limit witness and the parent late-distance comparisons used for convergence.

Use closedness of the admission row A under that parent limit witness to admit the limit row into the subspace packet. The limit is not chosen again; it is the same parent row now accompanied by the displayed admission evidence.

Finally apply Definition 1519.3. Every subspace convergence read is therefore the corresponding parent distance read after endpoint admission, transported by H and replayed by C through the same provenance and naming rows P, N. Since no additional carrier coordinate is present, quotient subset data, selected host equality, replacement limits, and independent ambient completeness data cannot enter the subspace witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSubspace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSubspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1519.1, Definition 1519.2, and Definition 1519.3 seed the finite L10 subspace-metric interface over parent metric, displayed admission, inherited distance, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSubspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subset equality, quotient membership, independent distance construction, ambient choice, open-cover compactness, replacement topologies, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subset-membership stability, inherited-distance restriction, restricted metric-law transport, and ledger non-escape for the same packet.

Constructive story: The construction starts from a displayed parent Metric row, filters points through an admission row, reads distance only from the parent metric ledger, and replays ball, closed-ball, completion, and topology consumers through the same finite route.

Chapter 1520

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyPair}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRegularCauchyPair}^{\uparrow}$ packet records the finite comparison surface between two regular Cauchy real names before the terminal $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the common finite-window schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the convergence admission route of chapter 1509, the terminal real-name seal of chapter 38, and the finite equality-inspection classifier of chapter 1517. The chapter names the paired regular-Cauchy comparison object needed by later completion and real-classifier consumers without quotienting Cauchy classes or selecting host limits.

Definition 1520.1 (BishopRegularCauchyPair carrier)**.** *A* $\mathsf{BishopRegularCauchyPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, W, D_A, D_B, R_A, R_B, C, T, H, K, P, S, N)$$

with the following displayed rows:

1. *A and B are the two regular Cauchy real-name source rows being compared.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to expose both sources at the same precision requests.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers read from A and B along W.*
4. *R_A and R_B are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows produced from the same window and tolerance data.*
5. *C is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *admission row witnessing that the displayed reads are regular Cauchy reads at the inspected tolerances.*
6. *T is the* $\mathsf{RealNameClassifier}^{\uparrow}$ *finite comparison row comparing the two displayed regular rational readbacks before the real seal is consumed.*
7. *H records componentwise* hsame *transport for $A, B, W, D_A, D_B, R_A, R_B, C, T$ and the structural support rows.*
8. *K records the displayed* Cont *replay from the paired sources through the common windows, dyadic tolerance ledgers, regular rational readbacks, convergence criterion, classifier row, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyPair}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{RealNameClassifier}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after both regular rational readbacks and the finite classifier row have been displayed.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyPair}^{\uparrow}}$ *row.*

The carrier stores no quotient Cauchy class, no selected host limit, no trichotomy witness, no open-cover compactness principle, and no host $\mathsf{Real}^{\uparrow}$ *equality coordinate.*

Theorem 1520.2 (BishopRegularCauchyPair RegSeqRat factorization)**.** *For an accepted* $\mathsf{BishopRegularCauchyPair}$ *carrier $Q = (A, B, W, D_A, D_B, R_A, R_B, C, T, H, K, P, S, N)$, every comparison read factors through the finite route*

$$A, B \longmapsto W \longmapsto D_A, D_B \longmapsto R_A, R_B.$$

Thus the paired comparison reaches $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks only by using the common* $\mathsf{StreamName}^{\uparrow}$ *window schedule and the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and it has no independent route to host sequence equality or quotient Cauchy classes.*

Proof. Project the carrier of Definition 1520.1. The only shared observation schedule for the two source names is W, so neither source has a separate precision route.

The tolerance rows D_A and D_B are attached to that same schedule. The replay row K therefore carries both sources through one displayed window route before any regular rational readback is visible.

The readback rows R_A and R_B occur after W, D_A, D_B in the carrier, and the transport row H preserves the same component order. Since no carrier coordinate contains host sequence equality or quotient classes, the displayed route is the whole $\mathsf{RegSeqRat}^{\uparrow}$ factorization surface. □

Theorem 1520.3 (BishopRegularCauchyPair Real classifier handoff)**.** *Let $Q = (A, B, W, D_A, D_B, R_A, R_B, C, T, H$ be an accepted* $\mathsf{BishopRegularCauchyPair}^{\uparrow}$ *carrier. Any* $\mathsf{RealNameClassifier}^{\uparrow}$ *consumer of Q reads the classifier row T only after the two regular Cauchy sources, the common finite-window schedule, the dyadic tolerance ledgers, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *admission row have been displayed. The subsequent* $\mathsf{Real}^{\uparrow}$ *seal row S exports only this finite classifier handoff, not quotient Cauchy equality, selected limits, trichotomy, open-cover compactness, or host real equality.*

Proof. Start with a classifier-facing consumer. Carrier admission displays $A, B, W, D_A, D_B, R_A, R_B, C, T$ in the stated dependency order, and the continuation row K replays the same order for every accepted read.

The classifier row T is downstream of the two $\mathsf{RegSeqRat}^{\uparrow}$ rows and the convergence row C. Hence it compares the displayed regular rational readbacks under the common finite window and dyadic tolerance data, rather than comparing host-level completed objects.

The seal row S is later than T. The package provenance P and local name N record the same packet, while the componentwise transport H moves the displayed rows without adding a new equality principle.

The carrier explicitly omits quotient Cauchy classes, selected limits, trichotomy, open-cover compactness, and host $\mathsf{Real}^{\uparrow}$ equality. Consequently the real-facing export is exactly the finite classifier handoff. □

Theorem 1520.4 (BishopRegularCauchyPair common-window induction)**.** *Let $Q = (A, B, W, D_A, D_B, R_A, R_B, C,$ be an accepted* $\mathsf{BishopRegularCauchyPair}^{\uparrow}$ *carrier. Every finite prefix of the paired comparison route is generated by induction on the displayed common* $\mathsf{StreamName}^{\uparrow}$ *window W. At each step, both*

source reads advance through the same W-coordinate before D_A, D_B, R_A, R_B, C, T, or S can be consumed.

Consequently no side-specific window, hidden tail oracle, quotient Cauchy equality, selected limit, trichotomy, or ambient completeness row can enter between the two sources and the $\mathsf{RealNameClassifier}^{\uparrow}$ *handoff.*

Proof. Induct on the finite displayed window rows in W. In the empty-window case, carrier admission exposes only the source rows, provenance rows, and local naming data, so no tolerance ledger, readback, classifier, or seal row has yet been consumed.

For the step case, extend the inspected window by one displayed coordinate. The componentwise transport row H keeps the new coordinate shared by the two sources, and the continuation replay row K advances both source reads through that same coordinate before any downstream row is replayed.

Projecting Definition 1520.1 then fixes the remaining order: the dyadic ledgers D_A, D_B feed the readbacks R_A, R_B, the convergence row C admits the displayed reads, the classifier row T follows those rows, and the seal S is terminal.

Composing this induction with Definition 1520.2 and Definition 1520.3 leaves no carrier coordinate through which a side-specific precision route, hidden tail oracle, quotient equality, selected limit, trichotomy, or ambient completeness witness could intervene. □

Theorem 1520.5 (BishopRegularCauchyPair symmetric classifier route)**.** *Let $Q = (A, B, W, D_A, D_B, R_A, R_B, C, T$ be an accepted* $\mathsf{BishopRegularCauchyPair}^{\uparrow}$ *carrier. Form the swapped displayed packet*

$$Q^{\mathrm{op}} = (B, A, W, D_B, D_A, R_B, R_A, C, T, H, K, P, S, N).$$

Then Q and Q^{op} expose the same common-window comparison route to $\mathsf{RealNameClassifier}^{\uparrow}$ *and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. The swap changes only the order in which the two source sides and their displayed tolerance and readback rows are named; it does not add a quotient Cauchy class, selected limit, side-specific window oracle, trichotomy, open-cover compactness, host equality, or ambient completeness coordinate.*

Proof. Apply Definition 1520.4 to Q. Both source reads are generated over the single displayed $\mathsf{StreamName}^{\uparrow}$ window W, so swapping the names of the two source sides preserves the finite induction spine and leaves no coordinate where a side-specific window route can enter.

Next use Definition 1520.2. The factorization route has the form

$$A, B \longmapsto W \longmapsto D_A, D_B \longmapsto R_A, R_B.$$

After the displayed swap, this is the same route with the two $\mathsf{RegSeqRat}^{\uparrow}$ readback rows and the two $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers interchanged over the unchanged window W.

Finally apply Definition 1520.3. Since the classifier row T is downstream of those displayed readbacks and the terminal seal row S is downstream of T, the handoff to $\mathsf{RealNameClassifier}^{\uparrow}$ and the $\mathsf{Real}^{\uparrow}$ seal boundary are the same finite BEDC packet after the swap. The carrier projection still contains no coordinate for quotient classes, selected limits, trichotomy, open-cover compactness, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyPair}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1520.1, Definition 1520.2, Definition 1520.3, Definition 1520.4, and Definition 1520.5 seed the finite paired regular-Cauchy comparison surface before the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, selected limits, trichotomy, open-cover compactness, host Real$^{\uparrow}$ equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-window factorization, dyadic tolerance compatibility, RegSeqRat readback exposure, convergence admission, classifier handoff, terminal seal nonescape, provenance, and ledger exhaustion for the same finite packet.

Constructive story: A BishopRegularCauchyPair$^{\uparrow}$ packet is generated from two regular Cauchy real-name source rows, a shared StreamName window schedule, two DyadicRatCore tolerance ledgers, two RegSeqRat readbacks, a CauchyConvergenceCriterion admission row, a RealNameClassifier comparison row, componentwise transports, replay routes, provenance, a terminal RealUp seal, and a local NameCert row.

Chapter 1521

A Concrete Naming Certificate for $\mathsf{MooreSmithConvergence}^{\uparrow}$

Following Kelley and Bourbaki, the $\mathsf{MooreSmithConvergence}^{\uparrow}$ packet records ordinary Moore–Smith convergence as a finite directed-net observation surface. It sits between the directed Cauchy evidence of chapter 589 and the boundary consumers in chapter 1473 and chapter 1506: the packet names convergence toward a displayed completion boundary without turning the directed net into a quotient object, a chosen limit point, or an ambient completeness theorem.

Definition 1521.1 (Moore–Smith convergence carrier)**.** *A* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier is a finite directed-net* BHist *packet*

$$M = (D, V, U, C, B, R, L, H, K, P, N)$$

with the following displayed rows:

1. *D is the finite directed index-window ledger, naming the inspected indices, the tail windows, and the common upper-window witnesses used by the packet.*
2. *V is the net-value window, exposing the finitely displayed values of the Moore–Smith net on the addresses recorded by D.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, recording the displayed entourages used to test convergence at the inspected boundary.*
4. *C is the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row, stating that the same finite directed windows support the Cauchy side of the net evidence.*
5. *B is the boundary row, read either through* $\mathsf{UniformCompletion}^{\uparrow}$ *or through* $\mathsf{MetricCompletion}^{\uparrow}$*, naming the displayed completion boundary to which the net is tested.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite rational coordinates exposed by the inspected net values and boundary reads.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *readback row reached from the regular rational row when a real-facing consumer asks for a displayed boundary coordinate.*
8. *H records componentwise* hsame *transport for D, V, U, C, B, R, L and the structural support rows.*
9. *K records the displayed* Cont *replay from directed windows through net values, entourages, Cauchy tail evidence, completion boundary reads, regular rational readbacks, and real readbacks.*

10. *P is the* Pkg *provenance over* $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithConvergence}^{\uparrow}}$ *row.*

The carrier exports only this finite convergence-to-boundary packet. It contains no quotient of nets, no selected Moore–Smith limit, no global completeness assertion, no cofinal choice function, and no host-level equality of completion points.

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergenceTasteGate single carrier alignment`

Theorem 1521.2 (Moore–Smith convergence NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MooreSmithConvergence}^{\uparrow}}$ *surface for Definition 1521.1 consists of six finite obligations:*

1. *carrier admission for the displayed directed-net packet M;*
2. *directed-tail coverage, stating that every displayed entourage request is routed to a tail window recorded in D;*
3. *net-value exposure, stating that the values used in the convergence test are exactly the displayed coordinates of V;*
4. *Cauchy compatibility, stating that the same directed windows feed the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row C;*
5. *completion-boundary exposure, stating that boundary reads pass through B before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback is exported;*
6. *ledger non-escape, stating that a consumer request without a displayed tail witness or boundary row is recorded outside the packet rather than exported as convergence data.*

Proof. Carrier admission is projection from the tuple in Definition 1521.1. The directed ledger, net-value window, entourage row, Cauchy tail row, completion boundary row, readback rows, transports, continuations, provenance, and local name are visible coordinates of one finite BHist packet.

Directed-tail coverage is read from D together with the entourage row U. A convergence request can use only the inspected entourages whose tail witnesses have been displayed in the directed ledger.

Net-value exposure is then forced through V. The continuation row K replays every accepted request from the directed window to the displayed net values before it reaches either the Cauchy tail row or the completion boundary row.

Cauchy compatibility follows because C is carried in the same packet and is indexed by the same displayed directed windows. The transport row H preserves those coordinates componentwise and does not add a cofinal choice function or a quotient relation on nets.

The boundary row B is the only route to $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$. Consequently the downstream readback rows R and L expose only boundary data already certified by the directed-window, entourage, and Cauchy-tail rows. If a request lacks one of these displayed witnesses, no coordinate of M can export it, giving ledger non-escape. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket namecert obligations`

Theorem 1521.3 (Moore–Smith convergence uniform handoff)**.** *Let $M = (D, V, U, C, B, R, L, H, K, P, N)$ be an accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{UniformSpace}^{\uparrow}$ *consumer of M reads convergence evidence through the finite route*

$$D \longmapsto U \longmapsto V \longmapsto C \longmapsto B.$$

Thus the uniform handoff exposes displayed entourages, directed tail witnesses, net values, Cauchy tail compatibility, and the completion boundary row, but it does not export a selected limit point, a quotient net, an ambient completeness theorem, or a cofinal choice operator.

Proof. Start with a uniform-facing consumer. The only entourage coordinate in the carrier is U, and U is attached to the finite directed ledger D.

The continuation row K sends each displayed entourage request through the net-value window V. The same replay then reaches the $\mathsf{CauchyNet}^{\uparrow}$ tail row C, so the uniform convergence read cannot separate from the finite directed-tail evidence.

The boundary row B occurs after those rows in the displayed packet. The package row P and local name row N record the same route, while H transports the listed coordinates componentwise.

Since no coordinate names a selected limit point, quotient net, ambient completeness theorem, or cofinal choice operator, the exported uniform evidence is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket uniform handoff`

Theorem 1521.4 (Moore–Smith convergence completion boundary)**.** *For an accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier* $M = (D, V, U, C, B, R, L, H, K, P, N)$*, every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *read exported by* B *is downstream of the directed index-window ledger, the net-value window, the entourage row, and the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row. The subsequent* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readbacks* R *and* L *therefore expose only finite boundary data certified by the same Moore–Smith convergence packet.*

Proof. Project the boundary-facing coordinates of Definition 1521.1. The boundary row B is included with the same directed ledger D, net-value window V, entourage row U, and Cauchy tail row C.

The continuation row K records the order in which boundary reads are replayed. A completion-boundary consumer therefore reaches B only after the directed window, value, entourage, and Cauchy-tail evidence has been displayed.

The readback rows R and L are later than B. They expose regular rational and real-facing coordinates read from the displayed boundary row, not from an independent completion object.

The carrier omits selected completion points, quotient nets, global completeness, and host-level equality of boundary points. Hence the completion boundary exported by M is exactly the finite Moore–Smith convergence boundary named by the same packet. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket completion boundary`

Theorem 1521.5 (Moore–Smith convergence boundary scope)**.** *For every accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *packet* $M = (D, V, U, C, B, R, L, H, K, P, N)$*, a route reaches* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *only after the directed index-window ledger* D*, the net-value window* V*, the entourage row* U*, and the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row* C *have been displayed. The* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readbacks* R, L *are downstream of the same boundary row* B*, so no completion-facing consumer can bypass the directed-net boundary ledger.*

Proof. Project the carrier of Definition 1521.1. The only completion-facing coordinate is B, and it is carried with the directed ledger D, net-value window V, uniform entourage row U, and Cauchy-tail row C.

Apply Definition 1521.3 to force uniform-facing reads through the directed window, entourage, value, and tail rows. Then apply Definition 1521.4 to place every $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ read at B and every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback after B.

The remaining rows H, K, P, N only transport, replay, source, and name this displayed boundary route. Because the carrier has no coordinate for quotient nets, selected limits, global completeness, or cofinal choice, ledger nonescape records those requests outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket boundary scope`

Theorem 1521.6 (Moore–Smith convergence directed-window totality)**.** *For every accepted convergence read of a* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier* $M = (D, V, U, C, B, R, L, H, K, P, N)$*, the read must first expose the directed index-window ledger* D*, the net-value window* V*, the entourage row* U*, the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row* C*, and the boundary row* B *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback is exported. The exposed route is total for the accepted directed-window packet, and it exports no quotient net, selected limit, cofinal choice, host equality of completion points, or ambient completeness.*

Proof. Project the carrier in Definition 1521.1. The convergence-facing coordinates available before readback are exactly the directed ledger D, value window V, uniform entourage row U, Cauchy-tail row C, and boundary row B.

Apply the NameCert obligations of Definition 1521.2. They force carrier admission, directed-tail coverage, net-value exposure, Cauchy compatibility, completion-boundary exposure, and ledger non-escape through the same displayed rows.

Next use the uniform handoff of Definition 1521.3. Every uniform-facing request reaches the entourage and value data through D, U, V and then passes through the Cauchy tail row C before boundary data can be consumed.

Apply the completion boundary theorem Definition 1521.4 and the boundary scope theorem Definition 1521.5. These place every $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ read at B and keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readbacks downstream of that boundary row.

The carrier has no coordinate for quotient nets, selected limits, cofinal choice, host equality, or ambient completeness. Thus the directed-window route D, V, U, C, B is total for accepted convergence reads before R or L can be exported. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket directed window totality`

Theorem 1521.7 (Moore–Smith convergence obligation exhaustion)**.** *For every accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier* $M = (D, V, U, C, B, R, L, H, K, P, N)$*, every consumer-visible convergence read is exhausted by the displayed rows*

$$D, V, U, C, B, R, L, H, K, P, N.$$

The rows are, respectively, the directed index window, value window, uniform entourage, $\mathsf{CauchyNet}^{\uparrow}$ *tail, completion boundary,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *readback, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$*. Quotient nets, selected limits, cofinal choice, and ambient completeness have no coordinate in the accepted packet.*

Proof. Project the carrier of Definition 1521.1. The tuple exposes exactly the directed index window D, value window V, uniform entourage row U, Cauchy tail row C, completion boundary row B, readback rows R and L, transport row H, replay row K, provenance row P, and local name row N.

Apply the NameCert obligations of Definition 1521.2. They account for carrier admission, directed-tail coverage, net-value exposure, Cauchy compatibility, completion-boundary exposure, and ledger non-escape using only those projected rows.

Next apply the uniform handoff of Definition 1521.3. It forces every uniform-facing convergence read through D, U, V, C, and B before any boundary information is available.

Finally apply the completion boundary theorem Definition 1521.4. It places the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readbacks downstream of B and prevents them from reading an independent completion object.

The excluded data have no projected coordinate. There is no row for a quotient net, selected limit, cofinal choice operator, or ambient completeness theorem, so ledger non-escape records such requests outside the packet rather than exporting them as convergence evidence. □

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket obligation exhaustion`

Theorem 1521.8 (Moore–Smith convergence directed-window stability)**.** *Let $M = (D, V, U, C, B, R, L, H, K, P, N$ and $M' = (D', V', U', C', B', R', L', H', K', P', N')$ be accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carriers. If D, V, U, C, B and D', V', U', C', B' are matched componentwise by displayed* hsame *rows, then every directed-window convergence read admitted by M transports to an admitted directed-window convergence read of M'. The transport preserves the inspected directed windows, net-value exposure, entourage row, Cauchy-tail row, and completion-boundary row, and it introduces no quotient-net coordinate or cofinal choice row.*

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket directed window stability`

Proof. Project the two accepted carriers. The only rows used by a directed-window convergence read are D, V, U, C, B together with the transport and replay rows H, K.

The displayed hsame witnesses match each of D, V, U, C, B with its primed counterpart. Apply the componentwise transport row to move the directed index window first, then the net values, the entourage row, the Cauchy-tail row, and finally the completion-boundary row.

The replay row K' records the same accepted route in the primed packet after the transport has reached B'. Since neither carrier has a coordinate for quotient nets or cofinal choice, the transported read remains a finite directed-window read and cannot escape into an ambient net construction. □

Theorem 1521.9 (Moore–Smith convergence completion-readback exactness)**.** *For every accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier $M = (D, V, U, C, B, R, L, H, K, P, N)$, any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback exported by R or L is downstream of the displayed completion-boundary row B, and B is downstream of the directed window, net-value, entourage, and Cauchy-tail rows D, V, U, C. Thus completion-facing readback is exact for the finite packet: it cannot read a selected limit, a quotient of nets, an ambient completeness theorem, or host equality of completion points.*

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket completion readback exactness`

Proof. Start with a readback request for R or L. The carrier places both rows after the completion-boundary coordinate B.

By Definition 1521.4, every boundary read reaches B only after the directed index window, value window, entourage row, and Cauchy-tail evidence have been displayed. Hence the readback request is already routed through D, V, U, C, B before any regular rational or real-facing coordinate is exposed.

The tuple has no row for a selected limit, quotient-net object, ambient completeness theorem, or host equality relation on completion points. Therefore R and L read back exactly the finite boundary data certified by the packet and nothing outside it. □

Theorem 1521.10 (Moore–Smith convergence ledger refusal)**.** *Let $M = (D, V, U, C, B, R, L, H, K, P, N)$ be an accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier. A consumer request that asks for a quotient net, a selected Moore–Smith limit, a cofinal choice function, ambient completeness, or host equality of completion points is not exported by the local* $\mathsf{NameCert}_{\mathsf{MooreSmithConvergence}^{\uparrow}}$ *row. It is recorded as outside the finite ledger because none of those objects is a row of M.*

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket ledger refusal`

Proof. Inspect the carrier rows in Definition 1521.1. They are exactly the directed window, net-value window, entourage row, Cauchy-tail row, completion-boundary row, two readback rows, transport, replay, provenance, and local name.

Apply the ledger non-escape clause of Definition 1521.2. A request without a displayed tail witness or boundary row is not exported as convergence data.

The named excluded objects have no coordinate in M. Consequently the local name row cannot certify them, and the packet refuses the request rather than treating it as Moore–Smith convergence evidence. □

Theorem 1521.11 (Moore–Smith convergence Cauchy-completion readback totality)**.** *For every accepted* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *carrier $M = (D, V, U, C, B, R, L, H, K, P, N)$, every* $\mathsf{CauchyNet}^{\uparrow}$ *completion-facing read exported by M traverses*

$$D, V, U, C, B$$

before any $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback R, L is visible. Consequently the total completion-readback surface of M is exactly the finite route*

$$D, V, U, C, B, R, L, H, K, P, N,$$

and it exports no quotient net, selected limit, cofinal choice, host equality of completion points, or global completeness route.

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket cauchy completion readback totality`

Proof. Project the carrier of Definition 1521.1. The directed ledger D, net-value window V, entourage row U, $\mathsf{CauchyNet}^{\uparrow}$ tail row C, and completion-boundary row B are the only rows that can feed a completion-facing read.

Apply the uniform handoff of Definition 1521.3, the completion boundary theorem Definition 1521.4, and the boundary scope theorem Definition 1521.5. These place every completion-facing route through D, V, U, C, B before any regular rational or real-facing readback can be consumed.

Now apply completion-readback exactness from Definition 1521.9. The readback rows R, L expose only data downstream of B, while H, K, P, N transport, replay, source, and name the same finite packet route.

Finally use ledger refusal from Definition 1521.10. Since quotient nets, selected limits, cofinal choice, host equality of completion points, and global completeness have no carrier coordinate, the displayed route is total for exported Cauchy-completion readback and nothing outside it is exported. □

Theorem 1521.12 (Moore–Smith directed-window obligation)**.** *Every accepted Moore–Smith convergence read exposes the directed-set row D, tail-window schedule V, net-value row U, Cauchy compatibility row C, completion-boundary row B, transport row H, replay row K, provenance row P, and local* NameCert *row N before any completion consumer sees a limit candidate. The read exports no cofinal choice, quotient nets, selected limits, host equality of completion points, or global completeness principle.*

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket directed window obligation`

Proof. Begin with the carrier of Definition 1521.1. Its convergence-facing route displays exactly the directed-set, tail-window, net-value, Cauchy compatibility, completion-boundary, readback, transport, replay, provenance, and local naming rows.

Use the uniform handoff of Definition 1521.3 and the completion boundary of Definition 1521.4. These force the directed window, net-value row, entourage or Cauchy compatibility evidence, and completion-boundary row to appear before any completion-facing readback.

The boundary scope of Definition 1521.5 and the obligation exhaustion theorem Definition 1521.7 identify the permitted rows as the displayed packet rows. The directed-window stability theorem Definition 1521.8 then shows that transport preserves the same finite route through H and K.

Finally apply completion readback exactness from Definition 1521.9 and ledger refusal from Definition 1521.10. Cofinal choice, quotient nets, selected limits, host equality of completion points, and global completeness have no carrier coordinate, so they cannot be exposed before or after the completion consumer sees the finite boundary row. □

Theorem 1521.13 (Moore–Smith convergence obligation-closure package)**.** *The carrier of Definition 1521.1, the directed-window stability of Definition 1521.8, the uniform handoff of Definition 1521.3, the completion boundary of Definition 1521.4, and the ledger refusal of Definition 1521.10 jointly form the complete paper-side obligation package for promoting the* MooreSmithConvergence$^{\uparrow}$ *surface from seed closure toward obligation closure. The package may cite the sibling* CauchyNet$^{\uparrow}$*,* UniformCompletion$^{\uparrow}$*, and* MetricCompletion$^{\uparrow}$ *chapters only through their displayed finite boundary rows, and it produces no selected limit and no quotient net.*

Lean4 ✓ `BEDC.Derived.MooreSmithConvergenceUp.MooreSmithConvergencePacket obligation closure package`

Proof. Project the carrier. The displayed packet already contains the directed index-window ledger, net-value window, uniform entourage row, Cauchy-net tail row, completion-boundary row, rational and real readbacks, transport, replay, provenance, and local naming rows.

Use directed-window stability to transport admitted reads between accepted packets without adding cofinal choice. Use the uniform handoff to force every uniform-facing read through the finite directed window, entourage, value, Cauchy-tail, and boundary rows.

Next use the completion-boundary theorem. It places every UniformCompletion$^{\uparrow}$ or MetricCompletion$^{\uparrow}$ consumer downstream of the same CauchyNet$^{\uparrow}$-compatible directed evidence, so completion-facing access remains a finite boundary read rather than a quotient construction.

Finally apply ledger refusal. Since selected limits, quotient nets, cofinal choice, ambient completeness, and host equality of completion points have no row in the carrier, the listed theorems exhaust the paper-side obligation package and no stronger completion object is produced. □

Closure status for NameCert$_{\text{MooreSmithConvergence}^{\uparrow}}$**.**

Constructive story: A MooreSmithConvergence$^{\uparrow}$ packet is generated from a finite directed index-window ledger, a net-value window, a UniformSpace$^{\uparrow}$ entourage row, a CauchyNet$^{\uparrow}$ tail row, a UniformCompletion$^{\uparrow}$ or MetricCompletion$^{\uparrow}$

boundary row, RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ readbacks, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MooreSmithConvergence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1521.1, Definition 1521.2, Definition 1521.5, Definition 1521.6, Definition 1521.9, Definition 1521.10, and Definition 1521.13 close the finite directed-window route $D, V, U, C, B, R, L, H, K, P, N$ from CauchyNet$^{\uparrow}$ and UniformSpace$^{\uparrow}$ evidence into UniformCompletion$^{\uparrow}$ and MetricCompletion$^{\uparrow}$ boundary consumers.

Formal verification: FormalStatus(NameCert$_{\text{MooreSmithConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient nets, selected limits, global completeness, cofinal choice, host equality of completion points, Lean verification, or bridge checking.

Upgrade path: The paper theory axis is mature for the directed-window bridge; Lean verification and bridge checking remain separate gates.

Chapter 1522

A Concrete Naming Certificate for $\mathsf{CauchySequenceBounded}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchySequenceBounded}^{\uparrow}$ packet records the boundedness surface that a Cauchy sequence exposes before any completed-real consumer is allowed to read it. It sits between the $\mathsf{StreamName}^{\uparrow}$ schedule of chapter 126, the $\mathsf{CauchyModulus}^{\uparrow}$ threshold rows of chapter 292, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the convergence boundary of chapter 1509. The classifier-facing boundedness handoff also consumes the Cauchy equivalence setoid route of chapter 1820 when a downstream consumer compares two bounded schedules by regular-rational closeness. The certificate names a finite bound packet for one displayed Cauchy schedule; it does not turn Cauchy data into a host-complete object, quotient stream, or selected limit.

Definition 1522.1 (Cauchy sequence bounded carrier)**.** *A* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, M, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule exposing the finite window of sequence reads.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row that says which tail requests are governed by the displayed Cauchy modulus.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the window reads and tail tolerances in dyadic or rational form.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that packages the accepted regular rational readback induced by S, M, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream schedule, modulus row, dyadic tolerance ledger, regular-rational handoff, and bound ledger have been displayed.*
6. *B is the explicit dyadic or rational bound ledger, consisting of a finite initial-window bound, a tail-bound row extracted from M and D, and a reconciliation row saying that both windows are contained in the same displayed bound.*
7. *H stores componentwise* hsame *transport for the stream schedule, modulus row, dyadic ledger, regular-rational handoff, real seal, bound ledger, continuation replay, provenance, and local naming row.*

8. *C stores displayed* Cont *replay from stream requests to modulus thresholds, from thresholds to dyadic tolerances, from tolerances to the bound ledger, and from the bound ledger to the regular-rational and real-facing rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceBounded}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, D, R, E, B, H, C, P, N$. It has no coordinate for host completeness, quotient streams, selected limits, real trichotomy, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedTasteGate single carrier alignment`

Theorem 1522.2 (Cauchy boundedness NameCert obligations)**.** *For an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier $X = (S, M, D, R, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceBounded}^{\uparrow}}$ *obligations are exactly carrier admission, finite-window classification, modulus-to-bound extraction, dyadic bound ledger stability,* $\mathsf{Real}^{\uparrow}$ *seal handoff, and ledger non-escape. These obligations are discharged by the displayed route*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E \longmapsto B$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier namecert obligations`

Proof. Carrier admission is the projection of the displayed tuple in Definition 1522.1. The finite-window classifier reads the schedule S and then uses M to identify the tail threshold where the Cauchy comparison becomes governed by the displayed modulus row.

The modulus-to-bound extraction applies the tolerance ledger D to the inspected initial window and to the tail window named by M. The ledger B records both finite data: an initial-window bound and a tail-bound row, reconciled into one dyadic or rational bound.

The rows H and C transport and replay the same route componentwise, so dyadic bound stability is a property of the displayed ledger rather than of an external order principle. The rows R and E are downstream handoff rows; they receive a bounded sequence packet after B is present.

Finally, P and N source and name the packet. Since the carrier has no coordinate for host completeness, quotient streams, selected limits, trichotomy, open-cover compactness, choice, or ambient real completeness, the listed obligations exhaust the NameCert surface. □

Theorem 1522.3 (Cauchy window bound handoff)**.** *Every accepted boundedness read from a* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packet factors through*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E \longmapsto B$$

before any $\mathsf{Real}^{\uparrow}$ *consumer or convergence consumer reads the sequence. The exported handoff is the finite tuple $S, M, D, R, E, B, H, C, P, N$, with no hidden host completeness, quotient-stream equality, selected limit, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier window bound handoff`

Proof. Start with a consumer that asks for boundedness. By Definition 1522.1, the only visible observation schedule is S, and the only tail control row is M.

The dyadic tolerance ledger D is read next, because it is the sole row that compares finite observations and tail tolerances in the packet. The regular-rational handoff R and real seal row E are downstream of this tolerance data.

Apply Definition 1522.2. The ledger B is the row where the initial-window bound and the tail bound are reconciled, so every real-facing or convergence-facing read must pass through it before consuming R or E as a public boundary.

The structural rows H, C, P, N preserve, replay, source, and name the same route. No row in the carrier can supply the excluded completeness, quotient, selection, trichotomy, compactness, or ambient-real principle. □

Theorem 1522.4 (Cauchy boundedness modulus tail bound)**.** *For an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, every tail-bound read exposed by the boundedness ledger* B *must first read the stream schedule* S*, the Cauchy modulus threshold row* M*, and the dyadic tolerance ledger* D*. The tail-bound component of* B *is therefore a finite consequence of* S, M, D*, not an ambient completeness claim, quotient stream equality, selected limit, real trichotomy, open-cover compactness, or countable-choice principle.*

Proof. Project the rows S, M, D, B from Definition 1522.1. The stream schedule fixes the finite inspected windows, while the modulus row fixes the tail threshold at which the displayed Cauchy comparison is allowed to govern later reads.

Use Definition 1522.2. The dyadic ledger D is the only coordinate that compares inspected values with the tail tolerance, and the bound ledger B records the initial-window and tail-bound data only after that comparison route is visible.

Thus the tail-bound read is generated inside the displayed finite packet. No excluded completeness, quotient, selection, trichotomy, compactness, or choice coordinate can supply a second tail-bound source. □

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier modulus tail bound`

Theorem 1522.5 (Cauchy boundedness dyadic stability)**.** *For an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, any componentwise* hsame *transport that preserves the displayed rows* $S, M, D, R, E, B, H, C, P, N$ *also preserves the dyadic or rational bound recorded in* B*. In particular, a transported consumer cannot replace* B *by an unrecorded order bound or by a bound obtained from host* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The bound ledger is a carrier coordinate. A transport of the packet must carry $S, M, D, R, E, B, H, C, P, N$ componentwise, so the row named B is transported together with the schedule, modulus, dyadic ledger, handoff, and Real seal rows that generate it.

Apply Definition 1522.3. Every boundedness read consumes B before a real-facing or convergence-facing row is available, so a transported consumer has no opportunity to substitute a different bound after the handoff.

The replay row C and provenance row P name the same route, and the local row N names the same packet. Therefore dyadic bound stability is exactly stability of the displayed ledger B under the displayed transports. □

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier dyadic bound stability`

Theorem 1522.6 (Cauchy boundedness Real seal handoff)**.** *For an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *may be consumed by a downstream real-facing packet only after the route*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E \longmapsto B, H, C, P, N$$

has displayed the bound ledger and structural rows. The seal exports the bounded source route, not a selected completed-real limit, quotient stream representative, trichotomy decision, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier real seal handoff`

Proof. Start with the carrier. The Real-facing row E is downstream of the stream schedule, modulus threshold, dyadic tolerance ledger, and regular-rational handoff rows S, M, D, R.

Use Definition 1522.2 to expose the boundedness ledger B. The obligations make B the row where the initial-window bound and tail-bound data are reconciled before a real-facing consumer may use the source.

Finally apply Definition 1522.3. Any downstream $\mathsf{Real}^{\uparrow}$ read must carry H, C, P, N with the same route, so the seal is a handoff for the displayed bounded source and nothing outside the packet. □

Theorem 1522.7 (Cauchy boundedness ledger nonescape)**.** *For an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, no boundedness, Real-seal, or convergence-facing consumer can bypass the rows* $S, M, D, R, E, B, H, C, P, N$*. The packet has no coordinate that names host boundedness, quotient stream equality, selected limits, real trichotomy, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier ledger nonescape`

Proof. Read the carrier surface. Its only displayed rows are the stream schedule S, modulus row M, dyadic ledger D, regular-rational handoff R, Real seal E, bound ledger B, transport H, replay C, provenance P, and local name N.

The two earlier handoff theorems force all boundedness and real-facing reads through those same rows. A consumer that omits any of them lacks the schedule, threshold, tolerance, handoff, seal, bound, transport, replay, provenance, or local name needed to identify the packet.

Since no additional carrier coordinate exists, none of the excluded host principles can be recovered from the packet. Ledger nonescape is therefore the direct exhaustion of the displayed rows. □

Theorem 1522.8 (CauchySequenceBounded scoped dependency surface)**.** *The* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packet closes its dependency scope over exactly* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. For an accepted carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, every boundedness, tail, Real-seal, or convergence-facing read factors through the displayed rows*

$$S, M, D, R, E, B, H, C, P, N$$

and no read may import host boundedness, quotient stream equality, selected limits, real trichotomy, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier scoped dependency surface`

Proof. Project the carrier of Definition 1522.1. The rows S, M, D, R, E, B are respectively the stream schedule, Cauchy modulus threshold, dyadic tolerance ledger, regular rational handoff, Real seal, and explicit bound ledger.

Apply Definition 1522.2 and Definition 1522.3. These rows force every boundedness read through the same finite schedule, threshold, dyadic, regular-readback, seal, and bound coordinates.

Use Definition 1522.5, Definition 1522.6, and Definition 1522.7. The structural rows H, C, P, N preserve, replay, source, and name the same dependency surface, so the listed excluded objects remain outside the packet. □

Theorem 1522.9 (Cauchy boundedness bridge surface)**.** *The public* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packet bridges to the standard bounded-sequence reading exactly through its displayed modulus tail bounds, dyadic stability,* $\mathsf{Real}^{\uparrow}$ *seal handoff, and ledger nonescape rows. For an accepted carrier* $X = (S, M, D, R, E, B, H, C, P, N)$*, a standard bounded-sequence consumer may read the finite initial-window bound and the tail bound only through*

$$S \longmapsto M \longmapsto D \longmapsto B \longmapsto R \longmapsto E$$

together with H, C, P, N*. The bridge exports a boundedness surface for the displayed Cauchy schedule; it does not select a limit, prove host sequence convergence, identify quotient stream representatives, or import ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier bridge surface`

Proof. Start with the public carrier and read the modulus tail rows. The stream schedule S fixes the finite requests, the modulus row M fixes the tail threshold, and the dyadic ledger D supplies the only tolerance comparisons available to the packet.

Apply Definition 1522.4 and Definition 1522.5. These theorems make the ledger B the stable source of the displayed initial-window and tail bounds, with no unrecorded order bound available after transport.

Next apply Definition 1522.6. The $\mathsf{Real}^{\uparrow}$ seal row E is a handoff for the bounded source route, and the regular-rational row R is consumed only after the bound ledger has been displayed.

Finally use Definition 1522.7. Since every read must remain inside $S, M, D, R, E, B, H, C, P, N$, the bridge can expose standard boundedness for the displayed schedule without selecting limits, proving host convergence, quotienting streams, or importing ambient completeness. □

Falsifiable prediction: Every $\mathsf{Real}^{\uparrow}$ or Cauchy-convergence read from a $\mathsf{CauchySequenceBounded}^{\uparrow}$ packet factors through the displayed stream schedule, Cauchy modulus threshold, dyadic tolerance ledger, regular-rational handoff, real seal row, and explicit bound ledger before the sequence is consumed.

Independence witness: streamname, cauchymodulus, dyadicratcore, regseqrat, real, cauchyconvergencecriterion: $\mathsf{CauchySequenceBounded}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a stream schedule, modulus threshold row, dyadic tolerance ledger, regular-rational handoff, real seal, explicit bound ledger, componentwise transport, continuation replay, provenance, and local naming.

Theorem 1522.10 (Cauchy boundedness mature consumer grid)**.** *Every completion-style consumer of an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *carrier* $X = (S, M, D, R, E, B, H, C, P, N)$ *reads*

the modulus-tail row, dyadic-stability row, $\mathsf{Real}^{\uparrow}$ *seal handoff, and ledger-nonescape bridge surface through the same finite grid*

$$S, M, D, R, E, B, H, C, P, N.$$

The grid supports $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readers that need bounded Cauchy source data, but it does not assert ambient* $\mathsf{Real}^{\uparrow}$ *completeness or select a completed-real limit.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier mature consumer grid`

Proof. Project the displayed carrier. The stream schedule, modulus row, dyadic ledger, regular-rational handoff, Real seal, bound ledger, transport, replay, provenance, and local name are the only rows available to the consumer.

Apply Definition 1522.4 and Definition 1522.5. They make the tail bound and its dyadic stability properties reads of S, M, D, B, H, C, P, N, not of an external order or completeness principle.

Apply Definition 1522.6 and Definition 1522.7. These keep $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers on the displayed handoff route and prevent any bypass through quotient streams, selected limits, trichotomy, compactness, choice, or ambient completeness. □

Theorem 1522.11 (Cauchy boundedness completion consumer example)**.** *A completion-style reader that consumes a* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packet may use the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *and* $\mathsf{Real}^{\uparrow}$ *seal* E *only as bounded source data certified by* S, M, D, B, H, C, P, N*. In particular, the reader may transport a bounded regular-rational source into a later completion argument, but it must supply any completeness theorem, limit selector, quotient-real equality, or convergence conclusion from outside this chapter.*

Lean4 ✓ `BEDC.Derived.CauchySequenceBoundedUp.CauchySequenceBoundedCarrier completion consumer example`

Proof. Start from the bounded source route in Definition 1522.9. The standard bounded-sequence reading consumes S, M, D, B before it can use the handoff rows R and E.

The mature consumer grid theorem identifies the same route as the complete paper-side consumer surface for completion-style readers. Thus a later argument may reuse the bounded regular-rational source and Real seal as named input data.

Nothing in the carrier supplies a completion result. The nonescape theorem excludes host completeness, quotient streams, selected limits, trichotomy, open-cover compactness, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so any downstream convergence or limit conclusion must be supplied by a separate packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceBounded}^{\uparrow}$ packet is generated from a StreamName request schedule, a CauchyModulus threshold row, a DyadicRatCore tolerance ledger, a RegSeqRat handoff, a RealUp seal, an explicit dyadic or rational bound ledger, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceBounded}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1522.1, Definition 1522.2, Definition 1522.3, Definition 1522.4, Definition 1522.5, Definition 1522.6, Definition 1522.7, Definition 1522.8, Definition 1522.9, Definition 1522.10, and Definition 1522.11 close the displayed public boundedness dependency surface, its standard bounded-sequence bridge, and its completion-style consumer surface for one Cauchy sequence schedule.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceBounded}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host completeness, quotient streams, selected limits, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: No paper-side theory upgrade remains below the standard bridge axis; Lean verification and bridge checking remain separate obligations.

Chapter 1523

A Concrete Naming Certificate for $\mathsf{AitkenDeltaSquared}^{\uparrow}$

Following Aitken's delta-squared process in numerical analysis, the $\mathsf{AitkenDeltaSquared}^{\uparrow}$ packet records finite acceleration evidence for a displayed real-name sequence. It sits next to the sequence surface of chapter 120, the rate ledger of chapter 415, the dyadic arithmetic core of chapter 291, the stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate names one finite acceleration window and its rate handoff; it does not import host limits, ambient completeness, quotient real equality, trichotomy, or a selected convergence witness.

Definition 1523.1 (Aitken delta-squared carrier)**.** *An* $\mathsf{AitkenDeltaSquared}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, W, O, F, G, Q, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Seq}^{\uparrow}$ *source sequence row whose finite real-name observations are to be accelerated.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selecting three consecutive displayed observations from S.*
3. *O stores the three observations x_n, x_{n+1}, x_{n+2} as finite* $\mathsf{Real}^{\uparrow}$*-facing names before any acceleration read is accepted.*
4. *F stores the first-difference rows $x_{n+1} - x_n$ and $x_{n+2} - x_{n+1}$ in dyadic or regular rational readback form.*
5. *G stores the second-difference row $x_{n+2} - 2x_{n+1} + x_n$ as a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger computation.*
6. *Q is the denominator-apartness ledger asserting that the displayed second-difference row is apart from the zero denominator at the requested finite precision.*
7. *K is the dyadic quotient estimate for the local accelerated read*

$$x_n - \frac{(x_{n+1} - x_n)^2}{x_{n+2} - 2x_{n+1} + x_n}$$

   computed only from O, F, G, Q.

8. *R is the* $\mathsf{CauchyRate}^{\uparrow}$ *handoff row recording the finite rate evidence obtained from the quotient estimate and the displayed source window.*

9. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row and terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the accelerated observation.*
10. *H stores componentwise* hsame *transport for the source sequence, selected window, three observations, first-difference rows, second-difference row, apartness ledger, quotient estimate, CauchyRate handoff, RegSeqRat readback, Real seal, continuation replay, provenance, and local naming row.*
11. *C stores displayed* Cont *replay from the sequence window to the three observations, from observations to first and second differences, from the apartness ledger to the quotient estimate, and from the quotient estimate to the CauchyRate, RegSeqRat, and Real-facing rows.*
12. *P is the* Pkg *provenance over* $\mathsf{AitkenDeltaSquared}^{\uparrow}$, $\mathsf{Seq}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AitkenDeltaSquared}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, O, F, G, Q, K, R, E, H, C, P, N$. It has no coordinate for host limits, ambient completeness, quotient real equality, trichotomy, selected convergence witnesses, or division by a hidden denominator.

Lean4 ✓ `BEDC.Derived.AitkenDeltaSquaredUp.AitkenDeltaSquaredTasteGate single carrier alignment`

Theorem 1523.2 (Aitken delta-squared NameCert obligations)**.** *For an accepted* $\mathsf{AitkenDeltaSquared}^{\uparrow}$ *carrier $A = (S, W, O, F, G, Q, K, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AitkenDeltaSquared}^{\uparrow}}$ *obligations are exactly carrier admission, three-observation window classification, first-difference extraction, second-difference ledger stability, denominator-apartness validation, dyadic quotient estimate construction,* $\mathsf{CauchyRate}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal factorization, and ledger non-escape. These obligations are discharged by the displayed route*

$$S \longmapsto W \longmapsto O \longmapsto F \longmapsto G \longmapsto Q \longmapsto K \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 1523.1. The tuple lists exactly the sequence row, stream window, observation rows, finite-difference rows, apartness ledger, quotient estimate, rate handoff, regular-rational readback, real seal, transport, replay, provenance, and local name.

The window classifier reads S only through the finite $\mathsf{StreamName}^{\uparrow}$ row W. The row O then supplies three consecutive displayed observations, and F and G are computed from those displayed rows by the dyadic arithmetic ledger rather than by an ambient real operation.

Denominator validity is the row Q. The quotient estimate K may be read only after Q is present, so the accelerated expression is a finite dyadic or regular-rational computation with an explicit apartness witness at the requested precision.

The rows R and E are downstream handoffs. They consume the same finite quotient route before exposing CauchyRate evidence, RegSeqRat readback, or a Real-facing seal.

Finally, H and C transport and replay the route componentwise, while P and N source and name it. Since the carrier has no field for host limits, ambient completeness, quotient real equality, trichotomy, selected convergence witnesses, or hidden division, the listed obligations exhaust the NameCert surface. □

Theorem 1523.3 (Aitken delta-squared CauchyRate handoff)**.** *Every accepted* $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *read from an* $\mathsf{AitkenDeltaSquared}^{\uparrow}$ *packet factors through the finite acceleration route*

$$S \longmapsto W \longmapsto O \longmapsto F \longmapsto G \longmapsto Q \longmapsto K \longmapsto R \longmapsto E.$$

Thus Real-facing consumers receive only the displayed acceleration estimate and rate ledger, not a host limit, an ambient completeness claim, quotient real equality, trichotomy, or a selected convergence witness.

Proof. Start with any rate, regular-rational, or real-facing consumer of the accepted packet. By Definition 1523.1, the consumer has no direct access to the source sequence except through the displayed window W over S.

The three observations in O are then the only rows from which first and second differences can be read. The first-difference row F and second-difference row G therefore determine the finite acceleration denominator and numerator surface visible to the packet.

Before the quotient estimate is exported, the consumer must read the apartness ledger Q. This row is the certificate that the displayed denominator is usable at the finite precision being requested, and K is the only row that stores the resulting dyadic quotient estimate.

Apply Definition 1523.2. The CauchyRate handoff R, the RegSeqRat readback, and the Real seal in E all stand downstream of K, and their transport and replay data are exactly H and C.

No row remains that could supply host limits, ambient completeness, quotient real equality, trichotomy, or a selected convergence witness. Hence every Real-facing read passes through the finite acceleration and rate ledgers. □

Falsifiable prediction: Every $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read from an $\mathsf{AitkenDeltaSquared}^{\uparrow}$ packet factors through the displayed sequence window, three consecutive observations, first-difference rows, second-difference row, denominator-apartness ledger, dyadic quotient estimate, CauchyRate handoff, regular-rational readback, real seal, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: seq, streamname, dyadicratcore, cauchyrate, regseqrat, real: $\mathsf{AitkenDeltaSquared}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source sequence, a three-observation stream window, finite-difference ledgers, denominator apartness, a quotient estimate, rate handoff, regular-rational and real-seal rows, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AitkenDeltaSquared}^{\uparrow}}$.

Constructive story: An $\mathsf{AitkenDeltaSquared}^{\uparrow}$ packet is generated from a source sequence, a finite stream window with three consecutive observations, first- and second-difference ledgers, an explicit denominator-apartness row, a dyadic quotient estimate, CauchyRate and RegSeqRat handoffs, a Real seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AitkenDeltaSquared}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1523.1, Definition 1523.2, and Definition 1523.3 seed the finite delta-squared acceleration packet for one displayed real-name sequence window.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AitkenDeltaSquared}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limits, ambient completeness, quotient real equality, trichotomy, selected convergence witnesses, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, three-observation classification, first- and second-difference ledger stability, denominator-apartness validation, quotient estimate construction, CauchyRate handoff, Real-facing factorization, and ledger non-escape for BEDC.Derived.AitkenDeltaSquaredUp.

Chapter 1524

A Concrete Naming Certificate for $\mathsf{DyadicRoundingWindow}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicRoundingWindow}^{\uparrow}$ packet records the finite precision-window surface used when a real name or regular rational name is inspected at one displayed unary precision and then rounded through adjacent dyadic endpoints. It sits between the finite windows of chapter 126, the adjacent endpoint packet of chapter 433, the readback route of chapter 335, the regular rational handoff of chapter 301, the dyadic arithmetic ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate names precision-window rounding as finite BEDC route data, without quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness.

Definition 1524.1 (DyadicRoundingWindow carrier)**.** *A* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, q, D, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window opened for the inspected real or regular rational name.*
2. *q is the unary precision request that fixes the finite observation scale.*
3. *D is the adjacent endpoint* $\mathsf{DyadicRounding}^{\uparrow}$ *packet at precision q, including its* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows and tolerance ledger.*
4. *A is the* $\mathsf{DyadicApproximation}^{\uparrow}$ *readback row exposing the rounded finite observation produced from S, q, D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that packages the same rounded window as regular rational data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream window, unary precision, adjacent endpoint packet, dyadic readback, and regular rational handoff are displayed.*
7. *H stores componentwise* hsame *transport for the stream window, unary precision, adjacent endpoint packet, dyadic readback, regular rational handoff, real seal, continuation replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from the precision request to the stream window, from the window to the adjacent endpoint packet, from the endpoint packet to the dyadic readback, and from the readback to the regular rational and real-facing rows.*

9. *P is the* Pkg *provenance over* DyadicRoundingWindow$^\uparrow$, StreamName$^\uparrow$, DyadicRounding$^\uparrow$, DyadicApproximation$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, DyadicRatCore$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DyadicRoundingWindow}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, q, D, A, R, E, H, C, P, N$. It has no coordinate for quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowTasteGate single carrier alignment`

Theorem 1524.2 (DyadicRoundingWindow NameCert obligations)**.** *For an accepted* DyadicRoundingWindow$^\uparrow$ *carrier $W = (S, q, D, A, R, E, H, C, P, N)$, the local* NameCert$_{\text{DyadicRoundingWindow}^\uparrow}$ *obligations are exactly carrier admission, precision-window classification, adjacent-endpoint compatibility, dyadic readback exactness,* RegSeqRat$^\uparrow$ *handoff,* Real$^\uparrow$ *seal factorization, and ledger non-escape. These obligations are discharged by the displayed route*

$$S \longmapsto q \longmapsto D \longmapsto A \longmapsto R \longmapsto E$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1524.1. The finite stream window, unary precision, adjacent endpoint packet, dyadic readback, regular rational handoff, real seal, transport rows, continuation routes, package provenance, and local naming row are exactly the coordinates available to the classifier.

Precision-window classification first reads q and then opens S at the displayed scale. Adjacent-endpoint compatibility reads the same precision row through the DyadicRounding$^\uparrow$ packet D, whose dyadic endpoints and tolerance ledger are already tied to DyadicRatCore$^\uparrow$.

Dyadic readback exactness and the two handoff clauses are route projections. The row A exposes the DyadicApproximation$^\uparrow$ observation produced by S, q, D; the row R repacks that observation as regular rational data; and the row E is the only real-facing seal coordinate.

The non-escape obligation is packet inspection. Since no row records quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness, every accepted consumer remains inside the displayed finite route. □

Theorem 1524.3 (DyadicRoundingWindow precision-window obligation)**.** *Every accepted* DyadicRoundingWindow *packet $W = (S, q, D, A, R, E, H, C, P, N)$ must open the* StreamName$^\uparrow$ *row S at unary precision q before D is read as the* DyadicRounding$^\uparrow$ *endpoint packet. Only after this displayed read may the* DyadicApproximation$^\uparrow$ *row A, the* RegSeqRat$^\uparrow$ *handoff R, and the* Real$^\uparrow$ *seal E be consumed, and then only through the displayed* hsame, Cont, Pkg, *and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier precision window obligation`

Proof. Project the carrier of Definition 1524.1. Its ordered rows expose S and q before the endpoint packet D, so an accepted consumer has a finite stream window and a unary precision request before any rounded endpoint is inspected.

Apply Definition 1524.2. Its route order is

$$S \longmapsto q \longmapsto D \longmapsto A \longmapsto R \longmapsto E$$

together with H, C, P, N, so the precision-window obligation is a projection of the local NameCert$_{\text{DyadicRoundingWindow}^\uparrow}$ surface.

Use Definition 1524.4 for nonescape. The error bound follows the same endpoint and readback route into $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, and the structural rows merely transport, replay, source, and name that route. No quotient equality, selected limit, trichotomy, host rounding, or ambient completeness row is introduced. □

Theorem 1524.4 (DyadicRoundingWindow error bound)**.** *Every accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier exports a finite error-bound route: the readback row A is bounded by the adjacent endpoint packet D at unary precision q, transported through H, replayed through C, and handed to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through R and E. No exported bound may be replaced by quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier error bound`

Proof. Begin with the accepted carrier and project its displayed precision row q. The row q fixes the only observation scale available to the packet, so an error-bound consumer must read the same finite window S at that scale.

Next read the adjacent endpoint packet D. By the $\mathsf{DyadicRounding}^{\uparrow}$ dependency surface, D supplies the adjacent dyadic endpoint rows and tolerance ledger at the displayed precision, with those endpoint rows sourced from $\mathsf{DyadicRatCore}^{\uparrow}$.

Now read the dyadic approximation row A. It is the only coordinate that exposes the rounded observation from S, q, D, so its error bound is the endpoint-and-tolerance surface already carried by D.

Finally route the bound through R, E, H, C, P, N. These rows preserve, replay, source, and name the same finite packet for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The carrier inventory contains no coordinate that can replace the bound by quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness. □

Theorem 1524.5 (DyadicRoundingWindow error-envelope monotonicity)**.** *Let*

$$W = (S, q, D, A, R, E, H, C, P, N)$$

and

$$W' = (S', q', D', A', R', E', H', C', P', N')$$

be accepted $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *packets. Suppose the two packets share the same* $\mathsf{StreamName}^{\uparrow}$ *row, endpoint route, and readback route under the displayed* hsame *and* Cont *data, and suppose the unary precision q' refines q. Then the exported error-bound route of W' factors through the endpoint ledger of W and cannot widen the tolerance envelope before the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff. The comparison is made only through the displayed unary precisions and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*

Proof. Project both packets through Definition 1524.1. The only rows that can affect the error envelope are the stream rows S, S', the unary precisions q, q', the adjacent endpoint packets D, D', and the readback rows A, A'.

Apply Definition 1524.4 to each packet. For W, the exported bound is the endpoint-and-tolerance surface carried by D at precision q. For W', the bound is the corresponding surface carried by D' at precision q'.

The shared StreamName row and shared endpoint/readback route force both bounds to read the same finite observation path. Since q' refines q, the later $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger is a subledger of the earlier endpoint ledger for the same route; it supplies a narrower observation budget, not an extra coordinate.

Finally inspect the remaining rows R, E, H, C, P, N and R', E', H', C', P', N'. They transport, replay, source, and name the already compared endpoint ledgers for the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff. No quotient equality, host rounding mode, trichotomy row, selected limit, or completeness row is present to widen the envelope. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier error envelope monotonicity`

Theorem 1524.6 (DyadicRoundingWindow precision classification)**.** *Every accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier opens the same* $\mathsf{StreamName}^{\uparrow}$ *row* S *at the displayed unary precision* q *before the adjacent endpoint packet* D *is read as* $\mathsf{DyadicRounding}^{\uparrow}$ *data. The precision classifier is therefore the finite route through* $S, q, D, A, R, E, H, C, P, N$*, not a host rounding mode, selected real approximation, trichotomy test, or ambient completeness argument.*

Proof. Start with the carrier inventory of Definition 1524.1. The rows S and q are displayed before the endpoint packet, so the classifier has a named stream window and a named unary precision before any rounded endpoint is consumed.

Apply the NameCert obligations of Definition 1524.2. The precision-window classification clause reads q and then opens S at that scale as part of the route

$$S \longmapsto q \longmapsto D \longmapsto A \longmapsto R \longmapsto E.$$

Finally use the error-bound surface of Definition 1524.4. Since the bound is attached to the same q and the same D, the classifier cannot swap in a host rounding mode, selected approximation, trichotomy test, or ambient completeness row. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier precision classification`

Theorem 1524.7 (DyadicRoundingWindow adjacent endpoint compatibility)**.** *In every accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier, the endpoint packet* D *and the readback row* A *share the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger at precision* q*, and their componentwise compatibility is transported only through the displayed* hsame *row* H*. Thus the adjacent endpoint readback cannot be replaced by quotient real equality, host rounding, selected limits, or an unstated metric-completeness witness.*

Proof. Project $W = (S, q, D, A, R, E, H, C, P, N)$ from Definition 1524.1. The row D contains the adjacent endpoint packet and its dyadic tolerance ledger, while A is the only dyadic readback coordinate produced from S, q, D.

The obligation theorem Definition 1524.2 ties adjacent-endpoint compatibility and dyadic readback exactness to the same route. Therefore D and A are compared inside the displayed precision-window packet rather than through an external real-equality principle.

Now apply the error-bound theorem Definition 1524.4. The endpoint tolerance ledger bounds A at the unary precision q, and H transports this componentwise compatibility through the later rows. No carrier coordinate can replace that ledger by quotient real equality, host rounding, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier adjacent endpoint compatibility`

Theorem 1524.8 (DyadicRoundingWindow readback handoff)**.** *Every accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier hands the approximation row* A *to later consumers only through the regular rational row* R *and then through the real seal row* E*. The route is*

$$A \longmapsto R \longmapsto E$$

inside the displayed packet $W = (S, q, D, A, R, E, H, C, P, N)$, so a consumer cannot bypass R by invoking quotient real equality, a selected limit, host rounding, or ambient completeness.

Proof. Project W from Definition 1524.1. The row A is the only dyadic approximation readback coordinate, while R and E are the only regular rational and real-facing rows.

Use Definition 1524.4. It states that the bound on A is preserved for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers only through R and E, with H and C transporting and replaying the same finite route.

Finally apply Definition 1524.7. The endpoint packet D and the readback row A remain tied to the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger at the displayed precision q. Since no other readback or real-facing coordinate is present, the handoff cannot escape the $A \mapsto R \mapsto E$ route. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier readback handoff`

Theorem 1524.9 (DyadicRoundingWindow Real-seal factorization)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *packet factors through $S, q, D, A, R, E, H, C, P, N$ before the rounded observation is consumed. The seal route cannot use quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness.*

Proof. Begin with Definition 1524.1. The rows R and E are downstream rows: R repackages the rounded observation as regular rational data, and E is the real-facing seal reached only after S, q, D, A are displayed.

Use Definition 1524.2. Its regular rational handoff, Real seal factorization, and ledger non-escape clauses force every consumer to read the same finite route through the stream window, unary precision, adjacent endpoints, dyadic readback, handoff, and seal.

Finally invoke Definition 1524.4. The error bound is preserved through R, E, H, C, P, N, so a consumer cannot bypass S, q, D, A by citing quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier real seal factorization`

Theorem 1524.10 (DyadicRoundingWindow ledger nonescape)**.** *In every accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *carrier, the rows H, C, P, N exhaust transport, replay, provenance, and local naming for S, q, D, A, R, E. Therefore the ledger exports no quotient real equality, selected limit, trichotomy, host rounding operation, ambient completeness theorem, or unnamed real-facing approximation row.*

Proof. Start with the carrier inventory of Definition 1524.1. Its structural rows are exactly H, C, P, N: H transports the displayed coordinates componentwise, C replays the continuation route, P records the package provenance, and N names the local packet.

Apply Definition 1524.8. The only path from the approximation row to a later consumer is through $A \mapsto R \mapsto E$, and that path is already guarded by the same H, C, P, N rows.

Use Definition 1524.9. Real-facing consumers factor through the displayed stream window, precision request, adjacent endpoint packet, readback row, regular rational handoff, and real seal before any rounded observation is consumed.

No remaining carrier coordinate can name quotient real equality, selected limits, trichotomy, host rounding, ambient completeness, or an extra approximation row. Thus the ledger is nonescaping by finite packet exhaustion. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier ledger nonescape`

Theorem 1524.11 (DyadicRoundingWindow mature completion boundary)**.** *The mature* DyadicRoundingWindow$^{\uparrow}$ *packet exhausts precision-window rounding through the displayed rows*

$$S, q, D, A, R, E, H, C, P, N$$

over StreamName$^{\uparrow}$*,* DyadicRounding$^{\uparrow}$*,* DyadicApproximation$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *data. Every rounded-observation consumer is confined to that route. No quotient real equality, selected limit, trichotomy, host rounding operation, or ambient completeness row is exported.*

Proof. Begin with the obligation package of Definition 1524.12. It identifies the carrier rows, precision-window classification, adjacent endpoint compatibility, dyadic readback, regular rational handoff, Real seal factorization, and ledger nonescape as one finite packet.

Now apply the scoped consumer and kernel-dependency boundaries, Definition 1524.13 and Definition 1524.14. They force each consumer to pass through StreamName$^{\uparrow}$, DyadicRounding$^{\uparrow}$, DyadicApproximation$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ before the rounded observation is read.

Finally read the bridge-facing handoff of Definition 1524.15. The handoff preserves the same rows H, C, P, N and adds no coordinate for quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness. Thus the completion boundary is exhausted by the displayed packet. □

Theorem 1524.12 (DyadicRoundingWindow obligation-closure package)**.** *The carrier of Definition 1524.1, together with Definition 1524.2, Definition 1524.4, Definition 1524.6, Definition 1524.7, Definition 1524.8, Definition 1524.9, and Definition 1524.10, assembles the full obligationClosure surface for* DyadicRoundingWindow$^{\uparrow}$*. The closed surface is exactly the displayed packet over* StreamName$^{\uparrow}$*,* DyadicRounding$^{\uparrow}$*,* DyadicApproximation$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. First project the carrier. The rows $S, q, D, A, R, E, H, C, P, N$ give the only finite precision-window object available to the certificate, with S naming the stream window, q fixing the unary precision request, D carrying the adjacent dyadic endpoint packet, A exposing the dyadic readback, R giving regular-rational readback, and E giving the real-facing seal.

Next apply the obligation and error-bound theorems. They identify carrier admission, precision-window classification, adjacent-endpoint compatibility, dyadic readback exactness, regular rational handoff, Real seal factorization, and ledger non-escape as obligations of the same route

$$S \longmapsto q \longmapsto D \longmapsto A \longmapsto R \longmapsto E.$$

Now read the remaining rows separately. Precision classification fixes the observation scale before endpoint data are consumed; adjacent endpoint compatibility ties D and A to the same DyadicRatCore$^{\uparrow}$ tolerance ledger; readback handoff forces A through R before E; and Real-seal factorization prevents a later consumer from bypassing those rows.

Finally use ledger nonescape. The structural rows H, C, P, N transport, replay, source, and name the same packet, and no coordinate records quotient real equality, selected limits, trichotomy, host rounding, ambient completeness, or an unnamed approximation row. This exhausts the obligationClosure surface over the listed BEDC rows. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier obligation closure package`

Theorem 1524.13 (DyadicRoundingWindow scoped consumer boundary)**.** *Every consumer of an accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *packet must scope the rounded observation through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRounding}^{\uparrow}$ *adjacent endpoint packet,* $\mathsf{DyadicApproximation}^{\uparrow}$ *readback row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. No consumer may replace that packet by quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness.*

Proof. Start with the carrier of Definition 1524.1. Its visible rows $S, q, D, A, R, E, H, C, P, N$ are the only coordinates available to a rounded-observation consumer, so the consumer first receives a stream window, a unary precision request, adjacent dyadic endpoints, a readback row, regular-rational handoff, a real-facing seal, transport, replay, provenance, and local naming.

Apply Definition 1524.12. The obligation package assembles those rows together with precision classification, adjacent endpoint compatibility, readback handoff, Real-seal factorization, and ledger nonescape. Thus a consumer cannot separate the rounded observation from the displayed finite route.

The handoff theorems identify the downstream boundary. By Definition 1524.8, the readback row passes only through $A \mapsto R \mapsto E$; by Definition 1524.9, any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ use factors through the same stream, endpoint, readback, handoff, and seal rows; and by Definition 1524.10, H, C, P, N exhaust the structural ledger.

Since the carrier contains no coordinate for quotient real equality, selected limits, trichotomy, host rounding, or ambient completeness, no scoped consumer can introduce one. The rounded observation remains a finite BEDC packet over the listed rows. □

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier scoped consumer boundary`

Theorem 1524.14 (DyadicRoundingWindow scoped kernel dependencies)**.** *Every precision-window rounding consumer of an accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *packet factors through the displayed* BHist *request rows,* $\mathsf{StreamName}^{\uparrow}$ *window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic,* $\mathsf{DyadicRounding}^{\uparrow}$ *adjacent endpoint rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. These rows are the scoped kernel dependencies for the obligationClosure-to-scopedClosure step; no quotient real equality, selected limit, trichotomy, host rounding mode, or ambient completeness row is part of the factorization.*

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier scoped kernel dependencies`

Proof. Start with the precision-window obligation, Definition 1524.3. It places the request row and the $\mathsf{StreamName}^{\uparrow}$ window in front of the adjacent endpoint packet.

Apply the error-bound theorem Definition 1524.4 and endpoint compatibility Definition 1524.7. Together they force the rounded observation to read the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance arithmetic and $\mathsf{DyadicRounding}^{\uparrow}$ adjacent endpoint rows before any readback is exported.

Next use the readback handoff and Real-seal factorization, Definition 1524.8 and Definition 1524.9. They route the approximation through $\mathsf{RegSeqRat}^{\uparrow}$ and then through the terminal $\mathsf{Real}^{\uparrow}$ seal, with no bypass around the displayed finite packet.

Finally combine ledger nonescape, Definition 1524.10, with the scoped consumer boundary of Definition 1524.13. The structural rows H, C, P, N supply transport, replay, provenance, and local naming for the same route, so the listed dependencies exhaust the scoped kernel surface. □

Theorem 1524.15 (DyadicRoundingWindow bridge-facing handoff)**.** *Every standard-facing read of an accepted* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *packet preserves the dyadic source row, the precision-window row, the tolerance budget, componentwise transport, displayed replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{DyadicRoundingWindow}^{\uparrow}}$ *rows before any rounded observation is exposed. The bridge-facing handoff is exactly the displayed route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRounding}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *already scoped by Definition 1524.14. It does not assert* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, selected limits, trichotomy, host rounding, or an ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier bridge facing handoff`

Proof. Start with Definition 1524.14. It fixes the finite dependency route through the stream window, regular rational readback, dyadic tolerance arithmetic, adjacent endpoint rows, transport, replay, provenance, and the terminal real seal.

Apply Definition 1524.13. A consumer cannot read the rounded observation without preserving $S, q, D, A, R, E, H, C, P, N$, so the standard-facing route keeps the dyadic source row, window row, tolerance budget, and local naming together.

Use ledger nonescape from Definition 1524.10. The structural rows only preserve and name the displayed finite route. Since no carrier coordinate stores $\mathsf{Real}^{\uparrow}$ completeness, quotient equality, selected limits, trichotomy, host rounding, or ambient completion, the bridge-facing handoff cannot export those claims. □

Falsifiable prediction: Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read from a $\mathsf{DyadicRoundingWindow}^{\uparrow}$ packet factors through the displayed stream window, unary precision, adjacent $\mathsf{DyadicRounding}^{\uparrow}$ endpoint packet, $\mathsf{DyadicApproximation}^{\uparrow}$ readback, regular rational handoff, real seal row, componentwise transport, continuation replay, provenance, and local naming before the rounded observation is consumed.

Independence witness: streamname, dyadicrounding, dyadicapproximation, regseqrat, real, dyadicratcore: $\mathsf{DyadicRoundingWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a stream window, unary precision request, adjacent endpoint packet, dyadic readback, regular rational handoff, real seal, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRoundingWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRoundingWindow}^{\uparrow}$ packet is generated from a StreamName window, a unary precision request, an adjacent DyadicRounding endpoint packet, a DyadicApproximation readback row, a RegSeqRat handoff, a RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicRoundingWindow}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1524.12, Definition 1524.11, Definition 1524.14, and Definition 1524.15 bind every public and standard-facing consumer to the displayed StreamName, DyadicRounding, DyadicApproximation, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicRoundingWindow}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.DyadicRoundingWindowUp.DyadicRoundingWindowCarrier\_bridge\_facing\_handoff`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, host rounding, ambient completeness, or bridge checking.

Upgrade path: No theory-axis upgrade remains; verification upgrade requires bridge checking for the mature precision-window boundary and bridge-facing handoff.

Chapter 1525

A Concrete Naming Certificate for $\mathsf{FanFunctional}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Bishop constructive analysis, the $\mathsf{FanFunctional}^{\uparrow}$ packet records the finite modulus-extraction surface that a continuous functional on Cantor space may expose after a finite fan argument. It consumes the finite-prefix carrier of chapter 1475, the decidable finite-bar and depth rows of chapter 400, the tolerance-to-precision ledger of chapter 391, and the compact metric finite-net surface of chapter 129. The packet exports an explicit $\mathsf{UniformModulus}^{\uparrow}$ row for Cantor-prefix consumers; it does not export a host functional, a choice-selected branch, open-cover compactness, or real completeness.

Definition 1525.1 (FanFunctional carrier surface)**.** *A* $\mathsf{FanFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$$

with the following visible rows:

1. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix row, including the StreamName schedule, Boolean observation ledger, and List prefix spine;*
2. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row, including the decidable bar classifier and the unary depth ledger for the displayed binary spread;*
3. *ε is the positive tolerance request read by the downstream metric or real-valued consumer;*
4. *B is the finite branch-prefix window obtained by restricting the Cantor prefix rows of C to the depth ledger of F;*
5. *D is the finite bar-depth evidence saying that every retained branch prefix in B reaches a barred prefix by the displayed unary depth;*
6. *W is the finite witness window pairing each retained prefix with the pointwise tolerance row requested at that prefix;*
7. *M is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, read as a unary prefix length sufficient for all Cantor histories sharing the retained prefix;*
8. *H records componentwise* hsame *transport for the Cantor rows, fan rows, tolerance request, witness window, depth evidence, and extracted modulus;*
9. *K records the displayed* Cont *replay route from Cantor-prefix reads through the finite fan rows into the modulus row;*

10. *P is the* Pkg *provenance over* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite branch, a host functional $2^{\mathsf{Nat}^{\uparrow}} \to \mathsf{Real}^{\uparrow}$, *an open cover, a selected bar proof, or a hidden compactness principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalTasteGate single carrier alignment`

Theorem 1525.2 (FanFunctional NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *surface of Definition 1525.1 consists of six finite obligations: carrier admission for the displayed packet* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$*; classifier stability for the Cantor-prefix and finite-fan rows under componentwise* hsame *transport; bar-depth exactness for the unary ledger D; witness-window coverage for all retained branch prefixes in B; uniform-modulus extraction of the row M; and non-escape, requiring every public read to factor through H, K, P, N and no host functional or choice principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalNameCertObligations`

Proof. Carrier admission is projection of the displayed coordinates of Definition 1525.1. The Cantor row, fan row, tolerance request, branch-prefix window, depth evidence, witness window, and modulus row are all finite BHist data.

Classifier stability is componentwise. The Cantor rows are compared by the finite-prefix classifier of chapter 1475, while the fan rows are compared by the finite bar classifier of chapter 400. Transport by H keeps the tolerance, witness window, depth evidence, and extracted modulus attached to the same displayed packet.

Bar-depth exactness reads the unary depth ledger of the $\mathsf{FanTheorem}^{\uparrow}$ row. For each retained prefix in B, the witness D records that the displayed decidable bar has already been met within the finite depth; no infinite branch or bar-induction rule is introduced.

The witness-window and modulus clauses are obtained by replaying K. Each retained prefix carries the local tolerance row in W, and the finite fan depth bounds the largest prefix length that a downstream consumer must inspect. Repacking this bounded inspection length as M gives the $\mathsf{UniformModulus}^{\uparrow}$ row.

Non-escape follows from coordinate exhaustion. The carrier contains only $C, F, \varepsilon, B, D, W, M, H, K, P, N$, so a public read cannot produce a host functional, a choice-selected branch, open-cover compactness, or real completeness. □

Theorem 1525.3 (FanFunctional root carrier admission)**.** *Every root-obligation read of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet must admit the full finite carrier*

$$\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$$

as BHist *data before any compact-uniform consumer reads it. The rows $C, F, \varepsilon, B, D, W, M, H, K, P, N$ expose the Cantor prefix, fan bar, epsilon request, branch window, finite depth, witness window, modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *surface as one packet.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootCarrierAdmission`

Proof. Project Definition 1525.1. Carrier admission reads the displayed tuple before any downstream consumer may inspect a modulus row.

The structural rows then bind the read. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve exactly $C, F, \varepsilon, B, D, W, M, H, K, P, N$, so a consumer has no entry point outside the admitted carrier. □

Theorem 1525.4 (FanFunctional root finite bar depth)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$*, the finite bar-depth row* D *is exposed after the* $\mathsf{CantorSpace}^{\uparrow}$ *and* $\mathsf{FanTheorem}^{\uparrow}$ *rows* C, F *and before any witness-window use of* W *or modulus read of* M*. Thus every* BHist *route through* hsame*,* Cont*,* Pkg*, and* NameCert *sees finite depth before it sees witness-window coverage.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootFiniteBarDepth`

Proof. Use the NameCert obligations. Bar-depth exactness is a separate row obligation, and witness-window coverage is downstream from that exactness.

The order is therefore C, F first, then D, then W, M. Transport through H, replay through K, provenance through P, and naming through N keep this order inside the same finite packet and do not add a selected branch or infinite bar proof. □

Theorem 1525.5 (FanFunctional root uniform-modulus handoff)**.** *Every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$ *routes its* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{UniformContinuity}^{\uparrow}$ *before the row* M *is exported. The route is a finite* BHist *package through* hsame*,* Cont*,* Pkg*, and* NameCert*, not a host functional, open-cover compactness proof, selected branch, or ambient Real-completeness argument.*

Proof. First read C and F to obtain the finite Cantor-prefix and fan-bar surfaces. The compact-metric row consumes only the finite windows B, D, W, and the uniform-continuity row consumes the epsilon request ε over those same windows.

The extracted row M is then the $\mathsf{UniformModulus}^{\uparrow}$ handoff. Rows H, K, P, N transport, replay, source, and name the same finite route, so the exported modulus is exactly the Cantor, fan, compact-metric, and uniform-continuity route displayed by the carrier. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUniformModulusHandoff`

Theorem 1525.6 (FanFunctional prefix-window carrier admission)**.** *Every consumer-visible modulus read from an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier must first admit the Cantor prefix row* C*, finite fan row* F*, tolerance row* ε*, branch-window row* B*, depth row* D*, witness-window row* W*, modulus row* M*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* K*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row* N*. No* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer may read a modulus before those rows have appeared on the same finite packet.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalPrefixWindowCarrierAdmission`

Proof. Project the carrier of Definition 1525.1. Its visible coordinates are exactly $C, F, \varepsilon, B, D, W, M, H, K, P, N$, so carrier admission exposes the Cantor prefix, finite fan, tolerance, branch-window, depth, witness, and modulus rows before any consumer-facing read.

Apply Definition 1525.2. The carrier admission, classifier stability, bar-depth exactness, witness-window coverage, uniform-modulus extraction, and non-escape clauses keep those rows on the same displayed hsame, Cont, Pkg, and local naming route.

Coordinate exhaustion closes the boundary. Since no coordinate names a host functional, selected branch, open cover, choice schedule, or ambient real-completeness object, every consumer-visible modulus read is forced through the admitted prefix-window carrier. □

Theorem 1525.7 (FanFunctional finite bar-modulus obligations)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier, the finite bar-depth row* D *and witness-window coverage row* W *jointly determine the* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *through the displayed* $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *packet. The determination uses the finite fan and witness windows only; it does not select branches, evaluate a host functional, import bar induction, or appeal to open-cover compactness.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalFiniteBarModulusObligations`

Proof. Project Definition 1525.1. The row D records the finite depth at which every retained branch prefix in B reaches the displayed bar, and W records the tolerance witness attached to each retained prefix.

Use Definition 1525.2. Its bar-depth exactness and witness-window coverage clauses are the only clauses that feed the uniform-modulus extraction clause, so M is read as the bounded prefix length supported by those finite rows.

The remaining rows H, K, P, N transport, replay, source, and name the same extraction. Coordinate exhaustion excludes selected branches, host functionals, bar-induction rules, and open-cover compactness from the modulus determination. □

Theorem 1525.8 (FanFunctional uniform-modulus consumer boundary)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet receives only the extracted finite prefix-modulus route through* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, *and* $\mathsf{UniformModulus}^{\uparrow}$. *The handoff exposes* $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *and no host functional, selected branch, open-cover compactness theorem, countable-choice selector, or ambient Real-completeness principle.*

Proof. Project the carrier in Definition 1525.1. The $\mathsf{CantorSpace}^{\uparrow}$ row C and $\mathsf{FanTheorem}^{\uparrow}$ row F supply the finite prefix and fan surfaces, while ε, B, D, W, M supply the tolerance, branch-window, depth, witness, and modulus rows read by downstream consumers.

Apply Definition 1525.2. It forces the modulus extraction through the same carrier admission, classifier stability, bar-depth exactness, witness-window coverage, and non-escape clauses that govern the local NameCert surface.

Finally route the public handoff through H, K, P, N. These rows give only componentwise transport, displayed replay, provenance, and local naming, so $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{UniformContinuity}^{\uparrow}$ consumers receive the finite $\mathsf{UniformModulus}^{\uparrow}$ route and no hidden compactness, choice, host-functional, or Real-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalUniformModulusConsumerBoundary`

Theorem 1525.9 (FanFunctional uniform modulus extraction)**.** *Let* Φ *be an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier. The finite fan depth row of* F*, the Cantor prefix window* B*, and the tolerance witness rows* W *determine the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row* M*. For any two accepted* $\mathsf{CantorSpace}^{\uparrow}$ *histories whose Boolean ledgers agree through the prefix length named by* M*, every consumer-visible value of the functional is routed through the same barred prefix window and hence through the same tolerance row. The extraction uses finite prefix inspection only.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalUniformModulusExtraction`

Proof. Project the accepted carrier and read its $\mathsf{FanTheorem}^{\uparrow}$ row. The finite bar handoff supplies a unary depth ledger and a finite branch-prefix window, so the inspection bound is visible before any downstream modulus row is formed.

Restrict the $\mathsf{CantorSpace}^{\uparrow}$ carrier to that window. Agreement of two Cantor histories through the prefix length named by M gives componentwise agreement of their Boolean ledgers on every prefix in B.

Replay the witness rows W through K. Each retained prefix already carries the local tolerance request, and the bar-depth evidence D says that no longer branch read is required. The same prefix window therefore supports the same consumer tolerance row for both histories.

Package the resulting bounded prefix length as the $\mathsf{UniformModulus}^{\uparrow}$ row M. Since the construction reads only the finite Cantor rows, finite fan depth, witness window, transports, continuation, provenance, and local certificate, it introduces no host functional and no choice-selected branch. □

Theorem 1525.10 (FanFunctional Cantor-prefix modulus handoff)**.** *An accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier routes every Cantor-prefix finite-bar row through* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *before exposing the extracted modulus row* M*. The handoff reads the Cantor prefix window* B*, finite bar and depth rows* F, D*, tolerance witnesses* W*, compact finite-prefix coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it exports no selected branch, host functional, open-cover compactness principle, or countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCantorPrefixModulusHandoff`

Proof. Project the carrier of Definition 1525.1. Its Cantor-facing finite rows are the prefix window B, the fan row F, the depth ledger D, and the tolerance witness family W.

Apply the NameCert obligations of Definition 1525.2. They keep those rows on the same displayed route through hsame, Cont, Pkg, and local naming before any consumer may inspect the extracted modulus.

Now use uniform modulus extraction, Definition 1525.9. The extracted row M is determined by the finite fan depth, Cantor prefix window, and witness rows, so the $\mathsf{UniformContinuity}^{\uparrow}$ and $\mathsf{CompactMetric}^{\uparrow}$ consumers receive only the finite route that reaches $\mathsf{UniformModulus}^{\uparrow}$.

Thus every Cantor-prefix finite-bar read passes through $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ before M is exposed. Any selected branch, host functional, open-cover compactness proof, or countable-choice schedule would require a coordinate absent from the accepted $\mathsf{FanFunctional}^{\uparrow}$ carrier. □

Theorem 1525.11 (FanFunctional compact-continuity consumer)**.** *A compact-continuity consumer citing an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet may read exactly the Cantor-prefix rows of* C*, the finite-bar and depth rows of* F*, the tolerance request* ε*, the witness window* W*, the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row* M*, and the support rows* H, K, P, N*. This is the Cantor-space instance of the compact-metric and uniform-continuity consumer surface: compactness is consumed only through finite prefix coverage and finite bar depth, while continuity is consumed only through the displayed tolerance-to-modulus ledger.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCompactContinuityConsumer`

Proof. Start with the compact-metric dependency. In the Cantor-space case, the compact carrier is presented by finite Boolean prefix coverage, so the consumer can read compactness only as the prefix rows already present in C and B.

Use the $\mathsf{FanTheorem}^{\uparrow}$ dependency to bound the prefix inspection. Its decidable bar and unary depth rows supply the finite branch-depth evidence D, and the witness window W records the tolerance rows attached to those prefixes.

Use the $\mathsf{UniformContinuity}^{\uparrow}$ dependency only at the modulus handoff. The row M is the explicit $\mathsf{UniformModulus}^{\uparrow}$ output supplied by the finite fan inspection, and the continuation route K is the only path by which a consumer may read it.

Thus the compact-continuity consumer receives exactly the displayed finite surface. Host compactness, open covers, selected branches, semantic continuity, and real completeness are absent from the carrier and cannot be exported. □

Theorem 1525.12 (FanFunctional Cantor modulus ledger)**.** *Let $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$ be an accepted $\mathsf{FanFunctional}^{\uparrow}$ carrier. The extracted $\mathsf{UniformModulus}^{\uparrow}$ row M is determined only by the finite Cantor-prefix row C, the fan row F, the branch-prefix window B, the depth evidence D, the witness window W, and the support route H, K, P, N. Any two accepted packets with the same displayed rows $C, F, B, D, W, H, K, P, N$ expose the same consumer-visible modulus ledger, and no host functional, selected branch, open-cover compactness principle, or $\mathsf{Real}^{\uparrow}$ completeness datum contributes to the determination of M.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCantorModulusLedger`

Proof. Project the carrier surface of Definition 1525.1. The Cantor row C, fan row F, branch-prefix window B, depth evidence D, and witness window W are finite BHist rows, so the modulus read begins from displayed prefix and fan data rather than from a host functional.

Use Definition 1525.2 to bind the carrier admission, classifier stability, bar-depth exactness, witness-window coverage, uniform-modulus extraction, and non-escape clauses. These obligations force M to be read only after the finite prefix, fan, depth, and witness rows have been admitted.

Apply Definition 1525.9 for the extraction route and Definition 1525.11 for the consumer scope. Transport by H, replay by K, provenance by P, and local naming by N preserve the same finite route, so equal displayed ledger rows give the same public modulus read and the excluded compactness, branch-selection, host-functional, and Real-completeness data never enter. □

Theorem 1525.13 (FanFunctional compact-metric finite-net route)**.** *For an accepted $\mathsf{FanFunctional}^{\uparrow}$ carrier $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$, the compact-metric input read by any consumer is the finite Cantor-prefix net B together with the depth ledger D and witness window W. The route from $\mathsf{CompactMetric}^{\uparrow}$ to the $\mathsf{UniformModulus}^{\uparrow}$ output is therefore*

$$\mathsf{CompactMetric}^{\uparrow}(B, D, W) \longmapsto \mathsf{FanTheorem}^{\uparrow}(F, D) \longmapsto \mathsf{UniformContinuity}^{\uparrow}(\varepsilon, W) \longmapsto \mathsf{UniformModulus}^{\uparrow}(M),$$

with all transport and replay confined to H, K, P, N.

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCompactMetricFiniteNetRoute`

Proof. Project the accepted carrier. The only compact-metric data present are the finite Cantor-prefix rows of C restricted to the retained window B, the bar-depth ledger D, and the tolerance witnesses W.

Replay the compact route through K. The finite-net read first exposes B, D, W, then uses the fan row F to certify that every retained prefix has met the displayed decidable bar within the named depth.

Use the uniform-continuity row only after that finite coverage has been read. The tolerance request ε and witness window W determine the output row M, while H, P, N preserve the same

finite packet under transport, provenance, and local naming. No open cover, selected branch, or host compact space is introduced. □

Theorem 1525.14 (FanFunctional fan-theorem uniform depth)**.** *Let Φ be an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier. The* $\mathsf{FanTheorem}^{\uparrow}$ *row F supplies a single unary depth ledger D for the displayed finite fan, and the extracted modulus row M may inspect Cantor histories only through prefixes bounded by that ledger. Thus any two accepted* $\mathsf{CantorSpace}^{\uparrow}$ *histories agreeing through the depth named by D reach the same retained prefix window before the* $\mathsf{UniformModulus}^{\uparrow}$ *row is read.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalFanTheoremUniformDepth`

Proof. Read F and D from the carrier. The fan theorem row is already presented as finite decidable-bar data, so the depth ledger is a displayed unary object and not a host proof over all infinite branches.

Restrict the Cantor rows of C to that depth. Agreement of two histories up to the ledger named by D gives the same retained prefix window B and hence the same indexed witness family W.

The modulus output M is downstream from this window. Replay through K and transport through H keep the read inside the displayed packet, while P and N record provenance and local naming. The construction extracts a uniform depth from finite fan data only. □

Theorem 1525.15 (FanFunctional uniform-modulus consumer scope)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet may read exactly the Cantor-prefix row C, finite prefix net B, fan-depth ledger D, tolerance request ε, witness window W, extracted modulus row M, and support rows H, K, P, N. The consumer scope excludes host branch choice, open-cover compactness, semantic continuity over a function space, and any modulus not obtained from the displayed finite fan route.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalUniformmodulusConsumerScope`

Proof. Start from the carrier coordinates. They expose $C, F, \varepsilon, B, D, W, M$ and the structural rows H, K, P, N; there is no coordinate for a host function space, a selected branch, or an open cover.

The consumer first reads the finite prefix net B and the depth ledger D. Those rows determine which Cantor prefixes are available before the modulus handoff.

It then reads the tolerance witnesses W and output row M through the replay route K. Componentwise transport, provenance, and local naming preserve this same finite surface, so every consumer-visible modulus factors through the displayed fan route. □

Definition 1525.16 (FanFunctional root bar carrier)**.** *A root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *carrier is the finite packet*

$$\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$$

where C is the $\mathsf{CantorSpace}^{\uparrow}$ *prefix StreamName row, K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-prefix coverage row, F is the* $\mathsf{FanTheorem}^{\uparrow}$ *decidable-bar row, U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance-to-prefix row, M is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row, B is the finite root-bar window, W is the retained* $\mathsf{ProbeBundle}$ *witness family, D is the unary depth ledger, H is componentwise* hsame *transport, R is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row. The packet has no coordinate for countable choice, selected infinite branches, host functionals, or open-cover compactness.*

Theorem 1525.17 (FanFunctional root uniform-modulus obligation)**.** *Every accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$ *exposes the* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *only after the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-prefix coverage,* $\mathsf{FanTheorem}^{\uparrow}$ *decidable bar,* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance row, finite root-bar window,* $\mathsf{ProbeBundle}$ *witnesses, and unary depth ledger have all been displayed. The obligation is a finite* BHist *handoff and never a countable-choice selection of branch witnesses.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUniformModulusObligation`

Proof. Project the carrier of Definition 1525.16. The rows C, K, F, U expose the Cantor prefix data, compact finite-prefix coverage, decidable fan bar, and tolerance-to-prefix ledger before any modulus output is available.

Read the finite root data next. The window B, witness family W, and depth ledger D record the finite bar and prefix budget consumed by the modulus row.

The row M is therefore downstream of finite displayed data. Transport, replay, provenance, and local naming through H, R, P, N preserve that ordering, so no countable-choice selector, selected infinite branch, host functional, or open-cover compactness row can be read. □

Theorem 1525.18 (FanFunctional root Cantor-window handoff)**.** *Every* $\mathsf{CantorSpace}^{\uparrow}$ *consumer of an accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet receives only the finite prefix window*

$$C \longmapsto B, W, D$$

before the $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$ *rows are inspected. The handoff is a StreamName and ProbeBundle window over Boolean prefixes, not an infinite branch, not a selected path through the fan, and not a countable-choice sequence.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootCantorWindowHandoff`

Proof. Start with the Cantor prefix row C. It exposes Boolean observations through finite StreamName windows and contains no infinite branch coordinate.

The root-bar rows B, W, D restrict those observations to the displayed finite prefix window. The witness family W is indexed by the finite ProbeBundle data, and the depth ledger D bounds the inspection.

Only after this window is displayed may F and M be read. Thus the Cantor consumer receives a finite handoff over C, B, W, D, with no selected branch or countable-choice sequence. □

Theorem 1525.19 (FanFunctional root choice-free nonescape)**.** *No accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet can export countable choice, a selected infinite branch, or a host functional. Every public read factors through the finite rows* $C, K, F, U, M, B, W, D, H, R, P, N$*, and any attempted read that bypasses the finite root-bar window or the displayed* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row leaves the packet.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootChoiceFreeNonescape`

Proof. Inspect the carrier coordinates in Definition 1525.16. They are finite Cantor-prefix, compact-prefix, fan-bar, uniform-continuity, uniform-modulus, root-window, witness-family, depth, transport, replay, provenance, and naming rows.

There is no coordinate whose type is a stream of choices, a selected branch, or a host-level functional. Componentwise hsame transport in H can move only the displayed coordinates, and replay in R reuses only the same finite route.

Thus every public read is exhausted by $C, K, F, U, M, B, W, D, H, R, P, N$. A reader that claims choice, branch selection, or a host functional has introduced data not present in the accepted packet. □

Theorem 1525.20 (FanFunctional root uniform-continuity consumer)**.** *Every* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer of an accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet reads the tolerance-to-prefix row* U *together with the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row* C*,* $\mathsf{CompactMetric}^{\uparrow}$ *finite coverage row* K*,* $\mathsf{FanTheorem}^{\uparrow}$ *bar row* F*, finite root-bar window* B, W, D*, and the output* $\mathsf{UniformModulus}^{\uparrow}$ *row* M*. The consumer receives a finite modulus surface over Cantor prefixes and ProbeBundle witnesses, not semantic continuity over a host function space.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUniformContinuityConsumer`

Proof. Project the accepted packet and read the uniform-continuity row U. Its tolerance request is attached to the same Cantor prefix and compact finite coverage rows C, K.

Use the fan row F and root-bar window B, W, D to bound the inspection. These rows provide the finite prefix budget that the consumer may use when replaying the tolerance-to-prefix ledger.

The output row M is then the visible $\mathsf{UniformModulus}^{\uparrow}$ handoff, and H, R, P, N preserve it as finite NameCert data. Since the packet has no host functional-space coordinate, the consumer obtains only the displayed finite modulus surface. □

Theorem 1525.21 (FanFunctional root Cantor compact modulus)**.** *For every accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$*, the row family*

$$C, \quad F, \quad U, \quad K, \quad M, \quad B, \quad D, \quad W, \quad H, \quad R, \quad P, \quad N$$

forces the exported $\mathsf{UniformModulus}^{\uparrow}$ *row* M *through the displayed* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, and* $\mathsf{CompactMetric}^{\uparrow}$ *rows only. A consumer reads* M *by first reading the Cantor prefix row of chapter 1475, the finite fan row of chapter 400, the compact finite-net row of chapter 129, and the tolerance row of chapter 391; the modulus surface then lands at chapter 369 as displayed* BHist *rows, not as a host compactness or continuity principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootCantorCompactModulus`

Proof. Project the root-bar carrier. The rows C, F, U, K are the only Cantor, fan, uniform-continuity, and compact-metric source rows available before the modulus row M is read.

The finite window rows B, D, W bind those sources to displayed prefixes. They record the root-bar window, unary depth ledger, and retained ProbeBundle witnesses, so the compact metric input is a finite-net row over the same Cantor prefixes.

Finally transport and replay through H, R, P, N. These structural rows preserve the displayed BHist route and cannot add a host compactness theorem, a semantic continuity principle, or a hidden modulus selector. Thus M is forced through the visible Cantor, fan, compact-net, and tolerance rows. □

Theorem 1525.22 (FanFunctional root finite-depth exhaustion)**.** *Every finite-depth read of an accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$ *is exhausted by the displayed rows*

$$C, \quad F, \quad B, \quad D, \quad W, \quad K, \quad U, \quad M, \quad H, \quad R, \quad P, \quad N.$$

The CantorSpace, FanTheorem, CompactMetric, UniformContinuity, and UniformModulus siblings are consumed only through these finite BHist *rows:* C *supplies Boolean prefix windows,* F

supplies the decidable fan bar, K supplies finite-net coverage, U supplies tolerance-to-prefix evidence, and M is exported only at the retained depth.

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootFiniteDepthExhaustion`

Proof. Start with the visible depth data. The rows C, B, D, W are finite Cantor-prefix, root-window, unary-depth, and witness-family data, so they contain no selected infinite branch.

Read the fan and compact rows at the same depth. The row F verifies the finite bar over the displayed prefixes, while K gives compact finite-net coverage for that same bounded window.

The tolerance and modulus rows are then downstream. The row U attaches the tolerance request to the bounded window, and M is the resulting UniformModulus readback. Transport, replay, provenance, and local naming keep this route inside H, R, P, N, so finite depth is exhausted before any hidden selector could be claimed. □

Theorem 1525.23 (FanFunctional root uniform-modulus readback)**.** *For every accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$*, the exported* $\mathsf{UniformModulus}^{\uparrow}$ *row M is read back from the* $\mathsf{UniformContinuity}^{\uparrow}$ *row U only after the* $\mathsf{CantorSpace}^{\uparrow}$ *row C, the* $\mathsf{FanTheorem}^{\uparrow}$ *row F, the* $\mathsf{CompactMetric}^{\uparrow}$ *row K, and the finite root rows B, D, W have been displayed. The readback is a displayed* BHist *route through H, R, P, N, not a quotient of host functionals, an open-cover compactness argument, or a selected branch through Cantor space.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUniformModulusReadback`

Proof. Project Θ and read the source tolerance row U. Its request is attached to the displayed Cantor prefix row C and cannot be interpreted as semantic continuity over a host function space.

Next use the finite fan and compact rows. The row F supplies the decidable bar depth, K supplies finite-net coverage, and B, D, W record the retained root-bar window and witnesses at that depth.

Only then replay the output row M. The rows H, R, P, N transport, replay, source, and name the same finite route, so the UniformModulus export is a displayed readback from Cantor, FanTheorem, CompactMetric, and UniformContinuity rows rather than an external compactness or choice principle. □

Theorem 1525.24 (FanFunctional modulus-extraction obligations)**.** *For an accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$*, the modulus-extraction obligation is the finite route that first reads the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row C, then the* $\mathsf{FanTheorem}^{\uparrow}$ *decidable-bar row F, then the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance row U, and only then the* $\mathsf{UniformModulus}^{\uparrow}$ *output row M. The extracted modulus is valid exactly for the Cantor prefixes retained by B, W, D and transported by H, R, P, N.*

Proof. Project the carrier of Definition 1525.16. The rows C, F, U are displayed before M, and the finite window B, W, D records which Cantor prefixes reach the decidable fan bar.

Replay the route through R. The tolerance row U is consumed only after the bar window has been exposed, so the output M is a bounded prefix row rather than a host functional-space modulus.

Componentwise transport through H and provenance through P, N keep the same finite packet attached to the modulus read. Therefore modulus extraction is exactly the displayed $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ handoff. □

Theorem 1525.25 (FanFunctional Cantor-window coverage obligations)**.** *Every accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet covers its public Cantor-window reads through the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-prefix row* K*, the retained window* B*, the witness family* W*, and the depth ledger* D*. A consumer may inspect only the finite-net rows displayed by* K, B, W, D *before reading the modulus row* M*.*

Proof. Read the compact row K from Θ. In this packet the compact-metric input is not an open cover; it is the finite Cantor-prefix net already recorded by the root-bar carrier.

The rows B, W, D refine that net. They select the retained prefix window, attach the Probe-Bundle witnesses, and give the unary depth ledger by which the fan row certifies coverage.

Replay through R and transport through H. Since every public read of M must pass through K, B, W, D, P, N, the Cantor-window coverage obligation is finite-net coverage and no stronger compactness principle is exported. □

Theorem 1525.26 (FanFunctional choice-free nonescape obligations)**.** *The root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet exports no selected infinite branch, no countable choice, no open-cover compactness principle, and no host continuity principle. Every public read factors through the displayed rows* $C, K, F, U, M, B, W, D, H, R, P, N$ *and through the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row.*

Proof. Inspect the carrier coordinates. They are finite Cantor-prefix, compact finite-net, decidable fan-bar, tolerance, modulus, root-window, witness, depth, transport, replay, provenance, and naming rows.

There is no row for an infinite branch selector, countable-choice sequence, open cover, or host continuity axiom. The replay row R can only revisit the displayed route, and H can only transport the listed coordinates.

Thus any consumer that remains inside the packet reads through $C, K, F, U, M, B, W, D, H, R, P, N$. A claim of branch selection, countable choice, open-cover compactness, or host continuity would require data absent from the finite $\mathsf{NameCert}$ surface. □

Theorem 1525.27 (FanFunctional root depth exhaustion)**.** *For every accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$*, every root-depth read is exhausted by the displayed* $\mathsf{CantorSpace}^{\uparrow}$ *windows* C, B*, the* $\mathsf{FanTheorem}^{\uparrow}$ *finite bar row* F*, the finite witness family* W*, the depth ledger* D*, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row* K*, and the structural rows* H, R, P, N*. The packet exports no countable choice sequence, host compactness principle, or hidden modulus selector.*

Proof. Project the carrier of Definition 1525.16. The rows C, B, W, D are finite Cantor-window and depth data, while F records the finite-bar route and K records the compact finite-net input.

Replay the public read through R. The depth ledger is consumed only together with C, K, F, B, W, so a consumer cannot detach D as an independent branch selector or as an open-cover compactness theorem.

Transport and provenance through H, P, N preserve the same finite packet. Since no additional coordinate names countable choice or a hidden selector, root depth is exhausted by the displayed rows. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootDepthExhaustion`

Theorem 1525.28 (FanFunctional Cantor-window modulus readback)**.** *For an accepted root-unblock* $\mathsf{FanFunctional}^{\uparrow}$ *packet* $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$*, the* $\mathsf{UniformContinuity}^{\uparrow}$ *source rows* U *may be read back into a* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row* M *only through the retained*

CantorSpace$^{\uparrow}$ *windows* C, B*, the* FanTheorem$^{\uparrow}$ *finite bar/depth rows* F, D*, the witness family* W*, and the* CompactMetric$^{\uparrow}$ *finite-net row* K*. The readback is a finite NameCert route through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, not a host continuity or compactness export.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCantorWindowModulusReadback`

Proof. Start with the uniform-continuity row U. Its tolerance request is attached to displayed Cantor prefixes rather than to a semantic function space.

Use the Cantor-window rows C, B and the fan rows F, D. These rows bound the prefix depth and identify the finite bar evidence used by the witness family W.

The compact row K supplies only finite-net coverage for those displayed windows. Replaying through R then delivers the modulus row M, while H, P, N keep the BHist, hsame, Cont, Pkg, and NameCert structure visible. □

Theorem 1525.29 (FanFunctional UniformModulus consumer package)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted root-unblock* FanFunctional$^{\uparrow}$ *packet receives the package*

$$C, K, F, U, M, B, W, D, H, R, P, N$$

as visible finite carrier rows: CantorSpace$^{\uparrow}$ *windows,* FanTheorem$^{\uparrow}$ *finite bar and depth rows,* UniformContinuity$^{\uparrow}$ *source rows, the* UniformModulus$^{\uparrow}$ *consumer row,* CompactMetric$^{\uparrow}$ *finite-net rows,* BHist *witnesses, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It receives no countable choice principle, hidden compactness theorem, or unrecorded modulus selector.*

Proof. Inspect the displayed package. The consumer row M is not read alone; it is attached to the source row U, the Cantor windows C, B, the fan/depth rows F, D, witness data W, and finite-net data K.

The replay row R supplies the route from source tolerance to consumer modulus. Componentwise transport through H and provenance through P, N preserve the same finite carrier rows and do not add a selector coordinate.

Therefore a UniformModulus$^{\uparrow}$ consumer gets exactly the visible NameCert package. Any claim of countable choice, host compactness, or a hidden modulus selector would require a row outside Θ. □

Theorem 1525.30 (FanFunctional root finite-modulus route)**.** *Every accepted root-unblock* FanFunctional$^{\uparrow}$ *packet exposes a* UniformModulus$^{\uparrow}$ *read only through the finite route*

$$C, K, F, U, M, B, W, D, H, R, P, N.$$

Here C *and* B *are the* CantorSpace$^{\uparrow}$ *prefix-window rows,* K *is the* CompactMetric$^{\uparrow}$ *finite-net row,* F *is the* FanTheorem$^{\uparrow}$ *finite-bar row,* U *is the* UniformContinuity$^{\uparrow}$ *source row,* W *is the* ProbeBundle *witness family,* D *is the displayed depth ledger,* H *transports the rows componentwise by* hsame*,* R *replays the displayed* Cont *route,* P *records provenance, and* N *is the local* NameCert *row. No other coordinate of the accepted packet can expose a selected branch, a countable-choice operator, a host functional, or an open-cover compactness theorem.*

Proof. Project the accepted carrier $\Theta = (C, K, F, U, M, B, W, D, H, R, P, N)$. The only rows that mention a modulus request are the UniformContinuity$^{\uparrow}$ row U, the UniformModulus$^{\uparrow}$ row M, and the finite Cantor, fan, witness, depth, transport, replay, provenance, and naming rows displayed with them.

The root-bar data are finite. The Cantor rows C, B bound the prefix windows, F, D name the accepted bar and depth, W supplies the displayed ProbeBundle witnesses, and K supplies only the compact finite-net input needed by those windows.

Replay through R and transport through H. These rows can only move the same finite packet to the consumer row M, while P, N record its source and local name. Since the carrier has no row for a branch selector, countable choice, host functional evaluation, or open-cover compactness, the $\mathsf{UniformModulus}^{\uparrow}$ read is exhausted by the displayed finite route. □

Theorem 1525.31 (FanFunctional compact-uniform consumer route)**.** *Any compact-uniform-continuity consumer that receives an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *root-unblock packet receives only the finite route of Definition 1525.30: Cantor prefix windows, the compact finite-net row, fan-bar and depth rows, uniform-continuity source rows, the uniform-modulus consumer row,* ProbeBundle *witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The handoff supplies no selected branch, countable choice, host functional, or open-cover compactness object.*

Proof. Start with a compact-uniform-continuity consumer read. By Definition 1525.29, the consumer receives the package $C, K, F, U, M, B, W, D, H, R, P, N$ as visible finite carrier rows, not as an ambient function-space principle.

Apply Definition 1525.30. The route from U to M factors through the Cantor windows, finite-net row, fan-bar row, witness bundle, depth ledger, replay row, transport row, provenance, and local name certificate.

Thus the compact-uniform-continuity handoff is a finite NameCert route. A selected branch, countable-choice schedule, host functional, or open-cover compactness object would require an additional row outside the accepted packet, so none is delivered to the consumer. □

Theorem 1525.32 (FanFunctional Cantor compact route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *row exported by an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *root-unblock packet factors through the Cantor finite-prefix rows, the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-depth ledger, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, and the* $\mathsf{UniformModulus}^{\uparrow}$ *readback route before any* $\mathsf{Real}^{\uparrow}$*-facing or compact-uniform consumer can read it. Thus the exported modulus is a finite Cantor-compact NameCert route over*

$$C, K, F, U, M, B, W, D, H, R, P, N$$

and not a selected branch, countable-choice schedule, host functional, or open-cover compactness theorem.

Proof. Start from the compact-uniform consumer route of Definition 1525.31. It already places every consumer read behind the finite package $C, K, F, U, M, B, W, D, H, R, P, N$.

Use Definition 1525.30 to locate the modulus row. The route from U to M passes through the Cantor prefix windows C, B, the fan-bar and finite-depth rows F, D, the witness windows W, and the compact finite-net row K before the readback row R is available.

Finally apply Definition 1525.29. The package delivered to a $\mathsf{UniformModulus}^{\uparrow}$ consumer is exactly the displayed finite NameCert packet, so no branch selector, countable-choice schedule, host functional, or open-cover compactness object can be exported to the Real-facing consumer. □

Definition 1525.33 (FanFunctional finite-window carrier)**.** *A* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window carrier is a finite* BHist *packet*

$$\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$$

where B is the $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix row, Q is the inspected prefix-query ledger, F, D are the* $\mathsf{FanTheorem}^{\uparrow}$ *finite bar and depth rows, U, T are the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance ledger and requested tolerance row, K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net consumer route, W is the finite witness-window family, H transports all displayed rows componentwise by* hsame*, R replays the displayed* Cont *route, P is the* Pkg *provenance over the displayed packets, and N is the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row. The classifier compares accepted packets only through those rows and has no coordinate for a host functional, selected branch, open-cover compactness proof, countable choice, or Real completeness.*

Theorem 1525.34 (FanFunctional Cantor-window obligation)**.** *Every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window carrier must expose its* $\mathsf{CantorSpace}^{\uparrow}$ *information as finite* BHist *rows B, Q, W before the* $\mathsf{FanTheorem}^{\uparrow}$ *bar/depth rows F, D or the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row may be consumed. No consumer may replace those rows by a selected infinite branch or host functional evaluation.*

Proof. Project the carrier of Definition 1525.33. The only Cantor-facing coordinates are B, Q, W, and they are finite rows in the same BHist packet.

The bar and naming rows are downstream. The $\mathsf{FanTheorem}^{\uparrow}$ rows F, D read prefix coverage and depth only from the displayed Cantor windows, while H, R, P, N transport, replay, source, and name that same finite route.

Since the carrier contains no selected branch or host functional coordinate, any consumer that bypasses B, Q, W leaves the accepted packet. □

Theorem 1525.35 (FanFunctional uniform-modulus obligation)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window carrier $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$, the uniform-modulus read must pass through the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance ledger U, T, the finite* $\mathsf{FanTheorem}^{\uparrow}$ *bar/depth rows F, D, the witness-window row W, componentwise* hsame *transport H, displayed* Cont *replay R, package provenance P, and the local* NameCert *row N. The packet exports no host functional, branch selector, countable-choice schedule, or Real-completeness coordinate.*

Proof. Read the tolerance face first. The rows U, T are the only $\mathsf{UniformContinuity}^{\uparrow}$ coordinates that name the requested tolerance and the ledger supporting it.

Attach the fan and window rows. The finite bar/depth rows F, D and witness row W provide the only bounded prefix information that can answer the tolerance request.

Transport and replay do not enlarge the surface. The rows H, R, P, N preserve, replay, source, and name the same finite packet, so the excluded host and choice principles cannot be recovered from an accepted uniform-modulus read. □

Theorem 1525.36 (FanFunctional compact-metric consumer obligation)**.** *Any* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net consumer of a* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window carrier receives only the displayed route $K, B, Q, F, D, U, T, W, H, R, P, N$. In particular the compact-metric handoff consumes finite Cantor prefixes, finite bar/depth rows, the uniform-continuity tolerance ledger, witness windows,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it receives no open-cover compactness theorem, selected branch, countable-choice selector, host functional, or Real completeness.*

Proof. Project the compact-facing row of the carrier. The row K is the only $\mathsf{CompactMetric}^{\uparrow}$ coordinate, and it is stored beside the finite Cantor, fan, tolerance, witness, transport, replay, provenance, and naming rows.

The consumer route is therefore finite. It reads B, Q for prefixes, F, D for bar and depth, U, T for the tolerance ledger, and W for the witness windows before receiving K.

Finally H, R, P, N keep the handoff on the same packet. Since no open-cover compactness proof, selected branch, choice selector, host functional, or Real-completeness row appears in Ω, the compact-metric consumer receives only the displayed route. □

Theorem 1525.37 (FanFunctional NameCert nonescape)**.** *The local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^\uparrow}$ *row of an accepted finite-window carrier* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$ *is exhausted by finite* BHist *rows for* $\mathsf{CantorSpace}^\uparrow$ *prefixes,* $\mathsf{FanTheorem}^\uparrow$ *bar/depth data,* $\mathsf{UniformContinuity}^\uparrow$ *tolerance ledger,* $\mathsf{CompactMetric}^\uparrow$ *finite-net consumption, witness windows, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local naming. It cannot expose a host functional, selected branch, open-cover compactness proof, countable choice, or Real-completeness principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalNameCertNonescape`

Proof. Combine the three obligation blocks. The Cantor-window obligation, Definition 1525.34, fixes the finite prefix rows that feed the fan bar/depth data.

The uniform-modulus obligation, Definition 1525.35, fixes the tolerance ledger and witness-window route. The compact-metric consumer obligation, Definition 1525.36, fixes the finite-net consumer route.

All three routes use the same structural rows H, R, P, N. Therefore the local NameCert row names exactly the displayed finite packet, and any host functional, selected branch, open-cover compactness proof, countable-choice selector, or Real-completeness principle would require a coordinate outside the accepted carrier. □

Theorem 1525.38 (FanFunctional root schema carrier)**.** *The root schema row for* $\mathsf{FanFunctional}^\uparrow$ *is the finite Cantor–fan–modulus carrier*

$$\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$$

of Definition 1525.33. Its root-facing fields are exactly the $\mathsf{CantorSpace}^\uparrow$ *finite-prefix rows* B, Q, W*, the* $\mathsf{FanTheorem}^\uparrow$ *bar and depth rows* F, D*, the* $\mathsf{UniformModulus}^\uparrow$ *and* $\mathsf{UniformContinuity}^\uparrow$ *tolerance rows* U, T*, the* $\mathsf{CompactMetric}^\uparrow$ *finite-net consumer row* K*, and the structural rows* H, R, P, N*.*

Proof. Project Definition 1525.33. The tuple displayed there already separates the Cantor prefix coordinates, fan bar-depth coordinates, uniform-modulus coordinates, compact-metric consumer coordinate, and structural coordinates.

No root schema row is added outside the tuple. The carrier has no coordinate for a host functional, selected branch, open-cover compactness theorem, Real completeness, or countable-choice schedule, so the listed rows are exactly the root-facing carrier fields. □

Theorem 1525.39 (FanFunctional root schema classifier)**.** *Two accepted* $\mathsf{FanFunctional}^\uparrow$ *root schema carriers classify together whenever their* $\mathsf{CantorSpace}^\uparrow$ *prefix windows,* $\mathsf{FanTheorem}^\uparrow$ *finite bar depths,* $\mathsf{UniformContinuity}^\uparrow$ *tolerance rows,* $\mathsf{UniformModulus}^\uparrow$ *witness windows,* $\mathsf{CompactMetric}^\uparrow$ *finite-net rows, and structural rows* H, R, P, N *transport componentwise by* hsame *over the displayed finite windows. The classifier has no branch-selector, host-functional, open-cover, or Real-completeness coordinate.*

Proof. Compare the two carriers coordinate by coordinate. Agreement on the Cantor rows fixes the inspected prefix windows, and agreement on the fan rows fixes the finite bar depth available to the modulus read.

Transport the tolerance and witness rows through the same windows. Componentwise hsame keeps U, T, W aligned with the displayed bar depth, and the compact-metric row K reads only that finite packet.

The structural rows preserve the comparison. Since H, R, P, N transport, replay, source, and name exactly the displayed fields, a classifier disagreement would require a coordinate outside the root schema carrier. □

Theorem 1525.40 (FanFunctional root schema ledger)**.** *Every downstream root-schema consumer of* FanFunctional$^{\uparrow}$ *must pass through* CompactMetric$^{\uparrow}$, UniformContinuity$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *as displayed by* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$. *The ledger records non-escape from finite Cantor windows and finite bar depth to the compact and uniform-modulus consumers, and it exports no host functional, selected infinite branch, open-cover compactness proof, countable-choice selector, or Real-completeness principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootSchemaLedger`

Proof. Start from the root schema carrier. The compact consumer row K is downstream from B, Q, F, D, U, T, W, so it cannot be read before the Cantor window, fan bar depth, tolerance, and witness rows are displayed.

Next read the uniform-modulus side. The rows U, T, W provide the finite tolerance and witness-window route, and the UniformModulus$^{\uparrow}$ consumer receives that route through the same finite bar depth.

Finally attach the structural ledger. Rows H, R, P, N keep the consumer inside the finite packet by componentwise transport, displayed continuation replay, package provenance, and local naming, so the excluded host and choice objects have no ledger slot. □

Definition 1525.41 (FanFunctional finite-modulus carrier)**.** *A* FanFunctional$^{\uparrow}$ *finite-modulus carrier is a finite* BHist *packet*

$$\Theta = (C, F, K, U, M, W, D, H, R, P, N)$$

whose rows are as follows:

1. *C is the* CantorSpace$^{\uparrow}$ *finite-prefix source row, including the bounded prefix windows inspected by the packet.*
2. *F is the* FanTheorem$^{\uparrow}$ *finite-bar row that supplies the displayed depth ledger for those windows.*
3. *K is the* CompactMetric$^{\uparrow}$ *finite-net row consumed by compact-metric downstream routes.*
4. *U is the* UniformContinuity$^{\uparrow}$ *tolerance request row.*
5. *M is the* UniformModulus$^{\uparrow}$ *extracted modulus row.*
6. *W is the finite witness-window family linking each inspected prefix to the modulus read.*
7. *D is the depth ledger that records the bounded fan depth used before M may be exported.*
8. *H, R, P, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert$_{\text{FanFunctional}^{\uparrow}}$ *rows.*

The classifier compares accepted packets only through these finite rows and has no coordinate for a host functional, selected branch, open-cover compactness object, countable-choice schedule, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 1525.42 (FanFunctional NameCert obligation surface)**.** *For an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-modulus carrier* $\Theta = (C, F, K, U, M, W, D, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *surface consists exactly of carrier admission for* Θ*,* $\mathsf{CantorSpace}^{\uparrow}$ *prefix exposure through* C*,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar exactness through* F, D*,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net handoff through* K*,* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance admission through* U*,* $\mathsf{UniformModulus}^{\uparrow}$ *extraction through* M, W*, and structural transport, replay, provenance, and naming through* H, R, P, N*.*

Proof. Project the carrier of Definition 1525.41. Its displayed rows are exactly the Cantor prefix source, fan bar and depth ledger, compact finite-net handoff, uniform-continuity tolerance request, extracted uniform-modulus row, witness windows, transport, replay, provenance, and local naming row.

The NameCert obligations are therefore the admission and exactness checks for those rows. Prefix exposure reads C; finite-bar exactness reads F, D; the compact-metric handoff reads K; the tolerance request reads U; and modulus extraction reads M, W.

The rows H, R, P, N account for componentwise transport, displayed consumer replay, package provenance, and local naming. Since no host functional, selected branch, open-cover compactness object, choice schedule, or Real-completeness row appears in Θ, the displayed list exhausts the local obligation surface. □

Theorem 1525.43 (FanFunctional Real uniform-modulus handoff)**.** *Every Real-facing uniform-modulus consumer of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-modulus carrier factors through the finite route*

$$\mathsf{CantorSpace}^{\uparrow} \longrightarrow \mathsf{FanTheorem}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{UniformContinuity}^{\uparrow} \longrightarrow \mathsf{UniformModulus}^{\uparrow}$$

as represented by the rows $C, F, K, U, M, W, D, H, R, P, N$*. The consumer receives only finite prefix windows, a finite fan depth, a compact finite-net row, a uniform-continuity tolerance row, witness windows, transport, replay, provenance, and local naming; it receives no host functional, selected branch, open-cover compactness proof, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Start with an accepted finite-modulus carrier. The only Cantor-facing coordinate is C, and the only fan-depth coordinates are F, D, so a consumer must read finite prefixes and the finite-bar ledger before any modulus row is visible.

Next the compact and uniform-continuity rows are read. Row K supplies the compact finite-net handoff, while row U supplies the tolerance request that the modulus must answer.

Finally the modulus export reads M through the witness windows W and the structural rows H, R, P, N. These rows preserve the same finite packet, so a Real-facing consumer cannot bypass the displayed route through a host functional, selected branch, open-cover compactness proof, choice schedule, or Real-completeness principle. □

Theorem 1525.44 (FanFunctional monotone bar modulus obligation)**.** *Every exported modulus row of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-modulus carrier must expose a monotone bar-modulus packet through the displayed route*

$$\mathsf{CantorSpace}^{\uparrow} \longrightarrow \mathsf{FanTheorem}^{\uparrow} \longrightarrow \mathsf{CompactMetric}^{\uparrow}, \mathsf{UniformContinuity}^{\uparrow} \longrightarrow \mathsf{UniformModulus}^{\uparrow}.$$

The obligation requires the $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix row* C*, the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar depth rows* F, D*, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net consumer row* K*, the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance row* U*, the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff rows* M, W*, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *rows* H, R, P, N*. It excludes selected branches, bar induction as a primitive, open-cover compactness, countable-choice schedules, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $\Theta = (C, F, K, U, M, W, D, H, R, P, N)$. The prefix row C is the only Cantor source, and the rows F, D are the only finite-bar depth witnesses available before a modulus is exported.

The compact and continuity consumers are therefore forced to read K and U after the prefix-depth rows. The modulus handoff can then read only M, W, with H, R, P, N preserving transport, replay, provenance, and local naming for the same finite packet.

Since no row records a selected branch, primitive bar induction, open-cover compactness proof, countable-choice schedule, or ambient Real-completeness assertion, the monotone bar-modulus obligation is exactly the displayed finite route. □

Theorem 1525.45 (FanFunctional root finite-cover retention)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$*, the root finite-cover read retains the displayed* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row* C*,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row* F*,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net consumer row,* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance row,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row* M*,* BHist *packet route, componentwise* hsame *row* H*, displayed* Cont *replay row* K*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *row* N *on the same packet before any modulus consumer may inspect* M*. The retention surface has no selected branch, host functional, open-cover compactness proof, countable-choice selector, or ambient Real-completeness coordinate.*

Proof. Project the carrier of Definition 1525.1. The rows $C, F, \varepsilon, B, D, W, M, H, K, P, N$ are the only available root coordinates, and the compact-metric and uniform-continuity consumers read them as finite BHist data.

The finite-cover side is retained by F, B, D, W. These rows expose the finite fan depth, retained prefix window, and witness window before the extracted $\mathsf{UniformModulus}^{\uparrow}$ row can be consumed.

Finally H, K, P, N transport, replay, source, and name the same packet. Since selected branches, host functionals, open covers, choice schedules, and Real-completeness principles have no coordinate, the root read cannot leave the displayed finite-cover surface. □

Theorem 1525.46 (FanFunctional root modulus-row totality)**.** *Every accepted root read of* $\mathsf{FanFunctional}^{\uparrow}$ *exposes a total displayed route from* $\mathsf{CantorSpace}^{\uparrow}$ *and* $\mathsf{FanTheorem}^{\uparrow}$ *through* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *before exporting the modulus row. Concretely, the packet route through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *must show* $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *together; omitting any one of the Cantor, fan, compact-metric, uniform-continuity, or modulus rows leaves the accepted carrier.*

Proof. Begin with the NameCert obligations of Definition 1525.2. They separate carrier admission, classifier stability, bar-depth exactness, witness-window coverage, uniform-modulus extraction, and non-escape as rows of one finite packet.

The modulus row is downstream from the other root rows. The Cantor and fan rows fix the finite prefix and bar-depth surface, while the compact-metric and uniform-continuity rows consume only the displayed finite windows and tolerance request.

The structural route through H, K, P, N is total for that packet. A read missing one displayed row cannot reconstruct it from a selected branch, host functional, open-cover compactness proof, countable-choice schedule, or Real-completeness principle, because none of those objects is part of the carrier. □

Theorem 1525.47 (FanFunctional root choice boundary)**.** *No accepted* $\mathsf{FanFunctional}^{\uparrow}$ *root obligation may replace the finite packet route through* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *by a branch selector, host functional, open-cover compactness theorem, countable-choice schedule, or ambient*

Real-completeness argument. The only admissible root boundary is the displayed carrier $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$ *and its componentwise transport, replay, provenance, and local naming rows.*

Proof. Use Definition 1525.1. The accepted carrier lists every coordinate available to a root obligation, including the Cantor prefix, finite fan, compact-metric, uniform-continuity, uniform-modulus, transport, replay, provenance, and naming rows.

Apply the root schema ledger of Definition 1525.40. Downstream consumers must pass through the compact and uniform-modulus route displayed by Ω, hence through the same finite root boundary.

Coordinate exhaustion closes the choice boundary. A selected branch, host functional, open-cover compactness proof, countable-choice selector, or ambient Real-completeness argument would require a coordinate not present in Φ, so such a read is outside the accepted $\mathsf{FanFunctional}^{\uparrow}$ packet. □

Theorem 1525.48 (FanFunctional root finite-prefix uniform modulus)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$*, the root finite-prefix read exports the row* M *only after the carrier surface of Definition 1525.1 and the local obligations of Definition 1525.2 have exposed* $C, F, \varepsilon, B, D, W, H, K, P, N$ *on the same* BHist *packet. Thus* M *is a finite-prefix* $\mathsf{UniformModulus}^{\uparrow}$ *row supported by the displayed Cantor prefix, fan-depth, tolerance, branch-window, and witness-window rows, not by a host functional, selected branch, or ambient compactness principle.*

Proof. Project the carrier. The rows $C, F, \varepsilon, B, D, W, M, H, K, P, N$ are already displayed as finite BHist coordinates, and the NameCert obligation surface separates carrier admission from the modulus extraction clause.

Read the finite fan-depth ledger before the modulus row. Rows C, F expose the Cantor prefix and finite fan surface, row ε fixes the tolerance request, rows B, D bind the branch window and depth, and row W records the witnesses whose bounded inspection length is repacked as M.

The structural rows keep the handoff root-local. Componentwise transport through H, displayed replay through K, provenance through P, and local naming through N preserve the same finite packet, so no external branch selector, host functional, or open-cover compactness object can contribute to the exported modulus. □

Theorem 1525.49 (FanFunctional root witness-window coverage)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier* $\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$*, the witness-window row* W *covers exactly the retained branch prefixes in* B *whose finite bar-depth exposure is certified by* D*. Every root read of the modulus row* M *must first pass through that* $C, F, \varepsilon, B, D, W$ *coverage surface and then through* H, K, P, N*; it may not omit a displayed prefix, add an unseen prefix, or use a selected infinite branch.*

Proof. Start with the carrier surface. The retained prefixes are named by B, and the fan row F together with the depth ledger D determines which finite prefixes have reached the displayed bar before any witness is read.

Use the NameCert obligations. Witness-window coverage is a separate finite clause between bar-depth exactness and uniform-modulus extraction, so W cannot be replaced by a later choice of branch or by a host-level compactness proof.

Finally route the coverage through H, K, P, N. These rows transport, replay, source, and name the same packet, forcing every public modulus read of M to use the displayed coverage window and excluding omitted, added, or infinitely selected prefixes. □

Theorem 1525.50 (FanFunctional root nonescape ledger)**.** *Every accepted root-obligation read of* $\mathsf{FanFunctional}^{\uparrow}$ *is exhausted by the rows* $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *of Definition 1525.1 and by the local NameCert obligations of Definition 1525.2. The nonescape ledger exports the finite Cantor-prefix route, finite fan-depth route, witness-window coverage, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming; it exports no host functional, choice-selected branch, open-cover compactness proof, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. List the available rows. Carrier admission gives exactly $C, F, \varepsilon, B, D, W, M, H, K, P, N$, and the existing NameCert surface assigns the root obligations to these coordinates.

Read the finite obligations in order. Classifier stability uses the displayed Cantor and fan rows, bar-depth exactness uses D, witness-window coverage uses W, and uniform-modulus extraction exports M only through those finite rows.

Coordinate exhaustion supplies the nonescape claim. Since the carrier has no coordinate for a host functional, branch selector, open cover, choice schedule, or Real-completeness witness, the structural route through H, K, P, N is the whole public ledger. □

Theorem 1525.51 (FanFunctional root bar-depth exactness)**.** *For an accepted finite-window carrier* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$*, the root read exposes the* $\mathsf{FanTheorem}^{\uparrow}$ *bar-depth row* D *before any* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{UniformContinuity}^{\uparrow}$ *modulus row is consumed. The depth seen by a modulus consumer is exactly the finite depth displayed by* F, D *over the Cantor prefix rows* B, Q*, not a selected branch, host functional, open-cover compactness proof, or Real-completeness witness.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootBarDepthExactness`

Proof. Project the finite-window carrier. Rows B, Q display the inspected Cantor prefixes, while F, D display the decidable bar and its finite depth before the tolerance and witness rows are read.

The modulus rows U, T, W are downstream from that display. Transport through H, R and provenance through P, N preserve the same finite depth, so a consumer cannot substitute an external branch selector or compactness proof for D. □

Theorem 1525.52 (FanFunctional root modulus-window coverage)**.** *Every root-schema modulus read of* $\mathsf{FanFunctional}^{\uparrow}$ *covers exactly the Cantor prefixes displayed in the finite windows* B, Q, W *of* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$*. The witness windows neither omit a displayed prefix before the modulus row is exported nor add a prefix outside the bar-depth boundary exposed by* F, D*.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootModulusWindowCoverage`

Proof. Use the root schema carrier and classifier theorems. The carrier fixes the prefix rows B, Q, W, and the classifier compares only those finite windows together with the bar-depth and tolerance rows.

The root schema ledger keeps the compact and uniform-modulus consumers on that route. Since no coordinate names an infinite branch, countable choice schedule, or open-cover compactness proof, coverage is exactly the displayed finite prefix family. □

Theorem 1525.53 (FanFunctional root NameCert acceptance)**.** *The local root-facing* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *acceptance row receives only* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *rows carried by* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$*. It does not receive a host functional, selected branch, arbitrary open-cover compactness row, choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootNamecertAcceptance`

Proof. Combine the root schema carrier, classifier, and ledger. They expose the finite Cantor prefix, bar-depth, tolerance, witness-window, compact-metric, uniform-continuity, and uniform-modulus rows before the local name is read.

The structural rows H, R, P, N provide exactly displayed replay, componentwise transport, package provenance, and local naming. Because the carrier has no host-functional, branch-selector, open-cover, choice, or Real-completeness coordinate, local NameCert acceptance receives only the listed rows. □

Theorem 1525.54 (FanFunctional root-unblock Cantor prefix)**.** *Every root-unblock read of an accepted* FanFunctional$^{\uparrow}$ *packet must first admit the displayed* CantorSpace$^{\uparrow}$ *finite prefix surface. Concretely, the read exposes the List spine, Bool-valued finite observation windows, StreamName schedule, and the surrounding* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before any fan-depth or modulus consumer can inspect the packet.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUnblockCantorPrefix`

Proof. Project the carrier of Definition 1525.1 and the finite-window carrier of Definition 1525.33. Their Cantor-facing coordinates are finite prefix data: List spines, Bool ledgers, StreamName windows, and the structural transport rows.

The root schema carrier of Definition 1525.38 reads those coordinates before the compact and uniform-modulus rows. Thus a root-unblock consumer receives the Cantor prefix as displayed finite data, not as an infinite branch or host functional.

Finally apply the root choice boundary of Definition 1525.47. Since no selector, open-cover proof, or ambient Real-completeness row is present, the Cantor prefix admission remains inside the accepted packet. □

Theorem 1525.55 (FanFunctional root-unblock finite fan depth)**.** *Every root-unblock read of* FanFunctional$^{\uparrow}$ *exposes the* FanTheorem$^{\uparrow}$ *finite fan-depth row through the displayed UnaryHistory depth ledger before witness-window coverage or uniform-modulus handoff is consumed. The depth read is a finite carrier projection over the same Cantor-prefix rows; it is not a bar-induction principle, selected branch argument, or open-cover compactness claim.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUnblockFanDepth`

Proof. Read the finite fan rows from Definition 1525.1. The row F supplies the decidable bar classifier, and the row D supplies the finite depth evidence attached to the retained branch-prefix window.

Use Definition 1525.4 and Definition 1525.51. Together they place the UnaryHistory depth after the Cantor-prefix rows and before any witness-window or modulus read.

The route is preserved by componentwise hsame, displayed Cont replay, Pkg provenance, and the local NameCert row. Coordinate exhaustion then excludes bar induction, selected branches, host functionals, and open-cover compactness from the fan-depth exposure. □

Theorem 1525.56 (FanFunctional root-unblock uniform modulus handoff)**.** *Every root-unblock consumer that reads the* UniformModulus$^{\uparrow}$ *row of an accepted* FanFunctional$^{\uparrow}$ *packet must keep the route through* CompactMetric$^{\uparrow}$*,* UniformContinuity$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *visible. The handoff uses the displayed Cantor prefix, finite fan depth, tolerance request, compact finite-window consumer row, and witness windows; it exports no selected branch,*

host functional, bar-induction principle, open-cover compactness proof, quotient stream equality, or ambient Real-completeness row.

Proof. Start with the Cantor-prefix admission of Definition 1525.54. It fixes the finite prefix windows and the structural rows available to the root-unblock read.

Next apply the finite fan-depth exposure of Definition 1525.55. The depth ledger bounds the retained prefix window before witness coverage or modulus handoff is consumed.

Use Definition 1525.5 and Definition 1525.52. They route the compact-metric and uniform-continuity consumers through the same finite windows before the $\mathsf{UniformModulus}^{\uparrow}$ row is exported.

Finally attach the root schema ledger. Rows BHist, hsame, Cont, Pkg, and NameCert keep the handoff on the displayed packet, so none of the excluded branch, host, induction, compactness, quotient, or Real-completeness objects can be read from the root-unblock surface. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUnblockUniformModulus`

Theorem 1525.57 (FanFunctional root-unblock compact route)**.** *Every root-unblock read of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet routes through* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *before exporting a modulus. The route exposes the Cantor prefix, finite fan-depth ledger, compact finite-window consumer, tolerance request, witness-window coverage, componentwise transport, displayed replay, package provenance, and local naming rows; it exports no selected branch, bar-induction principle, open-cover compactness proof, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUnblockCompactRoute`

Proof. Project the carrier rows of Definition 1525.1 and Definition 1525.33. The visible compact-route data are the Cantor-prefix windows, the finite fan-depth row, the compact metric consumer row, the uniform-continuity request, and the modulus handoff rows.

Invoke Definition 1525.54 for the Cantor-facing prefix and Definition 1525.55 for the finite fan-depth exposure. These theorems place $\mathsf{CantorSpace}^{\uparrow}$ and $\mathsf{FanTheorem}^{\uparrow}$ before any compact or modulus consumer can read the packet.

Use Definition 1525.56 to carry the compact-metric and uniform-continuity rows through the witness-window handoff to $\mathsf{UniformModulus}^{\uparrow}$. The structural rows BHist, hsame, Cont, Pkg, and NameCert keep the read on the same accepted packet.

Coordinate exhaustion gives the boundary. Since the accepted packet contains no selected branch, bar-induction row, open-cover compactness proof, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, the compact route exports only the displayed finite modulus surface. □

Theorem 1525.58 (FanFunctional root-unblock witness-window totality)**.** *Every root-unblock read that exposes the* $\mathsf{UniformModulus}^{\uparrow}$ *row of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet must also expose the witness-window row pairing retained* $\mathsf{CantorSpace}^{\uparrow}$ *prefixes with pointwise tolerance evidence. This window is read through* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*; it exports no selected branch, host functional, bar-induction row, open-cover compactness proof, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1525.54. It supplies the retained Cantor-prefix surface as finite List, Bool, and StreamName data before a modulus consumer can inspect the packet.

Apply Definition 1525.55. The finite fan-depth ledger bounds the retained prefix window and places the witness-window row after the Cantor prefix but before the uniform-modulus handoff.

Use Definition 1525.56. It routes the compact metric and uniform-continuity consumers through the witness-window handoff to UniformModulus$^{\uparrow}$, so exposing the modulus row entails exposing the paired prefix and pointwise tolerance evidence.

Finally invoke Definition 1525.57. The structural rows BHist, hsame, Cont, Pkg, and NameCert keep the totality read on the displayed packet. Coordinate exhaustion excludes selected branches, host functionals, bar-induction rows, open-cover compactness, quotient streams, and ambient Real$^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRootUnblockWitnessWindowTotality`

Theorem 1525.59 (FanFunctional finite bar-depth carrier scope)**.** *Every accepted* FanFunctional$^{\uparrow}$ *root read that exposes finite bar-depth data must route the* CantorSpace$^{\uparrow}$ *prefix row,* FanTheorem$^{\uparrow}$ *bar row,* CompactMetric$^{\uparrow}$ *finite-window consumer, and* UniformModulus$^{\uparrow}$ *target through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The carrier scope contains no choice-selected branch, host functional, open-cover compactness proof, quotient stream equality, or ambient Real-completeness principle.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalBarScopeObligations`

Proof. Project the carrier of Definition 1525.1. The Cantor-prefix row, finite fan row, branch-prefix window, bar-depth evidence, witness window, and extracted modulus are all displayed finite rows.

Use the root-unblock Cantor-prefix and finite fan-depth routes of Definition 1525.54 and Definition 1525.55. They place the CantorSpace$^{\uparrow}$ and FanTheorem$^{\uparrow}$ rows before any compact or modulus consumer can inspect the packet.

The CompactMetric$^{\uparrow}$ and UniformModulus$^{\uparrow}$ rows are then replayed through the same BHist, hsame, Cont, Pkg, and NameCert ledger. Since no coordinate contains a selected infinite branch or host functional, the finite bar-depth carrier cannot export one. □

Theorem 1525.60 (FanFunctional Cantor compactness scope)**.** *Every* FanFunctional$^{\uparrow}$ *consumer that reads Cantor compactness data reaches it through* CantorSpace$^{\uparrow}$*,* FanTheorem$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by the accepted packet. The scope is finite-prefix compactness replay and not an open-cover compactness theorem, choice-selected branch, host fan functional, quotient stream equality, or ambient real-order argument.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCantorCompactnessScope`

Proof. Read the Cantor prefix row from Definition 1525.1. It supplies finite Boolean observation windows and StreamName schedules before the fan-depth row is visible.

Apply Definition 1525.59. The finite bar-depth row bounds the retained prefix window, so the compactness-facing read is a finite-prefix replay over CantorSpace$^{\uparrow}$ and FanTheorem$^{\uparrow}$.

The compact metric consumer is admitted only through the displayed CompactMetric$^{\uparrow}$ row and the same transport, replay, provenance, and naming rows. Thus the compactness scope cannot detach into an open-cover theorem, selected branch, host functional, quotient stream equality, or ambient real-order argument. □

Theorem 1525.61 (FanFunctional uniform-modulus export scope)**.** *Every* UniformModulus$^{\uparrow}$ *row exported by an accepted* FanFunctional$^{\uparrow}$ *packet is scoped over* CantorSpace$^{\uparrow}$*,* FanTheorem$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The export is a finite row replay*

from prefix depth and witness windows, not a choice-selected branch, host functional, bar-induction proof, open-cover compactness proof, quotient stream equality, or ambient Real-completeness row.

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalUniformModulusScope`

Proof. Start with the finite bar-depth scope of Definition 1525.59. It fixes the Cantor prefix, fan-depth, compact-window, and structural rows available to a modulus export.

Use the Cantor compactness scope of Definition 1525.60. The compact metric row is consumed only as finite-prefix replay through the accepted packet.

Finally apply the root-unblock uniform-modulus handoff of Definition 1525.56. The exported $\mathsf{UniformModulus}^{\uparrow}$ row stays downstream of BHist, hsame, Cont, Pkg, and NameCert rows, so none of the excluded branch, host-functional, induction, compactness, quotient, or Real-completeness data can escape. □

Theorem 1525.62 (FanFunctional finite-window coverage)**.** *Every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window packet exposes a finite Cantor-prefix window before any* $\mathsf{UniformModulus}^{\uparrow}$ *row is read. Concretely, for the carrier* $\Omega = (B, Q, F, D, U, T, K, W, H, R, P, N)$ *of Definition 1525.33, the rows* B, Q, W *display the Cantor-prefix windows consumed by the root read before the fan bar row* F*, the finite depth row* D*, or the modulus row* M *of the root-schema consumer is exported. The coverage route is the displayed* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *path, not a selected infinite branch, host functional, open-cover compactness proof, or countable-choice schedule.*

Proof. Project the finite-window carrier of Definition 1525.33. Its Cantor-facing coordinates are B, Q, W, and Definition 1525.34 requires those finite rows to be visible before the fan bar, depth, or local naming rows are consumed.

Next use the root schema carrier and root NameCert acceptance, Definition 1525.38 and Definition 1525.53. These results keep the compact and uniform-modulus consumers on the same $B, Q, F, D, U, T, K, W, H, R, P, N$ route.

Finally apply the Cantor-window coverage obligations in the spine. The displayed CantorSpace, FanTheorem, UniformContinuity, CompactMetric, and UniformModulus rows exhaust the finite-window surface, so no consumer may replace them by an infinite branch selector, host functional, open-cover compactness proof, or countable-choice schedule. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalFiniteWindowCoverage`

Theorem 1525.63 (FanFunctional modulus-window monotonicity)**.** *The* $\mathsf{UniformModulus}^{\uparrow}$ *row extracted from an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window packet is read through the finite bar-depth ledger* F, D *and never through an infinite branch selector. If a later modulus request asks for a stronger displayed tolerance row, its witness-window read refines the earlier read only by extending the finite Cantor-prefix window already displayed in* B, Q, W *and by reusing the same* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *route.*

Proof. Start with Definition 1525.51. It places the bar-depth row D after the Cantor-prefix and fan rows and before any uniform-modulus or uniform-continuity row is consumed.

Use Definition 1525.52 to identify the witness-window surface. A stronger displayed tolerance can only enlarge or refine the finite witness windows already carried by B, Q, W under the same finite depth row.

Finally apply Definition 1525.35 together with Definition 1525.53. The extracted modulus row is therefore read through $F, D, U, T, W, H, R, P, N$ and the compact finite-prefix row K, with no coordinate for an infinite branch selector or host compactness argument. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalModulusWindowMonotonicity`

Theorem 1525.64 (FanFunctional Cantor-prefix nonescape)**.** *All Cantor-prefix consumers of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *finite-window packet remain inside the displayed route*

$$C, F, B, D, W, M, H, K, P, N.$$

Equivalently, a consumer may read Cantor prefixes, fan bar data, retained prefix windows, finite depth, witness windows, modulus output, componentwise transport, compact finite-prefix support, provenance, and the local NameCert *row, but it cannot escape to a selected infinite branch, host functional, open-cover compactness proof, countable-choice selector, or ambient Real-completeness witness.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCantorPrefixNonescape`

Proof. Begin with the carrier and NameCert obligation theorem in the spine, Definition 1525.33 and Definition 1525.53. They display the Cantor, fan, witness, modulus, compact, transport, replay, provenance, and local naming rows before any root consumer can accept the packet.

Next apply Definition 1525.34 and Definition 1525.36. The Cantor rows are finite prefix windows, and the compact-metric consumer receives only the displayed finite-net support attached to those prefixes.

Finally use Definition 1525.26. Since selected branches, host functionals, open-cover compactness proofs, countable-choice selectors, and ambient Real-completeness witnesses have no carrier coordinate, every Cantor-prefix consumer stays inside the displayed $C, F, B, D, W, M, H, K, P, N$ route. □

Theorem 1525.65 (FanFunctional local obligation surface)**.** *For the carrier*

$$\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$$

of Definition 1525.1, the rows $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *jointly form the complete local obligation surface for* $\mathsf{FanFunctional}^{\uparrow}$*. Carrier admission is read from the displayed* BHist *packet, classifier stability is read from the Cantor-prefix and finite-fan rows, and the remaining public obligations are exactly bar-depth exactness, witness-window coverage, uniform-modulus handoff, and nonescape.*

Proof. Project the displayed carrier. The coordinates $C, F, \varepsilon, B, D, W, M$ name the finite Cantor-prefix, finite fan, tolerance, branch-window, bar-depth, witness-window, and modulus rows.

The structural coordinates H, K, P, N then close the local reading surface: H supplies componentwise hsame transport, K supplies displayed Cont replay, P records package provenance, and N records the local NameCert name. No further carrier coordinate is available to the chapter. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalLocalObligationSurface`

Theorem 1525.66 (FanFunctional bar-depth and witness-window precedence)**.** *Every* $\mathsf{FanFunctional}^{\uparrow}$ *obligation read consumes the finite bar-depth row* D *and the witness-window row* W *before any modulus row* M *is exported to a* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer. Thus finite bar-depth exactness and witness-window coverage are prerequisites for modulus consumption, not consequences of an already accepted modulus.*

Proof. Read the finite rows in carrier order. The branch window B is cut from the Cantor-prefix row C by the finite fan row F, and D certifies the displayed bar depth over that finite window.

Only after this depth row is fixed can W attach the pointwise tolerance witnesses that feed the modulus row M. Consequently a consumer of M sees the already displayed D, W surface and cannot use the modulus row to choose or repair the preceding bar-depth and witness-window data. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalBarDepthWitnessWindowPrecedence`

Theorem 1525.67 (FanFunctional modulus handoff and nonescape)**.** *The uniform-modulus handoff M, H, K, P, N of Definition 1525.1 and Definition 1525.2 excludes host functionals, selected branches, open-cover compactness, countable choice, and Real completeness from the* $\mathsf{FanFunctional}^{\uparrow}$ *public surface. Every accepted read factors through the finite carrier rows, componentwise transport, displayed continuation replay, package provenance, and the local NameCert row.*

Proof. The handoff row M is produced from the finite windows B, D, W and is transported only by the displayed structural rows H, K, P, N.

Since the carrier contains no coordinate for a host functional $2^{\mathsf{Nat}^{\uparrow}} \to \mathsf{Real}^{\uparrow}$, selected branch, open-cover compactness proof, countable-choice schedule, or $\mathsf{Real}^{\uparrow}$ completeness witness, there is no projection through which such data can enter a public read. Nonescape is therefore a finite-coordinate statement about the displayed carrier. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalModulusHandoffNonescape`

Theorem 1525.68 (FanFunctional Real and RegSeqRat scope)**.** *Every* $\mathsf{FanFunctional}^{\uparrow}$ *modulus read consumed by a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *route must first pass through* $\mathsf{CantorSpace}^{\uparrow}$ *finite prefixes,* $\mathsf{FanTheorem}^{\uparrow}$ *decidable finite-bar depth,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data,* $\mathsf{UniformContinuity}^{\uparrow}$ *local tolerance rows, and the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row. The exported route contains no host function space, selected branch, open-cover compactness, countable choice, or Real completeness.*

Proof. Project the carrier surface of Definition 1525.1. The visible route begins with the finite Cantor-prefix row C, the finite fan row F, the tolerance row ε, the branch-window row B, the bar-depth row D, the witness-window row W, and the extracted modulus row M.

Apply the local obligation surface of Definition 1525.65. It fixes carrier admission and classifier stability before any downstream consumer can read a modulus value.

Now use the bar-depth coverage theorem and the modulus nonescape theorem. The row order is

$$C, F, \varepsilon, B, D, W, M, H, K, P, N.$$

Thus a Real or regular-rational consumer receives a finite modulus route through Cantor prefixes, decidable fan depth, compact-metric finite nets, uniform-continuity tolerance rows, and the extracted UniformModulus row.

Because no carrier coordinate stores a host function space, selected branch, open-cover compactness proof, countable-choice schedule, or $\mathsf{Real}^{\uparrow}$ completeness witness, those objects cannot be exported by the scoped consumer route. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalRealRegSeqRatScope`

Theorem 1525.69 (FanFunctional scoped consumer route)**.** *Every scoped consumer of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *carrier*

$$\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N)$$

must read the finite $\mathsf{CantorSpace}^{\uparrow}$ *prefix row* C*, the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row* F*, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-window row encoded by* B, D, W*, the* $\mathsf{UniformContinuity}^{\uparrow}$ *tolerance request* ε*, and the exported* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *on the same* BHist *route before it may use the modulus. The consumer surface is transported only by the displayed* hsame *rows* H*, replayed only by* K*, sourced only by* P*, and named only by* N*.*

Proof. Project the carrier of Definition 1525.1. The rows $C, F, \varepsilon, B, D, W, M$ are the only analytic rows visible to a consumer, and H, K, P, N are the only structural rows.

Apply the local obligation surface of Definition 1525.65. Carrier admission and classifier stability keep the Cantor-prefix and finite-fan rows in scope before any compact or uniform consumer reads M.

Use the precedence theorem Definition 1525.66. It requires the bar-depth and witness-window rows to be consumed before the modulus row is exported. Thus every scoped consumer sees the finite $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ route in the displayed order. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalScopedConsumerRoute`

Theorem 1525.70 (FanFunctional scoped choice nonescape)**.** *The scoped* $\mathsf{FanFunctional}^{\uparrow}$ *consumer route of Definition 1525.69 exports no selected branch, no host functional* $2^{\mathsf{Nat}^{\uparrow}} \to \mathsf{Real}^{\uparrow}$*, no open-cover compactness proof, no countable-choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness. Any accepted read of* M *factors through the finite rows* $C, F, \varepsilon, B, D, W, M, H, K, P, N$ *and through the local* $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$ *obligations.*

Proof. The modulus row M is a coordinate of the displayed carrier, not a host functional. Projection of Definition 1525.1 gives no coordinate for selected branches, open covers, choice schedules, or ambient real completeness.

Apply Definition 1525.67. Its nonescape clause already exhausts the handoff through M, H, K, P, N and excludes the same host objects from the public surface.

The scoped consumer route adds only the destination names $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$. Since those destinations receive the same finite packet, they cannot receive any omitted host datum. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalScopedChoiceNonescape`

Theorem 1525.71 (FanFunctional scoped finite-modulus export)**.** *For every accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet, the row* M *exported to* $\mathsf{UniformModulus}^{\uparrow}$ *is a finite modulus extracted from the displayed Cantor prefix, fan-bar, compact-window, and tolerance rows. Any* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer receives* M *together with its route through* $C, F, \varepsilon, B, D, W, H, K, P, N$*, and receives no separate compactness, function-space, branch-selection, choice, or Real-completion principle.*

Proof. Read C and F first. They expose the finite Cantor-prefix and finite fan-bar surfaces that bound the branch-prefix window.

Next read ε, B, D, W. The tolerance request is attached to the finite witness windows, and the bar-depth row is already fixed before the witness rows are used.

Finally export M through H, K, P, N. Componentwise transport, displayed replay, package provenance, and the local name preserve the same finite route, so a downstream compact or uniform-continuity consumer receives only the finite modulus packet. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalScopedFiniteModulusExport`

Theorem 1525.72 (FanFunctional finite bar-modulus scope)**.** *Any scoped read of the modulus row M in an accepted* FanFunctional$^{\uparrow}$ *carrier must first expose the* CantorSpace$^{\uparrow}$ *prefix row C, the* FanTheorem$^{\uparrow}$ *finite-bar-depth row F, the* CompactMetric$^{\uparrow}$ *finite-window rows B, D, W, the* UniformContinuity$^{\uparrow}$ *tolerance row ε, and the structural* BHist, hsame, Cont, Pkg, *and* NameCert *rows H, K, P, N. A consumer that omits one of these rows has not reached the scoped modulus surface.*

Proof. Begin with the scoped consumer route of Definition 1525.69. It orders the analytic rows before the exported modulus and records the structural route by which the consumer reaches them.

Use finite-modulus export in Definition 1525.71. The row M is not independent data: it is exported only after $C, F, \varepsilon, B, D, W$ have fixed a finite prefix, bar depth, tolerance request, and witness window.

The structural rows then bind the same read to the BEDC packet. Transport through H, replay through K, provenance through P, and naming through N keep the modulus read inside the displayed BHist route, so a scoped read missing any listed row is not an accepted modulus read. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalFiniteBarModulusScope`

Theorem 1525.73 (FanFunctional compact-uniform consumer scope)**.** *No* CompactMetric$^{\uparrow}$, UniformContinuity$^{\uparrow}$, *or* UniformModulus$^{\uparrow}$ *consumer of an accepted* FanFunctional$^{\uparrow}$ *packet may replace the finite fan evidence C, F, B, D, W with open-cover compactness, selected branches, countable choice, function-space compactness, or a host modulus theorem. The consumer surface is the finite route through $C, F, \varepsilon, B, D, W, M, H, K, P, N$.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCompactUniformConsumerScope`

Proof. Read the choice nonescape theorem Definition 1525.70. It excludes selected branches, host functionals, open-cover compactness, choice schedules, and ambient Real completeness from the scoped route.

Apply finite bar-modulus scope. A compact or uniform consumer obtains M only after the finite Cantor prefix, finite bar-depth, compact-window, tolerance, witness-window, and structural rows are present.

The excluded compactness and choice principles have no carrier slot in this finite route. Therefore a consumer that uses one of them is using evidence outside the accepted FanFunctional$^{\uparrow}$ packet rather than replacing the finite fan evidence inside it. □

Theorem 1525.74 (FanFunctional compact-metric uniform bar scope)**.** *Every accepted* FanFunctional$^{\uparrow}$ *compact/uniform consumer must expose the* CompactMetric$^{\uparrow}$ *finite-net support, the* UniformContinuity$^{\uparrow}$ *tolerance data, the* FanTheorem$^{\uparrow}$ *finite bar-depth rows, and the* UniformModulus$^{\uparrow}$ *output on the same* BHist, hsame, Cont, Pkg, *and* NameCert *route before it reads the modulus row M. The accepted bar-scope read is therefore the finite route through $C, F, \varepsilon, B, D, W, M, H, K, P, N$, not an open-cover compactness proof, a selected branch family, a host functional, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalCompactMetricUniformBarScope`

Proof. Start with the scoped consumer route of Definition 1525.69. It fixes the row order in which a consumer reads the finite Cantor prefix, finite fan bar, compact-metric support, tolerance request, exported modulus, and structural rows.

Apply finite bar-modulus scope in Definition 1525.72. The bar-depth and witness-window rows must be visible before the modulus row is consumed, so the $\mathsf{FanTheorem}^{\uparrow}$ bar data cannot be delayed until after M is read.

Finally use compact-uniform consumer scope in Definition 1525.73. It excludes replacement by open-cover compactness, selected branches, host functionals, and ambient $\mathsf{Real}^{\uparrow}$ completeness, leaving exactly the displayed compact-metric finite-net support, uniform-continuity tolerance row, finite bar-depth rows, output modulus, and BEDC structural route. □

Theorem 1525.75 (FanFunctional scoped closure record)**.** *The scoped consumer route, finite bar-modulus scope, compact-uniform consumer scope, and finite-modulus export assemble a paper witness for scoped closure of* $\mathsf{FanFunctional}^{\uparrow}$ *over the displayed* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalScopedClosureRecord`

Proof. First collect the carrier-facing route from Definition 1525.69. It states which finite analytic and structural rows every scoped consumer must read.

Next apply finite bar-modulus scope and finite-modulus export. These theorems force the modulus row to remain downstream of the Cantor-prefix, fan-bar, compact-window, tolerance, and witness-window rows.

Finally apply compact-uniform consumer scope. It rules out replacement by open-cover compactness, selected branches, choice schedules, function-space compactness, or host modulus theorems. The remaining consumer surface is exactly the displayed finite packet, which is the scoped paper witness recorded here. □

Theorem 1525.76 (FanFunctional uniform-modulus compact consumer)**.** *Any* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FanFunctional}^{\uparrow}$ *packet must read* $\mathsf{CantorSpace}^{\uparrow}$ *prefix rows,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar depth,* $\mathsf{UniformContinuity}^{\uparrow}$ *pointwise tolerance rows,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data, and the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row through the finite packet*

$$\Phi = (C, F, \varepsilon, B, D, W, M, H, K, P, N).$$

Here C records Cantor prefix rows, F records the finite bar supplied by $\mathsf{FanTheorem}^{\uparrow}$*, ε records the pointwise tolerance request, B records the bar-depth boundary, D records the extracted finite depth, W records the witness windows, M records the compact finite-net and uniform-modulus handoff, and H, K, P, N record componentwise transport, displayed replay, provenance, and local naming. The consumer exports no host functional, choice-selected branch, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the existing $\mathsf{FanFunctional}^{\uparrow}$ NameCert obligations. They admit a finite packet only by displaying Cantor prefix rows, the FanTheorem bar row, tolerance data, witness windows, transport, replay, provenance, and local naming.

Read the root finite-bar depth next. The root bar-depth exactness theorem in the FanFunctional chapter forces every modulus consumer to use the finite depth displayed by the FanTheorem rows rather than a selected branch or host functional.

The compact and uniform-modulus consumers are downstream of that depth. Compact finite-net data and the extracted $\mathsf{UniformModulus}^{\uparrow}$ row are therefore read through the same packet Φ, with M as the handoff row and H, K, P, N preserving, replaying, sourcing, and naming the route.

Since no coordinate of Φ stores a host functional, branch selector, open-cover compactness proof, or $\mathsf{Real}^{\uparrow}$ completeness theorem, none of those objects can enter the compact-uniform consumer handoff. □

Lean4 ✓ `BEDC.Derived.FanfunctionalUp.FanFunctionalUniformModulusCompactConsumer`

Closure status for $\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$, publicClosed)

Scope closed: The public export surface is closed over $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert through the finite modulus route and the compact consumer of Definition 1525.76.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FanFunctional}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.FanfunctionalUp.FanFunctionalScopedClosureRecord`

Bridge status: none

Not claimed: This chapter does not close a host functional, selected branch, open-cover compactness, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Bridged closure asks for a standard bridge from the finite fan and modulus packet to the public FanFunctional interface.

Constructive story: A $\mathsf{FanFunctional}^{\uparrow}$ packet is generated from finite $\mathsf{CantorSpace}^{\uparrow}$ prefix rows, a $\mathsf{FanTheorem}^{\uparrow}$ finite-bar depth ledger, compact-metric finite-net data, uniform-continuity tolerance rows, an extracted $\mathsf{UniformModulus}^{\uparrow}$ row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 1526

A Concrete Naming Certificate for $\mathsf{RiemannIntegral}^{\uparrow}$

Following Riemann and Darboux, the $\mathsf{RiemannIntegral}^{\uparrow}$ packet records a tagged-mesh integration surface whose accepted sums are routed through the Darboux upper-lower gap and dyadic step-function mesh rows. It sits after the Darboux carrier of chapter 1460, the stepwise approximation surface of chapter 428, and the dyadic mesh ledger of chapter 358. The packet names a finite constructive integration boundary over one displayed interval and integrand window; it does not assert host completeness, quotient equality of real functions, open-cover compactness, or a measure-theoretic integral.

Definition 1526.1 (Riemann integral carrier)**.** *A* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, T, F, S, D, G, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *row naming the interval endpoints, cell subdivision, mesh bound, and cell adjacency ledger.*
2. *T is the finite tag row, with each tag carried inside the corresponding mesh cell by an explicit dyadic or rational containment witness.*
3. *F is the integrand-read window, exposing only the finitely displayed values needed at the tags and at the upper/lower step approximants.*
4. *S is the finite Riemann-sum row computed from the tag values, cell widths, and displayed arithmetic ledger.*
5. *D is the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *comparison row, recording upper and lower dyadic step-function approximants that bracket the same displayed reads.*
6. *G is the Darboux gap and mesh-refinement ledger that bounds the distance between the tagged sum and the Darboux interval determined by D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff surface reached only after the displayed sums and gap ledger are present.*
8. *H records componentwise* hsame *transport for mesh, tags, integrand reads, sums, Darboux comparison, gap, handoff, provenance, and the local naming row.*

9. *C records displayed* Cont *replay from mesh cells to tag reads, from tag reads to finite sums, from sums to Darboux comparison, and from the gap ledger to the real-facing handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, F, S, D, G, R, H, C, P, N$. It has no coordinate for a host function quotient, a completed real equality principle, a choice-selected tag family, open-cover compactness, a measure space, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralTasteGate single carrier alignment`

Theorem 1526.2 (Riemann integral NameCert obligations)**.** *For an accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier $I = (M, T, F, S, D, G, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}$ *surface consists of carrier admission, mesh-tag containment, finite sum exactness, Darboux bracket compatibility, gap-to-real handoff, componentwise transport, continuation replay, provenance, and ledger non-escape. These obligations are discharged by the displayed route*

$$M \longmapsto T \longmapsto F \longmapsto S \longmapsto D \longmapsto G \longmapsto R$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralPacket namecert obligations`

Proof. Carrier admission is the projection of the tuple in Definition 1526.1. The mesh row M displays the finite cells, and the tag row T records containment inside those cells before any value of the integrand is read.

Finite sum exactness is then a ledger calculation over F and S. Each summand uses only the carried tag value and the carried cell width, so the sum is a finite BHist computation rather than a host-level limiting assertion.

Darboux bracket compatibility is provided by the comparison row D. The upper and lower dyadic step-function approximants bound the same displayed reads, and the gap row G records the visible estimate between the tagged sum and the Darboux bracket.

The rows H and C transport and replay the same route componentwise. The package row P and name row N source the packet, while R is downstream of the mesh, sum, Darboux, and gap data. Since none of the excluded host objects appears as a carrier coordinate, the listed obligations exhaust the certificate surface. □

Theorem 1526.3 (Darboux and step scope of Riemann sums)**.** *Every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *read factors through a* $\mathsf{DyadicMesh}^{\uparrow}$ *row, a finite tag row, a* $\mathsf{DyadicStepFunction}^{\uparrow}$ *bracket supplied by the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *comparison row, and the displayed gap ledger before the packet can be consumed as a real-facing integral. The exported scope is therefore a finite tagged-mesh comparison surface, not a quotient class of functions and not an ambient completeness theorem.*

Proof. Project the accepted carrier through Definition 1526.1. The mesh row M supplies the finite cell surface, and the tag row T is checked against those cells before the integrand-read row F is available.

The finite sum row S is computed from those displayed reads. The comparison row D then supplies the Darboux upper and lower step-function bracket, so any step-function evidence used by the packet is already part of the visible Darboux route.

The gap row G is read after the sum and bracket rows. Thus a real-facing consumer reaches R only through the displayed mesh, tags, finite sum, Darboux bracket, and gap data. No carrier coordinate can export quotient function equality or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier darboux step scope`

Theorem 1526.4 (Riemann integral real seal boundary)**.** *An accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *packet exports to* $\mathsf{Real}^{\uparrow}$ *only the real-facing handoff row R produced from the finite route*

$$M \longmapsto T \longmapsto F \longmapsto S \longmapsto D \longmapsto G.$$

The boundary seal records the tagged-mesh sum and Darboux-gap evidence already displayed in the packet, and it does not claim host completeness, quotient real equality, open-cover compactness, or a full measure-theoretic integral.

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralPacket real seal boundary`

Proof. The handoff row R is a coordinate of the carrier, but it is downstream of the mesh, tag, read, sum, Darboux, and gap rows. A $\mathsf{Real}^{\uparrow}$ consumer therefore receives only a row whose construction has passed through the displayed finite route.

Componentwise transport through H preserves the same coordinates, and continuation replay through C rebuilds the same route when the packet is consumed. The package row P and local name N record this provenance without adding analytic structure.

The excluded objects are absent from the carrier: there is no host completion witness, no quotient equality of real functions, no open-cover compactness row, and no measure-theoretic carrier. Hence the real seal boundary is exactly the displayed tagged-mesh and Darboux-gap handoff. □

Theorem 1526.5 (Riemann integral scope closure package)**.** *Every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *read is exhausted by the dyadic mesh row, tag-containment row, integrand-read window, finite-sum row, Darboux bracket, gap ledger, regular-rational and* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert rows named in Definition 1526.1. The scope contains no quotient function equality, open-cover compactness, measure-integration carrier, or ambient completeness coordinate.*

Proof. Start from the carrier description in Definition 1526.1. Its coordinates are exactly $M, T, F, S, D, G, R, H, C, P$ so any accepted read first exposes a dyadic mesh, tag containment, integrand reads, finite sum data, Darboux comparison, gap estimate, and real-facing handoff.

Apply Definition 1526.2. The NameCert surface names the same carrier admission, mesh-tag containment, finite sum exactness, Darboux bracket compatibility, gap-to-real handoff, transport, replay, provenance, and ledger non-escape rows.

Use Definition 1526.3 and Definition 1526.4. The first confines every integration read to the tagged-mesh and Darboux-step route; the second makes the $\mathsf{Real}^{\uparrow}$ seal downstream of that finite route.

The excluded host objects have no row in the displayed carrier and cannot be introduced by H, C, P, or N. Therefore the listed rows form the scoped package for every accepted $\mathsf{RiemannIntegral}^{\uparrow}$ read. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier scope closure package`

Theorem 1526.6 (Riemann integral tagged-sum totality)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier* $I = (M, T, F, S, D, G, R, H, C, P, N)$*, the tagged-sum row* S *is total only over the displayed* $\mathsf{DyadicMesh}^{\uparrow}$ *row* M*, tag-containment row* T*, and integrand-read window* F*. A scoped consumer cannot read* S *before the mesh cells, tags, and finite values have been exposed and replayed through* H, C, P, N*.*

Proof. Project the carrier of Definition 1526.1. The rows M, T, F, S are the only tagged-sum coordinates available before the Darboux comparison row D is read.

Apply the NameCert obligations of Definition 1526.2. They place mesh-tag containment and finite sum exactness on the route from M through T, F to S.

Use the Darboux-step scope and scope-closure package, Definition 1526.3 and Definition 1526.5. These results keep every scoped integration read inside the same $\mathsf{DyadicMesh}^{\uparrow}$ and finite tagged-sum boundary before a consumer reaches $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ rows. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier tagged sum totality`

Theorem 1526.7 (Riemann integral Darboux-gap exactness)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier* $I = (M, T, F, S, D, G, R, H, C, P, N)$*, the gap ledger* G *is exact only relative to the finite tagged sum* S *and the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *comparison row* D *built from the same* M, T, F *data. The scoped packet admits no Darboux bracket or gap estimate detached from the displayed* $\mathsf{DyadicStepFunction}^{\uparrow}$ *and tagged-mesh route.*

Proof. Start with the carrier and NameCert obligations. The Darboux comparison row D is read after the tagged-sum row S, and the gap row G is read after D on the displayed route.

Apply Darboux-step scope. Theorem 1526.3 binds the step-function bracket to the same $\mathsf{DyadicMesh}^{\uparrow}$ row, tag row, integrand reads, and finite sum already displayed by the packet.

The scope-closure package then keeps the gap ledger in that chain. Since G has no independent coordinate for host function equality, open-cover compactness, measure integration, or ambient completeness, its exactness is exactly the replayed relation between S and D through H, C, P, N. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier darboux gap exactness`

Theorem 1526.8 (Riemann integral RegSeqRat handoff totality)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier* $I = (M, T, F, S, D, G, R, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row* R *is total only after the tagged-sum row* S*,* $\mathsf{DarbouxIntegral}^{\uparrow}$ *comparison row* D*, and Darboux-gap ledger* G *have been displayed. A scoped consumer reaches* R *through* $M, T, F, S, D, G, H, C, P, N$ *and cannot import a separate real-completion assertion or quotient equality of functions.*

Proof. Read the real-facing boundary through Definition 1526.4. The theorem places R downstream of the finite route from mesh and tags to finite sum, Darboux comparison, and gap ledger.

Apply the NameCert obligations and Darboux-gap exactness. The obligations expose the carried route M, T, F, S, D, G, R, while Definition 1526.7 keeps G attached to the same tagged-sum and Darboux rows before R is read.

Finally use scope closure. Theorem 1526.5 confines the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff to R with componentwise transport, replay, provenance, and local naming supplied by H, C, P, N, so the consumer receives no separate host completion, quotient function equality, open-cover compactness, or measure-integration carrier. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier regseqrat handoff totality`

Theorem 1526.9 (Riemann integral Darboux-RegSeqRat handoff)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier* $I = (M, T, F, S, D, G, R, H, C, P, N)$*, any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff read from* R *factors through the same finite* $\mathsf{DarbouxIntegral}^{\uparrow}$ *bracket row* D *and gap ledger* G *that compare the tagged sum* S *against the displayed mesh and tag data. A consumer cannot replace that route by a detached regular rational sequence, a host integral, or a completed real equality claim.*

Proof. Start with the real-seal boundary and the RegSeqRat handoff totality theorem. Theorems 1526.4 and 1526.8 place R downstream of M, T, F, S, D, G.

The Darboux bracket is fixed by the same displayed rows. Theorem 1526.3 supplies the step-function bracket row D, while Definition 1526.7 keeps the gap ledger G attached to that bracket and to the finite tagged sum S.

Finally apply the NameCert obligations and scope-closure package. Theorems 1526.2 and 1526.5 preserve the route through H, C, P, N, so a regular-rational or real-facing read has no coordinate outside the displayed Darboux and gap ledger chain. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier darboux regseqrat handoff`

Theorem 1526.10 (Riemann integral regular-Cauchy Darboux handoff)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier* $I = (M, T, F, S, D, G, R, H, C, P, N)$*, any integral-value consumer must first read the Darboux upper and lower rows in* D*, the dyadic mesh row* M*, the dyadic step-function bracket implicit in* D*, the finite tagged-sum row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback carried by* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the value is consumed. The handoff excludes selected partitions, quotient equality of functions, measure completion, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1526.1. The rows $M, T, F, S, D, G, R, H, C, P, N$ are the only source of an accepted Riemann integral read, so the mesh, tag, integrand, finite-sum, Darboux, gap, handoff, and structural data are all displayed.

Use the Darboux-step scope and Darboux-gap exactness theorems. Theorems 1526.3 and 1526.7 attach the upper and lower dyadic step-function bracket in D to the same $\mathsf{DyadicMesh}^{\uparrow}$ row M, tag row T, integrand reads F, finite sum S, and gap ledger G.

Next apply the RegSeqRat handoff and real-seal results. Theorems 1526.8, 1526.9, and 1526.4 force every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read through R after the Darboux and gap rows have already been exposed.

Finally repack by the NameCert obligations. Theorem 1526.2 supplies transport, replay, provenance, and local naming, while the carrier contains no coordinate for selected partitions, quotient function equality, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier regular cauchy darboux handoff`

Theorem 1526.11 (Riemann integral Cauchy route)**.** *Every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *read used as a Cauchy integral value factors through a finite tagged-gauge row, a Darboux upper/lower gap row, a* $\mathsf{RiemannIntegrable}^{\uparrow}$ *gap witness, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}$ *row. The route is the integration-facing path through chapter 4115, chapter 1880, and chapter 1960; it is not a prose-level integral value, a host limit, quotient equality of functions, selected partition data, or ambient real completeness.*

Proof. Project the carrier of Definition 1526.1. The tagged-mesh and finite-sum rows M, T, F, S supply the finite tagged-gauge surface, while the Darboux comparison and gap rows D, G supply the upper/lower gap evidence.

Next read the Cauchy-facing handoff. The $\mathsf{RiemannIntegrable}^{\uparrow}$ gap witness is the displayed integrability surface attached to that Darboux gap, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R is available only after the tagged-gauge, Darboux, and gap rows have been exposed.

Finally apply the existing handoff results. Theorems 1526.9 and 1526.10 keep the readback and terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same finite route, while Definition 1526.2 supplies hsame transport, Cont replay, Pkg provenance, and the local naming row. Since no excluded host object appears in the carrier, every Cauchy integral-value read factors through the displayed route. □

Theorem 1526.12 (Riemann integral mesh-refinement locality)**.** *Every mesh-refinement read admitted by a* $\mathsf{RiemannIntegral}^{\uparrow}$ *packet can only refine the displayed* $\mathsf{DyadicMesh}^{\uparrow}$ *row M and tag-containment row T, then replay the corresponding finite reads through $F, S, D, G, R, H, C, P, N$. It cannot introduce host function equality, a new tag family selected outside the packet, an open-cover compactness assertion, or an ambient integration theorem.*

Proof. Project the carrier through Definition 1526.1. The only mesh and tag coordinates are M and T, so any refinement request begins by replacing or subdividing those displayed rows.

Use tagged-sum totality and Darboux-step scope. Theorem 1526.6 requires S to be computed from M, T, F, and Definition 1526.3 keeps the Darboux comparison row D on the same mesh and tag route.

The gap, handoff, and structural rows then replay the refined route. Theorems 1526.7 and 1526.8 keep G and R downstream, while H, C, P, N preserve provenance and naming. Since no carrier row stores host function equality or an outside tag selector, locality is exactly the displayed refinement route. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralCarrier mesh refinement locality`

Theorem 1526.13 (Riemann integral tagged-sum ledger nonescape)**.** *For every accepted* $\mathsf{RiemannIntegral}^{\uparrow}$ *carrier $I = (M, T, F, S, D, G, R, H, C, P, N)$, the tagged-sum ledger exposes only the displayed values in F, the cell widths carried by M, tag containment from T, the finite sum row S, componentwise transport H, replay C, provenance P, and local NameCert row N. The tagged sum cannot export a hidden integrand, a host equality of functions, a measure-theoretic integral, or an ambient completeness witness.*

Proof. Read the tagged-sum row first. Theorem 1526.6 makes S total only over the displayed mesh row M, tag-containment row T, and integrand-read window F.

Attach the certificate surface. Theorem 1526.2 lists finite sum exactness, transport, replay, provenance, and local naming as explicit obligations, so the ledger is exhausted by M, T, F, S, H, C, P, N before any Darboux or real-facing handoff is read.

Finally use the scope package and real-seal boundary. Theorems 1526.5 and 1526.4 exclude quotient function equality, open-cover compactness, measure-integration carriers, and ambient completeness from the packet. Hence the tagged-sum ledger has no escape beyond the displayed finite rows. □

Theorem 1526.14 (Riemann integral public tagged-mesh certificate)**.** *The public export of a* $\mathsf{RiemannIntegral}^{\uparrow}$ *packet is exactly the tagged mesh, finite tag row, integrand-read window, finite-sum ledger, Darboux bracket, Darboux-gap ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise transport, displayed replay, provenance, and local* $\mathsf{NameCert}$ *route already scoped by this chapter. No public consumer receives a host function quotient, choice-selected tag family, open-cover compactness theorem, measure-space integral, or ambient completeness assertion.*

Proof. Project the carrier of Definition 1526.1. Its public-facing rows are $M, T, F, S, D, G, R, H, C, P, N$, so a consumer can inspect only the displayed dyadic mesh, tag containment, integrand reads, finite sum, Darboux comparison, gap ledger, handoff, transport, replay, provenance, and local naming data.

Apply the NameCert obligations, Darboux-step scope, and Real-seal boundary from Definition 1526.2, Definition 1526.3, and Definition 1526.4. These results force the route through tagged mesh, finite sum, Darboux bracket, gap, and real-facing handoff before any public read is exported.

Use the scope-closure package and tagged-sum ledger nonescape theorem, Definition 1526.5 and Definition 1526.13. They identify the same rows as the complete scoped certificate and exclude host function equality, selected tags, open-cover compactness, measure integration, and ambient completeness from the carrier. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralPacket public tagged mesh certificate`

Theorem 1526.15 (Riemann integral bridge-schema handoff)**.** *The public tagged mesh, finite tag row, integrand-read window, finite-sum ledger, Darboux bracket, Darboux-gap ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *route form the paper bridge surface for* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumers. Any standard bridge consumer must read a Riemann integral claim through exactly these displayed rows before comparing it with an outside integration presentation. The surface contains no host function quotient, no choice-selected tag family, no open-cover compactness proof, no measure-space carrier, and no ambient completeness theorem.*

Proof. Begin with Definition 1526.14. It identifies the public export of the packet with the tagged mesh, tag row, integrand reads, finite sum, Darboux bracket, gap ledger, real-facing handoff, transport, replay, provenance, and local naming data.

Next attach the finite bridge ingredients. The NameCert obligations of Definition 1526.2, the tagged-sum ledger nonescape theorem of Definition 1526.13, and the Darboux-step scope of Definition 1526.3 force every consumer-facing read through the displayed finite rows.

Finally use the real-seal and scope-closure boundaries, Definition 1526.4 and Definition 1526.5. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff inside the packet and leave no coordinate for quotient function equality, hidden tag selection, open-cover compactness, measure integration, or ambient completeness. Thus the named rows are exactly the paper bridge surface. □

Lean4 ✓ `BEDC.Derived.RiemannIntegralUp.RiemannIntegralUp StdBridge`

Theorem 1526.16 (Riemann integral mature package)**.** *The* $\mathsf{RiemannIntegral}^{\uparrow}$ *chapter exports a downstream comparison package whose rows are exactly the tagged-sum ledger, Darboux-gap ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, mesh-refinement locality route, public tagged-mesh certificate, and bridge-schema handoff displayed above. Any comparison consumer must read the route through*

$$M, T, F, S, D, G, R, H, C, P, N$$

before it compares a Riemann integral claim with another integration presentation. The package does not expose quotient equality of functions, choice-selected tags, open-cover compactness, measure-space integration, host completeness, or an additional paper-side closure obligation.

Proof. Start with the public tagged-mesh certificate of Definition 1526.14. It names $M, T, F, S, D, G, R, H, C, P, N$ as the public export surface for every $\mathsf{RiemannIntegral}^{\uparrow}$ packet.

Attach the finite computational rows. The tagged-sum totality and tagged-sum ledger nonescape theorems, Definition 1526.6 and Definition 1526.13, keep S over the displayed mesh, tag, and integrand-read rows.

Next attach the Darboux and regular-rational rows. The Darboux-gap exactness, RegSeqRat handoff totality, and Darboux-RegSeqRat handoff theorems, Definition 1526.7, Definition 1526.8, and Definition 1526.9, force G and R to remain downstream of the same tagged-mesh and Darboux bracket route.

Finally apply mesh-refinement locality and the bridge-schema handoff, Definition 1526.12 and Definition 1526.15. They make refinement and bridge comparison consume the same rows before any outside presentation is compared, while the carrier has no coordinate for the excluded host objects. Thus the listed rows form the mature downstream comparison package. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegral}^{\uparrow}$ packet is generated from a dyadic mesh row, finite tag containment row, integrand-read window, finite Riemann-sum row, Darboux comparison row, gap ledger, regular-rational and real-facing handoff, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1526.1, Definition 1526.2, Definition 1526.3, Definition 1526.4, Definition 1526.15, and Definition 1526.16 bind the carrier, NameCert obligations, Darboux-step scope, Real-seal boundary, paper bridge surface, and mature downstream comparison package for the tagged-mesh Riemann integration route over $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegral}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.RiemannIntegralUp.RiemannIntegralUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This chapter does not close host completeness, quotient real equality, open-cover compactness, measure-theoretic integration, Lean verification, or bridge checking.

Upgrade path: No further formal-axis upgrade remains for the recorded standard bridge.

Chapter 1527

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUnit}^{\uparrow}$

Following Bishop and Bridges constructive completion, and the Kelley-style unit map from a metric source into its Cauchy completion, the $\mathsf{CauchyCompletionUnit}^{\uparrow}$ packet records the finite BEDC certificate for sending source data to the completion-facing surface. It sits over the finite stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the metric-completion boundary of chapter 1506. The packet is the unit-map handoff from displayed source rows into completion consumers; it is not a quotient completion, not a selected representative, not countable choice, not open-cover compactness, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1527.1 (CauchyCompletionUnit carrier)**.** *A* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, S, D, R, E, M, H, C, P, N)$$

with the following visible rows:

1. *X is the source row whose displayed point, metric, or regular-Cauchy data are to be admitted into a completion-facing consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row obtained by reading the source data as a constant stream or as an already displayed finite window schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to answer finite precision requests before any completion handoff is accepted.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from S and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the displayed route through S, D, R has been admitted.*
6. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *target row that consumes the source-side route as the unit image.*
7. *H records componentwise* hsame *transport for the source, stream-window, dyadic ledger, regular readback, real seal, metric-completion target, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from source admission through constant-window generation, tolerance readback, real sealing, and completion-unit handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitTasteGate single carrier alignment`

Definition 1527.2 (CauchyCompletionUnit classifier)**.** *The classifier of two accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packets relates them exactly when their source rows agree after the displayed* hsame *transport, their finite stream windows are the same constant-window or scheduled-window reads, their dyadic tolerance ledgers and regular readbacks agree, and their completion target rows consume the same routed unit image under the stored* Cont *replay.*

Equivalently, the classifier is the finite route

$$X \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto M \longmapsto H, C, P, N.$$

It is not equality of quotient classes, not host equality of completed points, and not a choice of a canonical Cauchy representative.

Lean4 (definition) `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitClassifier`

Theorem 1527.3 (CauchyCompletionUnit NameCert obligations)**.** *For an accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *carrier* $U = (X, S, D, R, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnit}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed source, stream-window, dyadic ledger, regular readback, real seal, metric-completion target, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *unit-window generation, requiring each source read to enter the completion route through the constant stream or finite scheduled window stored in S;*
3. *tolerance and readback exactness, requiring every precision request to pass through D and then R before the real seal or completion target is consumed;*
4. *classifier stability, requiring transported packets with the same X, S, D, R, E, M route to be identified by the classifier of Definition 1527.2;*
5. *ledger non-escape, stating that no quotient completion equality, selected representative, countable-choice schedule, open-cover compactness principle, ambient completeness theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitNameCert obligations`

Proof. Carrier admission is projection from Definition 1527.1. The tuple lists exactly the source row, finite-window row, tolerance ledger, readback row, real seal, completion target, transport, replay, provenance, and local name.

Unit-window generation is constructive by induction on the finite request window. The empty window reads no source data, and the extension step appends the same source read to the displayed constant stream or preserves the next scheduled window already stored in S.

Tolerance and readback exactness then follow by tuple projection from D and R. The continuation row C replays this route before the seal E or completion target M can be inspected.

Classifier stability is componentwise hsame transport along H followed by the classifier definition. Since the carrier fields are exhausted by $X, S, D, R, E, M, H, C, P, N$, the excluded quotient, choice, compactness, ambient completeness, and real-completeness principles have no row from which a consumer could read them. □

Theorem 1527.4 (CauchyCompletionUnit dense embedding handoff)**.** *Every dense-embedding or completion-facing consumer of an accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packet factors through the finite unit route*

$$X \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto M.$$

The source row is therefore handed to the completion boundary as displayed finite BEDC data, not as a quotient class, not as a selected Cauchy representative, not as host equality, and not as an appeal to countable choice or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitCarrier dense embedding handoff`

Proof. Start with the source row X. A consumer cannot inspect the completion target before the unit route has displayed how the source read becomes a finite stream-window request.

The window row S is generated as a constant stream when the source read is a point input, or read as the existing finite schedule when the source is already presented by a regular-Cauchy name. Induction on the finite window gives the required handoff at each precision request.

The dyadic ledger D and regular readback R answer the request before any Real or completion-facing row is reached. The seal E is terminal for the real-facing part of the route, and M consumes only this displayed route as the unit image.

Finally H, C, P, N transport, replay, source, and name the same packet. No field contains quotient completion equality, a selected representative, host equality, countable choice, or ambient completeness, so the dense-embedding handoff exports only the finite unit route. □

Theorem 1527.5 (CauchyCompletionUnit real-completion consumer boundary)**.** *Let* $U = (X, S, D, R, E, M, H, C$ *be an accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of* U *must read the source through* S*, account for tolerance by* D*, obtain regular rational readback by* R*, and then consume the terminal seal* E *or the completion target* M *through the same replay row* C*.*

Thus the consumer boundary is the displayed finite route S, D, R, E, M *over* X*, with componentwise transport by* H *and provenance by* P, N*. It does not close quotient completion equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitCarrier real completion consumer boundary`

Proof. Project the accepted packet and read the consumer-facing rows. The source row X is available to $\mathsf{Real}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ consumers only through the stream-window row S.

Precision requests are then routed through D and R. The dyadic ledger records the requested scale, while the regular readback row records the finite rational response supplied by the displayed source windows.

The continuation row C replays this same route to E and M. Transport by H preserves the route componentwise, and the package and local name rows P, N record that the consumer is reading the same accepted unit packet.

Since every consumer-facing read has passed through S, D, R, E, M over X, and since the carrier has no coordinate for the excluded principles, the packet supplies only the finite real-completion boundary stated above. □

Theorem 1527.6 (CauchyCompletionUnit constant-window induction)**.** *Let* $U = (X, S, D, R, E, M, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packet, and let a consumer request a finite source window from the unit route. Before any* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$ *row can*

be read, every admitted source row is generated either as the stored constant-window $\mathsf{StreamName}^{\uparrow}$ *row or as the already scheduled finite-window* $\mathsf{StreamName}^{\uparrow}$ *row recorded in* S*.*

Consequently the visible prefix of every consumer read has the form

$$X \longmapsto S$$

before the tolerance ledger, regular readback, real seal, or completion target is available.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitCarrier constant window induction`

Proof. Induct on the finite request window. For the empty window, no source read is exposed, so the only available consumer prefix is the stored packet projection X, S.

For the extension step, assume the claim for a finite window W. A further request appends one displayed source read. If S is the constant-window row, the same source row X is appended as the next constant stream entry. If S is a scheduled-window row, the next scheduled entry already belongs to the finite row stored in S.

In both cases the appended read is still a $\mathsf{StreamName}^{\uparrow}$ read. The tuple order in Definition 1527.1 places D, R, E, M after S, and the replay row C records the same order. Thus no dyadic ledger, regular readback, real seal, or completion target can be inspected before the finite stream-window generation step has occurred. □

Theorem 1527.7 (CauchyCompletionUnit classifier stability)**.** *Let* $U = (X, S, D, R, E, M, H, C, P, N)$ *and* $U' = (X', S', D', R', E', M', H', C', P', N')$ *be accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packets. If componentwise* hsame *transport identifies the displayed source, stream-window, dyadic ledger, regular readback, real seal, completion target, continuation replay, provenance, and local naming rows, then the classifier of Definition 1527.2 identifies* U *and* U'*.*

The transport uses only the listed tuple components. It cannot introduce quotient completion equality, selected representatives, countable-choice schedules, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the two accepted packets componentwise. The hypotheses give hsame transport for X with X', S with S', D with D', R with R', E with E', M with M', and likewise for H, C, P, N.

Apply the classifier definition. It asks exactly that source rows agree after displayed transport, stream windows agree as constant-window or scheduled-window reads, dyadic ledgers and regular readbacks agree, and the completion targets consume the same routed unit image under the stored continuation replay.

No further coordinate remains in the carrier. Since quotient completion equality, selected representatives, countable choice, compactness, ambient completeness, and real completeness are explicitly absent from Definition 1527.1, componentwise transport has no row from which any of those principles could be generated. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitCarrier classifier stability`

Theorem 1527.8 (CauchyCompletionUnit dense embedding universal route)**.** *Every dense-embedding or completion-universal-property consumer of an accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *packet factors through the finite unit route*

$$X \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto M.$$

Thus consumers of chapter 1453, chapter 1512, and chapter 397 can use the unit packet only after the source row has been routed through the stream window, tolerance ledger, regular readback, real seal, and metric-completion target displayed by the packet.

Proof. Start with a consumer asking for a dense-embedding or completion-universal-property handoff. The consumer receives only an accepted $\mathsf{CauchyCompletionUnit}^{\uparrow}$ packet, so its available data are the tuple components listed in Definition 1527.1.

The constant-window induction of Definition 1527.6 supplies the first step $X \mapsto S$. The dyadic ledger and regular readback projections then force every tolerance request through D and R before any real-facing or completion-facing row is consumed.

The terminal seal E and completion target M are reached only by the continuation replay C. Componentwise transport by H preserves the same route, while P and N record the provenance and local name of the packet being consumed.

Therefore any consumer in the cited dense-embedding, completion-embedding, or universal-property chapters factors through X, S, D, R, E, M. Since the packet has no quotient, selected-representative, countable-choice, compactness, ambient-completeness, or $\mathsf{Real}^{\uparrow}$-completeness coordinate, the factorization exports only this finite unit route. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitCarrier dense embedding universal route`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnit}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature finite unit-map treatment includes the carrier, classifier, NameCert obligations, dense-embedding handoff, real-completion consumer boundary, constant-window induction, classifier stability, dense-embedding universal route, constructive story, and nonescape exclusions over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnit}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyCompletionUnitUp.CauchyCompletionUnitNameCert\_obligations`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: A checked standard bridge would upgrade the verification axis for the same public unit-map certificate surface without adding quotient completion equality, selected representatives, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Constructive story: The construction starts from a displayed source row, generates finite constant or scheduled stream windows, routes tolerance requests through DyadicRatCore and RegSeqRat readback, reaches the Real seal, and hands the same route to MetricCompletion consumers as the unit image.

Chapter 1528

A Concrete Naming Certificate for $\mathsf{RegularCauchyMin}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMin}^{\uparrow}$ packet reads the pointwise minimum of two regular Cauchy real names by a finite selector over displayed rational windows. The certificate sits beside the maximum and absolute-value surfaces of chapter 1502 and chapter 1499, uses the regular rational readback of chapter 301, and seals only through the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. It does not compare completed reals by host trichotomy, quotient streams, selected limits, or ambient completeness.

Definition 1528.1 (RegularCauchyMin carrier)**.** *A* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

with the following visible coordinates:

1. *A and B are the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name rows.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to observe both sources at the same finite precision requests.*
3. *D_A and D_B are the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-and-tolerance rows read from the shared window schedule for the two sources.*
4. *J is the comparison-selector row whose finite alternatives are $A \preceq_W B$ and $B \preceq_W A$ on the displayed dyadic window data.*
5. *S is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *selector row: in the first alternative it replays the A windows, and in the second alternative it replays the B windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the selected windows and the displayed tolerance ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the readback row R has been exposed.*
8. *H records componentwise* hsame *transport for the two sources, the shared window, dyadic observations, selector row, selected regular row, readback, seal, provenance, and local name.*
9. *C records the displayed* Cont *routes from the sources to the shared windows and dyadic rows, through the selector row, through the selected regular row, and onward to the readback and real seal.*

10. *P records* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyMax}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *row.*

The carrier has no coordinate for host trichotomy on completed real names, quotient stream equality, selected limits, or a $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinTasteGate single carrier alignment`

Theorem 1528.2 (RegularCauchyMin NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *surface for Definition 1528.1 consists exactly of two-source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, shared* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance observations, the displayed comparison-selector row, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from the displayed packet M. The coordinates expose the two source regular names, their shared stream window, their dyadic endpoint-and-tolerance rows, the selector row, the selected regular row, the readback, the real seal, and the structural rows.

The operation obligation is finite because the only branch point is the displayed row J. In the $A \preceq_W B$ alternative, the selected row S replays the A windows and their tolerance ledger; in the $B \preceq_W A$ alternative, it replays the B windows and their tolerance ledger.

The sibling operation surfaces provide the algebraic checks used by consumers that prefer an identity route. The $\mathsf{RegularCauchyMax}^{\uparrow}$ and $\mathsf{RegularCauchyAbs}^{\uparrow}$ certificates already expose finite window transport for lattice-facing regular Cauchy operations, so the minimum packet can route compatibility checks through the same displayed-window, tolerance-ledger, readback, and seal surfaces without importing host order on completed reals.

The rows H, C, P, N transport, replay, source, and name this same finite route. No clause asks for trichotomy, quotient stream equality, a selected limiting real, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier namecert obligations`

Theorem 1528.3 (RegularCauchyMin selector ledger exactness)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier* $M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$*, every selector-facing consumer factors through exactly one of the two displayed selector alternatives in* J*. In the* $A \preceq_W B$ *case the selected regular row* S *is the finite replay of* A *on* W, D_A*; in the* $B \preceq_W A$ *case* S *is the finite replay of* B *on* W, D_B*. No further comparison data are exported.*

Proof. Begin with a selector-facing consumer of the accepted packet. The carrier gives it only the two source rows, the shared window, the two dyadic observation ledgers, and the displayed selector row.

Case-split on J. In the $A \preceq_W B$ branch, the continuation route in C points from A, W, D_A to the selected row S, and the transport row H preserves that same selected replay componentwise. Thus the readback data downstream of S are exactly the A window data recorded in the packet.

In the $B \preceq_W A$ branch, the same argument uses B, W, D_B. The selected row S is then the finite replay of the second source and its displayed tolerance ledger.

There is no third branch and no hidden comparison coordinate in Definition 1528.1. Hence the selector ledger is exhausted by the two displayed alternatives and exports no host trichotomy, quotient stream equality, selected limit, or completeness witness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinSelector ledger exactness`

Theorem 1528.4 (RegularCauchyMin selector idempotence)**.** *Let*

$$M = (A, A, W, D_A, D_A, J, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier whose two source rows are componentwise the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row over the shared* $\mathsf{StreamName}^{\uparrow}$ *window and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. Then both displayed selector alternatives replay that same source row through* W, D_A, D_A, J, S, R, E*. Consequently the minimum packet exposes the original* $\mathsf{Real}^{\uparrow}$ *seal route and no additional comparison coordinate.*

Proof. Apply Definition 1528.3. In the first selector alternative, S is the finite replay of the first source through W, D_A. Since the second source row and the second dyadic ledger are componentwise the same displayed data, this is the original regular Cauchy row.

In the second selector alternative, the same ledger identifies S as the replay of the second source through W, D_A. The displayed equality of the two source rows and ledgers makes this the same selected row, with the same readback R and terminal seal E.

Use Definition 1528.9 to keep this selected row fixed under the componentwise transport recorded by H, and use Definition 1528.7 to read the downstream order-facing route only through S, R, E. Thus idempotence is witnessed inside the existing selector ledger, not by a new host comparison coordinate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinSelector idempotence certificate`

Theorem 1528.5 (RegularCauchyMin lattice absorption)**.** *Any lattice-facing consumer that combines the* $\mathsf{RegularCauchyMax}^{\uparrow}$ *and* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *sibling routes with an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier must read absorption through the same displayed windows* W*, dyadic ledgers* D_A, D_B*, selector row* J*, selected row* S*, readback* R*, and seal* E*. The absorption route therefore remains a finite BEDC ledger over the visible regular Cauchy data, not a host trichotomy or quotient equality principle for completed real names.*

Proof. Start with the minimum carrier and read its selector ledger. By Definition 1528.3, every branch of the minimum route is already one of the two displayed replays through W, D_A or W, D_B.

The sibling $\mathsf{RegularCauchyMax}^{\uparrow}$ and $\mathsf{RegularCauchyAbs}^{\uparrow}$ chapters supply the max and absolute-value routes used by lattice consumers, but they are consumed as provenance-facing sibling surfaces named in P, not as hidden coordinates of M. Therefore an absorption check can only combine their visible regular Cauchy windows with the minimum selector route already exposed here.

Apply Definition 1528.7 to force the order-facing read through J, S, R, E, and apply Definition 1528.9 to preserve the same branch under componentwise transport. The resulting absorption surface is the displayed-window and dyadic-ledger route shared by the three sibling operations; it does not introduce host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier lattice absorption`

Theorem 1528.6 (RegularCauchyMin selector monotonicity obligation)**.** *Let*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier. If the displayed selector row* J *chooses* A *over* B*, then every* $\mathsf{RealAlgOrder}^{\uparrow}$*-facing consumer reads a minimum row bounded by the selected source through* W, D_A, S, R, E*. If* J *chooses* B *over* A*, the same bounded route is read through* W, D_B, S, R, E*. Moreover, any componentwise transport that preserves the selected row preserves the same monotone branch for transported packets.*

Proof. Case-split on the displayed selector row J. In the $A \preceq_W B$ branch, Definition 1528.3 identifies S as the replay of the first source through the shared window W and the dyadic ledger D_A. The downstream rows R and E therefore expose a minimum row bounded by the selected source, and the order-facing consumer reaches it through the route named in Definition 1528.7.

In the $B \preceq_W A$ branch, the same ledger exactness identifies S as the replay of the second source through W, D_B. The handoff route again passes through S, R, E, so the consumer receives the second selected source as the finite minimum row.

For transported packets, apply Definition 1528.9. Componentwise transport preserves the selected row, readback, real seal, and selector alternative together. Hence the same branch remains monotone after transport, without adding host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier selector monotonicity`

Theorem 1528.7 (RegularCauchyMin RealAlgOrder handoff)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$*-facing use of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier reaches the minimum row through the finite route*

$$(A, B, W, D_A, D_B) \longrightarrow J \longrightarrow S \longrightarrow R \longrightarrow E.$$

The handoff is therefore a regular Cauchy selector ledger over shared windows and dyadic tolerance observations, not a host-order comparison of completed real names.

Proof. Start with a $\mathsf{RealAlgOrder}^{\uparrow}$-facing consumer. The only real-facing endpoint in the carrier is the seal row E, and E is downstream of the readback row R.

By Definition 1528.3, the readback row R is downstream of a selected regular row S obtained by case-splitting only on the displayed selector row J. Each selector branch uses the same shared window schedule and one of the two displayed dyadic tolerance ledgers.

The handoff to order-facing consumers is therefore the listed finite route. Compatibility with existing lattice surfaces can be checked against the sibling $\mathsf{RegularCauchyMax}^{\uparrow}$ and $\mathsf{RegularCauchyAbs}^{\uparrow}$ routes, but the minimum packet itself does not expose host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier realalgorder handoff`

Theorem 1528.8 (RegularCauchyMin carrier admission obligation)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

carrier admission is exactly the admission of the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows* A, B*, the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers* D_A, D_B*, the selector row* J*, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, the* hsame *transport row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *row* N*. No admitted carrier has a further host-order, quotient-stream, selected-limit, or completeness coordinate.*

Proof. Project the displayed tuple M. The first projections expose the two regular rational source names, the shared finite window, and the two dyadic endpoint-and-tolerance ledgers.

Case-split on J. In the $A \preceq_W B$ branch, the selector admits S as the replay of the A source through W, D_A; in the $B \preceq_W A$ branch, it admits S as the replay of the B source through W, D_B.

The remaining projections expose the readback R, the terminal real seal E, the componentwise transport row H, the displayed continuation row C, the provenance row P, and the local naming

row N. This list is the full carrier inventory, so no hidden comparison or completion coordinate is available. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier admission obligation`

Theorem 1528.9 (RegularCauchyMin selector transport stability)**.** *Let*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier. Any componentwise* hsame *transport recorded in* H *preserves the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*, the downstream readback* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the same selector alternative in* J *over the transported* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Inspect the componentwise transport row H. It transports the two source rows, the shared window row, both dyadic ledgers, the selector row, the selected regular row, the readback, the seal, provenance, and local name together.

Case-split on J. In the $A \preceq_W B$ branch, transport carries the selected replay of A through the transported W, D_A rows, so S, R, and E remain downstream of the first source. In the $B \preceq_W A$ branch, the same argument carries the selected replay of B through the transported W, D_B rows.

The continuation row C replays the transported route in the same order, and P, N only record provenance and local naming. Thus selector transport is stable without adding host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier selector transport stability`

Theorem 1528.10 (RegularCauchyMin source-swap invariance)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

exchanging the two source rows A, B *together with their paired dyadic ledgers* D_A, D_B *only exchanges the two displayed selector branches. The selected row* S*, readback row* R*, and seal route* E *remain the same finite route after branch relabeling.*

Proof. By Definition 1528.3, the carrier exposes exactly the two selector alternatives listed by J: one branch replays A through W, D_A, and the other replays B through W, D_B. Swapping the paired source-and-ledger rows therefore has no third branch to enter.

Apply Definition 1528.9 to the componentwise transport that exchanges the two source rows and their dyadic ledgers while preserving the shared window, selected row, readback, seal, continuation, provenance, and local naming rows. The theorem keeps S, R, and E fixed along that transported carrier route; only the displayed name of the selector alternative changes.

Finally, Definition 1528.7 identifies the downstream order-facing path as the same finite chain through J, S, R, E. Hence the source-swap operation relabels the selector display but leaves the exported row, readback, and real seal route invariant. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier source swap invariance`

Theorem 1528.11 (RegularCauchyMin real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

reaches the seal row E only through

$$A, B, W, D_A, D_B, J, S, R.$$

The packet exports no host trichotomy on completed real names, no quotient stream equality, no selected limiting real, no hidden use of $\mathsf{RegularCauchyMax}^{\uparrow}$ *or* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *as an extra carrier coordinate, and no ambient completeness claim.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinRealSealNonescape`

Proof. Start with a Real-facing consumer. The carrier has only one Real endpoint, namely E, and the definition places E downstream of the selected regular row S and readback row R.

Case-split on J. In the first branch, S is obtained from A, W, D_A; in the second branch, S is obtained from B, W, D_B. Both branches still expose the two source rows and the shared window before the selected readback is consumed.

The sibling $\mathsf{RegularCauchyMax}^{\uparrow}$ and $\mathsf{RegularCauchyAbs}^{\uparrow}$ packets may be cited by later algebraic consumers for compatibility, but they are not additional projections of M. Since H, C, P, N only transport, replay, source, and name the same route, the Real seal cannot escape the finite selector ledger. □

Theorem 1528.12 (RegularCauchyMin obligation classifier scope)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

the classifier for accepted minimum packets is exhausted by the selected $\mathsf{RegSeqRat}^{\uparrow}$ *row S, the readback row R, and the* $\mathsf{Real}^{\uparrow}$ *seal E under the displayed selector J. No classifier-facing consumer can read an additional host-order comparison, quotient-stream equality, selected-limit row, or ambient completeness witness from the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier obligation classifier scope`

Proof. Start with carrier admission, Definition 1528.8. It lists all projections of the displayed tuple and exposes no classifier coordinate beyond the selector, selected regular row, readback, seal, transport, replay, provenance, and local name rows.

Apply selector ledger exactness, Definition 1528.3. The selected row S is obtained by one of the two displayed alternatives in J, and each alternative replays one source row through the shared window and its dyadic tolerance ledger.

Finally use the RealAlgOrder handoff, Definition 1528.7. Any order-facing classifier read must pass through J, S, R, E, so the classifier surface is exhausted by those rows and cannot export a hidden comparison or completion datum. □

Theorem 1528.13 (RegularCauchyMin selector stability scope)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier, componentwise* hsame *transport and displayed* Cont *replay preserve the chosen selector branch, its dyadic tolerance ledger, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinSelector stability scope`

Proof. Use selector transport stability, Definition 1528.9. The row H transports the two sources, the shared window, the two dyadic ledgers, the selector, the selected regular row, readback, seal, provenance, and local name together.

Case-split on the displayed selector row J. In the $A \preceq_W B$ branch, transport preserves the replay through W, D_A; in the $B \preceq_W A$ branch, it preserves the replay through W, D_B.

The continuation row C replays that transported route in the same order. Hence selector stability is scoped to the displayed branch and tolerance ledger, with no extra host-order, quotient, limit, or completeness coordinate. □

Theorem 1528.14 (RegularCauchyMin dyadic-order scope)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$*-facing minimum read of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

must expose the two $\mathsf{RegSeqRat}^{\uparrow}$ *sources* A, B*, the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers* D_A, D_B*, the selector row* J*, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*, the readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before any order-facing consumer sees the minimum. The exposed route is the displayed L10 chain*

$$(A, B, W, D_A, D_B) \longrightarrow J \longrightarrow S \longrightarrow R \longrightarrow E,$$

with componentwise hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *row* N *attached to the same chain. It exports no host trichotomy, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier dyadic order scope`

Proof. Project the accepted carrier. The tuple already displays the two regular Cauchy sources, shared stream window, dyadic tolerance ledgers, selector row, selected regular row, readback, real seal, transport, replay, provenance, and local name.

Use selector ledger exactness, Definition 1528.3. It forces the selector row J to choose one of the two visible source routes and to produce S from the corresponding dyadic ledger while keeping both A and B in the exposed packet.

Apply selector transport stability, Definition 1528.13. The same branch, tolerance ledger, selected row, readback row, and real seal are preserved under componentwise hsame transport and displayed Cont replay.

Finally route the read through the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff, Definition 1528.7. Since an order-facing consumer reaches the minimum only after J, S, R, E have been displayed, and since P, N name only the listed sources, no host trichotomy, quotient stream equality, selected limit, or ambient completeness witness is exported. □

Theorem 1528.15 (RegularCauchyMin provenance scope)**.** *The* Pkg *and* NameCert *rows of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier cite only* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegularCauchyMax}^{\uparrow}$*,* $\mathsf{RegularCauchyAbs}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *as source surfaces for the finite minimum packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier provenance scope`

Proof. Read the provenance coordinate P in Definition 1528.1. Its source list is exactly the two regular rational source surfaces, the shared stream window, the dyadic tolerance rows, the sibling maximum and absolute-value operation surfaces, the real seal boundary, and the structural BHist, hsame, Cont, and NameCert rows.

The local naming coordinate N records the same packet as $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$. By Definition 1528.2, this naming row is tied to the displayed carrier inventory and not to an unlisted comparison or completion principle.

Apply real seal non-escape, Definition 1528.11. Since every real-facing read reaches E only through the displayed selector ledger, the provenance row has no hidden source beyond the listed finite surfaces. □

Theorem 1528.16 (RegularCauchyMin obligation closure route)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

the carrier admission row, selector ledger exactness, selector monotonicity, $\mathsf{RealAlgOrder}^{\uparrow}$ *handoff, transport stability, Real-seal nonescape, classifier scope, and provenance scope exhaust the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *obligation surface. No host trichotomy on completed real names, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row remains outside those displayed obligations.*

Proof. Start with carrier admission, Definition 1528.8. It fixes the visible packet as the two source $\mathsf{RegSeqRat}^{\uparrow}$ rows, the shared $\mathsf{StreamName}^{\uparrow}$ window, the two $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, the selector row, the selected regular row, readback, seal, transport, replay, provenance, and local name.

Use selector ledger exactness and selector monotonicity, Definition 1528.3 and Definition 1528.6. They force every selector-facing read through one of the two displayed alternatives and keep the selected branch bounded along the same window and tolerance rows.

Apply the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff and transport-stability rows, Definition 1528.7 and Definition 1528.9. These place order-facing consumers downstream of J, S, R, E and preserve the same route under componentwise hsame transport and displayed Cont replay.

Finally combine real seal nonescape, classifier scope, selector stability scope, and provenance scope: Definition 1528.11, Definition 1528.12, Definition 1528.13, and Definition 1528.15. Their source lists leave no carrier coordinate for host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier obligation closure route`

Theorem 1528.17 (RegularCauchyMin shared-window scope)**.** *Every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *selector read must expose the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source readbacks* A, B*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows* D_A, D_B*, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison row used by* J*, the sibling* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *and* $\mathsf{RegularCauchyMax}^{\uparrow}$ *rows named by* P*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *row* N *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. The scope exports only this shared finite window; it does not expose quotient streams, host minimum on completed real names, trichotomy, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier shared window scope`

Proof. Project the accepted carrier $M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$. The carrier inventory already lists the two regular rational source rows, the shared window, dyadic endpoint-and-tolerance rows, selector row, selected regular row, readback row, real seal, and structural rows.

Use selector transport stability and real-seal nonescape. The transport theorem keeps W, D_A, D_B, J, S, R, E tied together under componentwise hsame, while nonescape forces every $\mathsf{Real}^{\uparrow}$-facing read of E through the displayed selector ledger.

Apply the classifier-scope and provenance-scope theorems. The classifier surface is exhausted by J, S, R, E, and the provenance row names only $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyMax}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, and NameCert surfaces.

Thus a selector consumer must expose the shared window, dyadic tolerance rows, order comparison, sibling operation rows, transport, replay, provenance, and local naming before it consumes the real seal. No quotient stream, host minimum, trichotomy, or ambient completeness row is present in the carrier. □

Theorem 1528.18 (RegularCauchyMin apartness selector scope)**.** *Every apartness-facing read of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

must pass through the shared $\mathsf{StreamName}^{\uparrow}$ *window* W*, the dyadic ledgers* D_A, D_B*, the selector row* J*, the selected row* S*, the readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. Any citation of* $\mathsf{RealAlgOrder}^{\uparrow}$ *is available only through the displayed selector route*

$$(A, B, W, D_A, D_B) \longrightarrow J \longrightarrow S \longrightarrow R \longrightarrow E.$$

Thus the packet supports apartness-facing minimum reads without exporting host trichotomy of completed reals, quotient streams, selected limits, or ambient completeness.

Proof. Start with the selector ledger exactness theorem, Definition 1528.3. It forces every selector-facing consumer to choose one of the two displayed branches in J and to read the selected row S from the shared window and the corresponding dyadic ledger.

Use selector monotonicity and the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff, Definition 1528.6 and Definition 1528.7. They place every order-facing read downstream of the same J, S, R, E chain, with the selected dyadic ledger still visible.

Apply selector stability scope and shared-window scope, Definition 1528.13 and Definition 1528.17. These keep W, D_A, D_B, J, S, R, E tied together under componentwise transport and displayed replay.

An apartness-facing consumer can therefore cite order information only through that displayed selector route. Since the carrier has no host trichotomy, quotient stream, selected-limit, or ambient-completeness coordinate, none is exported by the apartness read. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier apartness selector scope`

Theorem 1528.19 (RegularCauchyMin kernel scope route)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

every public minimum-selector read factors through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ *source rows* A, B*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *order-and-tolerance rows* D_A, D_B*, the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *and* $\mathsf{RegularCauchyMax}^{\uparrow}$ *comparison siblings named by* P*, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness-and-order handoff at* J*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *row* N *before any minimum consumer reads the result. The scoped route exports no host trichotomy on completed real names, quotient stream equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with selector ledger exactness, Definition 1528.3. It forces every minimum-selector read to inspect the two source rows, the shared window, the dyadic tolerance rows, and the selector row before the selected regular row can be consumed.

Apply the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff and dyadic-order scope, Definition 1528.7 and Definition 1528.16. These routes keep the apartness-and-order read attached to J, S, R, E and to the displayed dyadic tolerance ledgers rather than to a host trichotomy principle.

Next use shared-window scope and apartness-selector scope, Definition 1528.17 and Definition 1528.18. They keep W, D_A, D_B, J, S, R, E visible together with the sibling $\mathsf{RegularCauchyAbs}^{\uparrow}$ and $\mathsf{RegularCauchyMax}^{\uparrow}$ comparison rows named by provenance.

Finally apply selector transport stability and provenance scope, Definition 1528.9 and Definition 1528.15. The structural rows H, C, P, N transport, replay, source, and name the same finite kernel route, so a public minimum consumer cannot bypass the displayed rows into quotient stream equality, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier kernel scope route`

Theorem 1528.20 (RegularCauchyMin public NameCert export)**.** *For every accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N),$$

the carrier inventory, selector ledger exactness, idempotence, lattice absorption, selector monotonicity, $\mathsf{RealAlgOrder}^{\uparrow}$ *handoff, classifier scope, dyadic-order scope, apartness selector scope, and kernel scope route assemble a public* $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ *export over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyMax}^{\uparrow}$, *and* $\mathsf{RegularCauchyAbs}^{\uparrow}$. *The export is exactly the displayed finite selector surface and does not introduce host trichotomy, quotient stream equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier public namecert`

Proof. Start from the carrier and obligation surface of Definition 1528.1 and Definition 1528.2. These rows display the two source $\mathsf{RegSeqRat}^{\uparrow}$ reads, the shared $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, the selector, selected readback, terminal $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local naming.

Use selector ledger exactness, idempotence, lattice absorption, and selector monotonicity from Definition 1528.3, Definition 1528.4, Definition 1528.5, and Definition 1528.6. These bind the selector row to the displayed alternatives and to the sibling maximum and absolute-value surfaces rather than to a host minimum operator.

Apply the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff, classifier scope, dyadic-order scope, apartness selector scope, and kernel scope route of Definition 1528.7, Definition 1528.12, Definition 1528.16, Definition 1528.18, and Definition 1528.19. They keep every public read inside the same finite route through $D_A, D_B, W, J, S, R, E, H, C$

The public export is therefore the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ row attached to that route. Since no carrier coordinate contains host trichotomy, quotient stream equality, selected limits, or ambient completeness, the export cannot supply any of those principles. □

Theorem 1528.21 (RegularCauchyMin public selector export)**.** *Every* $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, *or finite-net L10 consumer of an accepted* $\mathsf{RegularCauchyMin}^{\uparrow}$ *packet must read the public selector surface through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, the selector row, the selected readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal,*

and the sibling $\mathsf{RegularCauchyMax}^{\uparrow}$ *and* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *comparison routes before interval or finite-net data are exported. The export route is therefore*

$$A, B, W, D_A, D_B, J, S, R, E, H, C, P, N$$

together with the sibling comparison rows named in P*, and it contains no host trichotomy, quotient stream equality, selected limit, ambient completeness row, or hidden interval endpoint choice.*

Proof. Begin with the selector ledger and kernel scope route. By Definition 1528.3 and Definition 1528.19, every accepted selector read displays the two $\mathsf{RegSeqRat}^{\uparrow}$ sources, the shared $\mathsf{StreamName}^{\uparrow}$ window, the two $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers, the selector row J, the selected row S, the readback R, and the terminal seal E.

Next apply the public NameCert export of Definition 1528.20. It attaches H, C, P, N to the same finite selector route and keeps the sibling $\mathsf{RegularCauchyMax}^{\uparrow}$ and $\mathsf{RegularCauchyAbs}^{\uparrow}$ comparison surfaces visible as provenance-facing routes, not as unlisted carrier coordinates.

For a $\mathsf{RealInterval}^{\uparrow}$ consumer, the terminal $\mathsf{Real}^{\uparrow}$ seal can be used only after the selector route has reached E and the sibling comparison rows named by P have been exposed. The interval read therefore receives a sealed Real-name boundary, not a host-selected endpoint or a quotient stream.

For a $\mathsf{DyadicIntervalNet}^{\uparrow}$ or finite-net L10 consumer, use the finite-cell route already visible in the dyadic tolerance ledgers and shared stream window. Since $D_A, D_B, W, J, S, R, E, H, C, P, N$ are the only exported rows, the finite-net data are read after the selector surface and its sibling comparison routes, with no additional completeness or endpoint-choice principle. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier public selector export`

Theorem 1528.22 (RegularCauchyMin apartness stability)**.** *Let*

$$M = (A, B, W, D_A, D_B, J, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMin}^{\uparrow}$ *carrier. Suppose the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* A, B *are classifier-stable under the displayed* $\mathsf{StreamName}^{\uparrow}$ *window* W *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers* D_A, D_B*, and suppose the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness rows for the two sources are transported through the sibling* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *and* $\mathsf{RegularCauchyMax}^{\uparrow}$ *routes named by* P*.*

Then the pointwise minimum packet preserves the $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and the* $\mathsf{Real}^{\uparrow}$ *apartness boundary. In the* $A \preceq_W B$ *branch it preserves the classifier and apartness boundary by replaying the* A *row through* S, R, E*; in the* $B \preceq_W A$ *branch it does the same through the* B *row. The exported route contains no host trichotomy, quotient stream equality, selected limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier apartness stability`

Proof. Case-split on the displayed selector row J. In the $A \preceq_W B$ branch, selector ledger exactness identifies S with the replay of the A source through W, D_A. The assumed classifier stability for A therefore transports directly to the selected $\mathsf{RegSeqRat}^{\uparrow}$ row and then to the readback R.

The apartness boundary in this branch is read through the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff and the sibling $\mathsf{RegularCauchyAbs}^{\uparrow}$ and $\mathsf{RegularCauchyMax}^{\uparrow}$ routes named by provenance. These rows are already transported componentwise, so the terminal $\mathsf{Real}^{\uparrow}$ seal E receives the same apartness boundary as the selected A row.

In the $B \preceq_W A$ branch, the same argument uses the B source and the dyadic ledger D_B. Selector ledger exactness identifies the selected row, and the transported absolute-value and maximum routes carry the apartness boundary through the same S, R, E chain.

Finally apply selector transport stability and the public NameCert export. They keep H, C, P, N attached to the displayed minimum route and prevent any hidden comparison coordinate from entering. Thus the pointwise minimum preserves both the regular Cauchy classifier and the Real apartness boundary without using host trichotomy, quotient stream equality, selected limits, or ambient completeness. □

Theorem 1528.23 (RegularCauchyMin formal target handoff)**.** *The public minimum selector surface consumed by future formal targets is exactly the finite chain through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchyMax}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *already assembled by the checked carrier, selector, handoff, stability, nonescape, scope, and export obligations of this chapter. A formal target may read the selected minimum only after the source regular names, shared window, dyadic tolerance rows, selector branch, selected readback, real seal, transport, replay, provenance, and local naming rows have all been displayed, and it receives no host trichotomy, quotient stream equality, selected limit, hidden completion row, or extra order primitive.*

Proof. Start with the public NameCert export, Definition 1528.20. It packages the two $\mathsf{RegSeqRat}^{\uparrow}$ sources, shared $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, selector row, readback, $\mathsf{Real}^{\uparrow}$ seal, and local $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$ row into one public surface.

Apply the kernel scope route of Definition 1528.19. This route inserts the sibling $\mathsf{RegularCauchyAbs}^{\uparrow}$ and $\mathsf{RegularCauchyMax}^{\uparrow}$ comparison surfaces and the $\mathsf{RealAlgOrder}^{\uparrow}$ handoff exactly where the selector branch is read, while keeping BHist, hsame, Cont, and Pkg visible as structural rows.

Finally use apartness stability, Definition 1528.22, together with real seal nonescape, Definition 1528.11. They keep the selected branch and the terminal real boundary inside the displayed chain. Since the carrier has no coordinate for host trichotomy, quotient streams, selected limits, completion, or an extra order primitive, future formal targets inherit exactly this public selector surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinUp.RegularCauchyMinCarrier formal target handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMin}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName window schedule, DyadicRatCore endpoint-and-tolerance observations, a comparison-selector row, a selected RegSeqRat row, a RegSeqRat readback row, a RealUp seal row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1528.19 binds every public minimum-selector read to the displayed RegSeqRat sources, DyadicRatCore order-and-tolerance rows, RegularCauchyAbs and RegularCauchyMax siblings, RealAlgOrder handoff, StreamName window, RealUp seal, transport, replay, provenance, and local naming before any consumer reads the result.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyMin}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host trichotomy on completed real names, quotient stream equality, selected limits, ambient completeness, or a public standard bridge.

Upgrade path: Public closure requires a checked consumer-facing route for the same selector surface without adding host trichotomy, quotient equality, selected limits, or completeness.

Chapter 1529

A Concrete Naming Certificate for $\mathsf{CauchyProductBounded}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyProductBounded}^{\uparrow}$ packet records the bounded-product surface for two bounded Cauchy sequence packets before the product is exposed as a regular rational sequence or a real seal. It refines the product route of $\mathsf{CauchyProduct}^{\uparrow}$ from chapter 464 with the two bounded-source ledgers of $\mathsf{CauchySequenceBounded}^{\uparrow}$ from chapter 1522, then routes the result through $\mathsf{RegSeqRat}^{\uparrow}$ from chapter 301 and $\mathsf{Real}^{\uparrow}$ from chapter 38. The packet contains no host multiplication on completed reals, quotient stream representative, selected product limit, countable choice, or ambient completeness principle.

Definition 1529.1 (Cauchy product bounded carrier)**.** *A* $\mathsf{CauchyProductBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (X, Y, P, W, D, R, E, B, H, C, L, N)$$

with the following displayed rows:

1. *X and Y are accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packets, carrying the two stream schedules, Cauchy-modulus rows, dyadic tolerance ledgers, regular-rational handoffs, real-seal rows, and explicit bound ledgers for the factors.*

2. *P is the accepted* $\mathsf{CauchyProduct}^{\uparrow}$ *route whose product observation is read only from the two factor schedules and dyadic product ledger.*

3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule aligning the two bounded factor windows with the product window used by P.*

4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and magnitude ledger containing the two factor bounds, the product tolerance row, and the finite cross-error budget used to compare the product read.*

5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row that receives the product readback after X, Y, P, W, D have been displayed.*

6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the product, consumed only after the bounded-source rows, product route, dyadic ledger, and regular-rational classifier row are present.*

7. *B is the product-bound ledger, recording the two source bounds, the product-bound row, and the reconciliation row saying that the product read remains inside the displayed dyadic or rational bound.*

8. *H stores componentwise* hsame *transport for $X, Y, P, W, D, R, E, B, C, L, N$ and the local packet shape.*
9. *C stores displayed* Cont *replay from bounded-source reads to product windows, from product windows to dyadic tolerances, from tolerances to the product bound, and from the bound ledger to the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows.*
10. *L is the* Pkg *provenance over* $\mathsf{CauchyProductBounded}^{\uparrow}$, $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, P, W, D, R, E, B, H, C, L, N$. It has no coordinate for host real multiplication, quotient-stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1529.2 (Cauchy product bounded NameCert obligations)**.** *For an accepted* $\mathsf{CauchyProductBounded}^{\uparrow}$ *carrier $Z = (X, Y, P, W, D, R, E, B, H, C, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}$ *obligations are exactly carrier admission, bounded-source admission for X and Y, product-route admission for P, shared-window exactness for W, dyadic product-bound stability for D and B,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier handoff for R,* $\mathsf{Real}^{\uparrow}$ *seal handoff for E, componentwise transport and continuation replay through H and C, provenance through L, and ledger non-escape through N.*

Proof. Carrier admission is the projection of the displayed tuple in Definition 1529.1. The first two coordinates are accepted $\mathsf{CauchySequenceBounded}^{\uparrow}$ packets, so each factor already exposes a stream schedule, modulus row, dyadic tolerance ledger, regular-rational handoff, real seal row, and explicit bound ledger.

The product-route admission is the row P. It is read through the $\mathsf{CauchyProduct}^{\uparrow}$ sibling surface, so the product observation comes from the paired schedules and dyadic product ledger rather than from host multiplication over completed reals.

The shared-window row W aligns the factor reads with the product read. The dyadic ledger D and product-bound ledger B then record the finite magnitude and tolerance data needed to keep the product read inside the displayed bound.

The rows R and E are downstream handoffs. They receive only the bounded product packet assembled from X, Y, P, W, D, B; the transport rows H, continuation rows C, provenance row L, and local naming row N preserve and name that same route.

No coordinate in the carrier supplies host real multiplication, quotient streams, selected limits, trichotomy, countable choice, or ambient completeness. Hence the listed obligations exhaust the local certificate surface. □

Theorem 1529.3 (Cauchy product bounded regular-sequence route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{CauchyProductBounded}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y \longmapsto W \longmapsto P \longmapsto D \longmapsto B \longmapsto R.$$

The two source rows are consumed as $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packets, the product row is consumed as the* $\mathsf{CauchyProduct}^{\uparrow}$ *sibling route, and the regular-sequence classifier receives no quotient stream, selected product limit, host multiplication primitive, trichotomy row, countable-choice row, or ambient completeness witness.*

Proof. Begin with a consumer that asks for the regular rational product readback. By Definition 1529.1, the only regular-sequence classifier row is R.

The row R is not source data. It is downstream of the bounded factor rows X, Y, the aligned window row W, the product route P, and the dyadic product-bound ledger D, B.

The sibling $\mathsf{CauchySequenceBounded}^{\uparrow}$ packets supply the two factor bounds, while $\mathsf{CauchyProduct}^{\uparrow}$ supplies the product observation route. Combining those rows gives the displayed finite path to R.

Since no other row in the carrier is a regular-sequence classifier, every exported $\mathsf{RegSeqRat}^{\uparrow}$ read factors through that path and cannot obtain any excluded object from the packet. □

Theorem 1529.4 (Cauchy product bounded RegSeqRat window factorization)**.** *For every accepted* $\mathsf{CauchyProductBounded}^{\uparrow}$ *carrier* $Z = (X, Y, P, W, D, R, E, B, H, C, L, N)$*, any* $\mathsf{RegSeqRat}^{\uparrow}$ *read through* R *first consumes the two bounded source rows* X, Y*, then the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*, then the product route* P *and the dyadic/product-bound ledgers* D, B*. The read exports no host multiplication, selected product limit, quotient stream equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier using Definition 1529.1. The rows X and Y are the only bounded source rows, and R is the only $\mathsf{RegSeqRat}^{\uparrow}$ classifier row available to a product read.

Apply Definition 1529.3. It gives the finite route

$$X, Y \longmapsto W \longmapsto P \longmapsto D \longmapsto B \longmapsto R.$$

In that route, W is the only schedule-aligning row: it is where the two bounded factor windows and the product window are displayed as one shared $\mathsf{StreamName}^{\uparrow}$ surface before P can be read.

The rows P, D, B then supply the product observation, dyadic tolerance data, and product-bound ledger consumed by R. Since the carrier has no coordinates for host multiplication, selected product limits, quotient stream equality, trichotomy, countable choice, or ambient completeness, the displayed window factorization is non-escaping. □

Theorem 1529.5 (Cauchy product bounded real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{CauchyProductBounded}^{\uparrow}$ *carrier factors through*

$$X, Y \longmapsto W \longmapsto P \longmapsto D \longmapsto B \longmapsto R \longmapsto E$$

together with the displayed hsame *transports,* Cont *replays,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}$ *row. Thus the real-facing product boundary is a finite bounded-source product certificate, not a host multiplication operation, quotient stream, selected limit, or ambient completeness theorem.*

Proof. The real-seal consumer can read only the row E as a $\mathsf{Real}^{\uparrow}$ boundary. In the carrier, E is declared downstream of the bounded-source packets, shared window row, product route, dyadic ledger, product-bound ledger, and regular-rational classifier.

Apply Definition 1529.3. The classifier row R is reached only after X, Y, W, P, D, B are displayed, so the seal row E inherits the same source and product-bound route.

The structural rows H, C, L, N transport, replay, source, and name this route without adding a second seal source. Therefore any real-facing product read is exhausted by $X, Y, P, W, D, R, E, B, H, C, L, N$.

Because the carrier has no coordinate for host multiplication, quotient streams, selected limits, trichotomy, countable choice, or ambient completeness, none of those objects can be exported by the seal boundary. □

Falsifiable prediction: Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer of a $\mathsf{CauchyProductBounded}^{\uparrow}$ packet factors through the two $\mathsf{CauchySequenceBounded}^{\uparrow}$ source ledgers, the $\mathsf{CauchyProduct}^{\uparrow}$ product

route, the shared $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ product-bound ledger, the regular-rational classifier row, and the real-seal row before the product is consumed.

Independence witness: cauchysequencebounded, cauchyproduct, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyProductBounded}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two bounded Cauchy source packets, a product route, a shared schedule, a dyadic product-bound ledger, regular-rational and real-seal handoffs, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductBounded}^{\uparrow}$ packet is generated from two bounded Cauchy sequence packets, a CauchyProduct product route, a shared StreamName schedule, a DyadicRatCore product-bound ledger, a RegSeqRat classifier row, a RealUp seal row, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1529.1, Definition 1529.2, Definition 1529.3, and Definition 1529.5 seed the finite bounded-product packet for two bounded Cauchy sequence schedules.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductBounded}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real multiplication, quotient stream equality, selected product limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source admission, product-route admission, shared-window exactness, dyadic product-bound stability, regular-sequence handoff, real-seal handoff, and ledger non-escape for BEDC.Derived.CauchyProductBoundedUp.

Chapter 1530

A Concrete Naming Certificate for $\mathsf{CantorSet}^{\uparrow}$

Following Cantor and Bishop–Bridges constructive analysis, the $\mathsf{CantorSet}^{\uparrow}$ packet records the middle-third closed subset of the real line as finite ternary-prefix and deleted-middle interval data. It is a real-set certificate downstream of the nested interval discipline of chapter 320, the dyadic endpoint surface of chapter 306, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The carrier names only finite prefixes, finite gap ledgers, nested interval rows, and real-seal routing; it does not import open-cover compactness, host powersets, quotient real equality, or a completed infinite intersection.

Definition 1530.1 (Cantor set carrier)**.** *A* $\mathsf{CantorSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (T, G, I, D, R, E, H, K, P, N)$$

with the following visible rows:

1. *T is the ternary-prefix ledger, a finite word over the left and right retained thirds, together with its generation depth.*
2. *G is the deleted-middle interval ledger, listing the middle-third gaps excluded at the displayed depths.*
3. *I is the retained nested-interval row whose endpoints are determined by T and whose containment route is read through the* $\mathsf{NestedInterval}^{\uparrow}$ *surface.*
4. *D is the auxiliary* $\mathsf{DyadicInterval}^{\uparrow}$ *or rational endpoint ledger used to expose the retained interval endpoints to finite consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for a real-name readback compatible with the retained interval chain.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the ternary prefix, deleted-gap ledger, retained interval row, endpoint ledger, and regular-rational handoff have been displayed.*
7. *H stores componentwise* hsame *transport for the ternary prefix, gap ledger, interval row, endpoint ledger, handoff row, real seal, continuation replay, provenance, and local naming row.*
8. *K stores displayed* Cont *replay from prefix requests to gap checks, from gap checks to retained intervals, and from retained intervals to R and E.*
9. *P is the* Pkg *provenance over* $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CantorSet}^\uparrow}$ *row.*

The classifier accepts a packet only when the displayed prefix T selects retained thirds, the ledger G contains exactly the finite deleted-middle gaps inspected at those depths, the interval row I avoids those gaps, and every real-facing read factors through R, E, H, K, P, N. It has no coordinate for a host subset of $\mathsf{Real}^\uparrow$*, open-cover compactness, quotient real equality, selected infinite branch, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetTasteGate single carrier alignment`

Theorem 1530.2 (Cantor set NameCert obligations)**.** *For an accepted* $\mathsf{CantorSet}^\uparrow$ *carrier $C = (T, G, I, D, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorSet}^\uparrow}$ *obligations are exactly carrier admission, finite ternary-prefix classification, deleted-middle gap exclusion, nested-interval containment, endpoint-ledger compatibility,* $\mathsf{Real}^\uparrow$ *seal handoff, and non-escape. These obligations are discharged by the displayed route*

$$T \longmapsto G \longmapsto I \longmapsto D \longmapsto R \longmapsto E$$

together with H, K, P, N.

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetNameCertObligations`

Proof. Carrier admission projects the finite tuple of Definition 1530.1. The prefix classifier reads T as a finite retained-third word and therefore inspects only finitely many ternary branch decisions.

The deleted-middle exclusion row G is the only place where removed middle-third intervals are named. The retained interval row I must pass through the $\mathsf{NestedInterval}^\uparrow$ containment surface, so every accepted prefix determines a retained nested interval before any real-facing row is read.

Endpoint compatibility is checked by D. This ledger exposes the same retained interval endpoints to dyadic or rational interval consumers and prevents a later consumer from replacing the ternary interval by an unrelated host interval.

Finally, R and E are downstream readback and seal rows. The transport, continuation, provenance, and naming rows H, K, P, N preserve the same finite route, and no carrier coordinate supplies open-cover compactness, host powersets, quotient real equality, a selected infinite branch, or ambient real completeness. □

Theorem 1530.3 (Cantor set finite-prefix induction)**.** *For every accepted* $\mathsf{CantorSet}^\uparrow$ *carrier $C = (T, G, I, D, R, E, H, K, P, N)$, retained-third prefixes are generated only by finite induction over the displayed ternary-prefix ledger T. No membership-facing read may replace this finite induction with a selected infinite branch, a host powerset element, quotient real equality, open-cover compactness, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 1530.1. The row T is a finite word over retained left and right thirds together with its displayed generation depth, so its generation rule is finite ledger induction rather than branch selection.

Use Definition 1530.2. Its finite ternary-prefix classification is the first obligation read by the local $\mathsf{NameCert}_{\mathsf{CantorSet}^\uparrow}$ surface, before deleted-gap exclusion, nested-interval containment, endpoint compatibility, or Real seal handoff.

The structural rows preserve this induction route. Componentwise hsame transport in H and displayed Cont replay in K move only the finite prefix ledger named by T, while P and N record the same finite provenance and local naming. Since no carrier coordinate stores a selected infinite branch or host powerset, every retained-prefix read is generated by the displayed finite induction. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetFinitePrefixInduction`

Theorem 1530.4 (Cantor set deleted-gap ledger exhaustion)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, every deleted-middle exclusion read factors through the displayed route*

$$G \longmapsto I \longmapsto D$$

before any regular-rational handoff R *or* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. Thus the exclusion surface is exhausted by the finite gap ledger, retained interval row, and endpoint ledger, not by open-cover compactness, host powersets, quotient real equality, selected infinite branches, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier deleted gap ledger exhaustion`

Proof. Begin with the deleted-middle coordinate in Definition 1530.1. The row G is the only carrier row where removed middle-third gaps are named, and the accepted classifier requires the retained interval row I to avoid exactly the displayed gap entries at the inspected depths.

Next read the endpoint ledger D. It exposes the retained interval endpoints determined by T and checked against G, so an exclusion read cannot pass directly from a gap name to R or E without first traversing I and D.

Finally apply Definition 1530.2. Deleted-middle gap exclusion, nested-interval containment, and endpoint-ledger compatibility all precede Real seal handoff. The rows H, K, P, N transport, replay, package, and name this same exhausted route, and no excluded host-level coordinate is available. □

Theorem 1530.5 (Cantor set Real membership handoff)**.** *Every Real-facing membership consumer of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier receives only the route*

$$T, G, I, D, R, E, H, K, P, N.$$

In particular, the handoff to a $\mathsf{Real}^{\uparrow}$ *membership surface cannot bypass the ternary-prefix ledger, deleted-gap ledger, retained interval row, endpoint ledger, regular-rational readback, seal, transport, continuation replay, provenance, or local* $\mathsf{NameCert}$ *row.*

Proof. Start from the Real seal coordinate E in Definition 1530.1. It is downstream of the finite prefix row T, the deleted-gap ledger G, the retained nested interval row I, the endpoint ledger D, and the regular-rational handoff R.

Use Definition 1530.2 to identify the local obligation order. The membership-facing read reaches the Real seal only after carrier admission, prefix classification, gap exclusion, nested-interval containment, endpoint compatibility, and seal handoff have all been read on the same packet.

The same route is stable under hsame and Cont. Rows H and K preserve the componentwise transport and replay, while P and N bind the package provenance and local name. Therefore a Real-facing membership consumer receives precisely $T, G, I, D, R, E, H, K, P, N$ and no open-cover compactness, host powerset, quotient real equality, selected branch, or ambient completeness claim. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier real membership handoff`

Theorem 1530.6 (Cantor set prefix-gap separation)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, a retained-prefix read from* T *excludes each displayed deleted-middle gap row in* G *before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The exclusion is witnessed inside the route*

$$T \longmapsto G \longmapsto I \longmapsto D$$

through the retained $\mathsf{NestedInterval}^{\uparrow}$ *row and the endpoint ledger, and it has no access to host powersets, quotient real equality, selected infinite branches, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1530.1. The prefix ledger T names only retained left and right thirds, while the deleted-middle ledger G is the unique row where excluded middle-third intervals are displayed.

The retained interval row I is read before the endpoint row D and before the Real seal E. Thus a prefix request must first compare its retained interval with the displayed gap ledger, using the same $\mathsf{NestedInterval}^{\uparrow}$ containment route and the same dyadic or rational endpoint ledger.

The structural rows H, K, P, N preserve this route under hsame transport and Cont replay. Since the carrier has no host powerset, quotient real equality, selected branch, compactness, or completeness coordinate, a retained-prefix read can exclude only the displayed gap rows before it reaches the seal. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier prefix gap separation`

Theorem 1530.7 (Cantor set triadic-window split stability)**.** *Let* $C = (T, G, I, D, R, E, H, K, P, N)$ *and* $C' = (T', G', I', D', R', E', H', K', P', N')$ *be accepted* $\mathsf{CantorSet}^{\uparrow}$ *carriers. If* T *and* T' *agree on the same retained ternary prefix window through a finite depth and* G *and* G' *display the same deleted-middle gap ledger through that depth, then every downstream* $\mathsf{Real}^{\uparrow}$*-facing read through* I, D, R, E *and* I', D', R', E' *factors through the same retained interval split at that depth. The factorization uses only retained prefixes, deleted gaps, endpoint ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *sealing; it uses no selected infinite branch, host powerset, quotient real equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the two accepted carriers. The common finite prefix window is stored in T and T', while the common deleted-middle gap ledger is stored in G and G'. By finite-prefix induction, the retained left-third or right-third decisions determine the same retained interval split at the inspected depth.

Apply Definition 1530.6. The displayed gap ledgers are checked before any Real seal is consumed, so the common retained prefix excludes the same deleted gaps in both packets and routes both reads into the retained interval rows I and I'.

Now read the endpoint and Real-facing rows. The retained interval split is passed through D and D', then through the regular-rational handoff rows R and R', and finally through the $\mathsf{Real}^{\uparrow}$ seal rows E and E'. The structural rows H, K, P, N and H', K', P', N' preserve the same finite route.

Since neither carrier has a coordinate for an infinite branch selector, host powerset, quotient real equality, compactness theorem, or ambient completeness witness, the downstream reads can factor only through the displayed retained interval split. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier triadic window split stability`

Theorem 1530.8 (Cantor set ternary-prefix classifier)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, a finite prefix read is classified only by the retained left-third and right-third symbols recorded in* T *before any deleted-gap ledger or* $\mathsf{Real}^{\uparrow}$ *row is read. The classifier therefore exposes a finite ternary-retention surface and not a host powerset, quotient real equality, selected infinite branch, compactness theorem, or ambient completeness principle.*

Proof. Project the carrier of Definition 1530.1. The prefix coordinate T is the only row that records retained left and right thirds, while the deleted-gap row G and Real seal E are downstream rows.

Use Definition 1530.2. Its finite ternary-prefix classification row is read before deleted-middle exclusion, nested-interval containment, endpoint compatibility, and Real seal handoff.

Finally apply Definition 1530.6 and Definition 1530.16. They keep every gap and Real-facing read behind the displayed route from T through G, I, D, R, E, so the prefix classifier cannot supply any excluded host-level principle. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier ternary prefix classifier`

Theorem 1530.9 (Cantor set nested-interval handoff)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, the retained prefix ledger* T *and deleted-gap ledger* G *hand the consumer to the retained* $\mathsf{NestedInterval}^{\uparrow}$ *row* I *before any endpoint readback through* D, R, E *is available. The handoff is a finite row route and not a selected infinite branch, quotient real equality, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness argument.*

Proof. Start from the retained-prefix and gap rows in Definition 1530.1. The row I is defined as the retained nested-interval row whose endpoints are determined by T and whose avoided gaps are the displayed entries of G.

Apply Definition 1530.6. It forces the consumer to compare the retained prefix with the deleted-middle ledger before the endpoint row D and before the Real seal E.

Use Definition 1530.2 for the remaining handoff. Nested-interval containment precedes endpoint-ledger compatibility and regular-rational readback, so D, R, E can only read the retained interval already named by I. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier nested interval handoff`

Theorem 1530.10 (Cantor set ternary-prefix density)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, every retained finite ternary prefix exposes a nonempty retained interval row through* T, G, I, D *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *or* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. The density read is finite-prefix data over the displayed ledger and not a host powerset, selected infinite branch, quotient real equality, compactness theorem, or ambient completeness principle.*

Proof. Induct on the finite prefix ledger T. The empty prefix exposes the initial retained interval, and the carrier definition places that interval in the retained $\mathsf{NestedInterval}^{\uparrow}$ row I with endpoint data in D.

For an appended retained left-third or right-third symbol, read the new prefix entry before any downstream row. The deleted-gap ledger G records the middle-third exclusions inspected at that depth, while I and D display the retained subinterval and its endpoints.

Finally apply Definition 1530.9. The handoff keeps the retained interval route ahead of R and E, so each retained finite prefix exposes a nonempty interval row before any Real-facing read is available. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier ternary prefix density`

Theorem 1530.11 (Cantor set deleted-gap density refusal)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, deleted-middle gap data refines only the finite exclusion ledger* G *and its retained-interval check through* I, D*. It cannot supply host powersets, selected infinite branches, quotient real equality, open-cover compactness, compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the gap coordinate in Definition 1530.1. The row G lists exactly the displayed middle-third gaps inspected at finite depths and has no coordinate for a host subset or an infinite branch selector.

Use Definition 1530.4. Each exclusion read passes through G, I, D before the regular-rational handoff or Real seal is visible.

The structural rows H, K, P, N transport, replay, source, and name that same finite route. Since the carrier lacks any powerset, quotient-equality, compactness, or completeness row, deleted-gap data can only refine the displayed finite exclusion ledger. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetDeletedGapDensityRefusal`

Theorem 1530.12 (Cantor set nested real handoff)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, the route from retained intervals to a real-facing read factors through the same* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows named in the carrier. No consumer may replace this route by a selected branch, quotient real equality, host powerset membership, compactness, or ambient completeness.*

Proof. Begin with the retained interval row I. By Definition 1530.1, its endpoints are determined by the retained prefix and deleted-gap ledgers and are exposed through the endpoint ledger D.

Next use Definition 1530.9. It forces the consumer to read T, G, I before endpoint readback is available, so the $\mathsf{NestedInterval}^{\uparrow}$ row is the entrance to the real-facing route.

Finally apply Definition 1530.16. The route from D to R and E is the displayed $\mathsf{DyadicInterval}^{\uparrow}$ or rational endpoint ledger followed by the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and terminal $\mathsf{Real}^{\uparrow}$ seal, with H, K, P, N preserving the same path. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier nested real handoff`

Theorem 1530.13 (Cantor set Real-seal membership boundary)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, every membership-facing* $\mathsf{Real}^{\uparrow}$ *seal is downstream of* $T, G, I, D, R, E, H, K, P, N$*. It cannot supply a host powerset, quotient real equality, selected infinite branch, compactness theorem, or ambient completeness principle.*

Proof. Begin with Definition 1530.16. It states that every Real-facing read factors through T, G, I, D, R, E and the structural rows H, K, P, N.

Use Definition 1530.2. The same rows cover carrier admission, prefix classification, gap exclusion, nested-interval containment, endpoint compatibility, Real seal handoff, and non-escape.

Finally apply Definition 1530.6. Since the carrier has no coordinate outside the displayed finite rows, the membership-facing seal cannot become a host powerset, quotient equality, selected branch, compactness, or completeness object. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetRealSealMembershipBoundary`

Theorem 1530.14 (Cantor set downstream membership consumer)**.** *Any downstream Real-facing closed-set or interval-membership consumer of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet must read the ternary-prefix ledger* T*, the deleted-gap ledger* G*, the retained* $\mathsf{NestedInterval}^{\uparrow}$ *row* I*, the endpoint ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the* $\mathsf{Real}^{\uparrow}$ *seal* E *before treating the packet as membership data. In particular, a locator-facing consumer such as chapter 1669 receives only this displayed finite route and not a host powerset, quotient real equality, selected infinite branch, compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the Real-seal membership boundary of Definition 1530.13. It places every membership-facing Real seal downstream of the displayed rows $T, G, I, D, R, E, H, K, P, N$.

Next use the nested-interval handoff, Definition 1530.9. The retained interval row I is available only after the prefix and gap ledgers have been read, and the endpoint ledger D is downstream of that retained interval route.

Finally apply Real seal nonescape, Definition 1530.16. It forces each Real-facing read through T, G, I, D, R, E with the same transport, replay, provenance, and local naming rows. Hence any downstream closed-set, interval-membership, or locator-facing consumer receives exactly the finite membership route and none of the excluded host-level data. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetDownstreamMembershipConsumer`

Theorem 1530.15 (Cantor set public membership route)**.** *Every public closed-set, finite-net, bounded-sequence, or locator-facing consumer of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet must read the finite route*

$$T, G, I, D, R, E, H, K, P, N$$

through $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before it treats the packet as membership data. The route exports the ternary-prefix ledger, deleted-gap ledger, retained nested interval row, endpoint ledger, regular-rational readback, terminal Real seal, transport, replay, provenance, and local naming rows, and it exports no host powerset, quotient Real equality, selected infinite branch, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the downstream membership consumer theorem, Definition 1530.14. It already places closed-set, interval-membership, and locator-facing reads downstream of the finite rows $T, G, I, D, R, E, H, K, P, N$.

Use the bounded-sequence and finite-net routes, Definition 1530.19 and Definition 1530.20. These make the bounded-window and finite-net consumers read the same ternary-prefix, retained-interval, endpoint, readback, and Real-seal route before any downstream package is visible.

Finally apply closed-interval nonescape, Definition 1530.25. The closed-set and interval consumers receive only the displayed finite rows, while the locator-facing route remains a Real-facing membership read through the same terminal seal. Hence the public membership surface is exactly the stated route through the four sibling packets and no excluded compactness or completeness datum is exported. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetPublicMembershipRoute`

Theorem 1530.16 (Cantor set Real seal nonescape)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the finite route*

$$T \longmapsto G \longmapsto I \longmapsto D \longmapsto R \longmapsto E$$

with the same transport, replay, provenance, and local name rows H, K, P, N*. No Real-facing consumer can bypass the retained-prefix ledger, deleted-gap ledger, nested interval row, endpoint ledger, regular-rational handoff, or local NameCert surface.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier real seal nonescape`

Proof. Start from a Real-facing read. By Definition 1530.1, the seal coordinate E is downstream of the ternary prefix, gap ledger, retained interval, endpoint ledger, and regular-rational handoff.

Use Definition 1530.2. Its deleted-middle exclusion, nested-interval containment, endpoint compatibility, and Real seal handoff rows require the consumer to traverse T, G, I, D, R before E is visible.

Finally read the structural coordinates. The rows H, K, P, N preserve and name the same finite route, and there is no coordinate from which a consumer could construct a bypassing seal, host subset equality, selected infinite branch, or ambient completeness proof. □

Theorem 1530.17 (Cantor set endpoint-ledger stability)**.** *Let $C = (T, G, I, D, R, E, H, K, P, N)$ and $C' = (T', G', I', D', R', E', H', K', P', N')$ be accepted* $\mathsf{CantorSet}^{\uparrow}$ *carriers whose prefix, gap, retained-interval, regular-rational, seal, provenance, and local naming rows are related by the componentwise* hsame *transports stored in H and H', and whose displayed continuations replay the same retained-prefix requests through K and K'. If the endpoint ledger D is admitted for C, then the transported endpoint ledger D' is admitted for C' and determines the same retained endpoint route for Real-facing reads.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier endpoint ledger stability`

Proof. Project the endpoint row. In an accepted carrier, D is not a free interval datum; it is read after the retained prefix T, the displayed deleted-gap ledger G, and the retained $\mathsf{NestedInterval}^{\uparrow}$ row I.

Apply the componentwise hsame transport rows. They carry the prefix, gap, retained interval, endpoint, regular handoff, seal, provenance, and local name rows together, so the endpoint ledger cannot be transported without preserving the retained interval route that generated it.

Now use the displayed Cont replay rows. The same prefix requests replay through the same gap checks and retained interval rows before the endpoint ledger is consumed. Therefore D' is admitted exactly when it continues the transported retained route, and it determines the same endpoint path for the downstream $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads. □

Theorem 1530.18 (Cantor set middle-third window exhaustion)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier $C = (T, G, I, D, R, E, H, K, P, N)$, every membership-facing read of the middle-third construction is exhausted by the displayed ternary prefix window T, deleted-gap ledger G, retained nested-interval handoff I, endpoint ledger D,* $\mathsf{Real}^{\uparrow}$ *handoff rows R, E, componentwise* hsame *transport H, displayed* Cont *replay K,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CantorSet}^{\uparrow}}$ *row N. No membership read may add a host powerset, quotient real equality, selected infinite branch, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Induct on the displayed ternary prefix window T. The empty window reads only the initial retained interval, and Definition 1530.8 places that read before any deleted-gap ledger, endpoint ledger, or Real seal is available.

For the induction step, append one retained left-third or right-third symbol to the finite window. The prefix classifier again reads the appended symbol as a retained-third decision, while Definition 1530.6 forces the corresponding deleted-middle exclusion to pass through the finite gap ledger G.

The retained interval is then handed to I by Definition 1530.9. Endpoint compatibility is preserved by Definition 1530.17, so the endpoint row D continues to determine the same retained endpoint route for the downstream regular-rational and Real-facing rows.

Finally apply Definition 1530.16. The rows R, E, H, K, P, N seal, transport, replay, source, and name exactly the finite route already constructed by the induction. Since the carrier has no coordinate outside those rows, the displayed middle-third window exhausts every membership-facing read. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier middle third window exhaustion`

Theorem 1530.19 (Cantor set bounded sequence window route)**.** *Every bounded Real sequence consumer of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier must read its sequence window through the finite ternary prefix ledger* T*, deleted-middle gap ledger* G*, retained* $\mathsf{NestedInterval}^{\uparrow}$ *row* I*, endpoint ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the same componentwise transport, replay, provenance, and local naming rows* H, K, P, N*. The read may be passed onward to a* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite-net surface only after this displayed route has been consumed.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier root bounded sequence window`

Proof. Project the carrier of Definition 1530.1. The bounded-sequence consumer receives no row outside $T, G, I, D, R, E, H, K, P, N$, so the first usable data are the finite ternary prefix and deleted-gap ledgers.

Apply Definition 1530.18 to exhaust the membership-facing read by the displayed middle-third window. Then apply Definition 1530.9 and Definition 1530.12 to route the retained prefix through the $\mathsf{NestedInterval}^{\uparrow}$ row, endpoint ledger, regular-rational handoff, and terminal Real seal.

The finite-net handoff is therefore downstream of the same route. A $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ consumer may inspect the bounded window as named finite interval data, but it does not receive open-cover compactness, a selected infinite branch, quotient Real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1530.20 (Cantor set finite-net subsequence refusal)**.** *For an accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier, finite-net reads over bounded sequence windows may use the displayed* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *handoff only as finite interval evidence over* $T, G, I, D, R, E, H, K, P, N$*. They cannot select an infinite subsequence branch, collapse the retained prefixes to quotient* $\mathsf{Real}^{\uparrow}$ *equality, import open-cover compactness, or appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier finite net subsequence refusal`

Proof. Begin with the finite-net request and project Definition 1530.1. The request must first traverse the finite retained-prefix ledger, gap ledger, nested interval row, endpoint ledger, regular-rational readback, and Real seal.

Use Definition 1530.19. It places the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ handoff after the Cantor finite-window route, so a finite-net read is evidence about displayed bounded cells rather than a branch selector.

Finally apply Definition 1530.13 and Definition 1530.16. These seal every Real-facing read behind the same finite rows. Hence finite-net evidence cannot become quotient Real equality, open-cover compactness, selected subsequence data, or ambient completeness. □

Theorem 1530.21 (Cantor set diagonal non-surjection route)**.** *For an accepted* $\mathsf{CantorSet}^{\uparrow}$ *carrier* $C = (T, G, I, D, R, E, H, K, P, N)$*, any consumer that passes a Cantor finite-prefix, deleted-gap, retained-interval, or endpoint route to* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *must do so through the displayed Cantor diagonal disagreement row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route of chapter 3793. The handoff may inspect* T, G, I, D, R, E *together with the structural rows* H, K, P, N*, but it cannot export a surjection witness, quotient real equality, selected infinite branch, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetRealDiagonalNonSurjectionRoute`

Proof. Start with the bounded-sequence window of Definition 1530.19. It forces every diagonal-facing read to open the finite ternary prefix, deleted-gap ledger, retained nested interval, endpoint ledger, regular readback, and Real seal before any downstream consumer sees the packet.

Next apply Definition 1530.20. The finite-net handoff remains evidence about displayed bounded cells and cannot select an infinite branch or identify retained prefixes by quotient Real equality.

Finally route the resulting finite read through chapter 3793. That sibling chapter consumes Cantor data only at its diagonal disagreement row, then reads the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seals. Since the present carrier exposes no row beyond $T, G, I, D, R, E, H, K, P, N$, the route is a Cantor-source disagreement handoff rather than a surjection, branch-selection, or completeness principle. □

Theorem 1530.22 (Cantor set root-unblock package)**.** *The accepted* $\mathsf{CantorSet}^{\uparrow}$ *NameCert package supplies the root-unblock surface needed by bounded-sequence and finite-net consumers exactly through finite prefixes, retained nested intervals, endpoint ledgers, regular-rational readback, Real seals, and the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *handoff. This package routes downstream compactness-adjacent reads without importing open-cover compactness, selected infinite branches, quotient Real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier root unblock package`

Proof. First project the local obligations of Definition 1530.2. Carrier admission, finite prefix classification, gap exclusion, nested-interval containment, endpoint compatibility, Real-seal handoff, and nonescape are the only rows exposed by the local certificate.

Next combine Definition 1530.19 with Definition 1530.20. The first theorem routes bounded Real sequence inspection through the displayed Cantor and interval rows; the second theorem keeps finite-net evidence from selecting branches or quotienting Real names.

It remains to repack the route as the downstream package. The transport, replay, provenance, and local naming rows H, K, P, N preserve the same finite route from $\mathsf{CantorSet}^{\uparrow}$ to $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$. Since no additional coordinate is available, the root-unblock package closes the stated surface without importing the refused compactness or completeness principles. □

Theorem 1530.23 (Cantor set triadic window stability)**.** *For an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet, every finite triadic window that survives the prefix classifier remains stable under the middle-third window exhaustion and endpoint-ledger transport. A membership-facing consumer may therefore read retained prefixes, deleted-gap witnesses, nested interval rows, endpoint rows, regular readback, and Real sealing, but it cannot introduce a selected infinite branch or an open-cover compactness witness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetCarrier triadic window stability`

Proof. Start with the prefix classifier from the NameCert obligations of Definition 1530.2. The classifier reads only the finite ternary prefix ledger T and the deleted-middle gap ledger G.

Apply middle-third window exhaustion from Definition 1530.18. Any membership-facing read is confined to the displayed retained prefix, gap, nested interval, endpoint, regular readback, and Real seal rows.

Use the endpoint-ledger stability supplied by the nested and Real handoffs of Definition 1530.9 and Definition 1530.12. The endpoint row is transported with the same finite prefix, so the triadic window remains the displayed finite window and not a chosen infinite branch. □

Theorem 1530.24 (Cantor set dyadic separability handoff)**.** *Every density, separability, or finite real-window consumer of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet must route its request through* $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{RealSeparability}^{\uparrow}$ *before* $\mathsf{Real}^{\uparrow}$ *membership is read. The consumer sees only the displayed triadic prefix, deleted-gap ledger, dyadic endpoint refinement, regular rational readback, finite density rows, and terminal Real seal.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetDyadicSeparabilityHandoff`

Proof. Project the carrier rows $T, G, I, D, R, E, H, K, P, N$. The dyadic endpoint information is the displayed endpoint ledger D, while R and E are the only regular readback and Real seal rows.

Use the nested interval and Real handoffs. They route retained prefixes through the dyadic or rational endpoint ledger, then through $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal.

For a separability-facing read, insert the sibling finite-density surface of chapter 1809 between the regular readback and the final membership read. Since the carrier supplies no other density coordinate, the request remains a finite dyadic-separability handoff rather than a selected point or quotient-real argument. □

Theorem 1530.25 (Cantor set closed-interval nonescape)**.** *Closed bounded interval, finite-net, and bounded-sequence consumers of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet receive only the displayed prefix row* T*, gap row* G*, nested-interval row* I*, endpoint row* D*, regular readback row* R*, Real seal* E*, and structural rows* H, K, P, N*. They receive no open-cover compactness, no selected infinite branch, no quotient-real equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the root-unblock package of Definition 1530.22. It packages bounded-sequence and finite-net reads exactly through finite prefixes, retained nested intervals, endpoint ledgers, regular rational readback, Real seals, and the closed bounded interval handoff.

Use Definition 1530.19 for bounded-sequence consumers and Definition 1530.20 for finite-net consumers. Both routes keep the consumer inside the displayed Cantor and interval rows.

Finally apply the Real-seal nonescape boundary of Definition 1530.16. The terminal seal prevents a closed-interval read from becoming open-cover compactness, a selected infinite branch, quotient-real equality, or an ambient completeness claim. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetClosedIntervalNonescape`

Theorem 1530.26 (Cantor set scoped nested-interval route)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ BHist *packet* $C = (T, G, I, D, R, E, H, K, P, N)$*, the scoped nested-interval route is the displayed path from the ternary-prefix row* T *and deleted-gap ledger* G *into the retained* $\mathsf{NestedInterval}^{\uparrow}$ *row* I*, then through* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint data* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface read by* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The route is preserved only by the componentwise* hsame *row* H*, displayed* Cont *replay* K*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CantorSet}^{\uparrow}}$ *row* N*.*

Proof. Project the carrier of Definition 1530.1. The BHist packet exposes finite prefix data, deleted gaps, a retained nested interval, endpoint rows, regular readback, a Real seal, and the structural rows H, K, P, N.

Apply Definition 1530.9. It places I after T and G and before any endpoint, regular-rational, or Real-facing read.

Use Definition 1530.5 to continue the route through D, R, E, H, K, P, N. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff reads the same finite $\mathsf{StreamName}^{\uparrow}$ window surface before the Real seal is consumed, so the scoped route remains a finite kernel route and not compactness, choice, quotient equality, selected branch, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetScopedNestedIntervalRoute`

Theorem 1530.27 (Cantor set scoped dyadic-branch route)**.** *Every dyadic branch read of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet* $C = (T, G, I, D, R, E, H, K, P, N)$ *is scoped by the finite rows* $T, G, I, D, R, E, H, K, P, N$*. The retained branch may be exposed to* $\mathsf{DyadicInterval}^{\uparrow}$ *consumers through* D *only after the* $\mathsf{NestedInterval}^{\uparrow}$ *row* I *has been read, and any downstream* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer must preserve the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetScopedDyadicBranchRoute`

Proof. Start with the prefix and gap rows. The ternary-prefix classifier and prefix-gap separation results force every retained branch to be a finite retained-third read from T checked against the deleted-middle ledger G.

Next apply Definition 1530.9 and Definition 1530.24. The dyadic endpoint row D is downstream of the retained nested interval row I, and separability-facing or finite-window reads pass through the dyadic endpoint surface before regular readback and Real sealing.

Finally read the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming preserve the same finite packet; none of these rows adds compactness, branch selection, quotient equality, countable choice, or ambient Real completeness. □

Theorem 1530.28 (Cantor set scoped Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *membership or closed-interval read of an accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet is scoped by the ordered route*

$$\mathsf{BHist} \ni C = (T, G, I, D, R, E, H, K, P, N) \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRa}$$

The route supplies scoped kernel support for the existing CantorSet rows, but it does not claim compactness, selected infinite branches, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetScopedRealSealRoute`

Proof. Project the BHist packet and read the route in order. The rows T, G, I, D, R, E expose the finite Cantor data, nested interval, dyadic endpoint ledger, regular readback through finite stream windows, and terminal Real seal.

Apply Definition 1530.25. Closed-interval and finite-net consumers receive only the displayed prefix, gap, nested-interval, endpoint, readback, seal, and structural rows.

Use Definition 1530.16 for the terminal boundary. The seal cannot leave the finite window and readback route, while H, K, P, N only transport, replay, package, and name that same route.

Thus the existing obligation rows acquire scoped kernel support through the listed BEDC primitives. The conclusion is a routing statement, not a compactness theorem, choice principle, selected branch, quotient-real equality, or ambient completeness assertion. □

Theorem 1530.29 (Cantor set public Real-membership bridge)**.** *For every accepted* $\mathsf{CantorSet}^{\uparrow}$ *packet* $C = (T, G, I, D, R, E, H, K, P, N)$*, the public* $\mathsf{Real}^{\uparrow}$ *membership route is exactly the finite ternary-prefix classifier transported through the retained nested interval row* I*, the dyadic branch or endpoint data* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, with* H, K, P, N *preserving the same route. The bridge exports no compactness import, completeness import, selected infinite branch, host powerset, or quotient real equality.*

Proof. First apply the ternary-prefix classifier of Definition 1530.8. It makes membership-facing data start with the finite retained-prefix ledger T, before any deleted-gap, interval, endpoint, readback, or seal row can be consumed.

Next use the nested-interval handoff, Definition 1530.9. The retained prefix and deleted-gap rows are transported into the retained nested interval row I, and the endpoint or dyadic branch data D can be read only after that handoff.

Finally apply the scoped Real seal route, Definition 1530.28. It carries the same finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while the structural rows H, K, P, N only preserve and name the displayed packet. Therefore public membership is the stated finite bridge rather than an appeal to compactness, completeness, branch selection, host powersets, or quotient equality. □

Lean4 ✓ `BEDC.Derived.CantorSetUp.CantorSetPublicRealMembershipBridge`

Falsifiable prediction: Every accepted $\mathsf{CantorSet}^{\uparrow}$ real-facing read factors through the displayed ternary-prefix ledger, deleted-middle interval ledger, retained nested-interval row, endpoint ledger, regular-rational handoff, and $\mathsf{Real}^{\uparrow}$ seal before the set membership surface is consumed.

Independence witness: nestedinterval, dyadicinterval, regseqrat, real, cantorspace: $\mathsf{CantorSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a ternary retained-prefix ledger, deleted-middle gap ledger, retained nested interval row, endpoint compatibility row, regular-rational handoff, real seal, transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSet}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorSet}^{\uparrow}$ packet is generated from a finite ternary retained-prefix ledger, a deleted-middle gap ledger, a retained NestedInterval row, a DyadicInterval or rational endpoint ledger, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorSet}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1530.1, Definition 1530.2, finite-prefix induction, deleted-gap ledger exhaustion, Real membership handoff, prefix-gap separation, nested-interval handoff, Real-seal nonescape, Definition 1530.15, and Definition 1530.29 bind the finite-prefix, deleted-gap, Real-membership, product, boundary, and cross-chapter rows for the mature paper treatment.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close located compactness, open-cover compactness, host powerset equality, quotient real equality, selected infinite branches, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Further verification requires Lean coverage for the displayed mature paper route; compactness, completeness, selected branches, host powersets, and quotient real equality remain outside the chapter.

Chapter 1531

A Concrete Naming Certificate for $\mathsf{PrecompactMetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis, where precompact metric data is read through explicit finite nets rather than through open-cover compactness, the $\mathsf{PrecompactMetric}^{\uparrow}$ packet records the finite bridge from total boundedness toward completion-facing Cauchy filters. It connects the net surface of $\mathsf{TotallyBounded}^{\uparrow}$ (chapter 127) with the finite filterbase and regular-filter surfaces of $\mathsf{CauchyFilter}^{\uparrow}$ (chapter 333), $\mathsf{RegularCauchyFilter}^{\uparrow}$ (chapter 1445), and $\mathsf{CauchyFilterBasis}^{\uparrow}$ (chapter 1501), using $\mathsf{RegularityModulus}^{\uparrow}$ (chapter 353) as the visible rate ledger.

Definition 1531.1 (Precompact metric finite packet carrier)**.** *A* $\mathsf{PrecompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, D, N, F, R, M, H, C, G, Q)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row, including the accepted point histories and the metric-distance classifier rows used by downstream reads;*
2. *D records the metric carrier comparison data, so every endpoint, distance history, and rational bound used below is transported by displayed* hsame *rows and by the metric classifier;*
3. *N assigns to each positive* $\mathsf{Rat}^{\uparrow}$ *tolerance history ε a closed finite* $\mathsf{ProbeBundle}$ *of center names, visible* $\mathsf{InBundle}$ *membership rows, center-carrier rows, distance-witness rows, and rational comparison ledgers, as in the totally bounded carrier of Definition 127.3;*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *inspection row exposing the finite filterbase packets, refinement rows, regular Cauchy observation rows, dyadic neighbourhood witnesses, and precision-to-tail reads;*
5. *R is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *inspection row naming the regular tail windows and their componentwise regularity checks;*
6. *M is a* $\mathsf{RegularityModulus}^{\uparrow}$ *row whose dyadic windows control the net tolerance and the Cauchy-filter tail requests through the same displayed rate ledger;*
7. *H is the evidence ledger of componentwise* hsame *transports for X, D, N, F, R, M and for every center, tail, distance, dyadic radius, and regular readback row exposed by those coordinates;*
8. *C is the finite* Cont *route ledger: net reads route from N to X, D, M, filter reads route from F, R to M, and basis reads route through the finite generator of* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *before any completion-facing consumer can inspect them;*

9. *G is the handoff row saying that a* $\mathsf{TotallyBounded}^{\uparrow}$ *consumer reads only the finite net rows in N, the metric rows in X, D, and the modulus row in M;*

10. *Q is the* Pkg *provenance and local* NameCert *row naming the source boundaries* $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, *and* $\mathsf{RegularityModulus}^{\uparrow}$.

The classifier on such packets is componentwise transport of these ten rows through H and the displayed Cont *routes in C. No host finite set, selected sequence, quotient completion, ambient complete space, or choice operator is a coordinate of the carrier.*

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetricTasteGate single carrier alignment`

Theorem 1531.2 (PrecompactMetricUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{PrecompactMetric}^{\uparrow}}$ *surface of Definition 1531.1 consists exactly of five obligations:*

1. *carrier admission: the ten displayed rows $P = (X, D, N, F, R, M, H, C, G, Q)$ are present and every row cited by a consumer is one of their finite subrows;*

2. *classifier transport: packet equality is componentwise* hsame *transport of metric endpoints, center histories, filterbase tails, regular observations, dyadic radii, modulus windows, provenance rows, and local naming rows, with every read following a displayed* Cont *route;*

3. *finite-net exactness: for each positive tolerance history, Definition 127.3 supplies the closed* ProbeBundle*, membership constructors, center rows, distance witnesses, and rational comparison ledgers recorded in N;*

4. *Cauchy-filter inspection: the rows F and R expose only finite filterbase packets, regular tail windows, refinement ledgers, regular Cauchy readbacks, and dyadic neighbourhood witnesses, with the rate read controlled by M;*

5. *provenance and handoff: Q names the source certificates and G states that every total-boundedness or completion-facing consumer reaches the packet through the displayed finite net, filter, regularity, and modulus rows.*

These obligations define a constructive precompact metric packet as a finite-row interface between total boundedness and Cauchy-filter completion data.

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetricNameCert obligations`

Proof. Carrier admission is Definition 1531.1. It lists the metric row, finite-net row, Cauchy-filter inspection row, regular-filter inspection row, modulus row, transport ledger, route ledger, handoff row, provenance row, and local naming row.

Classifier transport is also read from the carrier. The evidence ledger H moves each displayed history by hsame, while C records the continuation route used by each net, filter, basis, and modulus read. Thus two packets classify together only when the same finite rows can be replayed after transport.

Finite-net exactness is supplied by the $\mathsf{TotallyBounded}^{\uparrow}$ component named in N. The packet keeps the closed ProbeBundle spine and its InBundle constructors visible, so a consumer never replaces the net by an ambient finite set of representatives.

Cauchy-filter inspection is the combined role of F, R, and M. The filter rows expose finite tails, refinements, regular Cauchy observations, dyadic neighbourhoods, and regularity windows; the modulus row supplies the shared rate ledger that connects a net tolerance with a later Cauchy-tail request.

Finally, Q and G package the same rows as the local NameCert surface. They do not add a completed point, a quotient real, or a selected subsequence; they merely state which source certificates and which finite rows may be read by downstream consumers. □

Theorem 1531.3 (PrecompactMetricUp finite-net root obligations)**.** *For every accepted* PrecompactMetric$^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$*, the root finite-net obligations are exactly the carrier admission of* X, D, N, M, H, C, G, Q*, the* TotallyBounded$^{\uparrow}$ *finite-net rows in* N*, the* RegularityModulus$^{\uparrow}$ *tolerance ledger in* M*, and the provenance row* Q*. A downstream total-boundedness consumer may read the closed* ProbeBundle *nets,* InBundle *memberships, center histories, metric-distance witness rows, and rational comparison ledgers only through those displayed coordinates.*

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetricCarrier root finite net obligations`

Proof. Project the carrier of Definition 1531.1. The finite-net coordinate is N, and the only metric, tolerance, transport, route, handoff, provenance, and naming rows available with it are X, D, M, H, C, G, Q.

Apply Definition 1531.2. Its finite-net exactness clause identifies the TotallyBounded$^{\uparrow}$ net surface with the closed ProbeBundle, membership constructors, center rows, distance witnesses, and rational comparison ledgers already recorded in N.

The same theorem's carrier-admission, classifier-transport, and provenance clauses keep the read inside X, D, N, M, H, C, G, Q. Thus root finite-net obligations expose total-boundedness data as finite rows and do not export open-cover compactness, selected subsequences, quotient completion, host choice, or ambient completeness. □

Theorem 1531.4 (PrecompactMetricUp Cauchy-filter handoff obligations)**.** *For every accepted* PrecompactMetric$^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$*, every Cauchy-filter or regular-Cauchy-filter handoff reads* F *and* R *only after the metric rows* X, D*, finite-net row* N*, regularity-modulus row* M*, transport row* H*, continuation row* C*, handoff row* G*, and provenance row* Q *have fixed the same packet. The handoff reaches the* CauchyFilter$^{\uparrow}$*,* RegularCauchyFilter$^{\uparrow}$*, and* CauchyFilterBasis$^{\uparrow}$ *sibling surfaces as finite inspection rows, not as a completed point or quotient filter.*

Proof. Start from Definition 1531.1. The rows F and R are the only Cauchy-filter and regular-filter inspection coordinates, while C records that basis reads route through the finite generator of CauchyFilterBasis$^{\uparrow}$.

Use Definition 1531.2. Its Cauchy-filter inspection clause says that F and R expose finite filterbase packets, regular tail windows, refinement ledgers, regular Cauchy readbacks, and dyadic neighbourhood witnesses, all controlled by M.

The carrier-admission and provenance clauses force the same packet rows $X, D, N, F, R, M, H, C, G, Q$ to remain visible for the handoff. Therefore no downstream consumer can detach a completed point, a quotient filter, a selected subsequence, or ambient completeness from the Cauchy-filter route. □

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric cauchy filter handoff obligations`

Theorem 1531.5 (PrecompactMetricUp filter-net modulus handoff)**.** *For every accepted* PrecompactMetric$^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$*, a completion-facing handoff that consumes both finite nets and Cauchy-filter tails must read the finite-net coordinate* N*, the Cauchy-filter coordinates* F, R*, and the* RegularityModulus$^{\uparrow}$ *coordinate* M *inside the same packet before it can expose any basis row. The handoff is replayed only through* H, C, G, Q*, so the finite-net radius, filter tail, and modulus window are one displayed NameCert route rather than a quotient completion, selected subsequence, host finite set, or ambient complete space.*

Proof. Project the packet $P = (X, D, N, F, R, M, H, C, G, Q)$. The row N is the only finite-net coordinate, F and R are the only Cauchy-filter and regular-Cauchy-filter coordinates, and M is the only visible regularity-modulus coordinate.

Use Definition 1531.3 for the root net surface. It identifies the readable net data with the closed ProbeBundle rows, InBundle memberships, center histories, metric-distance witnesses, and rational comparison ledgers stored in N.

Apply Definition 1531.4 to the filter side. It keeps every filterbase packet, regular tail window, refinement ledger, regular Cauchy readback, and dyadic neighbourhood witness inside F, R and under the same modulus row M.

The remaining rows H, C, G, Q provide transport, replay, handoff, and provenance. Since these rows mention only the displayed carrier coordinates, the combined handoff exports no quotient completion, selected subsequence, host finite set, or ambient complete space. □

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric filter net modulus handoff`

Theorem 1531.6 (PrecompactMetricUp completion consumer non-escape)**.** *Let $P = (X, D, N, F, R, M, H, C, G, Q$ be an accepted* PrecompactMetric$^{\uparrow}$ *packet. Any completion-facing consumer that reads P can inspect only the metric rows X, D, finite-net row N, Cauchy-filter rows F, R, regularity-modulus row M, transport and route rows H, C, handoff row G, and provenance row Q. In particular, such a consumer cannot obtain a quotient completion point, a selected convergent subsequence, an external finite set of centers, a host complete-space witness, or a choice operator from the packet.*

Proof. Begin with carrier admission in Definition 1531.1. The carrier has exactly the ten coordinates $X, D, N, F, R, M, H, C, G, Q$, so every admissible consumer read must name one of those rows or a finite subrow displayed by them.

The finite-net part is controlled by Definition 1531.3. It exposes centers and distance witnesses only as ProbeBundle and InBundle data recorded in N, not as an external host finite set.

The filter part is controlled by Definition 1531.4. It exposes Cauchy-filter and regular-filter data only through F, R with the shared modulus row M, not through a completed point, quotient filter, or selected subsequence.

Finally H, C, G, Q only transport, replay, hand off, and name these same displayed rows. Therefore no completion-facing consumer can escape from the finite NameCert surface to a quotient completion, host finite set, selected sequence, ambient complete space, or choice operator. □

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric completion consumer nonescape`

Theorem 1531.7 (PrecompactMetricUp regular filter finite-net route)**.** *For every accepted* PrecompactMetric$^{\uparrow}$ *packet $P = (X, D, N, F, R, M, H, C, G, Q)$, the regular-filter route from finite nets to completion-facing basis data is the displayed path*

$$N \longrightarrow M \longrightarrow F, R \longrightarrow C, G, Q$$

inside the fixed metric context X, D, H. The route first reads the finite net row, then the regularity-modulus row, then the Cauchy-filter and regular-Cauchy-filter rows, and finally the continuation, handoff, and provenance rows; it does not pass through quotient completion, selected subsequence, host finite-set enumeration, or ambient completeness.

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetricRegularFilterFiniteNetRoute`

Proof. Read the metric context first. The rows X, D, H fix the metric carrier, metric comparison data, and componentwise transport for every later net, filter, and modulus read.

Next use the finite-net theorem Definition 1531.3. It makes N the displayed source of the finite centers, membership rows, distance witnesses, and rational comparison ledgers used by the route.

Then use the modulus and filter handoff theorems Definition 1531.8 and Definition 1531.5. The row M scopes the tolerance request shared by N and the filter rows, while F, R expose only finite filterbase and regular-tail inspection data.

The route terminates through C, G, Q. These rows replay the path, hand it to the relevant total-boundedness or completion-facing consumer, and record provenance without adding quotient completion, a selected subsequence, host finite-set enumeration, or ambient completeness. □

Theorem 1531.8 (PrecompactMetricUp regularity-modulus scope)**.** *For every accepted* PrecompactMetric$^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$*, the regularity-modulus row* M *is scoped simultaneously over finite-net tolerance requests in* N *and Cauchy-filter tail requests in* F, R*. The scope is transported through* H*, replayed through* C*, handed to total-boundedness consumers through* G*, and named by* Q*; it does not introduce an independent convergence rate, ambient compactness theorem, choice-selected tail, or completed-space coordinate.*

Proof. Read M from Definition 1531.1. The carrier says that its dyadic windows control both the net tolerance and the Cauchy-filter tail requests through one displayed rate ledger.

Apply Definition 1531.2. Finite-net exactness uses M with N, and Cauchy-filter inspection uses M with F and R; the provenance and handoff clauses keep the same row available to G and Q.

Finally use classifier transport from the same theorem. The row H transports modulus windows componentwise and C records the replay route, so the modulus scope is local to $P = (X, D, N, F, R, M, H, C, G, Q)$ and exports no independent rate object or completed ambient space. □

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric regularity modulus scope`

Theorem 1531.9 (PrecompactMetricUp totally bounded handoff)**.** *Every* TotallyBounded$^{\uparrow}$ *consumer of an accepted* PrecompactMetric$^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$ *reads only the displayed finite net, modulus, and filter-inspection rows:*

$$X, D, N, M, H, C, G, Q.$$

In particular, the consumer may inspect the metric carrier, the closed ProbeBundle *nets, the* InBundle *membership rows, the center histories, the* MetricDistanceWitness *rows, the rational bound ledgers, the* RegularityModulus$^{\uparrow}$ *windows, the componentwise* hsame *transports, the displayed* Cont *routes, and the provenance row, but it cannot read an open-cover compactness proof, a selected subsequence, a quotient completion, a host choice function, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric totally bounded handoff`

Proof. Project the handoff coordinate G from Definition 1531.1. It explicitly names the TotallyBounded$^{\uparrow}$ read route through the metric rows X, D, the finite-net row N, the modulus row M, the transport ledger H, the continuation ledger C, and the provenance row Q.

Now replay the route. A total-boundedness request first reads the accepted metric carrier X and its classifier data D. It then selects a positive tolerance history and follows C into the finite net row N, where the closed ProbeBundle, membership constructors, center rows, distance witnesses, and rational comparisons are displayed.

The only rate information available to the consumer is the $\mathsf{RegularityModulus}^{\uparrow}$ row M. The same row also governs the later $\mathsf{CauchyFilter}^{\uparrow}$ and $\mathsf{RegularCauchyFilter}^{\uparrow}$ inspection coordinates, but those coordinates are read only as finite filterbase and regular-tail evidence; they do not expose a completed object.

Therefore the handoff is exhausted by the displayed finite rows X, D, N, M, H, C, G, Q. The excluded objects are absent from the carrier coordinates, absent from the route ledger, and absent from the provenance row, so they cannot be produced by this local NameCert read. □

Theorem 1531.10 (PrecompactMetricUp bridged completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{PrecompactMetric}^{\uparrow}$ *packet* $P = (X, D, N, F, R, M, H, C, G, Q)$ *bridges to downstream completion data only through the displayed rows*

$$X, D, N, F, R, M, H, C, G, Q.$$

The bridge may read metric carrier data, finite-net rows, Cauchy-filter rows, regular-filter rows, regularity-modulus windows, componentwise transport, continuation replay, the handoff row, and provenance. It cannot read open-cover compactness, a selected subsequence, quotient completion, host choice, or ambient completeness.

Proof. Project the carrier of Definition 1531.1. The packet has exactly the displayed coordinates $X, D, N, F, R, M, H, C, G, Q$, and every completion-facing read must be routed by C and named by Q.

Use Definition 1531.5. It ties the finite-net coordinate N, the Cauchy-filter coordinates F, R, and the regularity-modulus coordinate M into one completion-facing handoff before any basis row is exposed.

Then use Definition 1531.6. It states that a completion-facing consumer can inspect only the metric, net, filter, modulus, transport, route, handoff, and provenance rows of the same packet. The excluded open-cover, subsequence, quotient, choice, and ambient completeness objects are therefore absent from the bridge surface. □

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric bridged completion handoff`

Theorem 1531.11 (PrecompactMetricUp mature completion reflection)**.** *Every accepted* $\mathsf{PrecompactMetric}^{\uparrow}$ *packet has a mature completion-facing reflection surface: finite nets, regular filters,* $\mathsf{CauchyFilterBasis}^{\uparrow}$*,* $\mathsf{RegularityModulus}^{\uparrow}$*, and the completion handoff are all read through the same ten carrier rows*

$$X, D, N, F, R, M, H, C, G, Q.$$

The reflection exposes finite-net centers, regular-filter tails, basis generators, modulus windows, transport, replay, handoff, provenance, and local naming as one packet. It excludes open-cover compactness, selected subsequences, quotient completion, host choice, and ambient completeness.

Lean4 ✓ `BEDC.Derived.PrecompactMetricUp.PrecompactMetric mature completion reflection`

Proof. Start with Definition 1531.7. It routes finite nets through the regularity modulus and then through the Cauchy-filter rows before the completion-facing continuation, handoff, and provenance rows can be read.

Use Definition 1531.8. The same modulus row M controls finite-net tolerance requests in N and Cauchy-filter tail requests in F, R, so the route has one completion-facing rate ledger.

Apply Definition 1531.9. It identifies the total-bounded finite-net surface as the displayed metric, net, modulus, transport, replay, handoff, and provenance rows, with no open-cover or choice-selected replacement.

Finally apply Definition 1531.10. The completion-facing consumer receives exactly $X, D, N, F, R, M, H, C, G, Q,$ and the excluded quotient, selected-subsequence, host-choice, and ambient-completeness objects remain outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrecompactMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrecompactMetric}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1531.1, Definition 1531.2, Definition 1531.3, Definition 1531.7, Definition 1531.8, and Definition 1531.10 bind the finite-net and regular-filter dependency route through total-bounded nets, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, and $\mathsf{RegularityModulus}^{\uparrow}$ inspection rows before any completion-facing bridge can consume it.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrecompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: Open-cover compactness, selected subsequences, quotient completion, host choice, and ambient completeness are not claimed.

Upgrade path: Bridge checking requires Lean standard-bridge evidence for the finite-net and regular-filter completion handoff.

Constructive story: The construction starts from an already certified metric carrier, attaches explicit finite epsilon-net rows and finite Cauchy-filter inspection rows, and uses a regularity-modulus ledger to route total-boundedness consumers toward completion-facing data without importing classical compactness.

Chapter 1532

A Concrete Naming Certificate for $\mathsf{SpreadLaw}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on spreads and choice sequences, the $\mathsf{SpreadLaw}^{\uparrow}$ packet records the finite prefix law that licenses which StreamName windows may extend a displayed prefix. It sits between the fan and tree surfaces of chapter 400, chapter 1475, and chapter 334; the finite-window naming discipline of chapter 126; and the regular-rational readback route of chapter 301. The packet names a finite admissibility law before any regular-Cauchy or $\mathsf{Real}^{\uparrow}$ consumer reads a seal row, and it does not import a host infinite branch, countable choice, quotient stream, or ambient real completeness.

Definition 1532.1 (SpreadLaw carrier)**.** *A* $\mathsf{SpreadLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, A, E, W, H, C, P, N)$$

with the following visible rows:

1. *T is the prefix-closed tree row, listing finite prefixes over the displayed* $\mathsf{Bool}^{\uparrow}$*, list, and* $\mathsf{Nat}^{\uparrow}$ *digit/index surfaces and recording the prefix relation used by the classifier.*
2. *A is the admissibility decision row. For every displayed finite prefix in the packet, A records whether the prefix is licensed by the spread law and whether all shorter prefixes are licensed.*
3. *E is the extension witness row. Each admissible prefix in T carries a displayed one-step or bounded finite continuation whose initial segment remains in T and passes the decision row A.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed to downstream consumers; it contains only prefixes admitted by A and only continuations witnessed by E.*
5. *H stores componentwise* hsame *transport for the tree row, admissibility decisions, extension witnesses, finite windows, continuation replay, provenance, and local naming row.*
6. *C stores displayed* Cont *replay from prefix requests to admissibility checks, from admissibility checks to extension witnesses, and from extension witnesses to W.*
7. *P is the* Pkg *provenance over* $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SpreadLaw}^{\uparrow}}$ *row.*

The classifier accepts a packet only when T is prefix closed, A decides the displayed finite prefixes, E supplies continuation witnesses for every admissible prefix, W contains no window outside that finite law, and H, C, P, N preserve the same route. The carrier has no coordinate for a total choice sequence, a host infinite branch, countable choice, quotient-stream equality, regular-Cauchy completion, or a $\mathsf{Real}^{\uparrow}$ *seal.*

Theorem 1532.2 (SpreadLaw NameCert obligations)**.** *For an accepted* $\mathsf{SpreadLaw}^{\uparrow}$ *carrier* $S = (T, A, E, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SpreadLaw}^{\uparrow}}$ *obligations are exactly carrier exposure, classifier stability, prefix-extension closure, finite-window compatibility, continuation replay, and ledger exactness. These obligations are discharged by projecting the displayed rows*

$$T \longmapsto A \longmapsto E \longmapsto W$$

together with H, C, P, N*.*

Proof. Carrier exposure projects the tuple of Definition 1532.1. The row T is the only tree surface, and the classifier can inspect only its displayed finite prefixes.

Classifier stability is read from A. If two presentations are componentwise hsame through H, the same admissibility decisions and the same rejected prefixes are replayed, so no later consumer can substitute a different law.

Prefix-extension closure is supplied by E. For every prefix accepted by A, the witness row names a finite continuation still governed by T and A, and the continuation replay row C records the route from the request to the witness.

Finite-window compatibility is the assertion that W contains only the prefixes and continuations exposed by T, A, E. The provenance and local naming rows P, N then make the ledger exact: every accepted $\mathsf{StreamName}^{\uparrow}$ window is accounted for by the same finite spread-law route, and no unrecorded infinite branch or completion seal is available. □

Theorem 1532.3 (SpreadLaw StreamName window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{SpreadLaw}^{\uparrow}$ *packet must first read the finite prefix law* T, A*, the extension witness row* E*, and the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*. Only after that route is displayed may the consumer read any regular-Cauchy row, regular-rational readback, or* $\mathsf{Real}^{\uparrow}$ *seal row.*

Proof. Read the accepted carrier of Definition 1532.1. The rows T, A, E, W are the only rows that expose finite prefix admission, continuation witnesses, and StreamName windows.

A $\mathsf{RegSeqRat}^{\uparrow}$ consumer is downstream of the window row. Its regular-rational readback therefore receives a prefix already certified by A and a continuation already witnessed by E.

A $\mathsf{Real}^{\uparrow}$ consumer is still later in the same route. Since the carrier contains no independent real seal coordinate, any real-facing read must pass through the finite law and the window handoff before it reaches a completion-facing row. □

Falsifiable prediction: Every accepted $\mathsf{SpreadLaw}^{\uparrow}$ handoff to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ factors through the displayed prefix tree, admissibility decision row, extension witness row, finite StreamName window, transport, continuation replay, provenance, and local NameCert rows.

Independence witness: fantheorem, cantorspace, bairespace, streamname, regseqrat: $\mathsf{SpreadLaw}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a prefix-closed finite tree row, admissibility decision row, extension witness row, finite StreamName window, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SpreadLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{SpreadLaw}^{\uparrow}$ packet is generated from a prefix-closed finite Bool/List/Nat tree row, an admissibility decision row, extension witnesses, a finite StreamName window, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpreadLaw}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1532.1, Definition 1532.2, and Definition 1532.3 seed the finite-prefix law surface that licenses StreamName windows before RegSeqRat or Real-facing consumers read completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpreadLaw}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close FanTheorem compactness, CantorSpace or BaireSpace completeness, host infinite sequences, countable choice, quotient-stream equality, regular-Cauchy completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, admissibility classification, prefix-extension closure, StreamName window compatibility, RegSeqRat handoff, Real-facing non-escape, and ledger exactness for BEDC.Derived.SpreadLawUp.

Chapter 1533

A Concrete Naming Certificate for $\mathsf{LocatedMetric}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedMetric}^{\uparrow}$ packet records the located metric carrier required before the completion interface reads an arbitrary metric source. It sits over the metric-distance witness of chapter 57, the dyadic locatedness ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the separated zero-distance boundary of chapter 1411. The packet supplies the finite interface consumed by $\mathsf{Completion}^{\uparrow}$; it is not a quotient completion, a selected limit, trichotomy on distances, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1533.1 (Located metric carrier)**.** *A* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, D, S, R, E, Z, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-carrier row with its local point classifier and the finite observation rows on which distance requests are evaluated.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-witness row. It displays, for each accepted pair of point observations, the finite metric evidence that a distance request may inspect.*
3. *D is the dyadic locatedness row. For each distance request and each positive dyadic tolerance, it records a finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison window locating the distance below or apart from the requested bound.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that determines which finite distance reads, tolerance reads, and locatedness comparisons are visible to a consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that packages the scheduled dyadic comparisons as a regular rational name for the displayed distance value.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the metric witness, dyadic locatedness window, stream schedule, and regular rational readback have all been displayed.*
7. *Z is the separated zero-distance boundary row. It exports the zero-distance-to-point-classifier route through* $\mathsf{SeparatedMetric}^{\uparrow}$ *and does not identify points by host equality.*
8. *H stores componentwise* hsame *transport for the point carrier, metric witness, dyadic locatedness row, stream windows, regular rational readback, real seal, zero-distance boundary, continuation replay, provenance, and local naming row.*

9. *C stores* Cont *replay from point observations to metric distance witnesses, from distance witnesses to dyadic locatedness comparisons, from locatedness comparisons to stream and regular-rational readbacks, and from those readbacks to the real seal and separated zero-distance boundary.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$ *row.*

The classifier compares accepted located-metric packets only through the displayed tuple $X, M, D, S, R, E, Z, H, C, P,$ It has no coordinate for quotient completion, selected limits, total trichotomy of distances, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricTasteGate single carrier alignment`

Theorem 1533.2 (Located metric NameCert obligations)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier $L = (X, M, D, S, R, E, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$ *obligations are exactly carrier admission, finite point classification, metric-distance witness readback, dyadic locatedness stability, scheduled regular-rational readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, separated zero-distance compatibility, and ledger non-escape. These obligations are discharged by the displayed route*

$$X \longmapsto M \longmapsto D \longmapsto S \longmapsto R \longmapsto E$$

together with Z, H, C, P, N.

Proof. Carrier admission is the projection of the displayed tuple in Definition 1533.1. The finite point classifier is read from X, and every distance request must pass through the metric witness row M before any dyadic or real-facing consumer may inspect it.

The locatedness obligation is the defining use of D. For each scheduled tolerance request, D supplies the finite $\mathsf{DyadicRatCore}^{\uparrow}$ comparison window that makes the metric distance located at that dyadic scale. Transport by H moves the points, windows, metric witness, and locatedness comparison componentwise, while C replays the same finite route after transport.

The scheduled readback obligation factors through S and R. The stream schedule determines the finite observations being read, and the regular rational row packages those reads before the real-facing seal E is consumed.

Zero-distance compatibility is isolated in Z. A consumer that wants to identify points from zero distance must use the separated-metric route of chapter 1411; no host equality or quotient equality is introduced inside the located-metric packet.

Finally, P and N source and name the same finite surface. Since the carrier has no coordinate for completion quotients, selected limits, trichotomy, choice, compactness, or ambient real completeness, the listed obligations exhaust the local NameCert interface. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier namecert obligations`

Theorem 1533.3 (Located metric completion handoff)**.** *Every* $\mathsf{Completion}^{\uparrow}$ *consumer that reads an arbitrary located metric source from an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *packet must factor through*

$$X \longmapsto M \longmapsto D \longmapsto S \longmapsto R \longmapsto E$$

and the separated boundary Z before forming completion data. The exported handoff is the finite tuple $X, M, D, S, R, E, Z, H, C, P, N$, with no hidden quotient completion, selected representative, countable choice, total comparison of distances, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a completion consumer asking for a metric source. The point carrier X supplies only finite point observations and their local classifier, so the consumer must obtain distance information from the metric witness row M.

Locatedness is then read through D. The dyadic row gives the requested finite comparison window and attaches it to the same point observations and distance witness. This is the step that turns a bare metric witness into a located metric input suitable for regular Cauchy completion.

The handoff to real-valued distance names proceeds through S, R, and E. The stream schedule fixes the finite reads, the regular rational readback packages them as a regular name, and the real seal is reached only after those rows are present.

If the completion route needs point identification at zero distance, it must use Z and hence the separated-metric sibling. The structural rows H, C, P, N preserve, replay, source, and name the same finite route, so the completion interface receives located metric data without importing any excluded quotient, selection, choice, trichotomy, compactness, or ambient-completeness principle. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier completion handoff`

Theorem 1533.4 (Dyadic radius localization)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, every locatedness read of a distance radius factors through*

$$M \longmapsto D \longmapsto S \longmapsto R$$

before the $\mathsf{Real}^{\uparrow}$ *seal* E *is available. Thus a consumer sees the metric witness, the positive dyadic comparison row, the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any real-valued distance observation is exposed.*

Proof. Begin with a locatedness request for a distance radius. The point observations in X do not carry a real value, so the request first reaches the metric witness M and obtains only the finite distance evidence displayed there.

The radius comparison is then localized by D. That row records the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance window and binds the comparison to the same metric witness, so no real seal or completion consumer can bypass the dyadic localization step.

Finally, S and R schedule and package the finite comparison reads. Only after these rows are present may E be consumed as a real-valued seal, which gives the stated factorization. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier dyadic radius localization`

Theorem 1533.5 (Separated zero route)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P$ *any identification of two point observations from zero distance must route through the separated metric row* Z*. The rows* $M, D, S, R, E, H, C, P, N$ *may transport, replay, source, and name the zero-distance evidence, but they do not identify points without the* $\mathsf{SeparatedMetric}^{\uparrow}$ *boundary recorded in* Z*.*

Proof. Suppose a consumer asks to identify two point observations because their displayed distance is zero. The metric and locatedness rows can exhibit the distance evidence and its dyadic localization, while S, R, E can package the same evidence as a scheduled real-valued read.

None of those rows contains the point-classifier quotient. The only row with a zero-distance-to-point-classifier route is Z, whose definition explicitly imports the separated metric boundary from chapter 1411.

The structural rows H, C, P, N preserve the route already chosen; they do not create a new equality principle. Therefore any valid zero-distance identification in the packet must pass through Z. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier separated zero route`

Theorem 1533.6 (Real seal readback)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$ *every* $\mathsf{Real}^{\uparrow}$*-valued distance read reaches* E *only through the finite route*

$$M \longmapsto D \longmapsto S \longmapsto R \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The readback therefore records the metric witness, dyadic locatedness row, $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *package, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$ *row before the real seal is consumed.*

Proof. Start from a request for a real-valued distance. The request must first be grounded in M, because only the metric witness row displays the finite distance evidence associated with the point observations.

The dyadic and scheduled readback rows then determine the visible approximation data. Row D gives the located comparison window, S fixes the finite schedule of reads, and R packages those reads as the regular rational object that can face the real seal.

It remains to check that the route is stable under the BEDC structural operations. Row H transports each component, row C replays the same route after transport, row P records provenance, and row N names the local certificate surface. Thus E is reached only after the listed route is present. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier real seal readback`

Falsifiable prediction: Every $\mathsf{Completion}^{\uparrow}$ read from a $\mathsf{LocatedMetric}^{\uparrow}$ packet factors through the displayed point carrier, metric distance witness, dyadic locatedness row, stream schedule, regular rational readback, real seal, separated zero-distance boundary, componentwise transport, continuation replay, provenance, and local naming row before completion data is consumed.

Independence witness: metric, dyadicratcore, streamname, regseqrat, real, separatedmetric: $\mathsf{LocatedMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a point carrier, metric distance witness, dyadic locatedness comparison, StreamName window schedule, RegSeqRat readback, RealUp seal, separated zero-distance boundary, componentwise transport, continuation replay, provenance, and local NameCert row.

Theorem 1533.7 (LocatedMetric radius-locality obligation)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, every radius-locality read is a finite BEDC obligation over the existing carrier rows* M, D, S, R, H, C, P, N*. The metric row* M *supplies the distance witness, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *supplies the positive tolerance window, the* $\mathsf{StreamName}^{\uparrow}$ *row* S *selects the finite read, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *packages the readback before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Proof. Project the carrier rows from Definition 1533.1. A radius request has no independent real-valued coordinate; it first reads the finite metric evidence in M and the dyadic locatedness window in D.

The schedule and readback rows are then forced by S and R. They keep the request inside a finite stream window and a regular rational package, while H, C, P, N only transport, replay, source, and name that same route.

Thus radius locality is a projection-and-replay obligation on the displayed rows. It is not supplied by quotient distance equality, a chosen radius representative, trichotomy on distances, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier radius locality obligation`

Theorem 1533.8 (LocatedMetric separated-zero obligation)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, any zero-distance-to-point-classifier read is a finite obligation through the existing separated boundary row* Z*. The rows* M, D, S, R, E *may display, locate, schedule, package, and seal the zero-distance evidence, but the point identification route must pass through* $\mathsf{SeparatedMetric}^{\uparrow}$ *as recorded by* Z*.*

Proof. Start with the zero-distance evidence. Rows M, D, S, R, E expose it as metric evidence, dyadic locatedness, a finite window, a regular rational readback, and a real-facing seal.

The carrier definition isolates point identification in Z. Since no other row contains the separated point-classifier boundary, projection from Definition 1533.1 leaves Z as the only admissible route from zero distance to point classification.

The structural rows H, C, P, N preserve the selected displayed route by transport, replay, provenance, and naming. They do not add quotient point equality or host equality, so the separated-zero obligation remains finite and local. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier separated zero obligation`

Theorem 1533.9 (LocatedMetric Real-seal obligation)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *distance seal read is a finite obligation over* $M, D, S, R, E, H, C, P, N$ *and the separated boundary* Z *when zero-distance compatibility is requested. The seal row* E *is consumed only after the* $\mathsf{Met}^{\uparrow}$ *witness,* $\mathsf{DyadicRatCore}^{\uparrow}$ *locatedness row,* $\mathsf{StreamName}^{\uparrow}$ *finite window, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed.*

Proof. Read the seal route in the order displayed by the carrier. The metric witness M grounds the distance request, D locates it at the requested dyadic tolerance, S selects the finite observations, and R packages the scheduled reads.

Only after those rows are present can E be consumed as a $\mathsf{Real}^{\uparrow}$ seal. If the same read is used to identify points at zero distance, Z supplies the separated metric boundary before the point classifier is reached.

Finally, H, C, P, N transport, replay, source, and name the same finite rows. The obligation therefore records a BEDC seal route rather than quotient real equality, choice of limits, or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier real seal obligation`

Theorem 1533.10 (LocatedMetric obligation closure package)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, the obligation surface of the chapter is the finite package consisting of carrier admission, the local* $\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$ *obligations, completion handoff, dyadic radius localization, separated zero route, Real seal readback, and ledger non-escape. Every public read factors through*

$$X \longmapsto M \longmapsto D \longmapsto S \longmapsto R \longmapsto E$$

together with Z, H, C, P, N *before any completion-facing, radius-facing, zero-distance-facing, or Real-facing consumer may inspect the packet.*

Proof. Carrier admission and the local naming obligations are projections of Definition 1533.1 and Definition 1533.2. They expose the point carrier, metric-distance witness, dyadic locatedness

row, stream schedule, regular rational readback, Real seal, separated boundary, transport, replay, provenance, and local NameCert row.

The completion and radius routes are already finite obligation rows. Apply Definition 1533.3 for the completion-facing consumer and Definition 1533.4 together with Definition 1533.7 for radius-local reads.

The zero-distance and Real-seal routes use the remaining displayed rows. Apply Definition 1533.5, Definition 1533.8, Definition 1533.6, and Definition 1533.9. Since the carrier has no coordinate for quotient completion, selected limits, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed package exhausts the local obligation surface and supplies ledger non-escape. □

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier obligation closure package`

Theorem 1533.11 (LocatedMetric scoped obligation rows)**.** *For an accepted* $\mathsf{LocatedMetric}^{\uparrow}$ *carrier* $L = (X, M, D, S, R, E, Z, H, C, P, N)$*, the radius-locality obligation, separated-zero obligation, and* $\mathsf{Real}^{\uparrow}$*-seal obligation depend only on displayed* BHist*,* hsame*,* Cont*,* NameCert*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows together with the carrier rows* $M, D, S, R, E, Z, H, C, P, N$*. No radius, zero-distance, or seal consumer may add a quotient metric, selected limit, trichotomy decision, countable-choice selector, open-cover compactness proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row outside that scope.*

Lean4 ✓ `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier scoped obligation rows`

Proof. The radius-locality theorem Definition 1533.7 displays the finite route through the metric row, dyadic locatedness row, stream schedule, regular-rational readback, transport, replay, provenance, and local naming row.

For zero distance, Definition 1533.8 keeps the separated boundary Z visible before any point classifier is reached. The surrounding rows only transport and name the same finite evidence.

For the real seal, Definition 1533.9 consumes E after M, D, S, R and retains H, C, P, N. Together with Definition 1533.10, these three obligations close the paper-side scope of the located-metric rows without changing the Lean verification state. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedMetric}^{\uparrow}$ packet is generated from a point carrier, a MetricUp distance witness, a DyadicRatCore locatedness ledger, StreamName windows, RegSeqRat readbacks, a RealUp seal, a separated zero-distance boundary, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1533.1, Definition 1533.3, Definition 1533.10, and Definition 1533.11 bind the public completion handoff, radius-locality, separated-zero, and Real-seal obligations to displayed BHist, hsame, Cont, NameCert, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedMetric}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.LocatedMetricUp.LocatedMetricCarrier\_completion\_handoff`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, trichotomy on distances, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: No further paper-side theory-grade closure remains; bridge checking remains a separate verification-axis matter.

Chapter 1534

A Concrete Naming Certificate for $\mathsf{SturmRootIsolation}^{\uparrow}$

Following Sturm and Bishop–Bridges constructive analysis, the $\mathsf{SturmRootIsolation}^{\uparrow}$ packet reads a finite polynomial root-isolation surface through Sturm-chain sign-variation data rather than through host algebraic closure, real-root choice, or ambient completeness. It consumes the polynomial source of chapter 50, the rational and dyadic interval ledgers of chapter 354 and chapter 306, and the adjacent sign-change bisection packet of chapter 1407. Its downstream completion boundary is the finite window route through chapter 126, chapter 301, and chapter 38.

Definition 1534.1 (Sturm root-isolation carrier)**.** *A* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$$

with the following visible rows:

1. *P is the* $\mathsf{Poly}^{\uparrow}$ *source row, including the displayed coefficient ledger and the finite derivative and pseudo-remainder inputs from which the Sturm chain is read;*
2. *I is the* $\mathsf{RationalInterval}^{\uparrow}$ *interval ledger carrying the inspected rational cells and their endpoint order rows;*
3. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger used for finite cell subdivision and endpoint-window export;*
4. *V is the Sturm-chain division and sign-variation ledger, recording each displayed division row, the endpoint sign rows for every chain entry, and the variation-count differences for the inspected cells;*
5. *B is the selected isolating branch, represented as the retained cell together with the finite comparison rows showing that its variation drop is the accepted one-root branch and that discarded cells have the displayed alternative counts;*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window surface exposed after the selected rational or dyadic cell has been fixed;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the selected interval windows and the requested unary precision;*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal for the retained endpoint names and for downstream real-facing consumers of the isolating window;*

9. *H stores the componentwise* hsame *transports for the polynomial row, interval rows, Sturm ledger, branch row, stream windows, regular readbacks, real seal rows, package provenance, and local certificate;*
10. *C stores the displayed* Cont *replay routes for polynomial inspection, Sturm-chain division replay, sign-variation counting, branch selection, window export, regular-sequence handoff, and real-seal consumption;*
11. *Q_0 is the* Pkg *provenance over* $\mathsf{Poly}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{BisectionRootIsolation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmRootIsolation}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite Sturm-chain root-isolation packet. It has no coordinate for an algebraic root object, a host factorization theorem, a classical completeness principle, a quotient real equality, or an ambient real-root existence theorem.

Lean4 (definition) `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier`

Theorem 1534.2 (Sturm root-isolation NameCert obligations)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$, the local* $\mathsf{NameCert}_{\mathsf{SturmRootIsolation}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the finite packet of Definition 1534.1;*
2. *polynomial-source admission through the coefficient, derivative, and pseudo-remainder rows of P;*
3. *interval admission through the rational cell ledger I and the dyadic refinement ledger D;*
4. *Sturm-ledger exactness, requiring every division row and every endpoint sign row used in V to be one of the displayed finite rows;*
5. *branch isolation, requiring the selected row B to be justified by the displayed sign-variation drop in V and handed to the adjacent bisection packet only as a finite retained-cell surface;*
6. *retained-window handoff through W, R, and S;*
7. *componentwise transport, replay, provenance, and naming through H, C, Q_0, and N.*

No further analytic or algebraic obligation is part of the packet.

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier namecert obligations`

Proof. Project the carrier of Definition 1534.1. The polynomial row supplies only the displayed coefficient, derivative, and pseudo-remainder inputs, while the rational and dyadic interval rows supply only the inspected cells and endpoint windows.

The Sturm ledger V accounts for the chain computation. Each sign row used in a variation count is attached to a displayed endpoint and a displayed chain entry, and each division row is recorded as finite ledger data rather than as an external factorization theorem.

The selected branch B is then read from the displayed variation-drop ledger. Its retained cell may be handed to the bisection surface of chapter 1407, but only as the already selected rational or dyadic window with its sign and variation evidence still attached.

Finally, W, R, and S expose the finite window to stream, regular-rational, and real-facing consumers. The rows H, C, Q_0, and N supply transport, replay, provenance, and local naming, so the packet has no remaining coordinate from which to extract an algebraic root object, host factorization, quotient real equality, or completeness principle. □

Theorem 1534.3 (Sturm root-isolation sign-variation handoff)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier and every selected branch row* B*, the branch handed to downstream interval consumers factors through the* $\mathsf{Poly}^{\uparrow}$ *row* P*, the* $\mathsf{RationalInterval}^{\uparrow}$ *and* $\mathsf{DyadicInterval}^{\uparrow}$ *interval rows* I, D*, the Sturm-chain division and sign-variation ledger* V*, the retained-cell row of* B*, and the replay rows* H, C, Q_0, N*. The handoff exports a finite isolating cell with displayed variation-count evidence and exports no host root selection.*

Proof. Read the selected branch coordinate. By construction, it is not independent of the Sturm ledger: the retained cell in B is accepted only after the endpoint signs and variation-count difference have been read from V.

The interval coordinates I and D provide the cell on which those signs are inspected. The polynomial coordinate P provides the finite chain entries whose signs are counted, and H, C, Q_0, N replay the same rows under transport and package provenance.

Consequently any downstream interval consumer receives the retained cell together with its displayed variation-count evidence. Since no coordinate stores a chosen host root or a completed real-root witness, the handoff remains a finite NameCert surface. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier sign variation handoff`

Theorem 1534.4 (Sturm root-isolation squarefree route)**.** *Every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier reads the squarefree polynomial route before a sign-variation count can be consumed. Concretely, the polynomial source row* P *and Sturm ledger* V *must display the squarefree factor row, the pseudo-remainder or resultant compatibility row, the endpoint sign rows, and the retained interval rows from* I, D *before the branch row* B *is available. The interval-refinement certificate may cite chapter 2079, chapter 7329, chapter 354, chapter 38, chapter 301, and chapter 126 only through these displayed* BHist *and* NameCert *rows, and it exports no host squarefree factorization theorem.*

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier squarefree route`

Proof. Project the carrier of Definition 1534.1. The polynomial source row P contains the coefficient, derivative, pseudo-remainder, and squarefree-route data from which the finite Sturm sequence is read.

Use the sign-variation handoff of Definition 1534.3. It places every branch consumer downstream of P, I, D, V, B and therefore downstream of the displayed squarefree and endpoint-sign rows that feed V.

The sibling chapters supply only their finite certificate surfaces: chapter 2079 supplies the chain rows, chapter 7329 supplies compatibility data, and the rational, stream, regular-rational, and Real siblings supply interval and completion rows. Since no carrier coordinate stores a host factorization theorem, the squarefree route is exactly the displayed packet route. □

Theorem 1534.5 (Sturm root-isolation subresultant sign-variation route)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier* $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$*, the sign-variation count used by* B *is downstream of the subresultant or pseudo-remainder compatibility rows displayed in* P *and* V*. The interval-refinement certificate cannot bypass those rows: any refinement that reaches* W, R, S *must first replay the polynomial resultant route, the Sturm sequence route, the endpoint sign rows, and the rational or dyadic interval rows through* H, C, Q_0, N*.*

Proof. Read the Sturm ledger V. Its variation-count entries are tied to displayed chain entries and endpoint signs, so a count cannot be consumed before the subresultant or pseudo-remainder compatibility rows for those chain entries have been displayed.

Apply the squarefree route theorem Definition 1534.4. It places the branch row B downstream of the squarefree polynomial route and the resultant compatibility rows, while chapter 2079 and chapter 7329 provide only named finite sibling surfaces.

Finally use interval refinement and Real seal nonescape, Definition 1534.7 and Definition 1534.9. The retained interval cannot reach $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ rows before the same polynomial, resultant, sign-variation, and interval rows have been replayed through H, C, Q_0, N. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier subresultant sign variation`

Theorem 1534.6 (Sturm root-isolation sign-variation scope)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier* $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$*, every accepted branch selection reads the polynomial chain rows in* P *and the endpoint sign rows in* V *before the branch row* B *is available. The branch classifier therefore acts only on displayed polynomial, endpoint-sign, and variation-count data, and it exports no root object or external sign oracle.*

Proof. Project the carrier of Definition 1534.1. The polynomial source row P stores the displayed coefficient, derivative, and pseudo-remainder inputs from which the finite Sturm chain is read.

Use the sign-variation handoff of Definition 1534.3. It places the selected branch downstream of the Sturm ledger V, so the endpoint sign rows and variation-count difference are already visible before B can be consumed.

The structural rows H, C, Q_0, N replay and name the same finite rows. Since the carrier has no coordinate for a host root, algebraic closure, or independent sign oracle, branch selection is scoped to the displayed polynomial chain and endpoint sign ledger. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier sign variation scope`

Theorem 1534.7 (Sturm root-isolation interval refinement)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier* $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$*, rational interval cells from* I *refine through the* $\mathsf{DyadicInterval}^{\uparrow}$ *row* D *before any* $\mathsf{StreamName}^{\uparrow}$ *window* W *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *is exposed. Thus a completion-facing consumer sees stream and regular-rational windows only after the retained rational cell has passed through the displayed dyadic refinement ledger.*

Proof. Read the interval coordinates of Definition 1534.1. The rational interval row I carries the inspected cells, while D records the dyadic refinement ledger used for finite subdivision and endpoint-window export.

Apply the branch handoff of Definition 1534.3. It keeps the retained cell attached to the rational and dyadic interval rows before the branch is handed to downstream interval consumers.

The Real seal nonescape theorem Definition 1534.9 then places the $\mathsf{StreamName}^{\uparrow}$ window W and $\mathsf{RegSeqRat}^{\uparrow}$ readback R downstream of that selected interval route. Hence no stream or regular-rational window is exposed before dyadic refinement has been displayed. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier interval refinement`

Theorem 1534.8 (Sturm root-isolation certificate ledger)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier* $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$*, the local certificate ledger is exhausted by the rows*

$$P, I, D, V, B, W, R, S, H, C, Q_0, N.$$

It exports polynomial source data, rational and dyadic interval rows, sign-variation rows, a selected branch, stream windows, regular rational readback, a Real-facing seal, transport, replay, provenance, and local naming, but no host root, algebraic closure, quotient equality, real trichotomy, or completeness principle.

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier certificate ledger`

Proof. Start from the NameCert obligations of Definition 1534.2. They list exactly the carrier, polynomial, interval, Sturm-ledger, branch, retained-window, transport, replay, provenance, and naming obligations.

The sign-variation scope theorem shows that branch selection consumes only P, V, B together with the interval route. The interval refinement theorem shows that I, D precede the stream and regular-rational rows W, R.

Finally use the Real seal nonescape theorem. It places the seal row S downstream of $I, D, V, W, R, H, C, Q_0, N$ and excludes algebraic roots, host root existence, quotient real equality, trichotomy, and ambient completeness. The displayed tuple therefore exhausts the certificate ledger. □

Theorem 1534.9 (Sturm root-isolation Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier is reached only after the selected rational or dyadic interval row, the displayed Sturm-chain sign-variation ledger, the* $\mathsf{StreamName}^{\uparrow}$ *window surface, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the transport, replay, provenance, and local naming rows have been read. The seal exposes the finite isolating window and exports no algebraic root object, host root existence theorem, quotient real equality, real trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the seal coordinate S. It is stored with the selected interval row, the Sturm ledger, the stream windows, the regular-rational handoff, and the BEDC transport and replay rows; it is not stored as a free real object.

First the selected branch is fixed by Definition 1534.3. Then the retained interval windows pass through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces at the requested precision.

Only after that route is fixed can the $\mathsf{Real}^{\uparrow}$ seal be read. Thus the seal records the same finite isolating window and cannot export an algebraic root object, host root existence, quotient real equality, trichotomy data, or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier real seal nonescape`

Theorem 1534.10 (Sturm root-isolation obligation closure route)**.** *For every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier* $Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$*, the polynomial source row, rational and dyadic interval rows, Sturm sign-variation ledger, selected branch,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* hsame*,* Cont*,* Pkg*, and* NameCert *rows exhaust the local obligation surface. The packet has no remaining obligation for a host root object, algebraic closure theorem, quotient real equality, real trichotomy, selected real root, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier obligation closure route`

Proof. Start with the NameCert obligations of Definition 1534.2. They list carrier admission, polynomial-source admission, rational and dyadic interval admission, the Sturm ledger, branch isolation, retained-window handoff, transport, replay, provenance, and local naming.

Use the sign-variation handoff and scope rows, Definition 1534.3 and Definition 1534.6. They place every accepted branch downstream of the displayed polynomial chain rows, endpoint sign rows, and variation-count differences rather than a host root selector.

Apply interval refinement and certificate ledger exhaustion, Definition 1534.7 and Definition 1534.8. These force rational cells through the dyadic refinement ledger before any stream window, regular-rational readback, or real-facing seal is exposed.

Finally apply Real seal nonescape, Definition 1534.9. Since the seal is downstream of the selected interval, Sturm ledger, stream windows, regular-rational readback, transport, replay, provenance, and naming rows, no algebraic root object, host root theorem, quotient equality, trichotomy datum, selected root, or completeness principle remains. □

Theorem 1534.11 (Sturm root-isolation scoped kernel binding)**.** *Every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *carrier*

$$Q = (P, I, D, V, B, W, R, S, H, C, Q_0, N)$$

is scoped exactly by the displayed $\mathsf{Poly}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{BisectionRootIsolation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before any branch consumer or Real-seal consumer reads it. The scoped packet exposes no algebraic root object, host factorization theorem, quotient real equality, real trichotomy, selected real root, or* $\mathsf{Real}^{\uparrow}$ *completeness principle outside those rows.*

Proof. Start with the NameCert obligations of Definition 1534.2. They bind carrier admission to the displayed polynomial source, rational and dyadic interval ledgers, Sturm sign-variation ledger, selected branch, stream window, regular-rational readback, Real seal, transport, replay, provenance, and local naming rows.

Use the sign-variation handoff of Definition 1534.3. It places the branch row downstream of the polynomial, interval, and sign-variation data, with the adjacent $\mathsf{BisectionRootIsolation}^{\uparrow}$ consumer receiving only the retained finite cell and its variation-count evidence.

Apply interval refinement, Definition 1534.7. It forces rational cells through the dyadic interval ledger before stream windows or regular-rational readback become visible.

Finally apply Real seal nonescape, Definition 1534.9. The seal remains downstream of the same displayed rows and cannot expose host algebraic roots, quotient equality, trichotomy, selected roots, or ambient completeness. Hence every branch or Real-seal consumer reads exactly the listed kernel rows before it can consume the packet. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier scoped kernel binding`

Theorem 1534.12 (Sturm root-isolation scoped interval and Real-seal route)**.** *Every accepted* $\mathsf{SturmRootIsolation}^{\uparrow}$ *branch-selection consumer must pass through the* $\mathsf{Poly}^{\uparrow}$ *source row,* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger,* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger, Sturm sign-variation ledger,* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *branch handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows before it can be used as a scoped interval or real-facing root-isolation route. The route does not claim algebraic root existence, factorization completeness, real trichotomy, quotient equality, selected real roots, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 1534.2. They expose the polynomial source row, rational and dyadic interval rows, Sturm ledger, branch row, stream windows, regular-rational readback, Real seal, transport, replay, provenance, and local naming as the finite carrier surface.

Use the sign-variation handoff and sign-variation scope, Definition 1534.3 and Definition 1534.6. These place every accepted branch downstream of the polynomial chain rows, endpoint sign rows, variation-count differences, and the retained $\mathsf{BisectionRootIsolation}^{\uparrow}$ branch handoff.

Apply interval refinement and certificate ledger exhaustion, Definition 1534.7 and Definition 1534.8. The rational cell ledger and dyadic refinement ledger therefore remain visible before any $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, or real-facing consumer is available.

Finally use Real seal nonescape, the obligation-closure route, and scoped kernel binding: Definition 1534.9, Definition 1534.10, and Definition 1534.11. Together they keep the branch and seal consumers inside the displayed polynomial, interval, Sturm-ledger, bisection, stream, regular-rational, and real-seal rows. Since the carrier has no coordinate for algebraic root existence, factorization completeness, trichotomy, quotient equality, selected real roots, or Real completeness, the consumer route is exactly the scoped interval and Real-seal route stated above. □

Lean4 ✓ `BEDC.Derived.SturmRootIsolationUp.SturmRootIsolationCarrier scoped interval real seal route`

Closure status for $\mathsf{NameCert}_{\mathsf{SturmRootIsolation}^{\uparrow}}$.

Constructive story: A $\mathsf{SturmRootIsolation}^{\uparrow}$ packet is generated from a $\mathsf{Poly}^{\uparrow}$ source row, $\mathsf{RationalInterval}^{\uparrow}$ and $\mathsf{DyadicInterval}^{\uparrow}$ interval rows, a finite Sturm-chain division and sign-variation ledger, a selected isolating branch, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal rows, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmRootIsolation}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1534.1, Definition 1534.2, Definition 1534.3, Definition 1534.9, and Definition 1534.11 bind finite Sturm-chain root isolation to the displayed polynomial, rational interval, dyadic interval, stream, regular-rational, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmRootIsolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close algebraic root existence, a host factorization theorem, quotient real equality, real trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Scoped kernel binding is the next paper-theory step, tying the finite Sturm-chain obligation package to a public interval and real-seal consumer boundary.

Chapter 1535

A Concrete Naming Certificate for $\mathsf{UltrametricSpace}^{\uparrow}$

Following Schikhof's non-Archimedean analysis and the Bosch–Guntzer–Remmert treatment of ultrametric geometry, the $\mathsf{UltrametricSpace}^{\uparrow}$ packet records a metric surface whose triangle evidence is the strong max-radius comparison. It is a standard metric neighbour of $\mathsf{Met}^{\uparrow}$ in chapter 57, the p-adic example surface of chapter 100, the ball ledgers of chapter 311 and chapter 1450, and the completion-facing boundary of chapter 128. The carrier names only finite distance comparisons, radius ledgers, nested-ball witnesses, example handoffs, transport, replay, provenance, and a local certificate; it does not import quotient classes, choice of representatives, host real equality, or a completed ambient field.

Definition 1535.1 (UltrametricSpace carrier)**.** *An* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, V, T, B, E, H, K, P, N)$$

with the following visible rows:

1. *M is the parent* $\mathsf{Met}^{\uparrow}$ *row carrying the displayed point names, distance classifier, symmetry ledger, zero-distance boundary, and ordinary triangle route.*
2. *V is the value and radius comparison ledger, recording the finite distance values or distance bounds inspected by the packet and the max-radius comparison used for ball consumers.*
3. *T is the strong-triangle ledger, asserting for every displayed triple read by the packet that the third distance is routed through the maximum of the other two displayed radii.*
4. *B is the nested-ball ledger, classifying displayed balls by the ultrametric rule that intersecting balls are nested once their centers and radii pass through V and T.*
5. *E is the example handoff row, exposing either a* $\mathsf{Padic}^{\uparrow}$ *prime-scale route or a* $\mathsf{DyadicBall}^{\uparrow}$ *radius route as a finite witness of the same strong-triangle discipline.*
6. *H stores componentwise* hsame *transport for the parent metric row, comparison ledger, strong-triangle ledger, nested-ball ledger, example handoff, continuation replay, provenance, and local naming row.*
7. *K stores displayed* Cont *replay from metric reads to comparison reads, from comparison reads to strong-triangle checks, and from strong-triangle checks to nested-ball,* $\mathsf{Padic}^{\uparrow}$*,* $\mathsf{DyadicBall}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers.*

8. *P is the* Pkg *provenance over* $\mathsf{UltrametricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{UltrametricSpace}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the parent metric row is already displayed, every inspected distance comparison is routed through V, every triangle request is answered by the strong max-radius row T, nested-ball claims are read from B, example consumers factor through E, and all downstream reads preserve H, K, P, N. It has no coordinate for quotient metric completion, selected representatives, host real equality of distances, open-cover compactness, or an ambient non-Archimedean field.

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceTasteGate single carrier alignment`

Theorem 1535.2 (UltrametricSpace NameCert obligations)**.** *For an accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier $U = (M, V, T, B, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UltrametricSpace}^{\uparrow}}$ *obligations are exactly the following:*

1. *carrier admission for the displayed parent metric, comparison ledger, strong-triangle ledger, nested-ball ledger, example handoff, transport, replay, provenance, and local naming rows;*
2. *inherited metric-row compatibility, requiring all point names, distance reads, symmetry checks, and ordinary triangle routes to be read from M before the ultrametric rows are inspected;*
3. *strong-triangle stability, requiring transported packets to preserve the max-radius comparison row T under the componentwise* hsame *data in H;*
4. *nested-ball classification, requiring every ball-consumer claim to pass through B after the relevant centers and radii have been compared by V and T;*
5. *p-adic or dyadic witness compatibility, requiring the example row E to expose only a* $\mathsf{Padic}^{\uparrow}$ *or* $\mathsf{DyadicBall}^{\uparrow}$ *route that reuses the same strong-triangle comparison;*
6. *ledger non-escape, excluding quotient completions, selected representatives, host real equality of distance values, open-cover compactness, and ambient non-Archimedean field laws.*

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1535.1. The tuple lists exactly the parent metric row, comparison ledger, strong-triangle ledger, nested-ball ledger, example handoff, transport, replay, provenance, and local name.

Inherited metric-row compatibility is read first. A consumer cannot ask for an ultrametric comparison before the point names, distance reads, symmetry checks, and ordinary metric triangle route have been displayed by M.

Strong-triangle stability is then componentwise transport along H. The comparison row V fixes the inspected radii, and T records that each displayed triple uses the maximum of the two comparison radii as the controlling bound.

Nested-ball classification follows from B. Every ball-facing read must pass through the displayed center and radius comparisons, so a later $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, or $\mathsf{CompleteMetric}^{\uparrow}$ consumer cannot replace the nested-ball route by an unrelated host-space assertion.

Finally, E, K, P, N replay, source, and name the same finite route for p-adic or dyadic examples. Since the carrier fields are exhausted by $M, V, T, B, E, H, K, P, N$, the excluded quotient, representative-choice, host-equality, compactness, and ambient-field principles have no row from which a consumer could read them. □

Theorem 1535.3 (UltrametricSpace root strong-triangle window)**.** *For every accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier* $U = (M, V, T, B, E, H, K, P, N)$*, every root-level strong-triangle read is a* BHist*-anchored window over the parent metric row* M*, the value and radius comparison ledger* V*, and the strong max-radius row* T*. The read may refine the displayed comparison window, but it cannot replace* M*, bypass Definition 1535.2, or import host quotient fields or chosen distance representatives.*

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceRootStrongTriangleWindow`

Proof. Project the carrier of Definition 1535.1. The parent metric data are stored in M, finite value comparisons are stored in V, and the strong-triangle evidence is stored in T.

Apply Definition 1535.2. Its inherited metric-row compatibility requires every point-name and distance read to pass through M before any ultrametric comparison is consumed, and its strong-triangle stability clause preserves T under the displayed transport row.

Thus a root consumer can only widen or refine the finite comparison window already visible in M, V, T. Quotient metric fields, selected representatives, and host equality of distances have no carrier row and cannot supply the strong max-triangle comparison. □

Theorem 1535.4 (UltrametricSpace root nested-ball ledger)**.** *For every accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier* $U = (M, V, T, B, E, H, K, P, N)$*, root-level nested-ball classification is read from the same* BHist *ledger* B *after the relevant center and radius comparisons have passed through* M, V, T*. A nested-ball consumer may not allocate a separate ball classifier, quotient completion row, selected-center representative, or ambient compactness principle.*

Proof. Read the packet through Definition 1535.1. The nested-ball row B is displayed as a carrier coordinate, and its inputs are the center and radius comparisons routed through the parent metric row, comparison ledger, and strong-triangle ledger.

Use Definition 1535.2. The nested-ball classification obligation says that every ball-consumer claim passes through B after V and T have compared the relevant data.

Therefore the root nested-ball surface is the finite ledger B over the same BHist route. No separate classifier, quotient completion, representative choice, or compactness principle is exposed by the accepted packet. □

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceRootNestedBallLedger`

Theorem 1535.5 (UltrametricSpace root example handoff)**.** *For every accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier* $U = (M, V, T, B, E, H, K, P, N)$*, any root example handoff to a* p*-adic, dyadic-ball, metric-ball, or complete-metric consumer must pass through the same finite* BHist *route displayed by the carrier and obligated by Definition 1535.2. The row* E *may expose a* $\mathsf{Padic}^{\uparrow}$ *or* $\mathsf{DyadicBall}^{\uparrow}$ *witness, but it cannot choose representatives, add a quotient field, or assert ambient non-Archimedean field laws.*

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceRootExampleHandoff`

Proof. Start from Definition 1535.1. The example handoff row E is stored together with M, V, T, B, H, K, P, N, so it is not an independent model of a host ultrametric space.

Apply Definition 1535.2. Its example-compatibility clause restricts E to the displayed p-adic or dyadic route, and its ledger non-escape clause excludes quotient completions, selected representatives, host equality, and ambient field laws.

Consequently every root example read reuses the same finite route. The handoff can serve downstream $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ consumers only by replaying the accepted BHist data already named by the carrier. □

Theorem 1535.6 (UltrametricSpace strong-triangle handoff)**.** *Every accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *packet exposes distance comparisons to* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{DyadicBall}^{\uparrow}$*,* $\mathsf{Padic}^{\uparrow}$*, or* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers only through the finite route*

$$M \longmapsto V \longmapsto T \longmapsto B \longmapsto E.$$

In particular, the max-radius strong-triangle row T *is read before any metric-ball, dyadic-ball, p-adic, or complete-metric consumer can inspect the route.*

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceStrongTriangle handoff`

Proof. Start with the parent metric row M. It supplies point names and distance reads, but it does not by itself certify the non-Archimedean comparison needed by an ultrametric consumer.

The comparison ledger V records the finite radii under inspection. The strong-triangle row T then binds every displayed triple to the max-radius bound determined by those comparisons.

Only after T has been read can the nested-ball row B classify ball relations. The example row E and the continuation replay K preserve that order for $\mathsf{Padic}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ consumers.

Thus each downstream consumer receives the same displayed finite route through M, V, T, B, E. No consumer-facing field bypasses the strong-triangle row, so host equality of distances, quotient completion equality, selected representatives, and ambient field laws remain outside the packet. □

Theorem 1535.7 (UltrametricSpace strong-triangle bridge route)**.** *Every accepted* $\mathsf{UltrametricSpace}^{\uparrow}$ *carrier exports a bridge route from the abstract metric interface to the strong max-radius triangle interface through the finite rows*

$$M, V, T, B, E, H, K, P, N.$$

The route preserves the parent $\mathsf{Met}^{\uparrow}$ *surface, the* $\mathsf{Padic}^{\uparrow}$ *or* $\mathsf{DyadicBall}^{\uparrow}$ *example handoff, the* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers, the* BHist *ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.UltrametricSpaceUp.UltrametricSpaceStrongTriangleBridgeRoute`

Proof. Start with the abstract metric interface. The carrier row M supplies the point names, distance reads, symmetry ledger, zero-distance boundary, and ordinary triangle route, so every later ultrametric read remains anchored in the public $\mathsf{Met}^{\uparrow}$ surface.

The bridge then reads the finite comparison rows. The value ledger V fixes the inspected radii, the strong-triangle row T turns those comparisons into the max-radius triangle interface, and the nested-ball row B exposes the ball-facing consequence to $\mathsf{MetricBall}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers.

The example handoff row E keeps the route tied to the displayed $\mathsf{Padic}^{\uparrow}$ or $\mathsf{DyadicBall}^{\uparrow}$ witness. The transport, replay, provenance, and naming rows H, K, P, N preserve the same finite path, so no consumer can bypass the strong-triangle row by importing quotient completion data, selected representatives, host equality of distances, or ambient non-Archimedean field laws. □

Falsifiable prediction: Every accepted $\mathsf{UltrametricSpace}^{\uparrow}$ ball-facing read factors through the parent $\mathsf{Met}^{\uparrow}$ row, value and radius comparison ledger, max-radius strong-triangle ledger, nested-ball ledger, example handoff, componentwise transport, continuation replay, provenance, and local NameCert before any $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, or $\mathsf{CompleteMetric}^{\uparrow}$ consumer reads the route.

Independence witness: metric, padic, dyadicball, metricball, completemetric: $\mathsf{UltrametricSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries parent metric data, value and radius comparisons, a strong-triangle ledger, nested-ball classification, a p-adic or dyadic example handoff, transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UltrametricSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{UltrametricSpace}^{\uparrow}$ packet starts from a displayed Metric row, records finite value and radius comparisons, certifies the strong max-radius triangle row, routes nested-ball classification through that row, exposes p-adic or dyadic examples as handoffs, and preserves the same finite route by transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UltrametricSpace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1535.1, Definition 1535.2, Definition 1535.3, Definition 1535.4, Definition 1535.5, Definition 1535.6, and Definition 1535.7 give the carrier, NameCert obligations, root windows, nested-ball ledger, example handoff, strong-triangle handoff, and strong-triangle bridge route over $\mathsf{Met}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UltrametricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient metric completion, selected representatives, host real equality of distances, open-cover compactness, ambient non-Archimedean field laws, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, inherited metric-row compatibility, strong-triangle stability, nested-ball classification, p-adic or dyadic witness compatibility, handoff ordering, and ledger non-escape for BEDC.Derived.UltrametricSpaceUp.

Chapter 1536

A Concrete Naming Certificate for $\mathsf{LowerSemicontinuous}^{\uparrow}$

Following Bishop and Bridges constructive analysis, lower semicontinuity is read through lower bounds and finite epigraph witnesses rather than through a host topology. The $\mathsf{LowerSemicontinuous}^{\uparrow}$ packet records that interface over the lower-real surface of chapter 1446, the upper-real comparison boundary of chapter 1447, the located readbacks of **??**, the modulus-bearing map rows of chapter 130, the scheduled stream windows of chapter 126, the regular rational source rows of chapter 301, and the terminal real-name seal of chapter 38.

Definition 1536.1 (LowerSemicontinuous carrier)**.** *A* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, F, E, W, R, O, H, C, P, N)$$

with the following visible rows:

1. *X is the source carrier row whose accepted points are read through displayed* BHist *histories and their classifier transport;*
2. *F is the function graph or map row, read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise carrier only when such a map surface is present;*
3. *E is the lower-real epigraph ledger, consisting of finite rows (x, q) saying that the value at the displayed source point admits the rational lower bound q at the inspected window;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting finite source and value windows for each epigraph inspection;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row giving the regular rational value windows used by E;*
6. *O is the* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison ledger used to read lower windows, upper exclusions, located endpoint checks, and finite lower-bound refinements;*
7. *H records componentwise* hsame *transport for source histories, graph rows, lower-real epigraph rows, stream windows, regular readbacks, comparison ledgers, provenance rows, and local naming rows;*
8. *C records displayed* Cont *replay from source admission through window selection, regular rational readback, lower-real epigraph inspection, located readback, and real-seal handoff;*
9. *P is the* Pkg *provenance over* $\mathsf{LowerSemicontinuous}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^\uparrow}$ *row.*

The classifier relates two accepted packets exactly when their source rows, finite epigraph windows, regular rational readbacks, lower-real comparisons, located readbacks, $\mathsf{Real}^\uparrow$ *seal rows, and provenance rows transport componentwise along H and replay through the same displayed routes in C. No host topology, open-set lattice, quotient real equality, semantic limit operator, or completeness principle is a carrier coordinate.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousTasteGate single carrier alignment`

Definition 1536.2 (LowerSemicontinuous BHist carrier row)**.** *The root* $\mathsf{LowerSemicontinuous}^\uparrow$ BHist *row is $L = (X, F, E, W, R, O, H, C, P, N)$ of Definition 1536.1, read only as source histories, epigraph windows,* $\mathsf{StreamName}^\uparrow$ *schedules,* $\mathsf{RegSeqRat}^\uparrow$ *value rows, located* $\mathsf{Real}^\uparrow$ *handoff data,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

Lean4 (definition) `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousBHistCarrierRow`

Theorem 1536.3 (LowerSemicontinuous kernel-source obligations)**.** *Every kernel-source read of an accepted* $\mathsf{LowerSemicontinuous}^\uparrow$ *carrier enters through Definition 1536.2, then passes through* $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, *located* $\mathsf{Real}^\uparrow$ *handoff,* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before reaching any lower-bound consumer. No carrier/classifier parameter transport is available outside that route.*

Proof. Project the root carrier row. A lower-bound request chooses a $\mathsf{StreamName}^\uparrow$ window, reads the $\mathsf{RegSeqRat}^\uparrow$ value row, passes the located $\mathsf{Real}^\uparrow$ handoff, and uses hsame and Cont only to preserve the displayed packet; the final Pkg and $\mathsf{NameCert}$ rows source and name that finite route. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousKernelSource obligations`

Theorem 1536.4 (LowerSemicontinuous NameCert scope)**.** *The* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^\uparrow}$ *scope for the root packet is exactly the finite* BHist, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, hsame, Cont, Pkg, *and local naming route of Definition 1536.2. It covers lower-bound windows and located handoff rows, but not parameter equivalence, host topology, semantic liminf data, quotient real equality, countable choice, compactness, or ambient completeness.*

Proof. Apply the carrier definition and the kernel-source obligations above. The $\mathsf{NameCert}$ row certifies only the listed finite route; parameter equivalence or host analytic structure would require an additional carrier coordinate. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousNameCertScope`

Theorem 1536.5 (LowerSemicontinuous NameCert obligation surface)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^\uparrow$ *carrier $L = (X, F, E, W, R, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^\uparrow}$ *surface consists exactly of six obligations:*

1. *carrier admission for the displayed source, graph, epigraph, schedule, readback, comparison, transport, replay, provenance, and local naming rows;*
2. *epigraph-window exactness, requiring every lower-bound read to appear as a finite (x, q) row in E after the schedule in W and readback in R have been replayed;*
3. *lower-real classifier stability, requiring lower refinements and rational-bound comparisons to be transported through the* $\mathsf{LowerReal}^\uparrow$ *rows in O;*

4. *located readback compatibility, requiring every inspected source or value window to pass through the* $\mathsf{LocatedReal}^{\uparrow}$ *rows before a real-facing consumer can read it;*
5. hsame *and* Cont *replay, requiring all source, graph, epigraph, readback, comparison, and seal rows to move together under the displayed transport and continuation ledgers;*
6. *provenance and non-escape, stating that the package exports only the named finite rows and no host topology, quotient equality, semantic limit, open-cover compactness, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Carrier admission is projection from Definition 1536.1. The packet lists exactly the source row, graph row, epigraph ledger, finite schedule, regular readback, comparison ledger, transport ledger, replay ledger, provenance row, and local name.

Epigraph-window exactness is read from E only after the requested source window has passed through W and the value readback through R. Thus a lower-bound claim is not an external predicate; it is a displayed finite row over the inspected source and rational bound.

Lower-real classifier stability is the role of O together with H. The lower-real comparisons, upper-side exclusions, and located endpoint checks move componentwise by hsame, and the continuation row C records the same inspection route after transport.

Located readback compatibility follows because every real-facing window is read through the $\mathsf{LocatedReal}^{\uparrow}$ rows before the terminal $\mathsf{Real}^{\uparrow}$ seal is available. The readback is therefore a finite stream and regular-rational route, not a host limit operation.

Finally, P and N package those rows as the local certificate. Since the carrier has no coordinate for the excluded principles, no consumer can obtain them from the $\mathsf{LowerSemicontinuous}^{\uparrow}$ NameCert surface. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousNameCertObligationSurface`

Theorem 1536.6 (LowerSemicontinuous epigraph window exactness)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, every lower-bound or epigraph read exposed by* E *is exact only along the finite window route*

$$W \longrightarrow R \longrightarrow E.$$

A consumer must first select the displayed source window in W*, then read the regular rational value data in* R*, and only then inspect the epigraph row* E*. The row* E *cannot be read as a host lower-set predicate, a semantic liminf assertion, quotient real equality, selected limits, countable choice, or ambient completeness.*

Proof. Project the carrier coordinates from Definition 1536.1. The epigraph row is one displayed coordinate of L, and the only finite schedule for inspecting it is W.

Apply Definition 1536.5. Its epigraph-window obligation places every lower-bound read after a scheduled window and a regular rational readback.

The route is therefore W, R, E inside the same BHist packet. Since the carrier contains no coordinate for the excluded host principles, the epigraph read cannot detach from that route. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphWindowExactness`

Theorem 1536.7 (LowerSemicontinuous located epigraph transport)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, the located lower-real and upper-real comparison rows recorded in* O *transport the displayed epigraph row* E *through* H *and* C*. A lower-bound read that*

has passed through W, R, E, O remains the same BEDC row after componentwise hsame *transport and displayed continuation replay; it cannot become a host lower-set predicate, a semantic liminf assertion, quotient equality, selected endpoints, countable choice, or ambient completeness.*

Proof. Start with the epigraph route of Definition 1536.6. It places every lower-bound read on W, R, E before the located comparison ledger can be used.

The row O then supplies the lower-real, upper-real, and located comparison data for that same displayed epigraph row. These comparisons are packet rows, not external topological predicates.

Transport and replay are componentwise. The row H moves E and O by hsame, and C replays the same finite inspection route, so the transported read is still the displayed W, R, E, O route. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedEpigraphTransport`

Theorem 1536.8 (LowerSemicontinuous epigraph located stability)**.** *For an accepted* LowerSemicontinuous$^{\uparrow}$ *carrier $L = (X, F, E, W, R, O, H, C, P, N)$, any lower-bound read transported through W, R, E, O, H, C remains a located lower-real epigraph row. It cannot become a host liminf, quotient equality, selected endpoint datum, countable-choice schedule, compactness principle, or ambient-completeness assertion.*

Proof. Use Definition 1536.6 to place the read on W, R, E and Definition 1536.7 to carry the same epigraph row through O, H, C.

The NameCert obligation surface records only finite windows, regular readback, located comparison rows, componentwise transport, replay, provenance, and local naming. None of these coordinates stores the excluded host principles, so the transported row remains a located lower-real epigraph row. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphLocatedStability`

Theorem 1536.9 (LowerSemicontinuous regular readback nonescape)**.** *Every lower-bound read from an accepted* LowerSemicontinuous$^{\uparrow}$ *carrier $L = (X, F, E, W, R, O, H, C, P, N)$ factors through*

$$W, R, E, O, H, C, P, N.$$

The readback route uses finite windows, regular-rational values, the epigraph row, located comparison rows, transport, replay, provenance, and local naming; it has no coordinate for host liminf, quotient equality, selected limits, countable choice, compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRegularReadbackNonescape`

Proof. The scheduled window row W fixes the inspected source window, and the regular-rational row R supplies the displayed value readback. By Definition 1536.6, the epigraph row E is readable only after those two rows are present.

Apply Definition 1536.7. The located comparison ledger O and structural rows H, C keep the lower-bound read on the displayed epigraph route under transport and replay.

Finally P and N source and name the same packet. Since no listed carrier row stores a host liminf operator, quotient equality, selected limit, choice schedule, compactness principle, or completeness theorem, the readback cannot escape the displayed route. □

Theorem 1536.10 (LowerSemicontinuous Real seal boundary)**.** *Any* Real$^{\uparrow}$*-facing consumer of an accepted* LowerSemicontinuous$^{\uparrow}$ *packet may read the terminal seal only after the* LowerReal$^{\uparrow}$, UpperReal$^{\uparrow}$, LocatedReal$^{\uparrow}$, StreamName$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *rows have been displayed through E, O, W, R, H, C, P, N.*

The Real-facing boundary therefore records a finite lower-semicontinuity certificate rather than host topology, semantic liminf data, quotient real equality, selected representatives, countable choice, compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealBoundary`

Proof. Use the NameCert obligation surface of Definition 1536.5. It requires source windows, graph data, epigraph rows, finite schedules, regular readback, located comparison rows, transport, replay, provenance, and local naming.

The lower-real and upper-real rows are displayed inside E and O, while W and R supply the StreamName and RegSeqRat route used to inspect them. The located comparison surface cannot be skipped because Definition 1536.7 keeps the epigraph row tied to O, H, C.

Now apply Definition 1536.9. It forces every lower-bound read through W, R, E, O, H, C, P, N, so a Real-facing consumer reaches the terminal seal only after the displayed lower, upper, located, stream, and regular rows are visible. □

Theorem 1536.11 (LowerSemicontinuous located readback compatibility)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing output read must pass through the located comparison ledger* O *before the terminal real seal is available. Thus source windows, regular rational value rows, lower-real epigraph data, and upper-side comparison rows may be exported to a real-facing consumer only along*

$$X, F, W, R, E, O, H, C, P, N.$$

The output cannot bypass O *by invoking host real equality, selected endpoint representatives, semantic limits, countable choice, open-cover compactness, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedReadbackCompatibility`

Proof. Start with a real-facing consumer of L. The source, graph, schedule, readback, and epigraph coordinates are displayed as X, F, W, R, E, but none of them alone supplies a located readback.

Use Definition 1536.5. The located-readback obligation requires the route to pass through O before a real-facing output can be read.

Transport and replay then use only H and C, and the resulting route is packaged and named by P and N. No additional host coordinate is present, so the real-facing output remains the stated finite BEDC route. □

Theorem 1536.12 (LowerSemicontinuous transport replay exactness)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, componentwise* hsame *transport and displayed* Cont *replay preserve exactly the rows*

$$X, F, E, W, R, O, H, C, P, N.$$

They do not add a host topology row, an open-set lattice, quotient equality, semantic limit data, selected witnesses, countable choice, open-cover compactness, or ambient completeness. Every transported lower-semicontinuity read is therefore the same finite carrier route with the same local $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousTransportReplayExactness`

Proof. Read the transport and replay ledgers from the carrier. The H row records componentwise hsame only for the displayed coordinates, while C records continuation replay only for the same inspection routes.

Apply Definition 1536.5. Its replay obligation lists the source, graph, epigraph, readback, comparison, seal, provenance, and naming rows as the complete transport surface.

It remains to identify what cannot appear after replay. Because $L = (X, F, E, W, R, O, H, C, P, N)$ has no coordinate for the excluded host principles, H and C can only preserve the displayed rows and cannot introduce a new semantic route. □

Theorem 1536.13 (LowerSemicontinuous NameCert basis obligations)**.** *For an accepted* LowerSemicontinuous$^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, every root-unblock obligation that exposes lower-real epigraph data to a downstream consumer is a finite row of the same packet. The basis consists of the* LowerReal$^{\uparrow}$ *epigraph ledger* E*, the* StreamName$^{\uparrow}$ *schedule* W*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the* $UpperRealUp$ *and* LocatedReal$^{\uparrow}$ *comparison rows in* O*, the terminal* Real$^{\uparrow}$ *seal boundary,* BHist *histories,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

No basis obligation is discharged by host topology, a semantic liminf operator, quotient real equality, selected limits, countable choice, or ambient completeness. Epigraph and comparison rows are finite carrier data rather than host-theoretic evidence.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousNameCertBasisObligations`
↪ variant `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousNameCertObligationBasis`

Proof. Project the carrier in Definition 1536.1. The only epigraph data available to a consumer is the finite ledger E, and the only inspection route to it is through the scheduled windows W and regular rational readbacks R.

The comparison row O records lower-real, upper-real, and located-real readbacks before the terminal Real$^{\uparrow}$ seal is exposed. Thus every root-unblock read remains inside the displayed carrier coordinates.

The structural rows H, C, P, N transport, replay, package, and name the same finite route. Since the excluded host principles are absent from $L = (X, F, E, W, R, O, H, C, P, N)$, they cannot serve as basis obligations. □

Theorem 1536.14 (LowerSemicontinuous Real seal nonescape)**.** *Let* $L = (X, F, E, W, R, O, H, C, P, N)$ *be an accepted* LowerSemicontinuous$^{\uparrow}$ *carrier. Any* Real$^{\uparrow}$ *readback from* L *must pass through the* LowerReal$^{\uparrow}$ *epigraph row* E*, the* StreamName$^{\uparrow}$ *schedule* W*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the* UpperReal$^{\uparrow}$ *and* LocatedReal$^{\uparrow}$ *comparisons in* O*, the* BHist *history rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

The Real$^{\uparrow}$ *seal is therefore a finite carrier boundary. It is not a route to host topology, a semantic limit, quotient real equality, selected limits, countable choice, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealNonescapeRoute`

Proof. Begin with a Real$^{\uparrow}$-facing consumer of L. By Definition 1536.1, the consumer can inspect only the displayed source, graph, epigraph, schedule, readback, comparison, transport, replay, provenance, and naming rows.

Apply Definition 1536.5. Its non-escape obligation places the terminal real seal downstream from epigraph-window exactness, lower-real classifier stability, located readback compatibility, and replay.

Hence a real readback cannot detach from E, W, R, O, H, C, P, N. The excluded principles have no coordinate in the carrier and no continuation row that could introduce them. □

Theorem 1536.15 (LowerSemicontinuous UpperReal handoff)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, every* $\mathsf{UpperReal}^{\uparrow}$ *comparison handed to a downstream lower-semicontinuity consumer is read from the same comparison ledger* O *that also records the* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readbacks. The handoff preserves the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *value windows,* BHist *histories,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming of the carrier.*

Thus upper-side comparison is finite BEDC data paired with lower-real epigraph rows. It is not an ambient order-completeness principle, a host topology assertion, a semantic upper envelope, quotient real equality, a selected limit, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the comparison ledger from Definition 1536.1. The row O is the only carrier coordinate that contains upper-real comparison data, and it is tied to the same lower-real and located-real checks used by epigraph reads.

The schedule and readback rows W and R determine which finite value windows the comparison may inspect. Transport through H and replay through C preserve those windows together with the epigraph and comparison rows.

The provenance and local name rows P, N certify this as a $\mathsf{LowerSemicontinuous}^{\uparrow}$ handoff. Since the carrier has no coordinate for the excluded host principles, the $\mathsf{UpperReal}^{\uparrow}$ consumer receives only the finite comparison surface stated above. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousUpperRealHandoff`

Theorem 1536.16 (Lower-real epigraph route)**.** *Every lower-real or real-seal consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier factors through the finite epigraph route*

$$X, F, W, R, E, O, H, C, P, N.$$

The consumer may inspect scheduled source windows, regular rational value readbacks, displayed lower-bound rows, lower-real refinements, located endpoint checks, componentwise transports, continuation replay, provenance, and local naming rows. It cannot bypass the epigraph ledger to read host topological openness, quotient real equality, a semantic liminf operator, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start from a real-facing consumer of the packet. The source row X and graph row F are visible only through the finite schedule W, so every value inspection begins with a displayed source window rather than an ambient neighbourhood.

The regular rational readback row R then supplies the finite value window. The epigraph ledger E records the lower-bound row (x, q) attached to that same inspection, and the comparison ledger O checks lower-real refinements, upper-side exclusions, and located endpoint compatibility.

Transport and replay are exhausted by H and C. They move the source, graph, readback, epigraph, comparison, and seal rows together, so the route remains the same after classifier transport.

The package and local name rows P, N record exactly this route for consumers. Since the excluded host principles are absent from the route and absent from the carrier coordinates, the lower-real epigraph handoff exposes only the finite BEDC rows stated above. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLowerRealEpigraphRoute`

Theorem 1536.17 (LowerSemicontinuous located readback stability)**.** *Let $L = (X, F, E, W, R, O, H, C, P, N)$ be an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier. Every epigraph-window comparison accepted by E and transported by H preserves the* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint checks in O before any* $\mathsf{Real}^{\uparrow}$*-facing consumer can read the transported lower bound. Equivalently, a consumer that receives a transported row (x, q) must pass through the same scheduled window in W, the same regular rational readback in R, and the located endpoint ledger in O before the terminal real-seal route is available.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedReadbackStability`

Proof. Project the carrier rows from Definition 1536.1. The only accepted lower-bound comparisons are the finite epigraph rows in E, and the only transport available for those rows is the componentwise hsame ledger H.

Apply Definition 1536.16. Its route places W and R before E, and places the lower-real, upper-real, and located-real comparison ledger O before any terminal $\mathsf{Real}^{\uparrow}$ seal can be read.

Thus the transported comparison cannot expose a bound by itself. The located endpoint checks in O remain on the route after transport, and C replays the same scheduled inspection for every Real-facing consumer. □

Theorem 1536.18 (LowerSemicontinuous Real seal nonescape)**.** *An accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet exports* $\mathsf{Real}^{\uparrow}$*-facing data only through the displayed rows*

$$E, W, R, O, H, C, P, N.$$

In particular, the packet cannot expose host topology, a semantic liminf operator, quotient real equality, a selected limit, countable choice, open-cover compactness, or ambient completeness as a route to the terminal real seal.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealTransportNonescape`

Proof. Read the export surface from Definition 1536.1. The terminal real-facing route is represented by epigraph rows, scheduled windows, regular rational readbacks, comparison rows, componentwise transport, continuation replay, package provenance, and the local name.

Apply Definition 1536.16. The theorem states that every lower-real or real-seal consumer factors through the finite epigraph route and cannot bypass it to host topological openness, quotient real equality, semantic liminf data, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

The listed excluded principles are not carrier coordinates and are not introduced by H or C. Therefore the $\mathsf{Real}^{\uparrow}$ seal row remains a finite BEDC export through E, W, R, O, H, C, P, N rather than a host-theoretic escape. □

Theorem 1536.19 (LowerSemicontinuous Baire-one source handoff)**.** *Let $L = (X, F, E, W, R, O, H, C, P, N)$ be an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier. Any* $\mathsf{BaireOneFunction}^{\uparrow}$ *source read that uses L as its lower-semicontinuous boundary must first pass through the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row F, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the epigraph ledger E, and the comparison ledger O before the structural rows H, C, P, N may hand the read to a* $\mathsf{Real}^{\uparrow}$*-facing consumer. The handoff supplies finite epigraph data only; it does not supply a host pointwise limit, quotient equality of functions, a selected approximating sequence, or semantic topology.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousBaireOneSourceHandoff`

Proof. Project the carrier from Definition 1536.1. The only map-facing coordinate is F, and it is tied to the scheduled windows W and regular rational readbacks R before a lower-bound row can be inspected.

Apply Definition 1536.5. Its epigraph-window exactness and located readback clauses force the $\mathsf{BaireOneFunction}^{\uparrow}$ source handoff through E, W, R, O rather than through an ambient pointwise-limit predicate.

Finally use Definition 1536.18. The structural rows H, C, P, N replay and name the same finite route before the $\mathsf{Real}^{\uparrow}$ seal is visible, so no selected approximating sequence, quotient function equality, or host topology is exported. □

Theorem 1536.20 (LowerSemicontinuous Real and regular-rational scope)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *carrier* $L = (X, F, E, W, R, O, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *scope is exactly the route that reads a finite schedule from* W*, regular rational value data from* R*, lower-bound evidence from* E*, comparison data from* O*, and then the transport, replay, provenance, and local name rows* H, C, P, N*. Thus a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the epigraph-ledger route, not a semantic liminf operation, quotient real equality, selected limit, countable choice, or ambient completeness.*

Proof. Begin with the root carrier route. The rows W and R determine the finite windows and regular rational values that can be read before any lower-bound claim is visible.

Use Definition 1536.16. It places the epigraph ledger E and comparison ledger O downstream of the schedule and readback rows, and upstream of any real-facing seal.

Now apply Definition 1536.17 and Definition 1536.18. Transport and replay preserve the same route, while the seal theorem excludes liminf semantics, quotient equality, selected limits, countable choice, and ambient completeness from the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scope. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealRegSeqRatScope`

Theorem 1536.21 (LowerSemicontinuous epigraph-ledger refusal)**.** *No accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet lets a consumer read* $\mathsf{BaireOneFunction}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *data while bypassing the epigraph rows* E, W, R, O, H, C, P, N*. A purported consumer that reaches a Baire-one source handoff, a continuous-map graph row, a regular rational readback, or a terminal real seal without those rows is refused by the local NameCert obligation surface.*

Proof. Read the purported consumer against the carrier. The graph row F has no standalone export path: every lower-semicontinuous read proceeds through scheduled windows, regular rational readbacks, epigraph rows, and comparison rows.

Apply Definition 1536.5. Carrier admission, epigraph-window exactness, located readback compatibility, replay, provenance, and non-escape are all obligations on the same packet.

Finally combine the Baire-one handoff and the Real–regular-rational scope theorems above. They identify the only visible source and seal routes with E, W, R, O, H, C, P, N, so any route omitting one of those rows has no accepted NameCert read. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphLedgerRefusal`

Definition 1536.22 (LowerSemicontinuous root carrier)**.** *The root packet for* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *is the accepted finite carrier*

$$L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$$

of Definition 1536.1, read with X as the displayed source row, F as the graph row, E as the lower-real epigraph ledger, W as the stream schedule, R as the regular rational readback row, O as the lower-real, upper-real, located-real, and real-seal comparison ledger, H as componentwise transport, C as displayed replay, P as provenance, and N as the local NameCert row. A root consumer may inspect only these rows and the routes certified by Definition 1536.5; it receives no separate topology carrier, semantic liminf operation, quotient real equality, selected limit, countable choice, open-cover compactness, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootCarrier rows exposed`

Theorem 1536.23 (LowerSemicontinuous real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of the root packet* $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ *factors through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. Concretely, a consumer first reads a stream window from W, then a regular rational value row from R, then a lower-real epigraph witness from E, then the located comparison data in O, and only then the terminal real-seal route recorded by O, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousReal handoff`

Proof. The root packet is the carrier of Definition 1536.22, so a consumer can start only from the rows $X, F, E, W, R, O, H, C, P, N$.

Apply Definition 1536.5. Its obligation surface places carrier admission, epigraph-window exactness, lower-real classifier stability, located readback compatibility, transport replay, provenance, and non-escape on the same local NameCert route.

Apply Definition 1536.16. That route orders the read through scheduled windows, regular rational readbacks, displayed lower-bound rows, lower-real refinements, located endpoint checks, transport, replay, provenance, and local naming.

Finally apply Definition 1536.17 and Definition 1536.18. They keep the located readback before the terminal real seal and exclude every host route not present in the finite packet. □

Theorem 1536.24 (LowerSemicontinuous open-sublevel route)**.** *Every sublevel or open-window read of the root packet* $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ *is a displayed epigraph route through* E, W, R, O, H, C, P, N*. It is not a read of host topological openness: the only available witness is a finite lower-bound row transported through the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison ledgers and replayed by the same continuation route.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousOpenSublevelRoute`

Proof. Start with a sublevel or open-window consumer of the root packet. By Definition 1536.22, the packet has no coordinate for a topology carrier or open-set lattice, so the consumer must read one of the displayed finite rows.

Use Definition 1536.16. The theorem identifies the lower-real route as

$$X, F, W, R, E, O, H, C, P, N.$$

Thus an open-window read can only mean that a scheduled source window and a regular rational value row have reached a displayed epigraph witness in E.

The located readback stability theorem keeps the comparison in O on the same route after transport. The real-seal nonescape theorem then prevents the consumer from replacing that displayed epigraph route by host topology, semantic liminf data, quotient real equality, choice, compactness, or ambient completeness. □

Theorem 1536.25 (LowerSemicontinuous epigraph window induction)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet*

$$L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N),$$

every finite epigraph inspection window is generated by induction over the displayed BHist *rows* W, R, E, O, H, C, P, N*. The base window reads the source row* X *and graph row* F *before exposing one scheduled stream window, and each successor window extends only by a* $\mathsf{StreamName}^{\uparrow}$ *schedule row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *value row, an epigraph row in* E*, and the comparison data in* O*. No induction step may replace this route by host topology, semantic liminf data, quotient real equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphWindowInduction`

Proof. Start with the root carrier of Definition 1536.22. The available rows are exactly $X, F, E, W, R, O, H, C, P, N$, so the induction base can expose only the source row, graph row, and one scheduled finite window.

For the successor step, use Definition 1536.24. It identifies an open-window read with a displayed epigraph route through E, W, R, O, H, C, P, N, not with a host open-set predicate.

The kernel-source obligations in Definition 1536.5 keep each added window inside the same local NameCert scope. Transport and replay through H and C preserve the finite row order, while P and N source and name the same packet.

Finally apply the real handoff of Definition 1536.23. Any Real-facing endpoint of the induction remains downstream of $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 1536.26 (LowerSemicontinuous located epigraph transport induction)**.** *Let*

$$L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$$

be an accepted $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet. Transporting a finite lower-bound row through the* $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{LowerReal}^{\uparrow}$ *comparison ledgers is an induction over the same* BHist *route: each step first reads the stream schedule* W*, then the regular rational value row* R*, then the lower-bound witness in* E*, and finally the located comparison data in* O*. The transported row remains a displayed epigraph row and never becomes parameter-equivalence transport, quotient real equality, semantic topology, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedEpigraphTransportInduction`

Proof. Read the located comparison ledger from Definition 1536.22. The row O is the only coordinate carrying lower-real, upper-real, located-real, and real-seal comparison data.

The induction base is a single lower-bound row already exposed by E after the schedule and readback rows W and R. The route theorem Definition 1536.16 places this row before the located comparison ledger.

For the induction step, apply Definition 1536.17. It transports the same regular rational readback and lower-bound row through the located comparison surface without introducing a new carrier or a parameter-equivalence argument.

The NameCert scope and real handoff then close the route. Use Definition 1536.5 and Definition 1536.23 to keep the transported row inside W, R, E, O, H, C, P, N before any terminal $\mathsf{Real}^{\uparrow}$ read is visible. □

Theorem 1536.27 (LowerSemicontinuous Real seal window exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read generated from an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet is exhausted by the finite window route*

$$X, F, W, R, E, O, H, C, P, N.$$

In particular, the terminal Real seal can be reached only after the $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, lower-real epigraph row, and located comparison ledger have been displayed. It exports no hidden Baire-one pointwise limit, quotient real equality, selected approximating sequence, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealWindowExhaustion`

Proof. Begin with Definition 1536.23. It states that every Real-facing read factors through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Use the epigraph window induction above to inspect the finite schedule. Each window reaches the epigraph row through W, R, E and is replayed through H, C, P, N inside the same BHist packet.

Next apply the located transport induction. It keeps lower-bound rows in the comparison ledger O and rules out parameter-equivalence transport, quotient real equality, and semantic topology as alternate exits.

Finally use Definition 1536.18. The terminal seal is exhausted by the displayed route, so the absent pointwise-limit, selection, compactness, and completeness principles are not exported by the root packet. □

Theorem 1536.28 (LowerSemicontinuous epigraph public export)**.** *Every public lower-semicontinuity read from an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet is exported through the finite route*

$$X, F, W, R, E, O, H, C, P, N.$$

The export combines the root epigraph basis, located readback route, transport replay, and terminal $\mathsf{Real}^{\uparrow}$ *seal boundary. It is a public BEDC NameCert route over displayed* BHist*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows, not a semantic topology theorem, host liminf operator, quotient-real equality, countable-choice schedule, compactness principle, or ambient completeness assertion.*

Proof. Start with the root epigraph basis of Definition 1536.45. It identifies the consumer-visible lower-real basis as the finite source, graph, schedule, readback, epigraph, comparison, transport, replay, provenance, and naming route.

Apply located readback and transport compatibility, using Definition 1536.46 together with Definition 1536.26. These results keep each lower-bound read on the same W, R, E, O, H, C, P, N path when it is transported or replayed.

Finally use the Real-seal exhaustion results, Definition 1536.27 and Definition 1536.51. They force the public endpoint through the terminal $\mathsf{Real}^{\uparrow}$ seal boundary while excluding host topology, semantic liminf data, quotient real equality, countable choice, compactness, and ambient completeness. The exported statement is therefore the finite NameCert route above. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphPublicExport`

Theorem 1536.29 (LowerSemicontinuous epigraph sibling route)**.** *The public export route of Definition 1536.28 factors every lower-real comparison through the* $\mathsf{Epigraph}^{\uparrow}$ *sibling of chapter 6224 before a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer inspects sublevel or superlevel rows. The sibling supplies the domain row, value row, lower-bound row, and comparison row consumed by the lower-semicontinuity packet, while* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *remain terminal readback rows.*

Proof. Start with the public export theorem Definition 1536.28. Its route names the finite source, graph, schedule, readback, epigraph, comparison, transport, replay, provenance, and naming rows used by public lower-semicontinuity consumers.

Read the epigraph coordinate through chapter 6224. The $\mathsf{Epigraph}^{\uparrow}$ sibling is the packet that supplies the displayed domain, value, lower-bound, and comparison rows before lower-semicontinuity sublevel or superlevel rows are inspected.

The located readback and Real-seal rows stay downstream. Thus $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ remain terminal readback boundaries, while the horizontal route through $\mathsf{Epigraph}^{\uparrow}$ provides the comparison lattice consumed by $\mathsf{LowerSemicontinuous}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphSiblingRoute`

Definition 1536.30 (LowerSemicontinuous closed-superlevel carrier)**.** *A closed-superlevel row for the root packet $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ is a finite* BHist *packet*

$$S = (q, E_q, O_q, B_q, H_q, C_q, P_q, N_q)$$

where q is the rational threshold being tested, E_q is the lower-real epigraph window read from E at threshold q, O_q is the $\mathsf{Real}^{\uparrow}$*-seal and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison route attached to the same threshold, B_q is the* BHist *evidence that the complement of the displayed sublevel window remains stable under the shown* hsame *and* Cont *transports, and H_q, C_q, P_q, N_q transport, replay, source, and name the same threshold row. The row records a constructive complement boundary for the finite lower-real window; it does not assert classical topological closedness of a host superlevel set.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousClosedSuperlevelCarrier surface`

Theorem 1536.31 (LowerSemicontinuous closed-superlevel stability)**.** *For every accepted closed-superlevel row*

$$S = (q, E_q, O_q, B_q, H_q, C_q, P_q, N_q)$$

attached to L_{root}, transport by the displayed hsame *rows and replay by the displayed* Cont *route preserves the finite superlevel complement boundary determined by q. Equivalently, a consumer that avoids the open-sublevel window at threshold q may keep that avoidance only through the lower-real epigraph row E_q, the located readback route O_q, the* $\mathsf{Real}^{\uparrow}$ *seal data, and the stability evidence B_q; it cannot replace them by host closedness, semantic liminf data, quotient real equality, countable choice, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousClosedSuperlevel stability`

Proof. Project the closed-superlevel carrier. Its threshold is the displayed rational q, and all boundary information is stored in $E_q, O_q, B_q, H_q, C_q, P_q, N_q$. There is no coordinate for a host topological closed set.

Apply Definition 1536.16. The threshold row E_q is read only through the lower-real epigraph window attached to the original root packet, after the scheduled source windows and regular rational value rows have been displayed.

Use Definition 1536.17. The located comparison row O_q remains on the same route under the componentwise hsame transport and the displayed Cont replay. Hence the complement of the open-sublevel window is carried by B_q as finite transport evidence, not as a detached topological predicate.

Finally apply Definition 1536.24 together with Definition 1536.18. The open-sublevel route identifies the boundary being avoided, and the real-seal nonescape row prevents the consumer

from substituting classical closedness, semantic liminf data, quotient real equality, countable choice, compactness, or ambient completeness for the displayed finite boundary. □

Definition 1536.32 (LowerSemicontinuous superlevel threshold surface)**.** *For a rational threshold q attached to an accepted closed-superlevel row*

$$S = (q, E_q, O_q, B_q, H_q, C_q, P_q, N_q),$$

the superlevel threshold surface is the finite reusable read

$$(q, E_q, O_q, B_q, H_q, C_q, P_q, N_q).$$

It records the threshold, lower-real epigraph window, located comparison and $\mathsf{Real}^{\uparrow}$*-seal route, complement-boundary evidence, componentwise transport, replay, provenance, and local naming needed by any closed-superlevel consumer.*

Lean4 (definition) `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousSuperlevelThresholdSurface`
Lean4 (definition) `BEDC.Derived.LowerSemicontinuousUp.lowerSemicontinuousSuperlevelThresholdSurface`
Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousSuperlevelThresholdSurface exact`

Theorem 1536.33 (LowerSemicontinuous closed-superlevel threshold exhaustion)**.** *Every closed-superlevel consumer of an accepted threshold surface*

$$(q, E_q, O_q, B_q, H_q, C_q, P_q, N_q)$$

must exhaust $E_q, O_q, B_q, H_q, C_q, P_q, N_q$ before reading a boundary at q. The consumer cannot replace those rows by host closedness, semantic liminf data, quotient real equality, countable choice, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousClosedSuperlevelThresholdExhaustion`

Proof. Start from the threshold surface of Definition 1536.32. Its only analytic rows are the lower-real epigraph window E_q, located comparison and Real-seal route O_q, and complement-boundary evidence B_q.

Apply closed-superlevel stability, Definition 1536.31. It preserves the finite complement boundary only through the displayed transport and replay rows, so H_q and C_q must be read with the same threshold.

The provenance and local naming rows P_q, N_q bind the threshold row to the original packet. Since no coordinate stores host topology, semantic liminf data, quotient equality, choice, compactness, or ambient completeness, the listed rows exhaust every boundary read at q. □

Theorem 1536.34 (LowerSemicontinuous Baire-one superlevel handoff)**.** *Every Baire-one or lower-real consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet receives the same superlevel threshold surface*

$$(q, E_q, O_q, B_q, H_q, C_q, P_q, N_q)$$

when it asks for a closed-superlevel read at threshold q. The handoff contains no host topology coordinate, semantic liminf coordinate, choice coordinate, quotient real equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousBaireOneSuperlevelHandoff`

Proof. Project the closed-superlevel carrier and the threshold surface. Both expose the same rows $q, E_q, O_q, B_q, H_q, C_q, P_q, N_q$, so there is no second Baire-one or lower-real boundary object to receive.

Use the threshold exhaustion theorem. It forces the consumer to read the epigraph window, located comparison and seal route, complement-boundary evidence, transport, replay, provenance, and local naming before a boundary at q is available.

Finally apply the Baire-window factorization theorem, Definition 1536.35. Baire-one and lower-real consumers already factor through the finite W, R, E, O route, and the threshold surface is the closed-superlevel read of that same route rather than a host topology, liminf, choice, quotient, or completeness coordinate. □

Theorem 1536.35 (LowerSemicontinuous Baire-window factorization)**.** *Every Baire-one or lower-real consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet* $L = (X, F, E, W, R, O, H, C, P, N)$ *factors its finite request through the route*

$$W \longmapsto R \longmapsto E \longmapsto O$$

before any $\mathsf{Real}^{\uparrow}$*-facing seal is read. The consumer cannot replace that route by host topology, semantic liminf data, quotient equality, selected limits, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousBaireWindowRealSealFactorization`

Proof. Project the carrier rows from Definition 1536.1. The finite request first chooses the inspected windows in W, then reads regular rational data from R, then reaches the lower-real epigraph ledger E, and only then enters the located comparison row O.

Use epigraph exactness and located readback compatibility, Definition 1536.6 and Definition 1536.11. These theorems keep lower-bound reads and real-facing comparison data on the displayed route rather than on a host liminf or topology predicate.

Finally apply closed-superlevel stability from Definition 1536.31. The open-sublevel and closed-superlevel boundary reads remain finite BEDC rows, so a Baire-one or lower-real consumer receives exactly the W, R, E, O factorization before any terminal seal is available. □

Theorem 1536.36 (LowerSemicontinuous kernel scope)**.** *Every lower-semicontinuous epigraph, located-readback, or Real-seal consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must route through the visible* BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the carrier. The route may read epigraph windows, open-sublevel boundaries, closed-superlevel stability, transport replay, and Real handoff data, but it cannot replace those rows by host topology, semantic liminf data, quotient real equality, countable choice, compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousKernelScope`

Proof. Start with the NameCert obligation surface of Definition 1536.5. It lists the finite source, graph, epigraph, window, readback, located comparison, transport, replay, provenance, and local naming rows that any consumer must expose.

Apply epigraph exactness and the epigraph-window route, Definition 1536.16 and Definition 1536.24. These results keep lower-real and sublevel reads inside the displayed BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, and $\mathsf{UpperReal}^{\uparrow}$ rows.

Next use located-readback stability and transport replay. The theorems Definition 1536.17 and Definition 1536.12 keep the $\mathsf{LocatedReal}^{\uparrow}$, hsame, and Cont rows visible when a comparison is moved or replayed.

Finally apply the Real handoff and nonescape statements, Definition 1536.23 and Definition 1536.18. They force every Real-facing read through the same Pkg and NameCert rows and exclude host topology, semantic liminf data, quotient real equality, countable choice, compactness, and ambient completeness. □

Theorem 1536.37 (LowerSemicontinuous root obligation split)**.** *Every lower-real epigraph window, located comparison row, and* $\mathsf{Real}^{\uparrow}$ *seal read consumed by a Baire-one or lower-real reader of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must factor through the displayed route*

$$W \longrightarrow R \longrightarrow E \longrightarrow O \longrightarrow P \longrightarrow N$$

before any consumer can inspect it. The route first displays source windows, then regular rational value rows, then lower-real epigraph witnesses, then located comparison and Real-seal data, then provenance and local naming; it exports no host topology, semantic liminf operator, quotient real equality, choice schedule, compactness principle, or ambient completeness.

Proof. Start with the NameCert obligation surface, Definition 1536.5. It forces the source windows, value rows, epigraph rows, comparison rows, provenance, and local name to be visible for the accepted packet.

Apply the lower-real epigraph route, Definition 1536.16. That route orders the lower-real read from W to R to E before any located comparison row can be consumed.

Finally use the kernel scope theorem, Definition 1536.36. It keeps the located comparison, Real-seal read, provenance, and local naming rows inside the same finite packet boundary, so every Baire-one or lower-real consumer receives exactly the displayed W, R, E, O, P, N route and none of the excluded host or completeness principles. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootObligationSplit`

Theorem 1536.38 (LowerSemicontinuous superlevel tail obligation)**.** *Every closed-superlevel tail consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must first expose the threshold row, lower-real epigraph window, located comparison route,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows carried by the same finite packet. The consumer cannot substitute host topology, semantic liminf data, quotient real equality, countable choice, open-cover compactness, or ambient completeness for those rows.*

Proof. Start with the closed-superlevel threshold exhaustion theorem, Definition 1536.33. It forces any boundary read at a displayed rational threshold to consume $E_q, O_q, B_q, H_q, C_q, P_q, N_q$ rather than a host closedness predicate.

Next apply the Baire-window factorization theorem, Definition 1536.35. It keeps lower-real and Baire-one requests on the finite route through the displayed window, readback, epigraph, and located-comparison rows before any Real-facing seal is read.

Use the kernel scope theorem, Definition 1536.36. The BHist, hsame, Cont, Pkg, and NameCert rows remain part of the same packet when the threshold data is transported or replayed.

Finally invoke root obligation split, Definition 1536.37. It orders the exposed route through the lower-real epigraph window, located comparison row, Real seal, provenance, and local naming, so the listed host and completeness principles have no coordinate from which to enter the superlevel tail. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousSuperlevelTailObligation`

Theorem 1536.39 (LowerSemicontinuous root epigraph carrier)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet*

$$L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N),$$

there is a finite root epigraph subcarrier

$$L_{\mathrm{epi}} = (X, F, W, R, E, O, H, C, P, N)$$

whose rows are read in that order. The row W *displays the finite* $\mathsf{StreamName}^{\uparrow}$ *inspection window,* R *displays the* $\mathsf{RegSeqRat}^{\uparrow}$ *value readback,* E *displays the lower-real epigraph ledger,* O *displays the* $\mathsf{LowerReal}^{\uparrow}$–$\mathsf{UpperReal}^{\uparrow}$ *comparison and located* $\mathsf{Real}^{\uparrow}$ *seal boundary,* H *records componentwise* hsame *transport,* C *records displayed* Cont *replay,* P *records* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$ *row. The carrier has no host liminf predicate, quotient real equality, selected approximating sequence, countable choice, open-cover compactness, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphCarrier`
↪ variant `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRoot epigraph carrier`

Proof. Project the rows of the root packet. The carrier definition already displays $X, F, E, W, R, O, H, C, P, N$, and the reordered subcarrier only makes the consumer route explicit: source and graph first, then finite window, rational readback, epigraph evidence, comparison, transport, replay, provenance, and local name.

The finite epigraph window is obtained by induction on the displayed window rows. The base read sees the source and graph rows; the successor read adds one $\mathsf{StreamName}^{\uparrow}$ schedule row, one $\mathsf{RegSeqRat}^{\uparrow}$ value row, and the corresponding epigraph witness in E.

Transport and replay do not add analytic data. They carry the same rows through H and C, with P and N sourcing and naming the accepted packet.

The exclusions follow from the carrier inventory. Since no coordinate contains a host liminf predicate, quotient equality, selector, choice row, compactness theorem, or completeness witness, no consumer can extract one from the subcarrier. □

Theorem 1536.40 (LowerSemicontinuous regular readback handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback consumed from* L_{epi} *reaches a* $\mathsf{LocatedReal}^{\uparrow}$ *handoff only through the displayed route*

$$W \longrightarrow R \longrightarrow E \longrightarrow O \longrightarrow H \longrightarrow C \longrightarrow P \longrightarrow N.$$

The comparison row O *keeps the lower-real and upper-real boundary attached to the same finite readback, so the handoff exports located comparison data and not semantic topology, hidden lower envelopes, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable choice, or a detached completion principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootRegularReadbackHandoff`

Proof. Read the finite schedule row W and the regular rational value row R. These are the only readback rows displayed before the epigraph ledger is inspected.

Apply the lower-real epigraph route and located readback stability already present in the chapter. The epigraph row E is reached from the scheduled value read, and O then compares the same lower-real and upper-real boundary before the located handoff is visible.

The remaining rows preserve that route. Componentwise hsame transport through H, displayed Cont replay through C, Pkg provenance through P, and the local $\mathsf{NameCert}$ row N keep the handoff attached to the same readback.

Thus the consumer receives only the finite located comparison surface. The absent semantic topology, envelope, quotient equality, choice, and completion coordinates cannot be supplied by this handoff. □

Theorem 1536.41 (LowerSemicontinuous Real seal boundary)**.** *For every accepted root epigraph subcarrier L_{epi}, a terminal* $\mathsf{Real}^{\uparrow}$ *seal can be read only after the finite epigraph window,* $\mathsf{LowerReal}^{\uparrow}$–$\mathsf{UpperReal}^{\uparrow}$ *comparison row,* $\mathsf{LocatedReal}^{\uparrow}$ *handoff,* BHist *transport,* hsame *ledger,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row have all been displayed. The seal boundary exports no Baire-one pointwise limit, quotient real equality, selected representative, countable choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Proof. Start from the subcarrier of Definition 1536.39. Its Real-facing route is finite because every row is already part of the accepted BHist packet.

Use the regular readback handoff of Definition 1536.40. It places the terminal seal after the finite window W, rational readback R, epigraph row E, comparison row O, transport row H, replay row C, provenance row P, and local name N.

The seal is therefore a boundary row, not an analytic limit principle. It confirms that the displayed located comparison is ready for Real-facing consumers while refusing the absent pointwise-limit, quotient-equality, selection, choice, compactness, and completeness data. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootRealSealBoundary`

Theorem 1536.42 (LowerSemicontinuous root epigraph obligation rows)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet exposes, as one finite surface, the lower-real row, epigraph row, located comparison row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, the consumer route is*

$$X, F, W, R, E, O, H, C, P, N,$$

where R is the regular readback, E is the lower-real epigraph ledger, O is the located comparison boundary, and the terminal Real seal is downstream of those rows. No row in this surface is a host epigraph closure theorem, quotient real equality, selected limit, countable-choice schedule, open-cover compactness proof, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphRows`

Proof. Project the root epigraph carrier of Definition 1536.39. It already displays the source, graph, finite window, regular readback, epigraph ledger, comparison row, transport, replay, provenance, and local naming rows.

Apply the regular readback handoff of Definition 1536.40. This places the $\mathsf{RegSeqRat}^{\uparrow}$ row before the epigraph and located comparison rows are consumed.

Use the Real seal boundary of Definition 1536.41. The terminal seal is visible only after the lower-real epigraph and located comparison rows, so the listed exclusions cannot be exported by the accepted packet. □

Theorem 1536.43 (LowerSemicontinuous root Real-seal route)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet passes through the regular readback row and epigraph rows before the Real seal is visible. Equivalently, the read must expose W, R, E, O, H, C, P, N in that order, and the terminal seal cannot be consumed directly from the source row, graph row, or an ambient completion principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootRealSealRoute`

Proof. Begin with the regular readback handoff Definition 1536.40. It forces the finite window W and regular rational readback R to appear before the epigraph ledger E and located comparison row O.

Apply the obligation rows theorem Definition 1536.42. The lower-real and epigraph rows are part of the same finite surface as the located comparison row.

Finally use the Real seal boundary Definition 1536.41. Since the seal is terminal for this route, a Real-facing consumer cannot bypass the regular readback and epigraph rows by appealing to the source row, graph row, or an ambient completion object. □

Theorem 1536.44 (LowerSemicontinuous root epigraph nonescape)**.** *No accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet exports host epigraph closure, quotient real equality, selected limits, countable choice, or ambient completeness. Every export is exhausted by the finite rows* $X, F, W, R, E, O, H, C, P, N$ *and by the downstream Real seal boundary already attached to those rows.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphNonescape`

Proof. Project the finite row surface of Definition 1536.42. The only analytic-facing data available to a consumer are the scheduled window, regular readback, epigraph ledger, located comparison row, and terminal seal boundary.

Use the Real-seal route of Definition 1536.43. It prevents a Real-facing read from detaching from W, R, E, O, H, C, P, N.

The carrier exclusions in Definition 1536.39 then finish the nonescape claim. The packet has no coordinate for host closure, quotient equality, selected limit, countable choice, or ambient completeness, so those objects cannot be returned as $\mathsf{LowerSemicontinuous}^{\uparrow}$ evidence. □

Theorem 1536.45 (LowerSemicontinuous root epigraph basis)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet carries its lower-real epigraph basis through the finite rows*

$$X, F, W, R, E, O, H, C, P, N.$$

The basis row is generated by scheduled source windows, regular rational readbacks, and displayed lower-bound witnesses; it is not a host liminf predicate, quotient real equality, selected approximating sequence, countable choice schedule, open-cover compactness proof, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphBasis`

Proof. Project the root epigraph carrier of Definition 1536.39. The only rows before the comparison ledger are the source, graph, finite window, regular rational readback, and lower-real epigraph rows.

Apply Definition 1536.40. It keeps each readback attached to the same epigraph witness before the located comparison row is consumed.

Finally use Definition 1536.41. The terminal seal is downstream of the displayed basis, so no excluded host analytic object can be exported by the root packet. □

Theorem 1536.46 (LowerSemicontinuous root located readback)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet, every located readback of a lower-bound row factors through the same scheduled window* W*, regular rational value row* R*, epigraph ledger* E*, comparison row* O*, transport row* H*, replay row* C*, provenance row* P*, and local name* N*. The readback cannot detach into a semantic topology, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected representative, countable choice, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedReadback`

Proof. Start with the regular readback handoff of Definition 1536.40. It places W, R, E, O, H, C, P, N in the exact order consumed by a located readback.

The comparison row O is reached only after the lower-bound witness in E. Transport through H and replay through C preserve that same finite route rather than creating a second located-real carrier.

The Real seal boundary of Definition 1536.41 excludes semantic topology, quotient equality, selection, choice, and ambient completeness from the endpoint. □

Theorem 1536.47 (LowerSemicontinuous root located threshold exhaustion)**.** *For an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet, every located threshold read from the accepted epigraph factors through the finite route*

$$W \longmapsto R \longmapsto E \longmapsto O \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Here W is the $\mathsf{StreamName}^{\uparrow}$ *window, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E is the lower-real epigraph ledger, and O is the located comparison boundary before the structural rows. The route exports no host liminf predicate, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable-choice schedule, open-cover compactness proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedThresholdExhaustion`

Proof. First use the regular readback handoff of Definition 1536.40. It places the scheduled window W and regular rational readback R before the lower-real epigraph ledger E and the located comparison boundary O.

Next apply the located readback theorem of Definition 1536.46. A threshold read accepted by the root epigraph packet therefore remains on W, R, E, O, H, C, P, N and cannot detach into a semantic topology or a selected approximating sequence.

Finally apply the Real seal boundary of Definition 1536.41. Since the terminal boundary is downstream of the same finite route, quotient real equality, countable choice, open-cover compactness, and ambient Real completeness have no export row. □

Theorem 1536.48 (Lower semicontinuous epigraph source scope)**.** *Every accepted root epigraph consumer of a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet factors through the concrete rows*

$$X, F, W, R, E, O, H, C, P, N.$$

Here W is the finite $\mathsf{StreamName}^{\uparrow}$ *inspection window, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, E is the lower-real epigraph evidence, O is the* $\mathsf{LowerReal}^{\uparrow}$–$\mathsf{UpperReal}^{\uparrow}$ *located comparison and terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, and H, C, P, N are the componentwise transport, replay, provenance, and local NameCert rows. Thus the consumer is source-scoped by the displayed stream-name and rational-readback route; it has no coordinate for semantic topology, host liminf, quotient real equality, selected representatives, countable choice, open-cover compactness, or ambient completion.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphSourceScope`

Proof. Begin with the root epigraph carrier of Definition 1536.39. It displays the only source rows available to an epigraph consumer: the source row X, graph-facing row F, finite window W, rational readback R, lower-real epigraph row E, comparison row O, and structural rows H, C, P, N.

Next use the regular readback handoff of Definition 1536.40. This keeps the $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the same lower-bound evidence before any located endpoint is visible.

Apply the Real seal boundary of Definition 1536.41. The row O is therefore a displayed $\mathsf{LowerReal}^{\uparrow}$–$\mathsf{UpperReal}^{\uparrow}$ comparison with a terminal $\mathsf{Real}^{\uparrow}$ boundary, not a hidden analytic completion principle.

Finally use the located readback theorem of Definition 1536.46. Every accepted located read of the epigraph endpoint has already passed through W, R, E, O, H, C, P, N, so the root epigraph consumer factors through the listed source-scope route and cannot export any of the excluded host objects. □

Theorem 1536.49 (LowerSemicontinuous epigraph to LocatedSet handoff)**.** *Any accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph read that is consumed as a* $\mathsf{LocatedSet}^{\uparrow}$ *packet must pass through the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, the root epigraph basis, the* $\mathsf{LocatedSet}^{\uparrow}$ *route,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The handoff exports no host topology, semantic liminf operator, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphLocatedSetHandoff`

Proof. Start with the root epigraph carrier of Definition 1536.39. It displays the finite source, graph, window, readback, epigraph, comparison, transport, replay, provenance, and local naming rows.

Use the regular readback handoff of Definition 1536.40 and the root epigraph basis of Definition 1536.45. Together they keep every $\mathsf{RegSeqRat}^{\uparrow}$ read attached to the same lower-bound row before any located consumer sees the endpoint.

Apply the Real seal boundary of Definition 1536.41. The terminal seal is visible only after the epigraph basis and located comparison rows have been displayed.

Finally use the located readback theorem above. A $\mathsf{LocatedSet}^{\uparrow}$ consumer therefore receives the same finite route through $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows, and the excluded host analytic objects remain outside the packet. □

Theorem 1536.50 (LowerSemicontinuous epigraph to LocatedSet exactness)**.** *An accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph read becomes a* $\mathsf{LocatedSet}^{\uparrow}$ *packet exactly when the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *value row* R*, lower-real epigraph ledger* E*, upper/lower comparison row* O*,* $\mathsf{LocatedReal}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary,* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N *are all displayed in the same finite route. The exactness route exports no host topology, semantic liminf operator, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphLocatedSetExactness`

Proof. Start with the root epigraph carrier of Definition 1536.39. It supplies the scheduled window, regular rational value row, epigraph ledger, comparison row, transport, replay, provenance, and local name as one finite packet.

Use the regular readback handoff and the root located readback theorem. These force the $\mathsf{RegSeqRat}^{\uparrow}$ value row and every $\mathsf{LocatedReal}^{\uparrow}$ endpoint to pass through the same W, R, E, O, H, C, P, N route before a located consumer can read it.

Apply the Real seal boundary of Definition 1536.41. The seal is terminal for the displayed epigraph comparison, so quotient equality, selected representatives, countable choice, compactness, and ambient completeness have no export coordinate.

Finally use the epigraph-to-$\mathsf{LocatedSet}^{\uparrow}$ handoff of Definition 1536.49. The forward direction reads the listed rows before forming the located-set packet; the reverse direction projects those same rows from any accepted located-set consumption of the epigraph read. Thus the handoff is exact for the displayed finite route and for no hidden host object. □

Theorem 1536.51 (LowerSemicontinuous root nonescape)**.** *Every root-level consumer of the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph packet is exhausted by the displayed source, graph, finite-window, readback, epigraph, located-comparison, transport, replay, provenance, and local naming rows. The packet exports no host topology, semantic liminf operator, quotient real equality, selected sequence, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootNonescapeStrengthened`

Proof. Use the root epigraph basis theorem to identify the consumer-visible rows. They are all part of the finite BHist packet and all pass through the local NameCert route.

The located readback theorem then accounts for every Real-facing endpoint. A consumer reaches the endpoint only after W, R, E, O, H, C, P, N have been displayed.

Since the excluded host objects have no coordinate in the carrier and no replay row, the root packet cannot export them. □

Theorem 1536.52 (LowerSemicontinuous finite epigraph threshold exhaustion)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet exhausts all displayed finite threshold reads through*

$$X, F, W, R, E, O, H, C, P, N.$$

Any lower-bound threshold visible to a $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer must appear in the scheduled* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *window rows before the epigraph ledger is consumed. The packet exports no semantic liminf predicate, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice, open-cover compactness, or ambient Real completeness.*

Proof. Start with the root epigraph carrier of Definition 1536.39. Its visible threshold route is exactly the source row X, graph row F, scheduled window row W, regular rational readback R, epigraph ledger E, comparison row O, transport H, replay C, provenance P, and local name N.

Apply the regular readback handoff of Definition 1536.40. A threshold cannot reach a lower-real, upper-real, located-real, or Real-facing consumer until the scheduled $\mathsf{StreamName}^{\uparrow}$ window and matching $\mathsf{RegSeqRat}^{\uparrow}$ value row have already been displayed.

Use the Real seal boundary of Definition 1536.41. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of W, R, E, O, H, C, P, N, so any visible lower-bound threshold must already be present in those finite rows before the seal is read.

Finally apply root nonescape. Since the carrier has no semantic liminf coordinate, quotient Real equality, selected approximating sequence, countable-choice schedule, open-cover compactness proof, or ambient completeness primitive, the displayed finite threshold rows exhaust every accepted epigraph read. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousFiniteEpigraphThresholdExhaustion`

Theorem 1536.53 (LowerSemicontinuous root epigraph closure package)**.** *The root epigraph carrier, regular readback handoff,* $\mathsf{Real}^{\uparrow}$ *seal boundary, epigraph basis, located readback,* $\mathsf{LocatedSet}^{\uparrow}$ *handoff, exactness, nonescape, finite threshold exhaustion, and* $\mathsf{LocatedSet}^{\uparrow}$ *threshold route assemble the* obligation *surface for* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *Every accepted root epigraph consumer reads the finite route*

$$X, F, W, R, E, O, H, C, P, N$$

or its threshold subroute

$$W, R, E, O, H, C, P, N$$

before consuming the lower-real, upper-real, located-real, located-set, or Real-facing endpoint. The package exports no semantic liminf predicate, quotient $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice, open-cover compactness, or ambient Real completeness.*

Proof. First assemble the carrier and readback spine. The root epigraph carrier of Definition 1536.39 displays the finite rows $X, F, W, R, E, O, H, C, P, N$, and the regular readback handoff of Definition 1536.40 forces every $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ read to pass through W, R, E, O, H, C, P, N before any located endpoint is consumed.

Next attach the Real-facing and epigraph-facing boundaries. The Real seal boundary of Definition 1536.41 places the terminal $\mathsf{Real}^{\uparrow}$ seal after the same finite rows, while the root epigraph basis of Definition 1536.45 identifies the lower-real epigraph rows generated by the scheduled windows and regular rational readbacks.

Now pass to located consumption. The root located readback theorem Definition 1536.46 keeps every located endpoint on the displayed route, the $\mathsf{LocatedSet}^{\uparrow}$ handoff of Definition 1536.49 gives the located-set consumer, and exactness from Definition 1536.50 says that consuming the located-set packet is equivalent to displaying those rows in one finite route.

Finally close the obligation package. Root nonescape from Definition 1536.51 excludes all absent analytic coordinates, finite threshold exhaustion from Definition 1536.52 accounts for every displayed lower-bound threshold, and the $\mathsf{LocatedSet}^{\uparrow}$ threshold route of Definition 1536.54 places located-set threshold consumption downstream of the same rows. Thus the listed results form the paper-side obligation surface and do not export semantic liminf data, quotient equality, selected sequences, choice, compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphClosurePackage`

Theorem 1536.54 (LowerSemicontinuous root LocatedSet threshold route)**.** *Every* $\mathsf{LocatedSet}^{\uparrow}$ *consumer of a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph threshold must read the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *value row* R*, the lower-real epigraph ledger* E*, the comparison row* O*, the* $\mathsf{LocatedReal}^{\uparrow}$ *handoff, the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, the* hsame *transport row* H*, the displayed* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* NameCert *row* N *before it consumes the located-set packet. Thus the threshold route is the finite route*

$$W, R, E, O, H, C, P, N$$

with the located-real and Real-seal boundary rows displayed at the comparison endpoint, not a host topology, semantic liminf operator, quotient $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Proof. First build the root epigraph basis. Apply Definition 1536.45 to expose the scheduled source window, regular rational value row, lower-real epigraph ledger, comparison row, transport, replay, provenance, and local name.

Next read the located endpoint. The located readback theorem Definition 1536.46 keeps every lower-bound read attached to the same W, R, E, O, H, C, P, N route, and the exactness theorem Definition 1536.50 identifies exactly when that route becomes consumable as a $\mathsf{LocatedSet}^{\uparrow}$ packet.

Finally apply finite threshold exhaustion from Definition 1536.52. It says that every displayed lower-bound threshold visible to lower-real, upper-real, located-real, or Real-facing consumers has already appeared in the same finite rows. Hence the located-set consumer must read the listed rows before consumption, and the excluded host analytic objects have no route into the packet. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedSetThresholdRoute`

Theorem 1536.55 (LowerSemicontinuous root epigraph specialization)**.** *Let an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet expose a concrete lower-bound threshold read. Then that read specializes the root route*

$$W, R, E, O, H, C, P, N$$

to the scheduled $\mathsf{StreamName}^{\uparrow}$ *window, the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *value row, the lower-real epigraph ledger, the comparison endpoint, transport, replay, provenance, and local naming rows already displayed by the packet. The specialization exports no semantic liminf predicate, selected infimum, host topology, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, open-cover compactness proof, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphSpecialization`

Proof. Start with the root epigraph carrier and the regular readback handoff. They place the scheduled window W, value row R, epigraph ledger E, comparison row O, and structural rows H, C, P, N before any concrete threshold read reaches a consumer.

Apply finite threshold exhaustion. Every lower-bound threshold visible to lower-real, upper-real, located-real, located-set, or Real-facing consumers has already appeared in the same scheduled rows, so specializing to one concrete threshold is just projecting that finite ledger.

Finally use the Real seal boundary and the root LocatedSet threshold route. The terminal seal and located-set consumer both remain downstream of W, R, E, O, H, C, P, N, and the excluded analytic objects have no carrier coordinate from which to enter the specialized read. □

Theorem 1536.56 (LowerSemicontinuous root LowerReal projection)**.** *Before the terminal* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet is consumed, the comparison row* O *projects the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *boundary reads through the displayed* W, R, E *threshold ledger. Thus a lower-real projection reaches the located endpoint only after the scheduled* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows have been displayed, and not by host real order, trichotomy, selected infimum, quotient equality, choice, compactness, or ambient completeness.*

Proof. Project the comparison row from the root epigraph carrier. The row O is downstream of the scheduled window, regular rational readback, and epigraph ledger, so its lower-real and upper-real reads are not independent endpoints.

Use the regular readback handoff and Real seal boundary. They force every lower or upper boundary value to pass through W, R, E, O before the $\mathsf{LocatedReal}^{\uparrow}$ handoff or terminal $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Finite threshold exhaustion supplies the nonescape clause. Since every visible threshold is already in the finite scheduled rows, the projection cannot be replaced by host order, trichotomy, selected infimum, quotient equality, choice, compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLowerRealProjection`

Theorem 1536.57 (LowerSemicontinuous root LocatedSet nonescape)**.** *No* $\mathsf{LocatedSet}^{\uparrow}$ *consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet can bypass the finite scheduled* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. Any such consumer must read the displayed route*

$$W, R, E, O, H, C, P, N$$

including the lower-real epigraph ledger, located comparison endpoint, terminal Real-seal boundary, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives no host topology, semantic liminf operator, selected approximating sequence, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedSetNonescape`

Proof. Begin with the epigraph-to-$\mathsf{LocatedSet}^{\uparrow}$ handoff and exactness theorems. They identify located-set consumption with the scheduled window, regular rational value row, epigraph ledger, comparison endpoint, transport, replay, provenance, and local name.

Apply the root LocatedSet threshold route. It requires the located-set consumer to pass through the same W, R, E, O, H, C, P, N rows before the located-set packet is consumed.

Finally use finite threshold exhaustion together with the Real seal boundary. The finite scheduled rows already contain every visible lower-bound threshold, and the terminal seal is downstream of those rows. Hence a located-set consumer has no route around the finite schedule and no coordinate for the excluded host analytic principles. □

Theorem 1536.58 (LowerSemicontinuous epigraph threshold monotonicity)**.** *Let two displayed* $\mathsf{Real}^{\uparrow}$ *threshold rows of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet be ordered by the dyadic tolerance ledger before the terminal seal is consumed. The later epigraph read refines the earlier read through the same finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{LocatedReal}^{\uparrow}, \mathsf{LowerReal}^{\uparrow}, \mathsf{UpperReal}^{\uparrow}, \mathsf{LocatedSet}^{\uparrow}$$

and through the same W, R, E, O, H, C, P, N *rows. The refinement is therefore a located-set routing fact internal to the displayed packet, not a host real-order comparison, trichotomy principle, selected supremum, countable-choice schedule, or ambient completeness argument.*

Proof. Start with finite threshold exhaustion from Definition 1536.52. It places every visible lower-bound threshold in the scheduled $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows before the epigraph ledger and comparison endpoint are read.

Next use the root epigraph basis and the regular readback handoff. The basis theorem Definition 1536.45 keeps both threshold rows in the same W, R, E, O, H, C, P, N carrier, while Definition 1536.40 attaches each read to the corresponding located endpoint before any $\mathsf{Real}^{\uparrow}$ seal is exported.

Finally apply the LocatedSet threshold route of Definition 1536.54. Since the dyadic tolerance ledger orders the displayed threshold rows before the located-set consumer reads them, the later row can only refine the earlier one along that finite route.

The exclusions follow by route exhaustion. No coordinate of the carrier supplies host real order, trichotomy, selected suprema, countable choice, or ambient completeness, so monotonicity is witnessed only by the displayed epigraph and located-set rows. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphThresholdMonotonicity`

Theorem 1536.59 (LowerSemicontinuous root epigraph carrier scope)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet reads its located-set predicate,* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *cut rows, regular rational stream witness, and terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the root epigraph carrier. The packet introduces no open-cover compactness proof, selected infimum, semantic liminf operator, host real order, quotient real equality, or countable-choice schedule.*

Proof. Start with the root epigraph carrier of Definition 1536.39. Its rows expose the source, graph, scheduled finite window, regular rational readback, lower-real epigraph ledger, comparison row, transport, replay, provenance, and local naming data.

The located-set predicate is reached through the handoff of Definition 1536.49. The lower and upper cuts are read through the regular readback handoff of Definition 1536.40 and the root epigraph basis of Definition 1536.45.

The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of those same rows by Definition 1536.41. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row keep the located-set and real-cut reads attached to the accepted BHist packet.

The exclusions are coordinate exhaustion. Since the carrier contains no open-cover compactness proof, selected infimum, host real order, semantic liminf operator, quotient real equality, or countable-choice schedule, the scoped root epigraph read cannot export any of them. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphCarrierScope`

Theorem 1536.60 (LowerSemicontinuous root epigraph coverage)**.** *Every accepted lower-bound threshold of a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet is covered by the displayed route*

$$W, R, E$$

before any $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer reads it. The finite window row* W*, regular rational readback* R*, and epigraph ledger* E *therefore exhaust threshold coverage before the comparison, transport, replay, provenance, and local NameCert rows are consumed.*

Proof. Start with the root epigraph carrier of Definition 1536.39. It displays the scheduled finite window, regular rational value row, and lower-real epigraph ledger before the comparison endpoint.

Apply the regular readback handoff of Definition 1536.40. A threshold can reach a located or Real-facing consumer only after the W, R, E route has already attached the scheduled value to its epigraph witness.

Finally use the root epigraph carrier scope of Definition 1536.59. The remaining rows O, H, C, P, N preserve and name the covered threshold; they do not create a hidden threshold outside the displayed finite window. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphCoverage`

Theorem 1536.61 (LowerSemicontinuous root epigraph coverage exactness)**.** *An accepted lower-bound threshold of a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet is covered exactly when the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *value row* R*, epigraph ledger* E*, located comparison*

endpoint O, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$ *row N are all displayed in one route. The exactness boundary exports no semantic liminf predicate, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected infimum, countable choice, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphCoverageExactness`

Proof. For the forward direction, start with the root epigraph coverage theorem. It places every accepted lower-bound threshold in the scheduled window, regular rational value row, and epigraph ledger before any located or Real-facing consumer reads the threshold.

Apply finite epigraph threshold exhaustion. The theorem forces any displayed threshold visible to lower-real, upper-real, located-real, or Real-facing consumers to pass through the same W, R, E, O, H, C, P, N route.

Use the LocatedSet threshold route to identify the comparison endpoint. The located-set consumer can read the threshold only after O and the structural rows H, C, P, N are displayed with the same scheduled value.

For the reverse direction, project an accepted route with all listed rows. The scheduled window and regular value row provide the finite threshold read, the epigraph ledger covers it, and the located comparison endpoint keeps the lower-bound threshold attached to the same packet.

Finally apply the root epigraph carrier scope. Since semantic liminf, quotient equality, selected infimum, countable choice, and ambient completeness have no carrier coordinate, the exactness statement is only the displayed finite coverage boundary. □

Theorem 1536.62 (LowerSemicontinuous root located comparison)**.** *The comparison row O of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet compares* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, and* $\mathsf{LocatedReal}^{\uparrow}$ *endpoints only after the epigraph ledger E has been displayed from the scheduled W, R readback. Thus located comparison is downstream of finite epigraph evidence, not a host order comparison, trichotomy principle, selected infimum, or quotient real equality.*

Proof. Project the rows of Definition 1536.39. The row order places W and R before E, and places O after the displayed epigraph ledger.

Use Definition 1536.40. It keeps every $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the same lower-bound witness before O may compare the lower, upper, and located endpoints.

The scope theorem Definition 1536.59 supplies the boundary. Since host order, trichotomy, selected infimum, and quotient equality have no coordinate in the carrier, the comparison row can only read the displayed epigraph ledger. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedComparison`

Theorem 1536.63 (LowerSemicontinuous root Real seal refusal)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet exports no semantic liminf operator, selected infimum, host topology, quotient equality, countable-choice schedule, or ambient completeness theorem. It seals only the displayed W, R, E, O, H, C, P, N route supplied by the finite epigraph carrier.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootRealSealRefusal`

Proof. Begin with the Real seal boundary of Definition 1536.41. It places the terminal seal after the finite epigraph window, comparison row, transport, replay, provenance, and local naming rows.

Apply root epigraph coverage and located comparison above. Coverage accounts for every accepted lower-bound threshold through W, R, E, while the comparison row O reads lower, upper, and located endpoints only after that ledger is displayed.

Finally use Definition 1536.59. The refused liminf, selected infimum, topology, quotient equality, choice, and completeness objects have no carrier coordinate, so the terminal seal cannot export them. □

Theorem 1536.64 (LowerSemicontinuous root epigraph finite infimum handoff)**.** *Any finite lower-bound infimum read consumed by a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet must pass through the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *value row, the lower-real epigraph ledger, the located comparison row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise transport, displayed replay, provenance, and local* NameCert *rows. The packet exports no selected infimum, semantic liminf operator, host topology, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, open-cover compactness proof, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphFiniteInfimumHandoff`

Proof. Start with the root epigraph carrier of Definition 1536.39. Its finite route displays the scheduled window, regular rational value row, lower-real epigraph ledger, comparison row, transport, replay, provenance, and local naming before any real-facing endpoint is consumed.

Apply finite threshold exhaustion through Definition 1536.52. Every lower-bound threshold read is accounted for inside the scheduled $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ value row, so an infimum-facing finite read cannot skip the epigraph ledger.

Use located comparison from Definition 1536.62. The comparison row reads lower, upper, and located endpoints only after the epigraph ledger has been displayed, so the lower-bound infimum route remains a finite BEDC comparison route rather than a host-order selection.

Finally apply the Real seal refusal of Definition 1536.63. The terminal seal refuses semantic liminf data, selected infima, host topology, quotient equality, choice schedules, compactness proofs, and ambient completeness. Hence the finite infimum handoff exports only the displayed W, R, E, O, H, C, P, N route. □

Theorem 1536.65 (LowerSemicontinuous epigraph threshold refinement)**.** *Let two displayed* $\mathsf{Real}^{\uparrow}$ *threshold rows of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph packet be ordered before the terminal seal is consumed. The refined row reaches every* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{LocatedSet}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumer through the same*

$$W, R, E, O, H, C, P, N$$

route as the coarser row, with the refinement witnessed before the terminal seal and not by a host real-order comparison, selected infimum, semantic liminf operator, countable-choice schedule, open-cover compactness proof, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphThresholdRefinement`

Proof. Start with finite epigraph threshold exhaustion. It places both displayed threshold rows in the scheduled $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows before the epigraph ledger is consumed.

Use the LocatedSet threshold route and epigraph threshold monotonicity. The located-set consumer reads the same W, R, E, O, H, C, P, N rows, and the ordered threshold ledger lets the refined row sharpen the coarser read only along that finite route.

Finally apply the root epigraph carrier scope. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of the displayed transport, replay, provenance, and local naming rows, so the refinement cannot import host order, selected infima, semantic liminf data, choice, compactness, or ambient completeness. □

Theorem 1536.66 (LowerSemicontinuous located epigraph filter stability)**.** *Every located-set filter consumer of an accepted* LowerSemicontinuous$^{\uparrow}$ *root epigraph packet reads the same finite epigraph threshold rows under componentwise* hsame *transport and displayed* Cont *replay. Thus a filter-stable located epigraph read is carried by*

$$W, R, E, O, H, C, P, N$$

and exports no detached topology, quotient Real$^{\uparrow}$ *equality, selected approximating sequence, countable-choice schedule, open-cover compactness proof, or ambient Real-completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedEpigraphFilterStability`

Proof. Begin with the epigraph-to-LocatedSet$^{\uparrow}$ exactness theorem. It identifies located-set consumption with the scheduled window, regular rational value row, epigraph ledger, comparison endpoint, transport, replay, provenance, and local name.

Apply finite threshold exhaustion and threshold refinement. Every lower-bound threshold visible to the located filter is already displayed in the same finite rows, and ordered threshold reads refine before the terminal seal.

Transport stability is then carrier-local. The hsame row preserves the displayed threshold rows componentwise, and the Cont row replays the same route for the filter consumer. The carrier scope theorem excludes detached topology, quotient equality, selection, choice, compactness, and ambient completeness from the endpoint. □

Theorem 1536.67 (LowerSemicontinuous epigraph filter route)**.** *Let an accepted* LowerSemicontinuous$^{\uparrow}$ *root epigraph packet expose threshold rows that are stable under located comparison. Then every filter-facing read of its epigraph factors through* LocatedSet$^{\uparrow}$ *rows,* LowerReal$^{\uparrow}$ *and* UpperReal$^{\uparrow}$ *boundary rows,* RegSeqRat$^{\uparrow}$ *readback,* StreamName$^{\uparrow}$ *windows, and the terminal* Real$^{\uparrow}$ *seal along the same*

$$W, R, E, O, H, C, P, N$$

route. The exported route contains no selected minimizer, quotient function equality, detached topology, selected approximating sequence, countable-choice schedule, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphFilterRoute`

Proof. Start with the root epigraph carrier. The rows W, R, E, O, H, C, P, N place the stream window, regular rational readback, epigraph ledger, located comparison endpoint, transport, replay, provenance, and local name before any filter consumer may inspect the packet.

Use the located readback and epigraph-to-LocatedSet$^{\uparrow}$ handoff. These rows identify the filter-facing epigraph as a located-set read whose lower and upper real boundary data are still tied to the same displayed threshold window.

Apply finite threshold exhaustion and threshold refinement. Every threshold requested by the filter is already present in the finite ledger, and each ordered located comparison refines through the displayed lower, upper, and located endpoint rows.

Finally use located epigraph filter stability. Componentwise hsame transport and displayed Cont replay preserve the same route for the filter consumer, while the root carrier scope excludes minimizer selection, quotient function equality, detached topology, selected sequences, choice schedules, and ambient completeness. □

Theorem 1536.68 (LowerSemicontinuous root epigraph filter directedness)**.** *Let an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet expose two epigraph threshold/filter rows over the same* $\mathsf{Real}^{\uparrow}$ *seal and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback source. Then the displayed located comparison, epigraph threshold refinement, and epigraph filter route admit a common refined threshold row carried by the same finite route*

$$W, R, E, O, H, C, P, N.$$

The common row is a BHist *and* hsame*-stable filter refinement whose* Cont *replay and* NameCert *provenance remain internal to the accepted packet. It exports no host liminf theorem, open-sublevel theorem, detached topology, selected approximating sequence, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphFilterDirectedness`

Proof. Start with the two displayed threshold/filter rows. Since they share the same $\mathsf{Real}^{\uparrow}$ seal and $\mathsf{RegSeqRat}^{\uparrow}$ readback source, both rows are already visible through the scheduled window W, regular value row R, epigraph ledger E, and located comparison endpoint O.

Apply the root located comparison theorem and the epigraph threshold refinement theorem. Located comparison keeps both lower-bound reads attached to the same W, R, E, O route, while threshold refinement supplies a row below the two displayed reads before the terminal seal is consumed.

Now use the epigraph filter route. The filter-facing read of each threshold factors through the same located-set, lower-real, upper-real, regular-readback, stream-window, and Real-seal rows, so the refined threshold is a common filter row rather than a second host filter object.

Finally repack through the structural rows. Componentwise hsame transport keeps the common row in the same BHist packet, Cont replay preserves the route for consumers, and P, N supply provenance and local naming. The excluded host liminf, open-sublevel, topology, selector, quotient, choice, and completeness objects have no coordinate in this directedness witness. □

Theorem 1536.69 (LowerSemicontinuous root epigraph filter basis closure)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph filter basis over the same* $\mathsf{Real}^{\uparrow}$ *seal and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback source is closed under displayed threshold refinement and common filter rows along*

$$W, R, E, O, H, C, P, N.$$

The closure read is a BHist*-routed basis package: lower thresholds refine through the epigraph ledger, common rows remain under the same located comparison endpoint, and componentwise* hsame *transport plus displayed* Cont *replay keep provenance and local naming internal to the accepted packet. It exports no host liminf predicate, detached topology, selected approximating sequence, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable choice schedule, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphFilterBasisClosure`

Proof. Begin with finite threshold exhaustion. Definition 1536.52 places every displayed lower-bound request inside the scheduled $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, epigraph ledger, comparison endpoint, transport, replay, provenance, and local naming route.

Next apply epigraph threshold refinement and located epigraph filter stability. Definition 1536.65 supplies refined threshold rows before the terminal seal is consumed, while Definition 1536.66 keeps those rows stable under componentwise transport and replay.

Now use the epigraph filter route and Real threshold boundary. Definition 1536.67 forces every filter-facing read through the same located-set, lower-real, upper-real, regular-readback, stream-window, and Real-seal rows, and Definition 1536.72 keeps any Real-facing threshold downstream of the displayed finite route.

Finally repack with directedness. Definition 1536.68 supplies the common refined filter row over the shared $\mathsf{Real}^{\uparrow}$ seal and $\mathsf{RegSeqRat}^{\uparrow}$ source; the structural rows H, C, P, N name that row as a basis closure witness. Since the carrier has no coordinate for host liminf, detached topology, selectors, quotient equality, choice, or ambient completeness, none of those objects is exported by the closure package. □

Theorem 1536.70 (LowerSemicontinuous root epigraph filter-basis exactness)**.** *An accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph filter-basis read is exact precisely when the displayed route*

$$W, R, E, O, H, C, P, N$$

is present and every common refinement is obtained from epigraph threshold refinement followed by root epigraph filter directedness. Thus the exact basis has no hidden host topology, selected infimum, semantic liminf predicate, quotient $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphFilterBasisExactness`

Proof. For the forward read, apply Definition 1536.69. It keeps the basis inside the displayed scheduled-window, regular-readback, epigraph-ledger, located-comparison, transport, replay, provenance, and local naming route.

The refinement witness is forced by the finite threshold route. Use Definition 1536.65 to refine displayed lower-bound thresholds before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed, and then apply Definition 1536.68 to obtain the common filter row over the same $\mathsf{RegSeqRat}^{\uparrow}$ source and $\mathsf{Real}^{\uparrow}$ seal.

Conversely, suppose the route W, R, E, O, H, C, P, N is present and the common refinement is supplied by threshold refinement plus filter directedness. The Real-facing threshold is already downstream of the finite packet by Definition 1536.72, so no outside topology, infimum selector, liminf predicate, quotient equality, choice schedule, or completeness principle can enter the basis read. This is exactly the finite epigraph basis advertised by the accepted root packet. □

Theorem 1536.71 (LowerSemicontinuous root filter-basis directed refinement)**.** *Let two displayed* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph filter-basis rows lie over the same* W, R, E, O, H, C, P, N *route. They admit a common displayed refinement only through epigraph threshold refinement, located epigraph filter stability, and root epigraph filter directedness. The refinement exports no host liminf theorem, open-sublevel theorem, detached topology, selected approximating sequence, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable choice, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootFilterBasisDirectedRefinement`

Proof. Begin with the filter-basis closure package. Definition 1536.69 keeps both basis rows inside the same scheduled window, regular readback, epigraph ledger, located comparison, transport, replay, provenance, and local naming route.

Use epigraph threshold refinement next. Definition 1536.65 supplies the only permitted way to refine the displayed lower-bound thresholds before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally apply filter directedness. Definition 1536.68 provides the common refined filter row over the shared $\mathsf{Real}^{\uparrow}$ seal and $\mathsf{RegSeqRat}^{\uparrow}$ source, while located epigraph filter stability keeps componentwise transport and replay inside the accepted packet. Since none of the refused host objects appears as a carrier coordinate, the directed refinement is exactly the displayed finite witness. □

Theorem 1536.72 (LowerSemicontinuous root filter real threshold)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph filter read that reaches a* $\mathsf{Real}^{\uparrow}$*-facing threshold must first expose the* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{LocatedSet}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows already named by the root carrier. In carrier notation the threshold route is the finite read*

$$W, R, E, O, H, C, P, N$$

with the scheduled window W, regular rational value row R, epigraph ledger E, located comparison endpoint O, transport row H, displayed replay row C, provenance row P, and local naming row N visible before the Real-facing threshold is public. The route exports no semantic liminf operator, quotient $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable choice schedule, open-cover compactness proof, or ambient Real-completeness theorem.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootFilterRealThreshold`

Proof. Start with the epigraph filter route above. It forces every filter-facing read to pass through the located-set handoff, the lower and upper real boundary rows, the scheduled stream window, the regular rational readback, and the terminal Real seal on the same displayed route.

Use located comparison and located readback. The comparison row O is the only endpoint at which $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$ data meet, and it is downstream of the finite W, R, E threshold ledger rather than a host order predicate.

Finally apply the Real seal refusal block. Since the terminal $\mathsf{Real}^{\uparrow}$ seal can only seal the already displayed W, R, E, O, H, C, P, N route, a Real-facing threshold cannot be read before those rows are exposed. The refused liminf, quotient-equality, selection, choice, compactness, and completeness objects have no carrier coordinate from which to enter the threshold read. □

Theorem 1536.73 (LowerSemicontinuous root epigraph threshold continuity)**.** *Every accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root epigraph filter read preserves the same threshold row when transported through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, located-comparison,* $\mathsf{LocatedSet}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. In carrier notation, if the threshold is read along*

$$W, R, E, O, H, C, P, N,$$

then every transported filter-facing threshold read of the same accepted packet reads that same row through the same finite route. The transport exports no host liminf predicate, quotient $\mathsf{Real}^{\uparrow}$ *equality, selected approximating sequence, countable-choice schedule, open-cover compactness proof, or ambient completeness theorem.*

Proof. Begin with the root epigraph carrier and the regular readback handoff. The carrier fixes W, R, E, O, H, C, P, N as the scheduled window, regular rational value row, epigraph ledger, located comparison endpoint, transport, replay, provenance, and local naming route, while the readback handoff keeps the threshold downstream of the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows.

Use located comparison next. The $\mathsf{LowerReal}^{\uparrow}$ and $\mathsf{UpperReal}^{\uparrow}$ rows meet only at the located comparison endpoint O, and the $\mathsf{LocatedSet}^{\uparrow}$ read is attached to that endpoint before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed.

Apply filter directedness and filter-basis exactness. Directedness supplies common displayed threshold rows for filter-facing reads over the same source, and exactness says those rows are obtained by epigraph threshold refinement rather than by an external topological or liminf object.

Finally use Definition 1536.72. It places every Real-facing threshold downstream of the same W, R, E, O, H, C, P, N route, so hsame transport and Cont replay preserve the displayed row without introducing host liminf, quotient equality, selectors, countable choice, open-cover compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphThresholdContinuity`

Theorem 1536.74 (LowerSemicontinuous public epigraph export route)**.** *Every public* LowerSemicontinuous$^{\uparrow}$ *export that exposes an epigraph read factors through the displayed root epigraph carrier, located threshold route,* LowerReal$^{\uparrow}$ *projection,* RegSeqRat$^{\uparrow}$ *readback, and terminal* Real$^{\uparrow}$ *seal rows. In carrier notation the public route is*

$$X, F, W, R, E, O, H, C, P, N,$$

with the scheduled window W and value row R read before the epigraph ledger E, the lower-real and upper-real boundary projection read at O, and the Real seal consumed only after transport, replay, provenance, and local naming are visible. The export provides a public epigraph surface for LowerReal, LocatedSet, RegSeqRat, and Real consumers; it exports no host topology, semantic liminf operator, selected infimum, quotient Real$^{\uparrow}$ *equality, countable-choice schedule, open-cover compactness proof, or ambient completeness theorem.*

Proof. Start with the root epigraph threshold continuity theorem Definition 1536.73. It keeps every transported filter-facing threshold on the same finite W, R, E, O, H, C, P, N route and prevents a public read from detaching into an external threshold object.

Next apply the LowerReal projection block Definition 1536.56. The lower-real and upper-real rows meet only through the displayed comparison endpoint O, so the public epigraph export cannot bypass the scheduled StreamName$^{\uparrow}$ window or RegSeqRat$^{\uparrow}$ value row.

Finally use the root epigraph carrier, Real seal boundary, and located-set handoff already assembled in this file. They place X, F before the threshold subroute and place the terminal Real$^{\uparrow}$ seal after E and O. Thus the public export is exactly the displayed carrier route and has no coordinate for the refused host analytic objects. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousPublicEpigraphExportRoute`

Theorem 1536.75 (LowerSemicontinuous formal-target bridge request)**.** *Every formalization target for the public* LowerSemicontinuous$^{\uparrow}$ *epigraph export must factor through the root epigraph carrier, located threshold exhaustion, lower-real projection, located-set nonescape, finite-infimum handoff, epigraph filter route, and real-threshold theorem already displayed in this file. In carrier notation the requested bridge target is confined to*

$$X, F, W, R, E, O, H, C, P, N,$$

with W the StreamName$^{\uparrow}$ *inspection window, R the* RegSeqRat$^{\uparrow}$ *readback row, E the lower-real epigraph ledger, O the located comparison endpoint, and H, C, P, N the structural transport, replay, provenance, and local naming rows. The requested target refuses host topology, quotient* Real$^{\uparrow}$ *equality, semantic limits, and ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousFormalTargetBridgeRequest`

Proof. Start with the root epigraph carrier and located threshold exhaustion, Definition 1536.39 and Definition 1536.52. These make the scheduled source, stream window, regular rational readback, epigraph ledger, comparison endpoint, and structural rows explicit before any public epigraph read is exported.

Apply the lower-real projection and located-set nonescape theorems, Definition 1536.56 and Definition 1536.57. They force the lower-real, upper-real, located endpoint, and located-set reads to remain on the same finite route rather than entering through host topology or quotient real equality.

Finally use the finite-infimum handoff, epigraph filter route, and real-threshold theorem, Definition 1536.64, Definition 1536.67, and Definition 1536.72. Their rows place the filter-facing and Real-facing threshold reads downstream of W, R, E, O, H, C, P, N, so a formal target for the public export can request exactly that bridge surface and no semantic limit or ambient completeness principle. □

Theorem 1536.76 (LowerSemicontinuous lower-real epigraph classifier)**.** *For the root packet $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$, every* $\mathsf{LowerReal}^{\uparrow}$ *epigraph classifier read is determined by the displayed source row X, graph row F, finite stream schedule W, regular rational value row R, and epigraph ledger E. The classifier may be transported by H and replayed by C, but it cannot be replaced by a host liminf predicate, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the root carrier from Definition 1536.22. The only lower-real coordinate available to a consumer is the epigraph ledger E attached to the source, graph, schedule, and readback rows.

Use Definition 1536.16. It orders the classifier read through X, F, W, R, E before the located comparison, transport, replay, provenance, and local naming rows are consumed.

Finally apply Definition 1536.18. Since the excluded host liminf, quotient equality, choice, and completeness principles have no carrier coordinate and no replay row, the epigraph classifier remains finite $\mathsf{LowerReal}^{\uparrow}$ data. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLowerRealEpigraphClassifier`

Theorem 1536.77 (LowerSemicontinuous regular readback transport)**.** *Every transported lower-semicontinuous readback of $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ carries the same* $\mathsf{StreamName}^{\uparrow}$ *schedule row W and* $\mathsf{RegSeqRat}^{\uparrow}$ *value row R into the located comparison ledger O. The transport exports a finite readback route through W, R, E, O, H, C, P, N and not a semantic liminf operation, selected representative, quotient real equality, countable choice, or ambient Real-completeness witness.*

Proof. Start with the transported readback. The root carrier gives H as the only componentwise transport row and C as the only displayed replay row, so the readback cannot leave the carrier surface.

Apply Definition 1536.17. It keeps the transported epigraph comparison on the same scheduled window W and regular rational readback R before the located route O is available.

Combine this with Definition 1536.23. The Real handoff reads the transported route only after W, R, E, O, H, C, P, N are visible, so the consumer receives no host liminf, selector, quotient equality, choice, or ambient completeness data. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRegularReadback transport`

Theorem 1536.78 (LowerSemicontinuous root epigraph located transport)**.** *Every located comparison read from $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ factors through the same finite schedule W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, epigraph ledger E, comparison row O,* hsame *transport row H,* Cont *replay row C, provenance row P, and local NameCert row N. The transported route may compare* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *evidence, but it cannot replace the displayed epigraph data by semantic liminf data, quotient real equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the lower-real epigraph classifier of Definition 1536.76. It pins the classifier to the displayed source, graph, finite stream schedule, regular rational readback, and epigraph ledger rows.

Next apply Definition 1536.77. The transport row keeps the located comparison on the same W, R, E, O, H, C, P, N surface, so a $\mathsf{LowerReal}^{\uparrow}$ or $\mathsf{UpperReal}^{\uparrow}$ comparison has no independent readback source.

Finally use Definition 1536.18. The Real-facing seal excludes semantic liminf data, quotient equality, selected representatives, choice, and ambient completeness. Hence the located transport factors through the root epigraph route already displayed. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphLocatedTransport`

Theorem 1536.79 (LowerSemicontinuous root epigraph carrier admission)**.** *Every accepted root packet $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ must expose the source row X, graph row F, epigraph ledger E, finite stream schedule W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, located comparison row O,* hsame *transport row H,* Cont *replay row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}$ *row N before any* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer reads lower-semicontinuity data. No accepted root packet may supply that read through semantic liminf data, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphCarrierAdmission`

Proof. Project the root carrier of Definition 1536.22. The displayed coordinates of L_{root} are exactly $X, F, E, W, R, O, H, C, P, N$, so any consumer-side read must first select one of those rows.

Apply Definition 1536.76 and Definition 1536.78. The classifier pins the lower-real epigraph data to X, F, E, W, R, while the located transport keeps the comparison on O, H, C, P, N before a $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer can inspect it.

Finally use coordinate exhaustion against Definition 1536.18. The carrier has no row for semantic liminf data, quotient equality, countable choice, or ambient Real completeness, so none of those readings can serve as the root epigraph admission route. □

Theorem 1536.80 (LowerSemicontinuous root epigraph RegSeqRat handoff)**.** *Every Real-facing read from the epigraph ledger of $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ must first pass through the* $\mathsf{StreamName}^{\uparrow}$ *schedule row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *value row R, the* $\mathsf{LowerReal}^{\uparrow}$ *epigraph row E, the located comparison row O, and the structural rows H, C, P, N. The handoff therefore exports a finite scheduled readback of the epigraph route, not an unscheduled Real value or a host liminf operation.*

Proof. Start with Definition 1536.76. It fixes the epigraph classifier on the displayed rows X, F, W, R, E before any located comparison is considered.

Use Definition 1536.77. The transported readback keeps the same StreamName schedule and RegSeqRat row visible when the located row O is consumed.

Now apply Definition 1536.78 and Definition 1536.82. These boundary steps force the Real-facing read through W, R, E, O, H, C, P, N, so the export is a scheduled epigraph handoff rather than a semantic Real operation. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootEpigraphRegSeqRatHandoff`

Theorem 1536.81 (LowerSemicontinuous located Real non-escape)**.** *The located comparison row O of $L_{\text{root}} = (X, F, E, W, R, O, H, C, P, N)$ cannot export semantic liminf data, quotient $\mathsf{Real}^{\uparrow}$ equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Any Real-facing located comparison remains a read of the displayed epigraph ledger E, schedule W, regular rational row R, transport H, replay C, provenance P, and local NameCert row N.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRootLocatedRealNonescape`

Proof. Read the comparison through Definition 1536.80. The only available Real-facing handoff has already exposed W, R, E, O, H, C, P, N.

The classifier and transport rows are controlled by Definition 1536.76 and Definition 1536.77. They keep the located comparison attached to the displayed lower-real epigraph route.

Finally use Definition 1536.78 with Definition 1536.82. Since the carrier has no coordinates for semantic liminf, quotient equality, selected representatives, choice, or ambient completeness, none of those data can escape through the located Real comparison. □

Theorem 1536.82 (LowerSemicontinuous Real-seal export boundary)**.** *Every $\mathsf{Real}^{\uparrow}$ export of $L_{\text{root}} = (X, F, E, W, R, O, H, C, P, N)$ is bounded by the displayed rows E, W, R, O, H, C, P, N. The export may name lower-real epigraph evidence, located comparison data, regular rational readback, componentwise transport, replay, provenance, and the local NameCert row, but it does not export host topology, semantic liminf data, quotient real equality, countable choice, selected limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.*

Proof. Read the Real-facing consumer through Definition 1536.23. The handoff orders the export from the stream schedule W to the regular rational row R, then through the epigraph ledger E and located comparison ledger O.

Use Definition 1536.76 and Definition 1536.77. The first keeps the lower-real classifier on the displayed epigraph route, and the second keeps transported readbacks on the same W, R, E, O, H, C surface.

Finally apply Definition 1536.18. It excludes host topology, semantic liminf data, quotient real equality, countable choice, selected limits, compactness, and ambient completeness from the terminal Real seal, so the export boundary is exactly the finite route stated above. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealExportBoundary`

Theorem 1536.83 (LowerSemicontinuous obligation closure route)**.** *For the root packet $L_{\text{root}} = (X, F, E, W, R, O, H, C, P, N)$, the carrier of Definition 1536.22, the NameCert obligation surface of Definition 1536.5, epigraph-window exactness from Definition 1536.6, located epigraph transport from Definition 1536.78, regular readback nonescape from Definition 1536.77, the Real seal boundary of Definition 1536.82, and the open-sublevel route of Definition 1536.24 jointly form the obligation-closure package for the displayed lower-semicontinuity certificate. Every consumer route is forced through $X, F, E, W, R, O, H, C, P, N$ before it may read a lower-real epigraph, located comparison, open-sublevel, regular rational readback, or terminal $\mathsf{Real}^{\uparrow}$ seal.*

Proof. Start with the root carrier and NameCert obligation surface. The carrier of Definition 1536.22 exposes exactly the source, graph, epigraph, stream schedule, regular readback, located comparison, transport, replay, provenance, and local naming rows, while Definition 1536.5 binds those rows as the local certificate surface.

Use epigraph-window exactness and located transport. The theorem Definition 1536.6 keeps every epigraph read attached to the displayed W, R, E window, and Definition 1536.78 carries that same route through O, H, C, P, N without importing semantic liminf data, quotient equality, selected representatives, countable choice, or ambient completeness.

Finally combine regular readback transport, the Real seal export boundary, and the open-sublevel route. The readback theorem keeps $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows visible, the seal theorem forces the terminal $\mathsf{Real}^{\uparrow}$ endpoint through E, W, R, O, H, C, P, N, and Definition 1536.24 identifies open-sublevel consumption with the same finite epigraph route. These clauses exhaust the obligation package and leave no hidden host-topological or completeness coordinate. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousObligationClosureRoute`

Theorem 1536.84 (LowerSemicontinuous epigraph-window monotone refinement)**.** *Let* $L_{\mathrm{root}} = (X, F, E, W, R, O, H, C, P, N)$ *be an accepted root packet. Refining the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row* R *preserves the lower-real epigraph classifier and the located comparison route. The refined read remains a consumer of the same displayed rows* W, R, E, O, H, C, P, N *and cannot be reinterpreted as semantic liminf data, quotient* $\mathsf{Real}^{\uparrow}$ *equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 1536.76. The classifier is already fixed by the source row X, graph row F, stream window W, regular rational row R, and epigraph ledger E, so a finer finite window only changes which displayed rows of the same schedule and tolerance surface are read.

Use Definition 1536.77. Transport of the refined readback keeps the same $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ coordinates visible before the located comparison row O is consumed.

Finally apply Definition 1536.80. The Real-facing handoff still runs through W, R, E, O, H, C, P, N, so the refinement has no coordinate for semantic liminf, quotient equality, selected representatives, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphWindowMonotoneRefinement`

Theorem 1536.85 (LowerSemicontinuous obligation closure package)**.** *The* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *root packet carries the paper-side obligation package through the finite route*

$$X, F, W, R, E, O, H, C, P, N.$$

Carrier admission, epigraph-window exactness, lower-real classifier stability, located readback compatibility, transport replay, provenance, and Real-seal nonescape are all read from the displayed rows of Definition 1536.1, Definition 1536.5, Definition 1536.16, and the root epigraph obligations of Definition 1536.53. The package does not add host topology, semantic liminf data, quotient real equality, selected approximating sequences, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousObligationClosurePackage`

Proof. Project the carrier and NameCert obligation surface. They list the source, graph, epigraph, schedule, readback, comparison, transport, replay, provenance, and local naming rows as the complete obligation inventory.

Use the lower-real epigraph route and the root epigraph obligation package. These results place every lower-bound read on $X, F, W, R, E, O, H, C, P, N$ and account for exactness, located comparison, finite thresholds, and root nonescape within that route.

The remaining rows are structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same finite packet, so no refused analytic principle is introduced by packaging the obligations together. □

Theorem 1536.86 (LowerSemicontinuous public epigraph export)**.** *Every public epigraph consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must read the finite route*

$$X, F, W, R, E, O, H, C, P, N.$$

The window row W is read through $\mathsf{StreamName}^{\uparrow}$*, the value row R through* $\mathsf{RegSeqRat}^{\uparrow}$*, the epigraph and comparison rows E, O through* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, and* $\mathsf{LocatedReal}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the transport, replay, provenance, and local naming rows H, C, P, N remain visible. The export provides no semantic liminf operator, host topology, selected approximants, quotient equality, choice schedule, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousPublicEpigraphExport`

Proof. Start with the obligation closure package. It identifies $X, F, W, R, E, O, H, C, P, N$ as the complete obligation inventory and fixes carrier admission, epigraph-window exactness, located readback, transport replay, provenance, and Real-seal nonescape on those rows.

Apply the located epigraph route and located-real obligation route. These force a public epigraph reader to expose W through $\mathsf{StreamName}^{\uparrow}$, R through $\mathsf{RegSeqRat}^{\uparrow}$, and E, O through the lower-real, upper-real, and located-real surfaces before the lower-bound claim can be used.

Use Real-seal nonescape and the scoped route next. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of the same displayed rows, while H, C, P, N preserve only componentwise transport, displayed replay, provenance, and local naming.

Finally apply public route export. Since that export is already the public composite of the displayed lower-bound route and none of the refused analytic principles is a carrier coordinate, every public epigraph consumer receives exactly the finite route above. □

Theorem 1536.87 (LowerSemicontinuous located epigraph route)**.** *Every located epigraph read from an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must expose the finite schedule row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the lower-real epigraph row E, and the comparison ledger O before the located consumer can use the lower-bound evidence. The read is therefore routed through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal only as displayed rows, not as a host topology or semantic liminf operator.*

Proof. Start with the root epigraph carrier. It orders the lower-bound read as $X, F, W, R, E, O, H, C, P, N$, so the located consumer cannot inspect O before the scheduled window and regular rational value row are visible.

Apply located readback stability and located epigraph transport induction. They keep the lower-bound witness in E attached to the same comparison ledger O after transport through the located and lower-real surfaces.

Finally use the Real handoff. The terminal seal is reached only downstream of the same displayed route, and the carrier has no coordinate for host topology, liminf semantics, quotient equality, selected sequences, choice, compactness, or completeness. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedEpigraphRoute`

Theorem 1536.88 (LowerSemicontinuous located-real obligation route)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$*-facing read of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must expose the full finite route*

$$X, F, W, R, E, O, H, C, P, N$$

before any lower-bound claim is used. The route opens the $\mathsf{StreamName}^{\uparrow}$ *window* W*, reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *value row* R*, compares the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *epigraph rows through* E *and* O*, exposes the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison data, and reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after transport, replay, provenance, and local naming remain visible.*

Proof. Project the carrier and obligation closure package. They make $X, F, W, R, E, O, H, C, P, N$ the complete displayed route for lower-bound reads, with the schedule, readback, epigraph row, comparison ledger, transport, replay, provenance, and local naming all present before the claim is consumed.

Use the located epigraph route above. It places every located lower-bound read through W, R, E, O and accounts for the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$ rows as displayed data rather than as a host topology.

Finally apply Real-seal nonescape. The terminal seal cannot be reached by semantic liminf data, selected approximants, quotient equality, countable choice, open-cover compactness, or ambient Real completeness, because none of those principles is a row of the accepted packet. □

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousLocatedRealObligationRoute`

Theorem 1536.89 (LowerSemicontinuous Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *obligation package remains downstream of the finite route*

$$X, F, W, R, E, O, H, C, P, N.$$

The route first opens the $\mathsf{StreamName}^{\uparrow}$ *finite window* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, then reads the* $\mathsf{LocatedReal}^{\uparrow}$ *threshold rows carried by the comparison ledger* O*, then consumes the one-sided* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *ledgers attached to the epigraph row* E *and comparison row* O*, and only then reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal through* H, C, P, N*. The seal can certify only this displayed L10 source route; it cannot export a semantic liminf operator, quotient real equality, selected approximating sequence, countable-choice schedule, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSealFullRouteNonescape`

Proof. Begin with the Real-seal window exhaustion theorem. It confines every Real-facing read to the displayed route through the scheduled $\mathsf{StreamName}^{\uparrow}$ window W, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, epigraph row E, and comparison ledger O.

Use the located epigraph route and the located-real obligation route to bind that route to its threshold rows. These theorems place the $\mathsf{LocatedReal}^{\uparrow}$ comparison data inside O and force the $\mathsf{LowerReal}^{\uparrow}$ and $\mathsf{UpperReal}^{\uparrow}$ one-sided ledgers in E, O to remain visible before a lower-bound claim is consumed.

Use the obligation closure package above to account for the same rows as the complete obligation inventory. The package adds no analytic coordinate beyond $X, F, W, R, E, O, H, C, P, N$.

Transport, replay, provenance, and local naming preserve that inventory. Since the refused principles are absent from the carrier and from the Real-seal handoff, the endpoint cannot escape the displayed finite route. □

Theorem 1536.90 (LowerSemicontinuous scoped route)**.** *Every scoped consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must traverse the finite route*

$$X, F, W, R, E, O, H, C, P, N$$

before any lower-bound claim is consumed. The route exposes the source row X*, the graph row* F*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *epigraph rows* E, O*, the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison data, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *still visible.*

The scoped route exports no semantic liminf operator, host topology, selected approximants, countable-choice schedule, quotient equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousScopedRoute`

Proof. Start with the obligation closure package. It identifies $X, F, W, R, E, O, H, C, P, N$ as the complete obligation inventory and refuses host topology, semantic liminf data, quotient equality, selected approximating sequences, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness at the package boundary.

Apply the located epigraph route and the located-real obligation route. These place every located lower-bound read through W, R, E, O and keep the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$ rows visible before the lower-bound claim is used.

Finally apply Real-seal nonescape. The terminal $\mathsf{Real}^{\uparrow}$ seal remains downstream of the same displayed route, while H, C, P, N preserve transport, replay, provenance, and naming. Since no refused principle is a coordinate of the accepted packet, a scoped consumer receives only the finite route stated above. □

Theorem 1536.91 (LowerSemicontinuous public route export)**.** *Every public consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet receives the finite route*

$$X, F, W, R, E, O, H, C, P, N$$

as the exported lower-bound route. The route factors through $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any lower-bound claim is consumed, and exports no semantic liminf operator, host topology, selected approximants, quotient equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousPublicRouteExport`

Proof. Start with the obligation closure package. It identifies $X, F, W, R, E, O, H, C, P, N$ as the complete lower-bound obligation inventory and adds no analytic coordinate beyond those displayed rows.

Use the located epigraph route and the located-real obligation route. Together they force every lower-bound read through the finite window W, the regular rational readback R, the lower and upper epigraph rows E, O, and the $\mathsf{LocatedReal}^{\uparrow}$ comparison data before the claim is available to a consumer.

Finally apply Real-seal nonescape and the scoped route. The terminal $\mathsf{Real}^{\uparrow}$ seal remains downstream of the same displayed route, and H, C, P, N preserve transport, replay, provenance, and local naming. The public export is therefore the composite of the existing route theorems and contributes no semantic liminf operator, host topology, selected approximant, quotient equality, countable-choice schedule, open-cover compactness theorem, or ambient completeness principle. □

Theorem 1536.92 (LowerSemicontinuous public-route exactness triad)**.** *Every public* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer factors through exactly three visible row groups. The first group is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *window-readback surface* W, R*. The second group is the* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*, and* $\mathsf{LocatedReal}^{\uparrow}$ *epigraph-comparison surface* E, O*. The third group is the terminal* $\mathsf{Real}^{\uparrow}$ *seal together with the structural rows* H, C, P, N *for componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. No public route exports a semantic liminf operator, host topology, selected approximants, quotient equality, countable-choice schedule, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness outside this triad.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousPublicRouteExactnessTriad`

Proof. Start with the obligation closure package. It fixes $X, F, W, R, E, O, H, C, P, N$ as the complete public inventory, so the source and graph rows only feed the three consumer-facing groups named in the statement.

Use the located epigraph route and the located-real obligation route. They place every lower-bound read through the window-readback rows W, R and then through the epigraph-comparison rows E, O, with $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$ all visible before the claim is consumed.

Apply Real-seal nonescape, the scoped route, and the public route export. These theorems put the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same displayed route and keep H, C, P, N attached as transport, replay, provenance, and local naming rows.

The three groups therefore exhaust the public route. Since the carrier has no coordinate for semantic liminf data, host topology, selected approximants, quotient equality, countable choice, open-cover compactness, or ambient completeness, no public consumer can obtain such data outside the triad. □

Theorem 1536.93 (LowerSemicontinuous real-series sibling route)**.** *Every* $\mathsf{RealSeries}^{\uparrow}$ *consumer of an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet in chapter 1581 must read the lower-semicontinuous endpoint through the displayed* $\mathsf{Real}^{\uparrow}$ *seal after the finite rows*

$$X, F, W, R, E, O, H, C, P, N$$

remain visible. The series-facing route may consume lower-bound information only after the $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *epigraph rows,* $\mathsf{LocatedReal}^{\uparrow}$ *comparison ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$ *row have all been exposed.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousRealSeriesSiblingRoute`

Proof. Apply the obligation closure package. It fixes $X, F, W, R, E, O, H, C, P, N$ as the complete lower-semicontinuous inventory and keeps semantic liminf data, host topology, quotient equality, selected approximants, countable choice, open-cover compactness, and ambient completeness outside the carrier.

Use the located epigraph route and located-real obligation route. They force the lower-bound read through W, R, E, O before the endpoint can be handed to a located or real-facing consumer.

Finally apply Real-seal nonescape and public route export. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of the same finite route, so a real-series consumer receives only the displayed endpoint rows and cannot bypass the lower-semicontinuous packet. □

Theorem 1536.94 (LowerSemicontinuous epigraph dependency route)**.** *Every* $\mathsf{Epigraph}^{\uparrow}$ *or* $\mathsf{RealSeries}^{\uparrow}$ *consumer using lower-bound information from an accepted* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *packet must read the same route*

$$X, F, W, R, E, O, H, C, P, N$$

through chapter 6224 and chapter 1581 before the lower-bound row can be consumed. The route displays the finite domain row, function row, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, lower and located-real endpoint rows, comparison ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$ *row. It exports no semantic liminf data, host topology, quotient equality, selected approximants, countable choice, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LowerSemicontinuousUp.LowerSemicontinuousEpigraphDependencyRoute`

Proof. Apply Definition 1536.93. It already forces every real-series read through $X, F, W, R, E, O, H, C, P, N$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Use the obligation closure package for the same carrier. The package fixes the lower-semicontinuous inventory as the displayed finite route and keeps liminf semantics, topology, quotient equality, choice-selected approximants, open-cover compactness, and ambient completeness outside the packet.

The epigraph consumer reads the lower-bound row through the same E, O endpoint and comparison rows before passing to chapter 6224. Hence both epigraph and real-series consumers depend on the identical sibling route rather than on an external lower-bound principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1536.86 and Definition 1536.74 give the bridge-facing public epigraph surface over finite source windows, epigraph rows, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, NameCert, and the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LowerSemicontinuous}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close host topological openness, semantic liminf operators, quotient real equality, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Lean-side verification remains to certify the public epigraph export route and any standard lower-semicontinuous bridge theorem over the same epigraph-window rows and Real seal.

Constructive story: The construction starts from finite source windows, reads regular rational value rows, records lower-real epigraph witnesses, transports them through hsame and Cont ledgers, checks located readbacks, and hands the accepted route to Real-facing consumers without importing host topology.

Chapter 1537

A Concrete Naming Certificate for $\mathsf{ClosedGraphTheorem}^{\uparrow}$

Following the Banach closed graph theorem tradition in Banach and Bourbaki-style functional analysis, the $\mathsf{ClosedGraphTheorem}^{\uparrow}$ packet records the finite BEDC certificate for reading a graph-closed linear or structured map as a locally bounded route between complete normed or complete-metric presentations. The packet is anchored in the Banach carrier of chapter 90, the complete-metric surface of chapter 128, the metric observation rows of chapter 57, and the bounded-map comparison interface of chapter 410. Its finite real-facing names pass through chapter 126, chapter 301, and chapter 38, so the certificate exposes only displayed graph closure, transported Cauchy control, and local boundedness rows rather than host graph equality, quotient function spaces, choice-selected limits, or ambient completeness.

Definition 1537.1 (ClosedGraphTheorem carrier)**.** *A* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, T, \Gamma, C_M, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *row, including the displayed metric observations through the* $\mathsf{Met}^{\uparrow}$ *surface used to read Cauchy input windows.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *row, including the displayed metric observations through the* $\mathsf{Met}^{\uparrow}$ *surface used to read Cauchy output windows.*
3. *T is the map row, read as a finite graph or action table whose bounded-map comparisons may be inspected through the* $\mathsf{LipschitzMap}^{\uparrow}$ *interface when a modulus or local bound is displayed.*
4. *Γ is the graph row, consisting of finite source–target observation pairs and the graph-membership witnesses by which a consumer reads that y is the displayed image of x.*
5. *C_M is the closed-graph witness row, recording the paired Cauchy-route test: source windows converge in X, output windows converge in Y, graph rows persist along the paired route, and the target limit row is accepted as the graph value.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting finite source, target, graph, and modulus windows for each inspection.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplying regular rational distance and bound observations for the scheduled metric windows.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row through which numeric distance, bound, and convergence reads are consumed.*
9. *H records componentwise* hsame *transport for source, target, map, graph, closed-graph, schedule, readback, seal, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from source and target admission through stream scheduling, regular rational readback, graph inspection, closed-graph transfer, bound extraction, and real-seal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{ClosedGraphTheorem}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedGraphTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for the open mapping theorem, bounded inverse theorem, host graph equality, quotient function spaces, choice-selected limits, or ambient completeness beyond the source and target completeness rows explicitly displayed in X and Y.

Theorem 1537.2 (ClosedGraphTheorem NameCert obligations)**.** *For an accepted* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *carrier $G = (X, Y, T, \Gamma, C_M, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedGraphTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source complete row, target complete row, map row, graph row, closed-graph witness, stream schedule, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*
2. *source and target completeness routing, requiring every Cauchy input and Cauchy output inspection to pass through the* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *rows in X and Y and their displayed* $\mathsf{Met}^{\uparrow}$ *observations;*
3. *graph-membership exactness, requiring every accepted graph read to be a finite row of Γ over the scheduled source and target windows;*
4. *closed-graph transfer, requiring the paired limit route in C_M to preserve Γ along the same stream schedule and regular rational readback;*
5. *bounded-route extraction, requiring any local boundedness or Lipschitz-facing consumer to read through T, Γ, C_M, S, R, and E rather than through an ambient function-space theorem;*
6. *classifier stability, requiring transported packets with the same displayed rows to be identified by the carried* hsame *data and replayed by the same* Cont *route;*
7. *ledger non-escape, stating that no open mapping theorem, bounded inverse theorem, host graph equality, quotient function space, choice-selected limit, or ambient-completeness principle is exported by the packet.*

Proof. Carrier admission is projection from Definition 1537.1. The listed rows are exactly the source, target, map, graph, closed-graph, schedule, readback, real-seal, transport, replay, provenance, and local name data available to a consumer.

The completeness routing is inherited only as displayed source and target rows. The source side is read through chapter 90 or chapter 128, and the target side is read through the same complete-metric vocabulary; the metric observations used by both sides are those of chapter 57.

Graph-membership exactness is the role of Γ. A graph consumer cannot infer equality of host functions; it reads finite source–target observation pairs, and those pairs are scheduled by S and measured through R and E using the naming route of chapter 126, chapter 301, and chapter 38.

Closed-graph transfer is then the finite witness row C_M. It records the paired Cauchy route, the persistence of graph rows along that route, and the accepted target limit row. When a bounded-map consumer is present, the read is compared through the interface of chapter 410, but the packet exports only the displayed route and not an external open-mapping or inverse theorem.

Finally H and C transport and replay the same fields, while P and N package the local certificate. Since the carrier fields are exhausted by $X, Y, T, \Gamma, C_M, S, R, E, H, C, P, N$, the excluded principles have no row from which a consumer could read them. □

Theorem 1537.3 (ClosedGraphTheorem graph-closure route)**.** *Let $G = (X, Y, T, \Gamma, C_M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *carrier. Every graph-closure read exported by G factors through the displayed route*

$$X, Y, T, \Gamma, S, R, E, C_M, H, C, P, N.$$

Thus a convergent source schedule and a convergent target schedule identify a graph value only after their finite graph rows have been replayed through C_M and sealed through the StreamName, RegSeqRat, and Real rows; the route does not assert host graph equality or equality inside a quotient function space.

Proof. Begin with the source and target Cauchy inspections. The rows X and Y expose the complete Banach or complete-metric data, and their metric windows are the observations read by the route rather than ambient points.

The map and graph information is then read through T and Γ. The schedule S selects the finite source, target, and graph windows; the regular readback R and real seal E measure the requested distances and bounds.

The closed-graph witness C_M is the only row that turns the paired Cauchy route into a graph-value read. It requires the graph rows to persist along the same schedule and accepts the target limit row as a displayed graph value.

Transport by H and replay by C preserve the same route after classifier movement, and P, N record its provenance and local certificate. Because no quotient function-space coordinate or host graph equality coordinate is present, the graph-closure read is exactly the displayed finite route. □

Theorem 1537.4 (ClosedGraphTheorem non-escape boundary)**.** *For every accepted* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *carrier $G = (X, Y, T, \Gamma, C_M, S, R, E, H, C, P, N)$, any boundedness, continuity-facing, or graph-facing conclusion exported by the packet is confined to the rows displayed in G. In particular, the packet does not export the open mapping theorem, the bounded inverse theorem, host graph equality, quotient function spaces, choice-selected limits, or ambient completeness beyond the source and target rows X and Y.*

Proof. Read an exported conclusion from the carrier. A graph-facing read must use Γ and C_M; a boundedness or continuity-facing read must use T together with the same graph, schedule, readback, and seal rows.

The source and target completeness information is limited to X and Y. These rows may expose the Banach or complete-metric certificate and the associated metric observations, but they do not add any global function-space carrier.

The numeric side is likewise finite. Stream windows come from S, regular rational observations from R, and real-facing distance or bound reads from E.

All remaining movement is componentwise transport by H, continuation replay by C, and package bookkeeping by P, N. Since no excluded principle is a coordinate of G, no accepted consumer can obtain one from the $\mathsf{ClosedGraphTheorem}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedGraphTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedGraphTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1537.1, Definition 1537.2, Definition 1537.3, and Definition 1537.4 seed the finite closed-graph certificate over displayed complete source and target rows, graph witnesses, StreamName schedules, RegSeqRat readbacks, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedGraphTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the open mapping theorem, bounded inverse theorem, host graph equality, quotient function spaces, choice-selected limits, or ambient completeness beyond the displayed source and target rows.

Upgrade path: Obligation closure requires checked carrier admission, graph-membership exactness, closed-graph transfer, bounded-route extraction, classifier stability, and ledger non-escape for the same packet.

Constructive story: The construction starts from displayed complete source and target rows, schedules finite graph observations, seals distance and bound reads through RegSeqRat and Real data, and exports only the local graph-closure route recorded by hsame and Cont ledgers.

Chapter 1538

A Concrete Naming Certificate for $\mathsf{OpenMappingTheorem}^{\uparrow}$

Following Banach and Rudin-style functional analysis, the $\mathsf{OpenMappingTheorem}^{\uparrow}$ packet records the finite BEDC certificate for reading a surjective bounded linear map between Banach rows as an open-ball image route with a bounded-inverse-facing handoff. It is downstream of the source and target Banach certificates of chapter 90, the bounded linear map surface of chapter 48, the normed real-line and real-seal surfaces of chapter 1500 and chapter 38, and the closed-graph consumer boundary of chapter 1537. The packet exposes only displayed finite rows: a source Banach row, a target Banach row, a bounded linear map row, a surjective image ledger, an open-ball image witness, an inverse-window ledger, transport and replay rows, package provenance, and a local NameCert row.

Definition 1538.1 (Open mapping theorem carrier)**.** *An* $\mathsf{OpenMappingTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, Y, T, S, B, I, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm and metric observations through the* $\mathsf{NormedRealLine}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *surfaces used to read source balls.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm and metric observations through the same real-facing surfaces used to read target balls.*
3. *T is the bounded* $\mathsf{LinMap}^{\uparrow}$ *row from X to Y, carrying only the finite action, linearity, and boundedness data displayed by the map certificate.*
4. *S is the surjective image ledger, recording that every displayed target window admitted by Y has a source preimage window scheduled through X and read through T.*
5. *B is the open-ball image witness, recording finite radii, norm comparisons, image windows, and ball-containment rows that turn source ball data into a target-neighborhood read.*
6. *I is the inverse-window ledger, recording the bounded-inverse-facing handoff: a target window may request a displayed source window only through S, B, and the same Banach and linear-map rows.*
7. *H records componentwise* hsame *transport for the source, target, map, surjectivity, open-ball, inverse-window, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from Banach admission through bounded linear map inspection, surjective image lookup, open-ball witness readback, inverse-window handoff, and closed-graph consumer routing.*

9. *P is the* Pkg *provenance over* $\mathsf{OpenMappingTheorem}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{NormedRealLine}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedGraphTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{OpenMappingTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for host quotient function spaces, choice-selected inverse maps, non-displayed inverse functions, or ambient completeness beyond the Banach rows X and Y.

Theorem 1538.2 (Open mapping theorem NameCert obligations)**.** *For an accepted* $\mathsf{OpenMappingTheorem}^{\uparrow}$ *carrier $O = (X, Y, T, S, B, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OpenMappingTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source Banach row, target Banach row, bounded linear map row, surjective image ledger, open-ball image witness, inverse-window ledger, componentwise transport, continuation replay, provenance, and local naming rows;*

2. *classifier stability, requiring transported packets with the same displayed rows to be identified by the carried* hsame *data and replayed by the same* Cont *route;*

3. *image-open ledger, requiring every target-neighborhood read to pass through the source ball data in X, the target ball data in Y, the bounded map row T, the surjective ledger S, and the open-ball witness B;*

4. *bounded-inverse handoff, requiring every inverse-facing consumer to read a source window through S, B, and I before any inverse boundary is exposed;*

5. *no-escape, stating that no host quotient function space, choice-selected inverse map, non-displayed inverse function, or ambient completeness principle is exported beyond the displayed Banach rows.*

Proof. Carrier admission is projection from Definition 1538.1. The tuple supplies exactly the source, target, map, surjectivity, open-ball, inverse-window, transport, replay, provenance, and local name rows, so a consumer has no other coordinate from which to read an open-mapping conclusion.

Classifier stability is componentwise. The transport row H compares the same displayed coordinates, and the continuation row C replays the same route after transport. Thus moving the packet cannot replace the Banach, LinearMap, norm, Real, or ClosedGraphTheorem dependencies by a host function-space principle.

For the image-open ledger, a target-neighborhood read begins with the source and target Banach rows X and Y. The norm and real observations used by those rows pass through chapter 1500 and chapter 38. The bounded map row T is then read through chapter 48, the surjective ledger S supplies the displayed preimage window, and B records the finite ball-containment witness.

For the bounded-inverse handoff, the inverse-facing consumer receives only the ledger row I. That row is downstream of S and B, so it cannot expose a selected inverse map; it can only report the displayed source-window request already justified by the open-ball image witness.

Finally P and N package the same finite route. Since the carrier fields are exhausted by $X, Y, T, S, B, I, H, C, P, N$, the excluded quotient, selection, inverse-function, and ambient-completeness principles have no row in the packet. □

Theorem 1538.3 (Open mapping theorem closed-graph consumer route)**.** *For every accepted* $\mathsf{OpenMappingTheorem}^{\uparrow}$ *carrier* $O = (X, Y, T, S, B, I, H, C, P, N)$*, every bounded-inverse or closed-graph consumer reads through the displayed route*

$$X, Y, T, S, B, I, H, C, P, N.$$

In particular, the consumer must pass through the Banach rows of chapter 90, the bounded linear-map row of chapter 48, the norm and Real rows of chapter 1500 and chapter 38, and the closed-graph boundary of chapter 1537 before any inverse boundary is exposed.

Proof. Start with the Banach source and target rows. A consumer can inspect source and target balls only through X and Y, and the finite norm data in those rows is read through the normed real-line and real-seal surfaces.

Next inspect the map route. The row T supplies bounded linear-map data, while S supplies the displayed surjective image ledger. No inverse-facing conclusion is available before these two rows have been read.

The open-ball and inverse-window rows then determine the handoff. The row B records the finite image-open witness, and I records the bounded-inverse-facing source-window request that depends on that witness.

Finally the route is transported, replayed, and packaged by H, C, P, N. A closed-graph consumer may compare this handoff with chapter 1537, but it still reads only the displayed Banach, LinearMap, norm, Real, and closed-graph rows before any inverse boundary is exposed. □

Closure status for $\mathsf{NameCert}_{\mathsf{OpenMappingTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpenMappingTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1538.1, Definition 1538.2, and Definition 1538.3 seed the finite open-mapping certificate over displayed Banach, LinearMap, normed Real, surjective-image, open-ball, inverse-window, and closed-graph consumer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpenMappingTheorem}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.OpenMappingTheoremUp`

Bridge status: none

Not claimed: This chapter does not close host quotient function spaces, choice-selected inverse maps, non-displayed inverse functions, or ambient completeness beyond the displayed Banach rows.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, image-open ledger exactness, bounded-inverse handoff, closed-graph consumer routing, and no-escape for the same packet.

Constructive story: The construction starts from displayed source and target Banach rows, reads the bounded LinearMap action through finite image windows, records surjectivity and open-ball witnesses as ledgers, and exposes bounded-inverse-facing consumers only through the same hsame and Cont route.

Chapter 1539

A Concrete Naming Certificate for $\mathsf{CauchyCompletionCounit}^{\uparrow}$

Following Bishop and Bridges constructive completion and Kelley completion terminology, the $\mathsf{CauchyCompletionCounit}^{\uparrow}$ packet records the finite BEDC certificate for retracting a completion-facing name back through the terminal real seal whenever the name is already displayed by the Real/RegSeqRat route. It is the counit side of the boundary opened by the unit packet of chapter 1527 and the reflection packet of chapter 403. The packet consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the finite-window naming surface of chapter 126, and the dyadic tolerance ledger of chapter 291; it does not form quotient streams, compare host real equality, choose representatives, assume countable choice, or appeal to ambient completeness.

Definition 1539.1 (CauchyCompletionCounit carrier)**.** *A* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, E, U, R, S, D, H, C, P, N)$$

with the following visible rows:

1. *M is the completion-facing source row whose accepted reads must be returned to the displayed real-seal boundary.*
2. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal through which the returned read is consumed.*
3. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route that records how source-side data entered the completion-facing surface.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplying regular rational observations before the seal is inspected.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the regular readback is named.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that accounts for every precision request used by S and R.*
7. *H records componentwise* hsame *transport for M, E, U, R, S, D and the structural rows.*
8. *C records displayed* Cont *replay from completion-facing reads through the unit route, window row, dyadic ledger, regular readback, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCounit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, host real equality, selected representatives, countable-choice schedules, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1539.2 (CauchyCompletionCounit NameCert obligations)**.** *For an accepted* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *carrier $Q = (M, E, U, R, S, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCounit}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the completion-facing source row, terminal Real seal, unit route, regular readback, stream window, dyadic ledger, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *counit exposure, requiring every completion-facing read in M to return through U before the seal E can be consumed;*
3. *readback exactness, requiring every returned read to pass through S, D, and R before reaching E;*
4. *classifier stability, requiring transported packets with the same M, E, U, R, S, D route to be identified by the carried* hsame *and* Cont *data;*
5. *ledger non-escape, stating that no quotient completion equality, host real equality, selected representative, countable-choice schedule, open-cover compactness, ambient-completeness theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Proof. Carrier admission is projection from Definition 1539.1. The tuple lists exactly the completion-facing source, terminal Real seal, unit route, regular readback, stream window, dyadic ledger, transport, replay, provenance, and local name.

Counit exposure reads the completion-facing source row M together with the unit route U. A consumer cannot inspect E directly from M; the displayed replay row C first returns the read through the route that admitted the source-side data.

Readback exactness is then forced by the order of the packet. The finite-window row S names the request, the dyadic ledger D accounts for its tolerance, and the regular readback row R supplies the rational observation before the terminal seal E is consumed.

Classifier stability is componentwise transport along H followed by replay through C. Since the carrier fields are exhausted by $M, E, U, R, S, D, H, C, P, N$, the excluded quotient, host-equality, representative-choice, compactness, ambient-completeness, and real-completeness principles have no row from which a consumer could read them. □

Theorem 1539.3 (CauchyCompletionCounit real-seal retraction)**.** *Let $Q = (M, E, U, R, S, D, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer read exported by Q factors through the displayed retraction route*

$$M \longmapsto U \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

Thus the counit returns completion-facing source data to the terminal Real seal only as finite BEDC route data, not as a quotient completion point, not as host real equality, not as a selected representative, and not as countable choice or ambient completeness.

Proof. Project the accepted carrier and begin with the completion-facing source row M. The packet exposes M only with the unit route U, so any retraction read starts by returning through the displayed route that admitted the source row.

The finite observation part is then fixed. The stream window S supplies the named finite request, the dyadic ledger D records its precision, and the regular rational readback R supplies the observation consumed by the real seal.

The terminal row E is reached only after that finite route has been replayed. Transport by H and continuation by C preserve the same route for equivalent packets, while P and N record its provenance and local certificate.

No further row is available in the carrier. Therefore the exported real-seal read is exactly the displayed retraction route, with no quotient point, host equality, selected representative, choice schedule, or ambient completeness witness. □

Theorem 1539.4 (CauchyCompletionCounit unit-counit triangle)**.** *For every accepted* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *carrier* $Q = (M, E, U, R, S, D, H, C, P, N)$ *whose completion-facing source row was admitted by the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route* U*, the composite*

$$M \longmapsto U \longmapsto S, D, R \longmapsto E$$

has the same displayed $\mathsf{Real}^{\uparrow}$ *seal read as the direct regular route*

$$S, D, R \longmapsto E.$$

The triangle is witnessed by the shared finite rows S, D, R, E, H, C, P, N *and does not assert equality of quotient completions, host real equality, a chosen representative, countable choice, or ambient completeness.*

Proof. Read the unit side first. The row U records the admission of source-side data into the completion-facing row M, and the counit packet requires any return from M to pass back through the same displayed route before E is consumed.

Read the direct regular side next. The rows S, D, and R already name the finite window, tolerance ledger, and regular rational readback that feed the terminal Real seal E.

Both sides therefore present the same seal-facing route once the completion-facing row has been returned through U. Componentwise transport in H and replay in C identify the shared rows, while P and N record that the comparison is internal to the same local certificate.

The carrier contains no quotient-completion equality, host real equality, selected representative, choice schedule, or ambient completeness coordinate. The triangle is therefore a finite-route triangle over S, D, R, E, not an external equality principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionCounit}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionCounit}^{\uparrow}$ packet is generated from a completion-facing source row, terminal Real seal, CauchyCompletionUnit route, RegSeqRat readback, StreamName finite window, DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionCounit}^{\uparrow}}$, seed)

Scope closed: Definition 1539.1, Definition 1539.2, Definition 1539.3, and Definition 1539.4 seed the finite counit/retraction side of the constructive completion boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionCounit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, host real equality, selected representatives, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, counit exposure, readback exactness, classifier stability, real-seal retraction, unit-counit triangle, and ledger non-escape for the same packet.

Chapter 1540

A Concrete Naming Certificate for $\mathsf{CauchyCompletionProduct}^{\uparrow}$

Following Bourbaki product uniformities, Kelley completion terminology, and Bishop–Bridges constructive metric completion, the $\mathsf{CauchyCompletionProduct}^{\uparrow}$ packet records the finite BEDC certificate for forming the completion-facing product of two displayed Cauchy-completion routes. It consumes the unit route of chapter 1527, the counit route of chapter 1539, the monadic completion boundary of chapter 378, the reflection packet of chapter 403, the regular readback surface of chapter 301, the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet is a finite product handoff for two coordinate routes; it is not a quotient completion product, not a selected pair of representatives, not countable choice, not a host product theorem, and not an ambient completeness principle.

Definition 1540.1 (CauchyCompletionProduct carrier)**.** *A* $\mathsf{CauchyCompletionProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (L, R, U_L, U_R, K_L, K_R, M, F, S_L, S_R, D_L, D_R, G_L, G_R, E_L, E_R, H, C, P, N)$$

with the following visible rows:

1. *L and R are the left and right completion-facing source rows whose product read is being exposed.*
2. *U_L and U_R are the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *routes admitting the two displayed source rows into completion-facing consumers.*
3. *K_L and K_R are the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *routes returning coordinate reads to their terminal real seals when the coordinates are already displayed.*
4. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *bind-and-return ledger tying the two coordinate routes to a single completion-facing product packet.*
5. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *seal that keeps the product read on the displayed completion boundary rather than on an external host product.*
6. *S_L and S_R are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows for the two coordinates.*
7. *D_L and D_R are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers used by the two coordinate window reads.*
8. *G_L and G_R are the coordinate* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows assembled from the corresponding window and dyadic ledger rows.*

9. *E_L and E_R are the* $\mathsf{Real}^{\uparrow}$ *terminal seal rows reached after the coordinate readbacks.*
10. *H records componentwise* hsame *transport for all coordinate, monad, reflection, window, dyadic, seal, continuation, provenance, and naming rows.*
11. *C records displayed* Cont *replay from the product read through the coordinate unit routes, coordinate counit routes, monad ledger, reflection seal, windows, dyadic ledgers, regular readbacks, and real seals.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionProduct}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionProduct}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, host product equality, selected representatives, countable-choice schedules, open-cover compactness, product completeness of $\mathsf{Real}^{\uparrow}$*, or an ambient completeness theorem.*

Theorem 1540.2 (CauchyCompletionProduct NameCert obligations)**.** *For an accepted* $\mathsf{CauchyCompletionProduct}^{\uparrow}$ *carrier Z, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionProduct}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two completion-facing source rows, the two unit routes, the two counit routes, the monad ledger, the reflection seal, the two stream-window rows, the two dyadic ledgers, the coordinate regular readbacks, the two real seals, componentwise transport, continuation replay, provenance, and local naming;*
2. *coordinatewise completion handoff, requiring each product read to split through the left and right* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *routes, return through the corresponding* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *routes when a coordinate is already displayed, and expose the two* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *routes before the product read is consumed;*
3. *product seal compatibility, requiring the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *ledger and* $\mathsf{CompletionReflection}^{\uparrow}$ *seal to bind the two coordinate routes into a single product-facing packet without adding a host product equality or quotient-completion equality;*
4. *transport stability, requiring* hsame *transport and displayed* Cont *replay to preserve the same coordinate routes, monad ledger, reflection seal, package provenance, and local* NameCert *row;*
5. *ledger exactness, stating that the packet exports exactly the rows sourced by* Pkg *over* $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *and exports no selected representatives, countable-choice schedule, product-completeness theorem for* $\mathsf{Real}^{\uparrow}$*, or ambient completeness principle.*

Proof. Carrier admission is projection from Definition 1540.1. The tuple lists exactly the two source rows, the unit and counit coordinate routes, the monad ledger, the reflection seal, the window, tolerance, readback, seal, transport, replay, provenance, and local naming rows.

The coordinate handoff reads the product packet one coordinate at a time. The left coordinate must pass through U_L, K_L, S_L, D_L, E_L, and the right coordinate must pass through U_R, K_R, S_R, D_R, E_R, with the regular readback route named by the surrounding $\mathsf{RegSeqRat}^{\uparrow}$ rows before either terminal seal is consumed.

The product seal is then the finite bind-and-reflect step. The monad ledger M ties the two coordinate routes into one product-facing route, and the reflection row F keeps that route inside the displayed completion boundary rather than creating an external host product.

Transport stability is componentwise transport through H followed by replay through C. Since the provenance row P and local naming row N source only the displayed rows, the excluded quotient, representative-choice, product-completeness, and ambient-completeness principles have no row from which a consumer could read them. □

Theorem 1540.3 (CauchyCompletionProduct coordinate handoff)**.** *For an accepted* $\mathsf{CauchyCompletionProduct}^{\uparrow}$ *carrier*

$$Z = (L, R, U_L, U_R, K_L, K_R, M, F, S_L, S_R, D_L, D_R, G_L, G_R, E_L, E_R, H, C, P, N),$$

every completion-facing product consumer factors through the coordinate route

$$L, R \longmapsto U_L, U_R \longmapsto K_L, K_R \longmapsto S_L, S_R \longmapsto D_L, D_R \longmapsto G_L, G_R \longmapsto E_L, E_R \longmapsto M, F, H, C, P, N.$$

Thus the product handoff is coordinatewise finite BEDC data, not a quotient product, not a host product equality, not a selected pair of representatives, and not countable choice or ambient completeness.

Proof. Project the accepted carrier and begin with the two source rows L and R. A product-facing consumer cannot inspect a product point before the unit rows U_L and U_R have admitted the two displayed coordinate routes.

For each coordinate, the counit row returns already displayed data to the real-facing boundary. The stream-window rows S_L, S_R and dyadic ledgers D_L, D_R account for the finite precision requests that produce the corresponding regular readbacks and terminal real seals E_L, E_R.

The monad row M binds these two coordinate reads into one completion-facing packet, and the reflection row F records that the packet remains on the displayed completion boundary. Transport, continuation, provenance, and local naming preserve the same route through H, C, P, N.

No further coordinate occurs in the carrier. Hence every product consumer factors through the displayed coordinate handoff and cannot obtain quotient equality, host product equality, selected representatives, countable choice, or ambient completeness from this packet. □

Theorem 1540.4 (CauchyCompletionProduct non-escape)**.** *An accepted* $\mathsf{CauchyCompletionProduct}^{\uparrow}$ *carrier exports no read outside the finite packet*

$$(L, R, U_L, U_R, K_L, K_R, M, F, S_L, S_R, D_L, D_R, G_L, G_R, E_L, E_R, H, C, P, N).$$

In particular, it cannot expose a product-completion consumer without the two coordinate unit routes, the two coordinate counit routes, the monad ledger, the completion-reflection seal, the stream-window rows, the dyadic ledgers, the regular readback rows, the real seals, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Proof. Assume a consumer reads an accepted product packet. By carrier admission, the only available rows are the fields displayed in Definition 1540.1.

If the consumer drops a coordinate unit row, one source has not entered the completion-facing surface. If it drops a coordinate counit row, an already displayed coordinate cannot return to its real seal. If it drops a window, dyadic ledger, regular readback, or real seal, the corresponding coordinate read is not displayed at the requested precision.

If the consumer drops M or F, the two coordinate routes are no longer bound and reflected as a single completion-facing product route. If it drops H, C, P, or N, the packet loses transport, replay, provenance, or local certificate evidence.

The carrier has no additional row. Therefore no product-completion read escapes the displayed packet, and none of the excluded quotient, host-product, representative-choice, countable-choice, or ambient-completeness principles is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionProduct}^{\uparrow}$ packet is generated from two completion-facing source rows, coordinate unit routes, coordinate counit routes, a CauchyCompletionMonad ledger, a CompletionReflection seal, paired StreamName windows, paired DyadicRatCore ledgers, paired RegSeqRat readbacks, paired RealUp seals, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1540.1, Definition 1540.2, Definition 1540.3, and Definition 1540.4 seed the finite coordinatewise product-completion certificate through unit, counit, monad, reflection, readback, window, tolerance, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, host product equality, selected representatives, countable choice, open-cover compactness, product completeness of $\mathsf{Real}^{\uparrow}$, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, coordinatewise completion handoff, product seal compatibility, transport stability, ledger exactness, and non-escape for the same packet.

Chapter 1541

A Concrete Naming Certificate for $\mathsf{LocatedSet}^{\uparrow}$

Following Bishop and Bridges, a located subset of a metric space is not merely a subset predicate: it is a constructive distance interface from ambient points to the set, readable at finite rational or real tolerances. The $\mathsf{LocatedSet}^{\uparrow}$ packet records this standard object on the L10 real and completion frontier. It sits over the parent metric surface of chapter 57, the admission discipline of chapter 1519, the located-distance surface of chapter 1533, and the real terminal seal of chapter 38. The carrier gives compactness, total-boundedness, completion, and constructive-analysis consumers a displayed located-subset dependency without importing open-cover compactness, choice-selected nearest points, quotient subset equality, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1541.1 (LocatedSet carrier)**.** *A* $\mathsf{LocatedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, Q, R, E, T, H, C, P, N)$$

with the following visible rows:

1. *X is the parent* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance witness, metric-law ledger, and finite observation histories.*
2. *A is the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row. It records which parent observations are admitted as members of the displayed set and exposes no host subset equality or quotient membership.*
3. *Q is the located-distance ledger. For each accepted ambient point and positive rational tolerance request, it records the finite evidence used to locate the distance from the point to the admitted set.*
4. *R is the rational distance row. It packages the finite lower and upper rational comparison windows supplied by Q and keeps them tied to the same parent metric observations from X and admission data from A.*
5. *E is the real distance row. It seals the compatible rational windows as a* $\mathsf{Real}^{\uparrow}$ *distance name only after the parent metric, subspace admission, located-distance ledger, and rational rows have all been displayed.*
6. *T is the located-metric handoff row. It records that any consumer requiring a located metric route reads the parent metric witness, located-distance ledger, rational windows, and real seal through the interface named by chapter 1533.*

7. *H stores componentwise* hsame *transport for the parent metric row, admission row, located-distance ledger, rational and real distance rows, located-metric handoff, continuation replay, provenance, and local naming row.*
8. *C stores* Cont *replay from parent point observations to subspace admission, from admission to located-distance comparisons, from rational windows to the real distance seal, and from the seal to located-metric, completion, compactness, or total-boundedness consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSet}^{\uparrow}}$ *row.*

The classifier compares located-set packets only through the displayed tuple $X, A, Q, R, E, T, H, C, P, N$. It has no coordinate for open-cover compactness, choice-selected nearest points, quotient subset equality, an independently completed ambient space, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedSetUp.LocatedSetCarrier`

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetTasteGate single carrier alignment`

Theorem 1541.2 (LocatedSet NameCert obligations)**.** *For an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *carrier $L = (X, A, Q, R, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedSet}^{\uparrow}}$ *obligations are exactly carrier admission, parent metric compatibility,* $\mathsf{MetricSubspace}^{\uparrow}$ *admission stability, located-distance stability, rational-window readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, located-metric consumer compatibility, and ledger non-escape. These obligations are discharged by the displayed route*

$$X \longmapsto A \longmapsto Q \longmapsto R \longmapsto E \longmapsto T$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 1541.1. The tuple lists exactly the parent metric row, subspace admission row, located-distance ledger, rational windows, real seal, located-metric handoff, transport, replay, provenance, and local naming row.

Parent metric compatibility and subspace admission stability are read first. A located-distance request can inspect an ambient point only through the point classifier and distance witness of X, and it can inspect set membership only through the admission row A inherited from the $\mathsf{MetricSubspace}^{\uparrow}$ discipline.

Located-distance stability is the role of Q. For each positive rational tolerance request, the ledger records the finite comparison data that locates the distance from the ambient point to the admitted set, while H transports the same point, admission, and comparison rows componentwise.

The rational and real readback obligations factor through R and E. The rational row stores the visible comparison windows, and the real row seals them as a $\mathsf{Real}^{\uparrow}$ distance name only after the preceding metric, admission, and locatedness rows have been displayed.

Finally, T, C, P, N replay, source, and name the same finite route for located-metric, completion, compactness, and total-boundedness consumers. Since the carrier has no coordinate for open-cover compactness, nearest-point selection, quotient subset equality, completed ambient space, or full real completeness, the listed obligations exhaust the local NameCert interface. □

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetCarrier namecert obligations`

Theorem 1541.3 (LocatedSet distance handoff)**.** *Every accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet exposes the distance from an ambient point to the displayed set only through the finite route*

$$X \longmapsto A \longmapsto Q \longmapsto R \longmapsto E.$$

Any $\mathsf{LocatedMetric}^{\uparrow}$*, completion, compactness, or total-boundedness consumer must read the parent metric row,* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row, located-distance ledger, rational comparison windows, and* $\mathsf{Real}^{\uparrow}$ *seal before it consumes located-subset distance data.*

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSet distance handoff`

Proof. Start with an ambient point request. The parent metric row X supplies the point classifier and all metric-distance observations available to the packet.

The admission row A then determines which displayed observations count as set members. No host subset equality or quotient membership is exposed, so the distance request must proceed through the finite admission surface rather than an ambient subset object.

The located-distance ledger Q supplies the constructive comparison windows for the requested tolerance. The rational row R packages those windows, and the real row E seals the compatible readback as a $\mathsf{Real}^{\uparrow}$ distance name.

Thus every downstream consumer receives located-set distance data through X, A, Q, R, E and the structural rows T, H, C, P, N. The route does not select a nearest point, prove open-cover compactness, identify quotient subsets, complete the ambient metric space, or import full $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1541.4 (LocatedSet Real-distance seal exactness)**.** *Let* $L = (X, A, Q, R, E, T, H, C, P, N)$ *be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Every Real distance read from* L *is exhausted by the route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{MetricSubspace}^{\uparrow} \longmapsto Q \longmapsto R \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{LocatedMetric}^{\uparrow}.$$

Concretely, the consumer first reads the parent metric row X*, then the displayed subspace admission row* A*, then the located-distance ledger* Q*, then the rational comparison windows* R*, then the Real distance seal* E*, and only then the located-metric handoff* T*, with transport and replay through* H, C, P, N*.*

The exactness claim exports no nearest-point selection, open-cover compactness, quotient subset equality, completed ambient metric space, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetRealDistanceSealExactness`

Proof. Project the carrier of Definition 1541.1. The only rows available to a distance consumer are the parent metric row, admission row, located-distance ledger, rational windows, Real seal, located-metric handoff, and structural rows.

Apply Definition 1541.2. It identifies parent metric compatibility, subspace admission stability, located-distance stability, rational-window readback, Real seal handoff, and located-metric compatibility as the local certificate obligations.

Now apply Definition 1541.3. The distance handoff forces every ambient-point read through X, A, Q, R, E before any completion, compactness, total-boundedness, or located-metric consumer can inspect the result.

The final handoff is therefore exact. The rows H, C, P, N transport, replay, source, and name this same route, while T exposes it to $\mathsf{LocatedMetric}^{\uparrow}$ consumers only after the Real seal has been displayed. Since the carrier has no coordinate for nearest points, open covers, quotient subset equality, completed ambient spaces, or full real completeness, none of those principles can appear in the Real-distance seal. □

Theorem 1541.5 (LocatedSet nearest-point refusal boundary)**.** *Every consumer asking for a nearest-point or projection endpoint from an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet must supply an additional endpoint witness row outside*

$$(X, A, Q, R, E, T, H, C, P, N).$$

The $\mathsf{LocatedSet}^{\uparrow}$ *packet itself exports only the parent* $\mathsf{Met}^{\uparrow}$ *row,* $\mathsf{MetricSubspace}^{\uparrow}$ *admission, located-distance ledger, rational comparison windows,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff, componentwise transport, continuation replay, provenance, and local* $\mathsf{NameCert}$ *row.*

Proof. Use Definition 1541.1. The carrier tuple lists the parent metric row, subspace admission row, located-distance ledger, rational windows, real distance row, located-metric handoff, and the four structural rows.

Apply Definition 1541.3. It forces every distance consumer through X, A, Q, R, E before the result can be read by located-metric, completion, compactness, or total-boundedness consumers.

Apply Definition 1541.4. The real distance read is exactly the displayed metric, subspace, located-distance, rational-window, real-seal, and located-metric route.

No row of $(X, A, Q, R, E, T, H, C, P, N)$ is an endpoint witness row. Hence a $\mathsf{ProximinalSet}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, compactness, or projection consumer that needs a nearest point or projection endpoint must provide that endpoint evidence outside the $\mathsf{LocatedSet}^{\uparrow}$ packet. □

Theorem 1541.6 (LocatedSet metric-projection carrier admission)**.** *Every* $\mathsf{MetricProjection}^{\uparrow}$ *carrier that consumes an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet must first display the parent* $\mathsf{Met}^{\uparrow}$ *row* X*, the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row* A*, the located-distance ledger* Q*, the rational windows* R*, the* $\mathsf{Real}^{\uparrow}$ *distance seal* E*, the* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff* T*, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows* H, C, P, N*. The admission route may then add its own projection-endpoint witness, but that witness is not a coordinate of the* $\mathsf{LocatedSet}^{\uparrow}$ *packet.*

Proof. Project the carrier of Definition 1541.1. It lists exactly the metric, subspace, located-distance, rational-window, real-seal, located-metric, transport, replay, provenance, and local naming rows.

Use Definition 1541.2 to bind these rows as the local certificate surface. A projection carrier can read set admission only through A and distance data only through Q, R, E, T.

Finally apply Definition 1541.5. Since the located-set packet contains no endpoint witness row, metric-projection carrier admission must add any projection endpoint outside the displayed route. □

Theorem 1541.7 (LocatedSet distance-witness obligation)**.** *Let* $L = (X, A, Q, R, E, T, H, C, P, N)$ *be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Any downstream located-metric, projection, or proximinal consumer that cites a distance witness for* L *must read it through*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{MetricSubspace}^{\uparrow} \longmapsto \mathsf{LocatedMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the visible BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows retained. No consumer may replace the displayed located-distance ledger* Q*, rational windows* R*, or real seal* E *by a selected nearest point.*

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetCarrier distance witness obligation`

Proof. Start with the distance handoff of Definition 1541.3. It forces every distance read through X, A, Q, R, E before any located-metric, completion, compactness, or total-boundedness consumer sees the result.

Apply the Real-distance seal exactness theorem, Definition 1541.4. The $\mathsf{Real}^{\uparrow}$ row is exact only as the seal of the parent metric, subspace admission, located-distance ledger, rational windows, and located-metric handoff.

The structural rows H, C, P, N preserve the same route by componentwise transport, continuation replay, provenance, and local naming. The nearest-point refusal boundary then excludes replacing this witness by a selected endpoint. □

Theorem 1541.8 (LocatedSet distance-window monotonicity)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted $\mathsf{LocatedSet}^{\uparrow}$ packet. If a displayed positive rational tolerance request for L is refined to a smaller positive rational tolerance, then the corresponding rational distance windows remain monotone inside the same route*

$$X, A, Q, R, E, T, H, C, P, N.$$

The refinement may shrink the visible lower and upper rational comparison windows in R, but it cannot change the parent metric row, the $\mathsf{MetricSubspace}^{\uparrow}$ admission row, the located-distance ledger, the $\mathsf{Real}^{\uparrow}$ seal, or the structural transport rows.

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetCarrier distance window monotonicity`

Proof. Project the carrier in Definition 1541.1. The only coordinates available to a tolerance request are the parent metric row X, admission row A, located-distance ledger Q, rational windows R, real seal E, located-metric handoff T, and structural rows H, C, P, N.

Use Definition 1541.2. Positive tolerance handling is part of the located-distance stability and rational-window readback surface, so a refinement must be recorded in the same displayed rows rather than in a detached metric object.

Apply Definition 1541.3. It keeps every distance read downstream of X, A, Q, R, E, and Definition 1541.4 keeps the $\mathsf{Real}^{\uparrow}$ readback sealed to the same rational windows. Hence refinement changes only the window bounds displayed in R, preserving monotonicity of the accepted route. □

Theorem 1541.9 (LocatedSet positive-tolerance readback)**.** *For an accepted $\mathsf{LocatedSet}^{\uparrow}$ packet $L = (X, A, Q, R, E, T, H, C, P, N)$, every $\mathsf{Real}^{\uparrow}$ distance readback from L factors through a positive rational tolerance request in Q and a displayed rational-window read in R. Thus a consumer may read the Real distance seal E only after the route*

$$X \longmapsto A \longmapsto Q \longmapsto R$$

has supplied the parent metric observations, subspace admission data, positive tolerance evidence, and rational comparison windows.

Proof. Start from Definition 1541.1. The row Q is the located-distance ledger for positive rational tolerance requests, and R is the rational distance row packaging the lower and upper comparison windows supplied by Q.

Use Definition 1541.2. It makes located-distance stability, rational-window readback, and $\mathsf{Real}^{\uparrow}$ seal handoff local obligations of the same $\mathsf{NameCert}_{\mathsf{LocatedSet}^{\uparrow}}$ row.

Now apply Definition 1541.3 and Definition 1541.4. Together they force every Real-distance read to pass through X, A, Q, R, E in that order, so E cannot be consumed before a positive tolerance request in Q and a rational-window read in R have been displayed. □

Theorem 1541.10 (LocatedSet subspace-carrier transport)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Carrier transport along the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row preserves the full located-distance route*

$$X, A, Q, R, E, T, H, C, P, N.$$

In particular, an admitted subspace presentation may transport the parent metric row and membership evidence through H and replay it through C, but it may not detach Q, R, E, T, P, N from the same carrier route.

Proof. Project Definition 1541.1. The admission row A is displayed as part of the same finite packet as the parent metric row, located-distance ledger, rational windows, real seal, located-metric handoff, transport, replay, provenance, and local name.

Use Definition 1541.2. Parent metric compatibility and $\mathsf{MetricSubspace}^{\uparrow}$ admission stability are local obligations, and componentwise hsame transport is carried by H for every analytic and structural row.

Finally apply Definition 1541.3 and Definition 1541.4. The distance and Real-readback routes remain $X, A, Q, R, E, T, H, C, P, N$, so carrier transport along admission preserves the located-distance route and supplies no nearest-point choice, quotient subset equality, ambient completion, or full real-completeness principle. □

Theorem 1541.11 (LocatedSet open-ball distance window)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Any open-ball, proximinal, or projection consumer that reads a located-set distance window from L must first pass through the parent* $\mathsf{Met}^{\uparrow}$ *row of chapter 57, the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission route of chapter 1519, the* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff of chapter 1533, the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows H, C, P, N.*

The window therefore exposes only the route $X, A, Q, R, E, T, H, C, P, N$; it does not supply an open-ball center selector, nearest-point endpoint, projection endpoint, quotient subset equality, ambient completed metric space, or full $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the distance handoff of Definition 1541.3. It orders every distance read through the parent metric row X, the subspace admission row A, the located-distance ledger Q, the rational window row R, and the Real seal E.

Apply the Real-distance seal exactness theorem, Definition 1541.4. It identifies the sibling route through chapter 57, chapter 1519, chapter 1533, and chapter 38 as the only route by which a Real distance read becomes available.

Now use Definition 1541.7. A downstream open-ball, proximinal, or projection consumer that cites the distance window must retain the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows while reading the same witness.

The nearest-point refusal boundary and metric-projection carrier admission then keep endpoint evidence outside the $\mathsf{LocatedSet}^{\uparrow}$ packet. Thus the open-ball distance window is a routed finite witness, not a selected center, nearest point, projection endpoint, quotient subset, completed metric space, or full real-completeness row. □

Theorem 1541.12 (LocatedSet proximinal consumer nonescape)**.** *Every* $\mathsf{ProximinalSet}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet must expose the carrier route $X, A, Q, R, E, T, H, C, P, N$ before using the packet as located-set input. If the proximinal consumer supplies a nearest-point or projection endpoint, that endpoint is an additional consumer row; it cannot be read from the* $\mathsf{LocatedSet}^{\uparrow}$ *packet itself and cannot bypass* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *or* $\mathsf{NameCert}$.

Proof. Use Definition 1541.2. It identifies the finite obligation surface that every accepted $\mathsf{LocatedSet}^{\uparrow}$ packet displays.

Then use Definition 1541.7. A proximinal consumer that needs a distance witness reads the same metric, subspace, located-metric, real-seal, and structural rows.

Finally apply Definition 1541.5 and Definition 1541.6. Endpoint or projection evidence is a consumer-supplied row outside the located-set carrier, so the proximinal route cannot escape the displayed packet or import open-cover compactness. □

Theorem 1541.13 (LocatedSet parent-subspace admission)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Every consumer that admits L as a located subset must first read X as the parent* $\mathsf{Met}^{\uparrow}$ *row and A as the displayed* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row before any located-distance, real-seal, or proximinal route is public. The admission surface is preserved only through the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N.*

Proof. Project the carrier of Definition 1541.1. The first two analytic rows are exactly the parent metric row X and the subspace admission row A.

Use Definition 1541.2. Parent metric compatibility and $\mathsf{MetricSubspace}^{\uparrow}$ admission stability are local NameCert obligations, so a consumer cannot begin with Q, R, E, T as detached located-distance data.

Finally apply Definition 1541.12. Even a proximinal consumer must expose the full route $X, A, Q, R, E, T, H, C, P, N$ before reading the packet as located-set input. Thus parent and admission rows remain public prerequisites, with H, C, P, N preserving the same route. □

Theorem 1541.14 (LocatedSet carrier admission)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Carrier admission for L is exhausted by the displayed* $\mathsf{Met}^{\uparrow}$ *row X,* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row A,* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff row T,* $\mathsf{Real}^{\uparrow}$ *seal E,* BHist *transport row H, componentwise* hsame *data,* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N. The admission route does not add nearest-point selection, open-cover compactness, quotient subset equality, ambient completion, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1541.1. The tuple lists exactly the parent metric, subspace admission, located-distance ledger, rational-window, Real-seal, located-metric handoff, transport, replay, provenance, and local naming rows.

Apply Definition 1541.2. It identifies carrier admission, parent metric compatibility, $\mathsf{MetricSubspace}^{\uparrow}$ admission stability, located-distance stability, rational-window readback, $\mathsf{Real}^{\uparrow}$ seal handoff, located-metric consumer compatibility, and ledger non-escape as the local NameCert obligations.

Finally use Definition 1541.3 and Definition 1541.13. They keep every consumer downstream of $X, A, Q, R, E, T, H, C, P, N$, so admission exposes only the displayed finite route and none of the excluded endpoint, compactness, quotient, completion, or full-completeness principles. □

Theorem 1541.15 (LocatedSet classifier stability)**.** *For accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packets, classifier stability is computed only from the displayed rows $X, A, Q, R, E, T, H, C, P, N$ over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricSubspace}^{\uparrow}$*,* $\mathsf{LocatedMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. If those rows are transported componentwise by the same* hsame *data and replayed by the same* Cont *route, the located-set classifier remains stable; it cannot be changed by a hidden nearest-point selector, open-cover compactness proof, quotient subset equality, ambient completion, or full Real-completeness row.*

Proof. Read the classifier clause in Definition 1541.1. It compares located-set packets through the displayed tuple and has no coordinate for endpoint selection, open covers, quotient subset equality, completion, or full Real completeness.

Use Definition 1541.2. The stability obligations for parent metric compatibility, subspace admission, located-distance data, rational windows, Real sealing, and located-metric handoff are all local obligations of the same NameCert row.

The transport row H and replay row C preserve those rows componentwise through hsame and Cont. Therefore any accepted classifier read remains the same finite BEDC route through $X, A, Q, R, E, T, H, C, P, N$ and cannot be altered by data outside the carrier. □

Theorem 1541.16 (LocatedSet distance exactness)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Every distance read from L is exact as the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{MetricSubspace}^{\uparrow} \longmapsto Q \longmapsto R \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{LocatedMetric}^{\uparrow}$$

with BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows retained. The exactness route exposes no nearest-point selection, open-cover compactness, quotient subset equality, ambient completion, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1541.3. It forces each ambient-point distance read through X, A, Q, R, E before any located-metric, completion, compactness, or total-boundedness consumer sees the result.

Apply Definition 1541.4. The $\mathsf{Real}^{\uparrow}$ read is exact only as the seal of the parent metric row, subspace admission row, located-distance ledger, rational windows, and located-metric handoff.

Use Definition 1541.5. Endpoint evidence is not a carrier coordinate, and the same refusal excludes open-cover compactness, quotient subset equality, ambient completion, and full Real completeness from the distance route. □

Theorem 1541.17 (LocatedSet ledger nonescape)**.** *Every* $\mathsf{LocatedSet}^{\uparrow}$ *root-obligation ledger read that cites* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricSubspace}^{\uparrow}$*,* $\mathsf{LocatedMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *remains inside the accepted carrier route $X, A, Q, R, E, T, H, C, P, N$. A downstream projection, proximinal, completion, compactness, or Real-distance consumer may add its own endpoint or completion evidence, but it cannot read nearest-point selection, open-cover compactness, quotient subset equality, ambient completion, or full Real completeness from the* $\mathsf{LocatedSet}^{\uparrow}$ *ledger itself.*

Proof. Start with Definition 1541.14. It fixes the admitted carrier rows and the local NameCert obligations inside $X, A, Q, R, E, T, H, C, P, N$.

Use Definition 1541.15. Componentwise hsame transport and Cont replay preserve the same classifier-facing rows, so the ledger cannot introduce a hidden classifier coordinate.

Finally apply Definition 1541.16 together with Definition 1541.12. Distance and projection consumers must keep the displayed route public before adding their own evidence, so the located-set ledger cannot escape to selected endpoints, open-cover compactness, quotient subset equality, ambient completion, or full Real completeness. □

Theorem 1541.18 (LocatedSet distance-ledger totality)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Every admitted ambient-point distance request handled by L is accounted for by the finite route*

$$X \longmapsto A \longmapsto Q \longmapsto R \longmapsto E \longmapsto T \longmapsto H, C, P, N.$$

No accepted request may skip the located-distance ledger Q, replace the rational-window row R, or read the $\mathsf{Real}^{\uparrow}$ *seal E before the parent metric and subspace admission rows have been displayed.*

Lean4 ✓ `BEDC.Derived.LocatedSetUp.LocatedSetDistanceLedger totality`

Proof. Start with Definition 1541.3. It orders every distance read through X, A, Q, R, E before any located-metric, completion, compactness, or total-boundedness consumer can use the result.

Apply Definition 1541.4. The real distance seal is exact only as the seal of the displayed parent metric, admission, located-distance, rational-window, and located-metric route.

The totality claim is therefore local to accepted requests: once a request is admitted by X and A, its comparison evidence is in Q, its rational windows are in R, and its real seal is in E. The rows T, H, C, P, N expose this same ledger to consumers without adding nearest-point selection, open-cover compactness, or hidden completion data. □

Definition 1541.19 (LocatedSet root obligation carrier)**.** *The root-obligation carrier of an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet* $L = (X, A, Q, R, E, T, H, C, P, N)$ *is the three-row public interface*

$$\mathsf{Root}_{\mathsf{LocatedSet}^{\uparrow}}(L) = (D, J, S)$$

where:

1. *D is the distance-witness row that reads the parent* $\mathsf{Met}^{\uparrow}$ *row X, the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row A, the located-distance ledger Q, the rational windows R, the* $\mathsf{Real}^{\uparrow}$ *seal E, and the* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff T.*
2. *J is the projection-admission row. It records that any* $\mathsf{ProximinalSet}^{\uparrow}$ *or* $\mathsf{MetricProjection}^{\uparrow}$ *consumer must add its own endpoint or projection witness after reading $X, A, Q, R, E, T, H, C, P, N$.*
3. *S is the Real-metric nonescape row. It records that every Real-distance or metric-projection read stays inside the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *route.*

The root carrier has no coordinate for selected nearest points, quotient subset equality, ambient completion, open-cover compactness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1541.20 (LocatedSet root distance witness)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet and let* $\mathsf{Root}_{\mathsf{LocatedSet}^{\uparrow}}(L) = (D, J, S)$ *be its root-obligation carrier. The row D is total for accepted distance-witness requests: every downstream* $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{ProximinalSet}^{\uparrow}$, *or* $\mathsf{MetricProjection}^{\uparrow}$ *consumer that cites a distance witness from L must read $X, A, Q, R, E, T, H, C, P, N$ and cannot replace Q, R, E by an endpoint selector.*

Proof. Start from Definition 1541.18. It accounts for each admitted ambient-point distance request by the route $X, A, Q, R, E, T, H, C, P, N$.

The row D of Definition 1541.19 is exactly this route presented as the root distance-witness obligation. It does not introduce a second distance object or a detached witness.

Apply Definition 1541.7. A downstream located-metric, proximinal, or projection consumer must retain the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows while reading the same $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Finally use Definition 1541.5. Since no row of L is an endpoint witness row, the distance witness in D cannot be replaced by selected nearest-point data. □

Theorem 1541.21 (LocatedSet root projection obligation)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet with root-obligation carrier (D, J, S). Any* $\mathsf{ProximinalSet}^{\uparrow}$ *or* $\mathsf{MetricProjection}^{\uparrow}$ *consumer admitted over L must first expose the located-set route $X, A, Q, R, E, T, H, C, P, N$ and then supply any endpoint, projection, or proximinal witness as a consumer row outside the* $\mathsf{LocatedSet}^{\uparrow}$ *packet.*

Proof. Read the projection-admission row J from Definition 1541.19. Its only source data are the displayed rows of the accepted located-set packet and the statement that endpoint evidence is added by the consumer.

Apply Definition 1541.6. A metric-projection carrier may consume L only after displaying $X, A, Q, R, E, T, H, C, P, N$.

Now apply Definition 1541.12. The same route is required for a proximinal consumer, and any nearest-point or projection endpoint remains outside the carrier.

Thus the projection obligation is a route-exhaustion statement: all available located-set evidence is read before the consumer endpoint row appears, and no projection row is smuggled back into L. □

Theorem 1541.22 (LocatedSet root Real-metric nonescape)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet with root-obligation carrier (D, J, S). Every consumer that reads a* $\mathsf{Real}^{\uparrow}$ *distance seal or a* $\mathsf{MetricProjection}^{\uparrow}$ *route from L remains inside the displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricSubspace}^{\uparrow}$*,* $\mathsf{LocatedMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows; it receives no host metric equality, quotient subset equality, selected endpoint, completed ambient metric space, or full real-completeness principle from the located-set packet.*

Proof. Read the nonescape row S from Definition 1541.19. It names the exact sibling route available to Real-distance and projection consumers.

Use Definition 1541.4. The $\mathsf{Real}^{\uparrow}$ distance read is exhausted by the parent metric row, subspace admission row, located-distance ledger, rational windows, Real seal, located-metric handoff, and structural rows.

Use Definition 1541.23. Completion, compactness, projection, and proximinal consumers must keep E downstream of X, A, Q, R and upstream of T, H, C, P, N.

Finally combine the root distance witness with the projection obligation. The first fixes the distance witness inside D, and the second keeps endpoint or projection evidence in the consumer row. Hence a Real-metric or projection read cannot escape to host equality, quotient subset equality, selected endpoint data, ambient completion, or full real completeness. □

Theorem 1541.23 (LocatedSet real-seal consumer boundary)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Any completion, compactness, projection, or proximinal consumer that reads the* $\mathsf{Real}^{\uparrow}$ *distance seal E must keep that seal downstream of the displayed route X, A, Q, R and upstream of the located-metric handoff T and structural rows H, C, P, N. The consumer receives no selected nearest point, open-cover compactness proof, quotient subset equality, completed ambient metric space, or full real-completeness row from E.*

Proof. Use Definition 1541.4. It identifies E as the seal of the parent metric, subspace admission, located-distance ledger, rational windows, and located-metric handoff.

Now use Definition 1541.5. No row of the carrier is an endpoint witness row, so a projection or proximinal consumer cannot reinterpret E as a selected nearest point.

Finally combine Definition 1541.7 with Definition 1541.12. The consumer boundary remains the same route through $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$, and the excluded completion, compactness, quotient, and endpoint principles are not carrier coordinates. □

Falsifiable prediction: Every $\mathsf{LocatedSet}^{\uparrow}$ read from an accepted packet factors through the parent $\mathsf{Met}^{\uparrow}$ row, $\mathsf{MetricSubspace}^{\uparrow}$ admission row, located-distance ledger, rational comparison

windows, $\mathsf{Real}^{\uparrow}$ distance seal, located-metric handoff, componentwise transport, continuation replay, provenance, and local $\mathsf{NameCert}$ before any completion, compactness, or total-boundedness consumer reads the route.

Independence witness: metric, metricsubspace, locatedmetric, real: $\mathsf{LocatedSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries parent metric data, displayed subspace admission, a located-distance ledger, rational windows, a RealUp distance seal, located-metric handoff, transport, continuation replay, provenance, and local naming.

Theorem 1541.24 (LocatedSet root distance obligation)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted $\mathsf{LocatedSet}^{\uparrow}$ packet. Every root distance consumer of L factors by projection through the displayed $\mathsf{Met}^{\uparrow}$ row X, $\mathsf{MetricSubspace}^{\uparrow}$ admission row A, $\mathsf{LocatedMetric}^{\uparrow}$ distance ledger Q, rational comparison windows R, terminal $\mathsf{Real}^{\uparrow}$ distance seal E, located-metric handoff T, BHist transport row H, hsame identifications, Cont replay row C, Pkg provenance row P, and local $\mathsf{NameCert}$ row N.*

Proof. Project the accepted packet onto $X, A, Q, R, E, T, H, C, P, N$. These rows are the only coordinates displayed by the located-set carrier.

Use the root distance witness theorem together with the Real-distance seal exactness theorem. The distance read starts at the parent $\mathsf{Met}^{\uparrow}$ row, passes through the displayed $\mathsf{MetricSubspace}^{\uparrow}$ and $\mathsf{LocatedMetric}^{\uparrow}$ rows, and reaches $\mathsf{Real}^{\uparrow}$ only through Q, R, E.

Transport, replay, provenance, and local naming are then read from H, C, P, N, with the componentwise hsame data carried by the same packet. Since no other coordinate is available, every root distance consumer follows this route. □

Theorem 1541.25 (LocatedSet root locatedness window)**.** *For an accepted $\mathsf{LocatedSet}^{\uparrow}$ packet $L = (X, A, Q, R, E, T, H, C, P, N)$, every locatedness-window consumer is exhausted by the finite rational windows R sitting between the $\mathsf{LocatedMetric}^{\uparrow}$ ledger Q and the $\mathsf{Real}^{\uparrow}$ seal E. The consumer must also preserve the surrounding $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, and it receives no selected nearest point, open-cover compactness proof, quotient subset equality, completed ambient metric space, or full Real-completeness row.*

Proof. Begin with the rational-window rows displayed in the carrier. They are downstream of the located-distance ledger and upstream of the Real seal.

Apply the distance-witness obligation and the real-seal consumer boundary. They identify the only route by which a locatedness read can reach a Real-facing endpoint: $X, A, Q, R, E, T, H, C, P, N$.

The structural rows carry this finite route through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. The excluded endpoint, compactness, quotient, completion, and full-completeness data are not rows of the packet. □

Theorem 1541.26 (LocatedSet root nonescape)**.** *Every root consumer of an accepted $\mathsf{LocatedSet}^{\uparrow}$ packet $L = (X, A, Q, R, E, T, H, C, P, N)$ that asks for distance data, locatedness windows, or a downstream root route remains inside the displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. No root consumer obtains host metric equality, quotient subset equality, selected endpoint data, open-cover compactness, completed ambient metric space, or full $\mathsf{Real}^{\uparrow}$ completeness from L.*

Proof. Use the root distance obligation to account for distance reads. It fixes the route through $X, A, Q, R, E, T, H, C, P, N$.

Use the root locatedness-window theorem for rational-window reads. The same carrier rows are displayed, with R placed between the located-distance ledger and the Real seal.

Finally combine the existing projection obligation with the Real-metric nonescape theorem. Downstream root consumers may add their own endpoint or projection evidence, but that evidence is outside the $\mathsf{LocatedSet}^{\uparrow}$ carrier, so the listed host and completion objects cannot be exported by L. □

Definition 1541.27 (LocatedSet MetricSubspace exactness row)**.** *For an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet* $L = (X, A, Q, R, E, T, H, C, P, N)$*, the MetricSubspace exactness row is the finite subrow*

$$M_L = (X, A, Q, R, E, T, H, C, P, N)$$

read with X *as the parent* $\mathsf{Met}^{\uparrow}$ *row,* A *as the displayed* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row,* Q *as the located-distance ledger,* R *as the rational-window row,* E *as the* $\mathsf{Real}^{\uparrow}$ *distance seal, and* T, H, C, P, N *as the located-metric handoff, transport, replay, provenance, and local naming rows. It synchronizes the parent metric, subspace admission, and located-distance ledger before any consumer reads the Real-facing seal.*

Theorem 1541.28 (LocatedSet MetricSubspace exactness)**.** *Every accepted* $\mathsf{LocatedSet}^{\uparrow}$ *read preserves the MetricSubspace exactness row* M_L *through* $X, A, Q, R, E, T, H, C, P, N$*. In particular, the parent* $\mathsf{Met}^{\uparrow}$ *row,* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row, and located-distance ledger are read together before rational windows, the* $\mathsf{Real}^{\uparrow}$ *seal, located-metric handoff, transport, replay, provenance, and local naming are exposed to a consumer.*

Proof. Start with the accepted carrier projection. The definition of M_L uses exactly the displayed rows of the packet, so preserving the carrier rows preserves the exactness row.

Apply the root distance obligation to force distance reads through $X, A, Q, R, E, T, H, C, P, N$. It places the parent metric and subspace admission before the located-distance ledger reaches the rational windows and Real seal.

Use the root nonescape theorem for the consumer side. Since no host metric equality, quotient subset equality, or selected endpoint coordinate is present, a consumer cannot detach Q from the same X, A source route. The read therefore preserves M_L. □

Theorem 1541.29 (LocatedSet LocatedMetric readback coverage)**.** *Every* $\mathsf{LocatedMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet exhausts the exactness row* M_L *before reading the* $\mathsf{Real}^{\uparrow}$ *seal* E*. The consumer receives the located-distance ledger* Q *only after the parent metric row* X *and MetricSubspace admission row* A*, and it reaches* E *only through the rational-window row* R *and the displayed handoff route* T, H, C, P, N*.*

Proof. Read the LocatedMetric-facing route from the carrier. The handoff row T is attached to the same tuple as $X, A, Q, R, E, H, C, P, N$, so it cannot expose an independent located-metric ledger.

Apply the locatedness-window theorem. It exhausts R between Q and E, while the root distance obligation keeps Q downstream of X, A.

Finally use the exactness theorem. The consumer can read the Real seal only after the synchronized row M_L has supplied the parent metric, subspace admission, ledger, windows, handoff, transport, replay, provenance, and local naming data. □

Theorem 1541.30 (LocatedSet Real-seal window monotonicity)**.** *If an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet refines its rational-window row* R *along the displayed located-distance route, the* $\mathsf{Real}^{\uparrow}$ *seal route remains monotone over the same exactness row* M_L*. The refinement may shrink or*

strengthen the rational windows, but it cannot change the parent metric row, MetricSubspace admission, located-distance ledger, located-metric handoff, transport, replay, provenance, or local NameCert row used to read the Real seal.

Proof. Use the locatedness-window theorem to locate the refinement inside R. The surrounding rows $X, A, Q, E, T, H, C, P, N$ remain the rows of the same accepted packet.

Apply MetricSubspace exactness. It synchronizes X, A, Q before the rational windows and keeps E downstream of that same route.

The Real-seal consumer boundary and root nonescape theorem rule out changing the route by importing completion, compactness, quotient equality, or selected endpoint data. Thus refinement of R is monotone for the Real-seal route over M_L. □

Theorem 1541.31 (LocatedSet distance-window totality obligation)**.** *Let $L = (X, A, Q, R, E, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet. Every accepted distance-window request handled by L is total over the displayed route*

$$X, A, Q, R, E, T, H, C, P, N.$$

That is, the request first reads the parent $\mathsf{Met}^{\uparrow}$ *row X, the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row A, and the located-distance ledger Q; then it reads the rational windows R, the* $\mathsf{Real}^{\uparrow}$ *distance seal E, the located-metric handoff T, the* BHist *transport row H, the* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}$ *row N. No accepted distance-window request may replace those rows by a selected endpoint, a quotient-subset equality, an open-cover compactness proof, an ambient completion, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the distance-ledger totality theorem. It accounts for every admitted ambient-point distance request by the finite route $X, A, Q, R, E, T, H, C, P, N$.

Use the locatedness-window theorem and the readback coverage theorem. They place the rational-window row R between the located-distance ledger Q and the Real seal E, with the same parent metric and subspace admission rows upstream.

Finally apply MetricSubspace exactness and root nonescape. The exactness row keeps X, A, Q synchronized before any window is read, while nonescape excludes endpoint choice, quotient equality, compactness, completion, and full real-completeness data from the request. □

Theorem 1541.32 (LocatedSet projection-proximinal obligation package)**.** *For an accepted* $\mathsf{LocatedSet}^{\uparrow}$ *packet $L = (X, A, Q, R, E, T, H, C, P, N)$, projection and proximinal admission is a consumer-supplied endpoint row outside* $\mathsf{LocatedSet}^{\uparrow}$*. A* $\mathsf{MetricProjection}^{\uparrow}$ *or* $\mathsf{ProximinalSet}^{\uparrow}$ *consumer may cite the route $X, A, Q, R, E, T, H, C, P, N$, but it must package any projection point, nearest-point witness, or proximinal endpoint as its own row rather than as a coordinate of L.*

Proof. Read the root projection obligation. It requires every projection or proximinal consumer to expose the full located-set route before any endpoint-facing row appears.

Apply metric-projection carrier admission and proximinal nonescape. These theorems permit the consumer to reuse $X, A, Q, R, E, T, H, C, P, N$, but they keep projection endpoints and nearest-point witnesses outside the located-set carrier.

The nearest-point refusal boundary supplies the final exclusion. Since no row of L stores an endpoint witness, the projection or proximinal package is admitted only as consumer evidence beyond $\mathsf{LocatedSet}^{\uparrow}$. □

Theorem 1541.33 (LocatedSet obligation consumer nonescape assembly)**.** *The carrier row of Definition 1541.1, the distance handoff of Definition 1541.3, the* $\mathsf{Real}^{\uparrow}$ *seal discipline of Definition 1541.4, the projection obligation of Definition 1541.32, and the nonescape rows of Definition 1541.26 assemble an obligation-closure surface for* $\mathsf{LocatedSet}^{\uparrow}$*. Every downstream metric projection, proximinal, compactness, completion, or total-boundedness consumer receives only the displayed rows* $X, A, Q, R, E, T, H, C, P, N$ *unless it supplies its own endpoint, compactness, completion, or bridge row.*

Proof. Project the carrier first. The displayed rows $X, A, Q, R, E, T, H, C, P, N$ are the entire located-set interface available to a consumer.

Use distance-window totality and distance handoff. They force distance reads through the parent metric row, subspace admission, located-distance ledger, rational windows, Real seal, and located-metric handoff.

Use the projection-proximinal obligation package for endpoint-facing consumers. It allows later projection and proximinal packets to add their own endpoint rows, while keeping those rows outside $\mathsf{LocatedSet}^{\uparrow}$.

Finally apply root nonescape and Real-seal boundary results. They exclude host equality, quotient subset equality, nearest-point choice, open-cover compactness, ambient completion, and full $\mathsf{Real}^{\uparrow}$ completeness from the located-set packet itself, so the assembled surface is an obligation-closure interface rather than a stronger compactness or choice principle. □

Theorem 1541.34 (LocatedSet public export)**.** *The public* $\mathsf{LocatedSet}^{\uparrow}$ *export surface consists of the carrier row of Definition 1541.1, the distance handoff of Definition 1541.3, the* $\mathsf{Real}^{\uparrow}$ *distance seal exactness of Definition 1541.4, the MetricSubspace synchronization of Definition 1541.28, the distance-window totality of Definition 1541.31, the projection and proximinal obligation package of Definition 1541.32, and the root nonescape assembly of Definition 1541.33. A downstream public consumer may cite those rows as the located-set interface, but it receives no endpoint selector, quotient subset equality, open-cover compactness, ambient completion, or full* $\mathsf{Real}^{\uparrow}$ *completeness unless it supplies a separate consumer packet.*

Proof. Project the carrier first. The public object exposes the displayed route $X, A, Q, R, E, T, H, C, P, N$ and no hidden row.

Use the distance handoff, Real-seal exactness, MetricSubspace exactness, and distance-window totality theorems to identify the public distance interface. Together they force every accepted distance read through the parent metric row, subspace admission row, located-distance ledger, rational windows, Real seal, located-metric handoff, transport, replay, provenance, and local naming.

Use the projection-proximinal obligation package for endpoint-facing consumers. It lets projection and proximinal chapters cite the located-set route while keeping nearest-point or projection witnesses in their own packets.

Finally apply the root nonescape assembly. Since the excluded compactness, completion, quotient, endpoint-selection, and Real-completeness data have no coordinate in $\mathsf{LocatedSet}^{\uparrow}$, the listed rows form the public export surface and no stronger interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedSet}^{\uparrow}$ packet starts from a displayed Metric row, filters candidate set members through a MetricSubspace admission row, records finite located-distance comparisons, packages rational windows, seals a RealUp distance name, and preserves the same route by located-metric handoff, transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSet}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1541.1, Definition 1541.2, Definition 1541.3, Definition 1541.4, Definition 1541.28, Definition 1541.31, Definition 1541.32, and Definition 1541.33 close the carrier, NameCert obligations, distance handoff, Real-seal exactness, MetricSubspace exactness, distance-window totality, projection-proximinal package, and obligation consumer nonescape assembly.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedSet}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.LocatedSetUp.LocatedSetCarrier\_distance\_witness\_obligation`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected nearest points, quotient subset equality, completed ambient metric spaces, full Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Bridge checking can upgrade the verification axis once a standard bridge theorem is available; the theory axis records the displayed located-set package and downstream examples.

Chapter 1542

A Concrete Naming Certificate for $\mathsf{BaireCategory}^{\uparrow}$

Following Baire and Bishop–Bridges constructive analysis, the $\mathsf{BaireCategory}^{\uparrow}$ packet records the finite certificate surface for complete-metric dense-open intersection data. It depends on the prefix interface of chapter 334, the limit-witness row of chapter 128, the distance and ball classifier of chapter 57, the finite schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter names the finite BEDC handoff for displayed dense-open rows; it does not assert the full classical Baire category theorem as a host theorem.

The dense-open schedule is the sibling row consumed by chapter 1843 and chapter 2267: $\mathsf{CompactBaire}^{\uparrow}$ restricts the $\mathsf{BaireCategory}^{\uparrow}$ row to a compact-metric source, while $\mathsf{MeagreSet}^{\uparrow}$ hands complementary dense-open rows to the same $\mathsf{BaireCategory}^{\uparrow}$ packet.

The same dense-open schedule is consumed through the Baire-space source of chapter 334 and the complete-metric Cauchy-thread row of chapter 128.

Definition 1542.1 (BaireCategory carrier)**.** *A* $\mathsf{BaireCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, M, D, O, R, T, H, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet supplying the finite stream window through which dense-open requests are named.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row supplying the metric carrier, ball classifier, displayed Cauchy modulus, and limit-witness route used by the intersection construction.*
3. *D is the finite dense-open schedule. Each listed row contains an open-ball admission datum, a density witness for the displayed predecessor ball, and the regular-rational tolerance read needed to shrink the next ball.*
4. *O is the open-row ledger recording the displayed ball inclusions and the finite meet of the dense-open rows in D.*
5. *R is the refinement row. It records the nested-ball shrinkage, positive-radius comparisons, and metric-distance witnesses that keep each next ball inside the previous ball and inside the next dense-open row.*
6. *T is the Cauchy thread produced by the refinement row. It carries the finite list of centers, radii, metric comparison rows, and the terminal* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff for the displayed limit read.*

7. *H records componentwise* hsame *transport for B, M, D, O, R, T and the structural rows.*
8. *C records displayed* Cont *replay of the prefix schedule, metric ball reads, dense-open admissions, refinement route, Cauchy thread, and terminal real-name handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice, a host set intersection, open-cover compactness, ambient completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BaireCategoryUp.BaireCategoryUp`

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryTasteGate single carrier alignment`

Theorem 1542.2 (BaireCategory complete-metric obligation surface)**.** *For an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier $Q = (B, M, D, O, R, T, H, C, P, N)$, the complete-metric obligation surface consists of the following displayed BEDC rows:*

1. *the complete metric carrier row M, including the metric carrier, ball classifier, Cauchy-modulus route, and limit-witness handoff;*
2. *the nested dense-open request row D, O, R, where each listed dense-open request is read only after its predecessor ball is displayed and its successor ball is recorded by the refinement ledger;*
3. *the meagre-set exclusion ledger, consumed only as a negative boundary saying that complementary meagre rows cannot be exported as a positive dense-open intersection object;*
4. *the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *finite observation row B, T, recording the prefix schedule, finite center list, regular-rational tolerance reads, and terminal real-name handoff;*
5. *the* $\mathsf{Real}^{\uparrow}$*-valued radius budget, recording positive-radius comparisons and distance bounds inside the same metric source;*
6. *the local* $\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}$ *provenance row P, N together with componentwise transport H and replay C.*

No row in this surface exports open-cover compactness, a countable-choice selector, or a host-level intersection theorem.

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCompleteMetricObligationSurface`

Proof. Project the BaireCategory carrier. The complete metric carrier is the row M, and every dense-open request is routed through the same metric ball classifier before it can be refined.

Route each dense-open request through the displayed complete metric and radius rows. The schedule D supplies the request, O records the predecessor ball, R records the successor ball and positive-radius comparison, and T stores the finite center and tolerance observations used for the Cauchy thread.

The meagre-set ledger is used only as a negative boundary. It can say which complementary route is excluded from the displayed dense-open schedule, but it does not create a positive intersection object or a selector for all dense-open rows.

Finally, read the structural rows. The $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ observations and $\mathsf{Real}^{\uparrow}$ radius budget are carried by B, T, R, while H, C, P, N transport, replay, source, and name exactly that finite complete-metric surface. Since no carrier coordinate stores open-cover compactness or choice, no such principle is exported. □

Theorem 1542.3 (BaireCategory NameCert obligations)**.** *For an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier* $Q = (B, M, D, O, R, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the Baire-space prefix packet, complete-metric row, dense-open finite schedule, open-row ledger, refinement row, Cauchy thread, transport, replay, provenance, and local naming row;*
2. *dense-open classifier exposure, requiring every displayed dense-open row to present an open-ball admission datum and a density witness over the current predecessor ball;*
3. *refinement stability, requiring the nested-ball shrinkage, positive radius comparison, and metric-distance rows to transport componentwise by* hsame *and replay by* Cont*;*
4. *Cauchy-thread exactness, requiring the terminal* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *read to pass through the displayed center list, radius ledger, and complete-metric limit-witness route in* M*;*
5. *ledger non-escape, stating that no countable-choice selector, host set intersection, open-cover compactness theorem, ambient-completeness theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1542.1. The tuple lists exactly the prefix, metric, dense-open, open-ledger, refinement, Cauchy-thread, transport, replay, provenance, and local naming rows.

The dense-open classifier exposure is read from D and O. Each displayed row in the finite schedule supplies an open-ball admission and a density witness for the predecessor ball already present in the ledger.

Refinement stability is componentwise. The row R stores the nested-ball shrinkage, radius comparison, and metric-distance witnesses, while H and C transport and replay those rows without changing the carrier shape.

Cauchy-thread exactness is then forced by T and M. The thread lists the centers and radii generated by the finite refinement route, and the complete-metric row supplies the displayed limit-witness route consumed by the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff.

No remaining packet coordinate names a selector over all dense-open rows, a host intersection object, an open-cover compactness principle, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$. The five rows therefore exhaust the local NameCert surface. □

Theorem 1542.4 (BaireCategory finite meet density handoff)**.** *Let* $Q = (B, M, D, O, R, T, H, C, P, N)$ *be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. The finite meet of the dense-open rows displayed by* D *routes through the complete-metric Cauchy thread* T*: each successive density witness refines the current displayed ball, the row* R *records the nested shrinkage and positive radius comparison, and the thread* T *presents the terminal regular-rational and real-name handoff through* M*.*

This handoff uses only the listed finite rows. It does not use countable choice, a host set intersection, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier finite meet density handoff`
↪variant `BEDC.Derived.BaireCategoryUp.BaireCategory finite meet density handoff`

Proof. Start with the finite schedule D. Its first dense-open row is applied to the initial displayed ball supplied by the metric and prefix data, producing an open subball and a density witness recorded in O.

For the next listed row, use the predecessor ball supplied by the previous refinement step. The refinement row R records the new center, the smaller positive radius, the inclusion into the predecessor ball, and the metric-distance witnesses showing that the new ball lies inside the next dense-open row.

Iterating over the displayed finite list yields the thread T. The thread is not a choice sequence: every center, radius, inclusion row, and comparison row appears in the finite packet, and each step is replayed by the displayed Cont data.

The complete-metric row M is then read only along this thread. It supplies the Cauchy limit-witness route for the displayed centers and radii, after which the terminal read is handed to the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows.

Since the construction consumes a finite list of dense-open rows and records each refinement explicitly, there is no call to countable choice. Since the carrier exposes only ball, refinement, thread, and handoff rows, it also has no host intersection object, open-cover compactness principle, ambient completeness theorem, or $\mathsf{Real}^{\uparrow}$ completeness theorem available for the handoff. □

Theorem 1542.5 (BaireCategory complete-metric dense thread)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. The complete-metric dense-thread obligation is the finite route that starts with the complete-metric row M, reads each displayed dense-open request through D and O, records the nested refinement in R, and assembles the Cauchy thread T before any terminal* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *read is available.*

The route exports no countable-choice selector, no host intersection object, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row. Every accepted dense-thread read remains inside $B, M, D, O, R, T, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier complete metric dense thread`

Proof. Project the carrier of Definition 1542.1. The complete-metric limit witness is held in M, while dense-open admission is held in the finite schedule D and the open ledger O.

Apply the finite meet density handoff, Definition 1542.4. It supplies each successor ball by reading the predecessor ball from O, the dense-open witness from D, and the nested-ball data from R.

The thread row T is then the displayed Cauchy thread assembled from those refinements. Since the structural rows H, C, P, N only transport, replay, source, and name the same finite packet, no selector over an external dense-open family or host intersection object is introduced.

Finally consume M along the thread. The complete-metric row supplies the limit-witness handoff only for the displayed centers and radii, so the terminal $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ read has no coordinate for countable choice, host intersection, or ambient real completeness. □

Theorem 1542.6 (BaireCategory Cauchy thread limit handoff)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Once the refinement row R has assembled the thread row T, every terminal limit read factors through the* $\mathsf{CompleteMetric}^{\uparrow}$ *witness in M and then through the recorded* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff inside T. The handoff cannot replace the thread by a host intersection point, a countable-choice selection of centers, or a separate completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier cauchy thread limit handoff`

Proof. Start with complete-metric thread extraction, Definition 1542.14. It identifies T as the finite thread assembled from D, O, R and transported by H, C, P, N.

The complete-metric row M is consumed only after that thread is present. Its limit witness applies to the displayed centers, radii, and metric comparison rows recorded in T, so the limit read remains attached to the accepted packet.

The regular-rational and real-name handoff is likewise part of the thread row. The carrier has no separate coordinate for a host intersection point, a chosen sequence outside the finite schedule, or completeness of $\mathsf{Real}^{\uparrow}$ as an ambient theorem.

Therefore the terminal read factors through M and T exactly, with D, O, R supplying the dense-open and refinement history needed for the handoff. □

Theorem 1542.7 (BaireCategory ProbeBundle refinement induction)**.** *For an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier* $Q = (B, M, D, O, R, T, H, C, P, N)$*, every finite ProbeBundle-style refinement of the dense-open schedule is handled by induction over the displayed schedule row* D*. At the base stage the predecessor ball is read from the prefix and metric rows* B, M*; at each successor stage the dense-open row in* D*, the open ledger* O*, and the refinement row* R *determine the next recorded ball and extend the Cauchy thread* T*.*

The induction exports no countable-choice selector, host intersection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row;* H, C, P, N *only transport, replay, source, and name the same finite refinement packet.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier probe bundle refinement induction`

Proof. Proceed by induction on the finite schedule displayed in D. In the base case, the prefix row B and complete-metric row M supply the initial ball and metric classifier, so the thread has only the initial recorded center and radius data.

For the successor step, assume the previous predecessor ball and partial thread are already recorded. The next dense-open row in D is read against that predecessor ball, the open ledger O records its admission, and the refinement row R records the smaller successor ball together with the positive-radius and metric-distance witnesses.

Extend T by this displayed successor data. The extension is finite and recorded in the packet, so it is ProbeBundle-style replay of visible rows rather than a choice over an external family.

Finally use the structural rows H, C, P, N to transport and name the result. Since the carrier lacks coordinates for a selector, host intersection, or ambient real completeness theorem, the induction remains a finite refinement of the accepted $\mathsf{BaireCategory}^{\uparrow}$ packet. □

Theorem 1542.8 (BaireCategory ProbeBundle dense-open induction)**.** *Let* $Q = (B, M, D, O, R, T, H, C, P, N)$ *be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. The finite dense-open schedule in* D *is consumed by induction over the displayed ProbeBundle schedule: the base read uses the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row* B *and the* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *ball classifier in* M*, while each successor read consumes the next dense-open row through* O *and* R *before extending the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *thread* T*.*

The induction is exactly the carrier, finite meet, and refinement-thread surface of Definition 1542.1, Definition 1542.4, and Definition 1542.7. It does not assert the full classical Baire theorem, countable choice, a host intersection point, open-cover compactness, ambient completeness, or a separate completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier probe bundle dense open induction`

Proof. Project the carrier of Definition 1542.1. The rows available for the schedule are $B, M, D, O, R, T, H, C, P, N$, with B supplying the $\mathsf{BaireSpace}^{\uparrow}$ prefix, M supplying the $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ source, and T holding the terminal $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff.

For the base stage, read the initial displayed ball from B and the metric ball classifier in M. No dense-open choice is made at this stage; the packet has only the displayed predecessor ball and its metric source.

For a successor stage, apply Definition 1542.4. The next dense-open entry of D is read against the predecessor ball in O, and the refinement row R records the smaller successor ball, positive-radius comparison, and metric-distance witnesses.

Finally apply Definition 1542.7. The displayed successor data extend the finite thread T, and the structural rows H, C, P, N transport, replay, source, and name the same packet. Since no carrier row stores countable choice, a host intersection point, open-cover compactness, ambient completeness, or a separate $\mathsf{Real}^{\uparrow}$ completeness theorem, the induction remains the finite dense-open ProbeBundle schedule claimed above. □

Theorem 1542.9 (BaireCategory choice-free refinement thread)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. Every finite dense-open schedule read by Q routes through displayed predecessor balls, positive-radius comparisons, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ tolerance reads, and the $\mathsf{CompleteMetric}^{\uparrow}$ limit witness. The route is the finite thread*

$$B, M, D, O, R, T, H, C, P, N,$$

so no countable-choice selector, host-level intersection object, meagre cover, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is available to the consumer.

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier refinement choice free`

Proof. Project the carrier of Definition 1542.1. The available rows are exactly $B, M, D, O, R, T, H, C, P, N$, with D holding the finite dense-open schedule and M holding the complete-metric limit witness.

Induct over the displayed ProbeBundle schedule in D. The base stage reads the predecessor ball from B, M. At a successor stage, the open ledger O displays the dense-open admission, the refinement row R records the successor ball and positive-radius comparison, and the thread row T records the $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ tolerance read.

At the terminal stage, consume M only through the Cauchy thread already recorded in T. The structural rows H, C transport and replay that same route, while P, N preserve provenance and local naming.

The carrier has no coordinate for a countable-choice selector, a host intersection, a meagre cover, open-cover compactness, or a separate ambient real-completeness theorem. Thus every accepted refinement read remains choice-free and packet-local. □

Theorem 1542.10 (BaireCategory refinement-schedule obligation)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. The dense-open schedule row D, open ledger O, refinement row R, and Cauchy thread T form the complete finite refinement surface of Q. Every complete-metric limit read and every terminal $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff must pass through D, O, R, T before it can consume the $\mathsf{CompleteMetric}^{\uparrow}$ row M or the structural rows H, C, P, N.*

This surface refuses countable choice, host intersections, and ambient $\mathsf{Real}^{\uparrow}$ completeness: the schedule is a finite displayed row, the refinements are recorded predecessor-ball steps, and the terminal handoff is the thread row already present in the carrier.

Proof. Proceed by induction on the finite schedule row D. In the empty stage, the only available predecessor ball is the one supplied by the prefix and complete-metric rows B, M, and the thread T has no dense-open refinement beyond the initial displayed data.

At a successor stage, the next dense-open entry of D is read against the predecessor ball already recorded by O. The refinement row R records the successor ball, its positive-radius comparison, and its metric-distance witnesses, so the partial Cauchy thread is extended by visible packet rows rather than by a selected external point.

After the finite induction terminates, the thread T contains the complete list of centers, radii, inclusions, and tolerance rows generated by D, O, R. The complete-metric row M is then consumed only along this thread, and the terminal $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff is read from the same displayed thread.

The carrier inventory leaves no coordinate for a countable-choice selector, a host intersection of dense opens, or a separate completeness theorem for $\mathsf{Real}^{\uparrow}$. Hence D, O, R, T are the complete refinement surface for accepted $\mathsf{BaireCategory}^{\uparrow}$ limit reads. □

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier refinement schedule obligation`

Theorem 1542.11 (BaireCategory dense-open thread obligation)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. Every dense-open request consumed by Q is routed through the finite source chain*

$$B, M, D, O, R, T, H, C, P, N,$$

where B supplies the $\mathsf{BaireSpace}^{\uparrow}$ prefix window, M supplies the $\mathsf{CompleteMetric}^{\uparrow}$ metric and limit-witness rows, D and O display the dense-open request and predecessor-ball ledger, R records the $\mathsf{Met}^{\uparrow}$ refinement witnesses, and T records the $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ thread handoff.

The obligation exports no countable-choice selector, host intersection theorem, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness row.

Proof. Project the accepted carrier to $B, M, D, O, R, T, H, C, P, N$. The prefix row B fixes the finite Baire-space window in which dense-open requests may be read, and the complete-metric row M supplies the metric carrier and ball classifier used by each request.

Read a dense-open entry from D only after the predecessor ball is present in O. The refinement row R then records the successor ball, positive-radius comparison, and metric-distance witnesses inside the same $\mathsf{Met}^{\uparrow}$ source.

The thread row T stores the resulting finite center, radius, and tolerance data as a $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Re}$ handoff. The rows H, C, P, N only transport, replay, record provenance, and name this same finite route.

Since the carrier has no coordinate for a selector over external dense-open rows, no host intersection object, no open-cover compactness principle, and no ambient real-completeness theorem, the displayed chain exhausts the dense-open thread obligation. □

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier dense open thread obligation`

Theorem 1542.12 (BaireCategory limit-thread nonescape)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. Every terminal limit read from Q factors through the displayed Cauchy thread T and the complete-metric witness row M after the dense-open schedule has already been recorded by B, D, O, R. No accepted read may replace T by a host intersection point, a countable-choice sequence of centers, open-cover compactness, ambient completeness, or a separate completeness theorem for $\mathsf{Real}^{\uparrow}$.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier limit thread nonescape`

Proof. Start with the refinement-schedule obligation, Definition 1542.10. It says that the complete finite refinement surface is D, O, R, T, with every terminal $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff passing through those rows.

The complete-metric row M is consumed only along that displayed thread. Thus a terminal limit read must use the centers, radii, inclusions, and tolerance rows already recorded in T, rather than an external sequence or a host intersection point.

The structural rows H, C, P, N preserve this route componentwise. They do not add a coordinate for countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, so the limit-thread read cannot escape the accepted packet. □

Theorem 1542.13 (BaireCategory NameCert export surface)**.** *For an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier* $Q = (B, M, D, O, R, T, H, C, P, N)$*, the exported NameCert surface consists exactly of the prefix row* B*, complete-metric row* M*, dense-open schedule* D*, open ledger* O*, refinement row* R*, Cauchy thread* T*, componentwise transport* H*, replay row* C*, provenance row* P*, and local naming row* N*. A downstream consumer may read these rows through* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, but no countable-choice selector, host intersection theorem, open-cover compactness row, or ambient real-completeness row is exported.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier namecert export surface`

Proof. The carrier definition lists precisely $B, M, D, O, R, T, H, C, P, N$. The NameCert obligations of Definition 1542.3 bind carrier admission, dense-open classifier exposure, refinement stability, Cauchy-thread exactness, and ledger nonescape for those rows.

Apply Definition 1542.11 to identify the dense-open route through $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Apply Definition 1542.12 for the terminal limit-read boundary.

The exported surface is therefore the finite NameCert packet itself: $B, M, D, O, R, T, H, C, P, N$. The refusal clauses remove countable choice, host intersection, open-cover compactness, and ambient real completeness from the exported interface. □

Theorem 1542.14 (BaireCategory complete-metric thread extraction)**.** *Let* $Q = (B, M, D, O, R, T, H, C, P, N)$ *be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. The finite dense-open schedule in* D*, the open ledger* O*, and the refinement row* R *determine a displayed nested-ball Cauchy thread* T*. Every terminal* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *read from the packet factors through the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness route in* M*, the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet* B*, and the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier complete metric thread extraction`

Proof. Project the carrier along Definition 1542.1. The rows $B, M, D, O, R, T, H, C, P, N$ are the only available coordinates, so the extraction must be assembled from the displayed schedule, ledger, refinement data, thread, transport, replay, provenance, and local naming row.

Apply Definition 1542.4 to the finite schedule D. At each listed dense-open row, the current predecessor ball is already present in O, and the handoff supplies a successor subball admitted by the dense-open witness for that row.

Read the positive-radius comparison, nested inclusion, and metric-distance witnesses from R. These rows give the center and radius data for the next displayed ball and certify that it sits inside the predecessor ball and inside the next dense-open row.

Assembling these finitely many center and radius rows gives the thread T. The componentwise hsame data in H and displayed Cont replay in C keep the thread stable under the accepted packet identifications, while P and N record that the same data are the named $\mathsf{BaireCategory}^{\uparrow}$ surface.

Finally, consume M only through this thread. The complete-metric row supplies the displayed limit-witness route for the nested centers and radii, and the terminal read is then handed through the recorded $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows. No terminal real-name read bypasses T or appeals to an ambient completeness theorem. □

Theorem 1542.15 (BaireCategory dense-open thread obligations)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. The dense-open thread surface consists of the following obligations:*

1. *dense-open schedule exposure through the finite row D;*
2. *predecessor-ball density witnessing through the open ledger O;*
3. *nested refinement through the refinement row R;*
4. *Cauchy-thread extraction through T using the $\mathsf{CompleteMetric}^{\uparrow}$ row M;*
5. *ledger refusal of countable choice, host set intersection, open-cover compactness, ambient completeness, and completeness of $\mathsf{Real}^{\uparrow}$.*

No dense-open thread obligation is stored outside $B, M, D, O, R, T, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier dense open thread obligations`

Proof. Project the carrier of Definition 1542.1. The dense-open schedule is visible only in D, and the predecessor-ball density witnesses are recorded by the open ledger O.

Apply Definition 1542.14. The refinement row R supplies the nested successor balls, and the thread row T is assembled from those finitely displayed refinements before the complete-metric row M is consumed.

The structural rows H, C, P, N preserve and package the same route. Since the carrier inventory has no coordinate for countable choice, host set intersection, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, the thread obligations are exhausted by the displayed finite rows. □

Theorem 1542.16 (BaireCategory complete-metric refinement scope)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted $\mathsf{BaireCategory}^{\uparrow}$ carrier. Every refinement read exported by Q factors through the displayed $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. Concretely, the predecessor ball is read through the metric classifier in M, the finite schedule is named by the stream-prefix row B, the positive-radius and tolerance entries are read through the regular-rational row of T, and the terminal scalar seal is read through the $\mathsf{Real}^{\uparrow}$ handoff recorded by the same thread.*

Proof. Project the carrier of Definition 1542.1. The refinement row R is not an independent object; it is tied to the complete-metric row M, the finite dense-open schedule D, the open ledger O, and the thread T.

Apply the dense-open thread obligations of Definition 1542.15. They force each predecessor-ball request to pass through the displayed open ledger and then through the nested refinement row.

Now use the complete-metric thread extraction theorem. The extracted thread reads the metric carrier and ball classifier from M, reads the finite schedule through the prefix packet B, and records the regular-rational tolerance and terminal real handoff in T.

Thus every refinement read reaches the complete-metric, metric, regular-rational, stream-name, and real rows as displayed carrier rows. There is no separate refinement surface outside those rows. □

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier complete metric refinement scope`

Theorem 1542.17 (BaireCategory dense-open schedule scope)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Finite dense-open schedules are consumed only through the displayed ball-admission rows in D and the predecessor-density rows recorded in O. A downstream consumer may replay the schedule through R and T, but it cannot consume an unlisted dense-open family, an external intersection object, or a host enumeration of opens.*

Proof. Start with the finite schedule row D. By the carrier definition, each schedule entry contains its own open-ball admission datum and is not a pointer to an unrecorded family of dense-open sets.

The predecessor-density data are held in O. Applying the finite meet density handoff shows that each listed dense-open row is used only after the previous displayed ball has been recorded in the open ledger.

The replay through R and T preserves that order. The refinement row records the successor ball and the thread row records the resulting center and radius data, while H, C, P, N transport, replay, source, and name the same finite list.

Since no coordinate stores an external enumeration, a host intersection, or a family of opens outside D, the dense-open schedule is consumed exactly through the displayed ball-admission and predecessor-density rows. □

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier dense open schedule scope`

Theorem 1542.18 (BaireCategory countable-choice boundary)**.** *The* $\mathsf{BaireCategory}^{\uparrow}$ *packet exports no countable-choice selector, host intersection, open-cover compactness theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem. Every accepted consumer read is confined to the carrier rows of Definition 1542.1, the five NameCert obligations of Definition 1542.3, the dense-open handoff of Definition 1542.4, and the complete-metric thread extraction of Definition 1542.14.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier countable choice boundary`

Proof. Read the carrier inventory. The rows $B, M, D, O, R, T, H, C, P, N$ contain a prefix packet, complete-metric row, finite schedule, open ledger, refinement row, Cauchy thread, transport, replay, provenance, and local naming row.

The NameCert obligations include ledger non-escape. That row explicitly refuses countable-choice selectors, host set intersections, open-cover compactness, ambient completeness, and completeness of $\mathsf{Real}^{\uparrow}$ as exported coordinates.

The finite meet density handoff and complete-metric thread extraction describe the accepted route that remains: finite dense-open rows refine displayed predecessor balls, assemble a finite Cauchy thread, and hand terminal reads through the regular-rational and real-name surface.

Therefore a consumer asking for a selector, host intersection, open-cover compactness theorem, or real completeness theorem asks for data that are not carried by the packet. The boundary is exactly the displayed finite route. □

Theorem 1542.19 (BaireCategory countable-choice refusal)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Any* $\mathsf{BaireCategory}^{\uparrow}$ *consumer that asks for a countable selector, a host intersection, an open-cover compactness proof, an ambient completeness theorem, or a* $\mathsf{Real}^{\uparrow}$ *completeness row lies outside the carrier surface. Accepted reads are exhausted by $B, M, D, O, R, T, H, C, P, N$.*

Proof. The carrier inventory in Definition 1542.1 lists the entire accepted surface. Its coordinates are the prefix packet, complete-metric row, finite dense-open schedule, open ledger, refinement row, Cauchy thread, transport row, replay row, provenance row, and local naming row.

The ledger non-escape clause in Definition 1542.3 rules out extra exported coordinates for countable selectors, host intersections, open-cover compactness, ambient completeness, and completeness of $\mathsf{Real}^{\uparrow}$. Thus a consumer requesting one of those objects has left the named packet.

The finite meet density handoff, Definition 1542.4, explains the only accepted dense-open route: displayed finite rows are refined into nested balls and then handed to the thread. The extraction theorem Definition 1542.14 identifies that thread as the sole complete-metric path to the terminal $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ read.

Combining the inventory, non-escape clause, finite handoff, and thread extraction leaves no remaining carrier coordinate through which a countable choice principle or host-level completeness theorem could be read. Therefore the accepted reads are exactly the displayed rows $B, M, D, O, R, T, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier countable choice refusal`

Theorem 1542.20 (BaireCategory finite-schedule choice-free induction)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Every dense-open schedule read in Q is handled by finite induction over the displayed row D: the base stage reads the prefix and complete-metric rows B, M, and each successor stage consumes the next dense-open entry through D, O, R before extending the Cauchy thread T.*

The induction uses the finite meet density handoff, the complete-metric dense thread, ProbeBundle refinement induction, dense-open schedule scope, and countable-choice refusal already displayed by the packet. It exports no countable-choice selector, host intersection, open-cover compactness theorem, ambient completeness theorem, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier finite schedule choice free induction`

Proof. Proceed by induction on the finite schedule row D. In the base stage, the prefix packet B and complete-metric row M supply the initial displayed ball and metric classifier.

At a successor stage, apply the finite meet density handoff of Definition 1542.4. The next dense-open row is read against the predecessor ball already recorded in O, and the refinement row R records the smaller successor ball and its positive-radius data.

Use the ProbeBundle refinement induction of Definition 1542.7 to extend the displayed thread T. The complete-metric dense thread of Definition 1542.5 then keeps the terminal handoff attached to M and T.

Finally apply dense-open schedule scope and countable-choice refusal, Definition 1542.17 and Definition 1542.19. The carrier never leaves the finite rows $B, M, D, O, R, T, H, C, P, N$. □

Theorem 1542.21 (BaireCategory nested-ball thread totality)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Every accepted finite-schedule dense-open read determines a nested-ball thread inside T, and every terminal* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff from that read passes through*

$$B, M, D, O, R \longmapsto T \longmapsto H, C, P, N.$$

No terminal read may bypass the displayed thread by using a host intersection point, a countable-choice sequence of centers, an open-cover compactness theorem, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier nested ball thread totality`

Proof. Start with Definition 1542.14. The finite schedule in D, the open ledger O, and the refinement row R determine the displayed nested-ball Cauchy thread T.

Apply Definition 1542.20. The induction over D accounts for the base and each successor refinement without selecting data outside the packet.

Now consume the complete-metric row through Definition 1542.5. The terminal regular-rational and real-name reads are attached to the same thread T and the same structural rows H, C, P, N.

The refusal clauses close the boundary. By Definition 1542.19, the carrier has no coordinate for a host intersection, choice sequence, compactness theorem, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1542.22 (BaireCategory dense-open thread totality)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. Every accepted finite dense-open schedule D, O, R, T yields a displayed complete-metric Cauchy thread through T before any* $\mathsf{Real}^{\uparrow}$ *seal or meagre-boundary refusal can be read. The totality route factors through the complete-metric obligation surface, dense-open thread obligations, limit-thread nonescape, and countable-choice refusal, and it exports no countable selector, host intersection point, open-cover compactness principle, ambient completeness theorem, or detached* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier dense open thread totality`

Proof. Begin with the complete-metric obligation surface. The rows B and M display the prefix packet and complete-metric classifier before the dense-open schedule is inspected.

Next apply the dense-open thread obligations and the finite-schedule choice-free induction. The rows D, O, R determine each dense-open refinement stage, and the induction extends the same displayed thread T at every accepted step.

Use limit-thread nonescape to keep the terminal thread inside the complete-metric surface. Thus any later regular-rational or $\mathsf{Real}^{\uparrow}$ read is downstream of T and cannot bypass the displayed Cauchy thread.

Finally apply countable-choice refusal. Since the carrier has no coordinate for a selector, host intersection object, open-cover compactness theorem, ambient completeness principle, or detached $\mathsf{Real}^{\uparrow}$ completeness row, the meagre-boundary read must occur only after the finite thread totality route has been displayed. □

Theorem 1542.23 (BaireCategory meagre boundary refusal)**.** *Let $Q = (B, M, D, O, R, T, H, C, P, N)$ be an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier. A meagre-boundary consumer may read only the negative boundary supplied by the dense-open schedule and refinement rows. It cannot convert the packet into a full classical Baire theorem, a countable intersection object, an open-cover compactness principle, a countable-choice selector, ambient completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier meagre boundary refusal`

Proof. Project the carrier surface. The only rows available for dense-open and meagre-boundary reasoning are D, O, R, T together with the prefix, metric, transport, replay, provenance, and local naming rows.

Use Definition 1542.15. The dense-open thread obligations include ledger refusal of countable choice, host set intersection, open-cover compactness, ambient completeness, and completeness of $\mathsf{Real}^{\uparrow}$.

Apply Definition 1542.21. Any positive terminal read remains attached to the nested-ball thread rather than to a host intersection point.

Thus the meagre-boundary consumer receives only a refusal boundary over the finite schedule. It has no carrier coordinate that could supply the full classical Baire conclusion or any of the excluded principles. □

Definition 1542.24 (BaireCategory complete-metric source route)**.** *For an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier* $Q = (B, M, D, O, R, T, H, C, P, N)$*, the complete-metric source route is the ordered finite route*

$$B \longrightarrow M \longrightarrow D, O, R \longrightarrow T \longrightarrow H, C, P, N.$$

The first row is the $\mathsf{BaireSpace}^{\uparrow}$ *prefix source. The second row is the* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *ball-classifier source. The middle rows display the finite dense-open schedule, open ledger, and refinement thread. The thread row* T *carries the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff, and* H, C, P, N *transport, replay, source, and name that same route.*

Lean4 (definition) `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier complete metric source route`

Theorem 1542.25 (BaireCategory source route nonescape)**.** *Every downstream theorem-level read of an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *carrier factors through the complete-metric source route of Definition 1542.24. The carrier exports no host intersection object, countable-choice selector, open-cover compactness principle, quotient stream equality, ambient completeness theorem, or detached* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier source route nonescape`

Proof. Project the carrier of Definition 1542.1. The rows $B, M, D, O, R, T, H, C, P, N$ are exactly the rows listed by the complete-metric source route.

Use the dense-open thread obligation theorem Definition 1542.11. It places every dense-open read over the Baire prefix row, the complete-metric and metric rows, the finite schedule, and the refinement thread.

Apply limit-thread nonescape, Definition 1542.12. The terminal $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads remain attached to the same thread row T rather than to a host intersection or ambient completion object.

Finally H, C, P, N only transport, replay, source, and name rows already present in the route. Since the excluded host, choice, compactness, quotient, and detached-completeness coordinates are absent from the carrier, no theorem-level read can export them. □

Theorem 1542.26 (BaireCategory L10 completion-source boundary)**.** *Every accepted* $\mathsf{BaireCategory}^{\uparrow}$ *packet whose dense-open schedule is consumed by an L10 completion route exposes the ordered finite source chain*

$$\mathsf{BaireSpace}^{\uparrow} \longrightarrow \mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the same BHist, hsame, Cont, Pkg, *and* NameCert *rows. The packet exports no countable-choice selector, host intersection, open-cover compactness, quotient stream, or detached* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier l10 completion source boundary`

Proof. Project the carrier of Definition 1542.1. The rows $B, M, D, O, R, T, H, C, P, N$ expose the Baire-space prefix source, the complete-metric and metric ball classifier, the finite dense-open schedule, the refinement ledger, the terminal thread, and the structural transport, replay, provenance, and local naming rows.

Apply Definition 1542.2. The complete-metric source and the dense-open schedule are read through M, D, O, R, while the finite observation and regular-rational readback are carried by B, T before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Apply Definition 1542.12 and Definition 1542.25. These force every terminal completion read to remain on the same thread T and on the complete-metric source route, with H, C, P, N preserving only that displayed route.

No remaining carrier coordinate names a countable-choice selector, host intersection object, open-cover compactness theorem, quotient stream, or detached $\mathsf{Real}^{\uparrow}$ completeness row. Hence an L10 completion consumer sees exactly the stated ordered source chain and no excluded boundary object. □

Theorem 1542.27 (BaireCategory mature consumer completeness)**.** *Every* $\mathsf{CompactBaire}^{\uparrow}$ *or* $\mathsf{MeagreSet}^{\uparrow}$ *consumer of an accepted* $\mathsf{BaireCategory}^{\uparrow}$ *packet must read the complete-metric row, dense-open schedule, finite refinement row, Cauchy thread,* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *rows before using the dense-intersection surface. No such consumer obtains countable choice, host intersection, open-cover compactness, ambient completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Lean4 ✓ `BEDC.Derived.BaireCategoryUp.BaireCategoryCarrier mature consumer completeness`

Proof. Start with the complete-metric obligation surface, Definition 1542.2. It forces dense-open use through the complete-metric source, the dense-open schedule, the open-row ledger, and the finite refinement row.

Next use the finite meet density handoff and complete-metric dense thread results already established in the chapter. They make the refinement row and dense thread the only route by which a consumer can pass from the schedule to the dense-intersection surface.

Apply the Cauchy thread limit handoff, together with Definition 1542.25 and Definition 1542.26. The terminal observations must pass through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff carried by the thread row, with H, C, P, N preserving only that displayed route.

The carrier therefore gives $\mathsf{CompactBaire}^{\uparrow}$ and $\mathsf{MeagreSet}^{\uparrow}$ consumers a complete finite reading order before any dense-intersection use. Since the excluded objects have no carrier coordinates, the consumer-completeness row exports no countable choice, host intersection, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BaireCategory}^{\uparrow}$ packet is generated from a $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, $\mathsf{CompleteMetric}^{\uparrow}$ row, finite dense-open schedule, open-row ledger, refinement row, Cauchy thread, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1542.1, Definition 1542.16, Definition 1542.17, Definition 1542.25, and Definition 1542.26 bind the public complete-metric dense-open export surface, including refinement scope, dense-open schedule scope, source-route nonescape, and L10 completion-source boundary for the finite packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Not claimed: This chapter does not close the full classical Baire category theorem as a host theorem, countable choice, host set intersections, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: The theory axis is mature for the finite consumer surface; formal verification and bridge checking remain on the verification axis.

Chapter 1543

A Concrete Naming Certificate for $\mathsf{IntervalDomain}^{\uparrow}$

Following Bishop and Bridges' constructive completion through located intervals and Scott's interval-domain reading of real approximation, the $\mathsf{IntervalDomain}^{\uparrow}$ packet records a finite approximation-domain certificate for the Real-completion boundary. It sits between the endpoint-cell packet of chapter 394, the nested-window packet of chapter 320, the rational-cell packet of chapter 354, the stream-window packet of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The certificate names the directed finite route by which completion-facing consumers read approximants before a $\mathsf{Real}^{\uparrow}$ seal is exposed; it is not a quotient-real construction, a host equality principle, an open-cover compactness theorem, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1543.1 (IntervalDomain carrier)**.** *An* $\mathsf{IntervalDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, R, N, W, Q, E, H, C, P, A)$$

with the following visible rows:

1. *L is a finite family of* $\mathsf{LocatedInterval}^{\uparrow}$ *cells whose endpoint windows are already named by the underlying real-name interface.*
2. *R is the* $\mathsf{RationalInterval}^{\uparrow}$ *refinement ledger attached to those cells, including endpoint order, containment, and width-budget rows.*
3. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *directed nesting row recording which later cells refine earlier cells under the displayed containment route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which endpoint requests and refinement checks are inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family serving the same windows with regular rational observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located cells, rational refinements, nesting row, stream windows, and regular readbacks have been displayed.*
7. *H records componentwise* hsame *transport for L, R, N, W, Q, E and the structural rows.*
8. *C records displayed* Cont *routes for replaying endpoint reads, refinement reads, nesting reads, window reads, regular readbacks, and seal reads in that order.*

9. *P is the* Pkg *provenance over* $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *A is the local* $\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}$ *evidence row.*

The carrier exports only the displayed finite approximation domain. It contains no coordinate for quotient real equality, host real equality, open-cover compactness, a selected limiting representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainTasteGate single carrier alignment`

Theorem 1543.2 (IntervalDomain NameCert obligations)**.** *For an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *carrier* $D = (L, R, N, W, Q, E, H, C, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}$ *surface consists exactly of carrier admission, refinement stability, directedness, endpoint-window transport, and real-seal non-escape:*

1. *carrier admission exposes precisely the ten rows* $L, R, N, W, Q, E, H, C, P, A$*;*
2. *refinement stability keeps every* $\mathsf{RationalInterval}^{\uparrow}$ *refinement row attached to its transported* $\mathsf{LocatedInterval}^{\uparrow}$ *cell and its transported window data;*
3. *directedness requires every pair of displayed cells admitted for a common completion read to pass through a later* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row before the seal row is inspected;*
4. *endpoint-window transport moves endpoint reads only through the paired* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows named by the carrier;*
5. *real-seal non-escape states that any* $\mathsf{Real}^{\uparrow}$ *consumer of* E *must first read the located cells, rational refinements, directed nesting row, stream windows, regular readbacks, and structural rows* H, C, P, A*.*

These obligations do not export quotient reals, host real equality, open-cover compactness, selected limiting representatives, or ambient completeness.

Proof. Carrier admission is projection from Definition 1543.1. The packet lists the located interval cells, rational refinement ledger, nesting row, stream windows, regular readbacks, real seal, transports, continuations, provenance, and local naming row as its whole visible surface.

Refinement stability reads L, R, H, C. A transported located cell carries its rational interval ledger with it, and the displayed continuation route keeps the refinement read attached to the same endpoint-window data.

Directedness reads N after the refinement ledger. For a common completion-facing request, two visible cells cannot be consumed independently; the nesting row supplies the later common refinement before the real seal can be exposed.

Endpoint-window transport reads W and Q as a pair. The stream row names the finite endpoint request, and the regular rational row supplies the readback for that request, so a transported endpoint read has no route outside the displayed window and readback rows.

Finally, real-seal non-escape follows because E is downstream of L, R, N, W, Q and the structural rows. Since the carrier has no quotient, host-equality, compactness, selected-limit, or completeness coordinate, none of those principles can be read from the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainNameCertObligations`

Theorem 1543.3 (IntervalDomain completion approximation scope)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *carrier. Every completion-facing consumer of the displayed* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite route*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{RationalInterval}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto (H, C,$$

Thus the completion-facing interface is an interval-domain approximation route over finite NameCert data, not a quotient of real names, not host real equality, not open-cover compactness, and not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with the endpoint cells. The row L supplies the visible $\mathsf{LocatedInterval}^{\uparrow}$ data, and R attaches the $\mathsf{RationalInterval}^{\uparrow}$ containment and width ledger used by each cell.

Next read the directed approximation layer. The row N records the $\mathsf{NestedInterval}^{\uparrow}$ refinement order, so a completion-facing consumer moves from finite cells to a common directed refinement before any seal-facing request is available.

Then read the observation layer. The stream windows W and regular rational readbacks Q supply the finite endpoint observations for the same directed refinement route.

The seal row E is reached only after those rows have been consumed. The structural rows H, C, P, A transport, replay, source, and name the same route, so every completion-facing consumer factors through the displayed chain and receives no additional quotient, host-equality, compactness, selected-limit, or completeness data. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainCompletionApproximationScope`

Theorem 1543.4 (IntervalDomain carrier admission)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. Before any interval-domain read is exported, the packet must expose* $\mathsf{LocatedInterval}^{\uparrow}$ *cells,* $\mathsf{NestedInterval}^{\uparrow}$ *nesting,* $\mathsf{RationalInterval}^{\uparrow}$ *refinement rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}$ *rows.*

Proof. Project the carrier of Definition 1543.1. Its visible rows are exactly $L, R, N, W, Q, E, H, C, P, A$, and the introductory dependency route ties those rows to the located interval, nested interval, rational interval, stream, regular rational, and Real seal sibling chapters.

Now apply the carrier-admission clause of Definition 1543.2. A public interval-domain read must consume the listed rows as one finite packet before the local NameCert row A can certify the read.

The completion approximation scope of Definition 1543.3 keeps the same row order for Real-facing consumers, so no interval-domain read can be exported from a strict subpacket or from a host interval primitive. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainCarrierAdmission`

Theorem 1543.5 (IntervalDomain regular Cauchy window)**.** *For every accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet $D = (L, R, N, W, Q, E, H, C, P, A)$, each interval refinement read factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks Q, with* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance support supplied by the rational refinement route and* $\mathsf{Real}^{\uparrow}$ *seal support supplied by E. It does not factor through host intervals, quotient cuts, selected endpoints, or ambient real equality.*

Proof. Start from the endpoint-window transport clause of Definition 1543.2. It binds every endpoint and refinement read to the paired stream-window and regular rational rows W, Q.

Next use Definition 1543.1. The rational refinement ledger R supplies the finite width and containment data for the located cells, while the sibling dyadic and rational interval routes named in the introduction provide the tolerance surface consumed before Q is read.

Finally apply Definition 1543.3. The Real seal row E is downstream of L, R, N, W, Q, so the refinement read is the displayed regular Cauchy window route and not a host interval, quotient cut, selected endpoint, or host equality principle. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainRegularCauchyWindow`

Theorem 1543.6 (IntervalDomain finite endpoint order)**.** *Every accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet* $D = (L, R, N, W, Q, E, H, C, P, A)$ *must expose the* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint-order and containment rows attached to each* $\mathsf{LocatedInterval}^{\uparrow}$ *cell before any* $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer may read the approximation route. The endpoint-order row is a finite BEDC row of the packet, not a host interval primitive, selected endpoint comparison, quotient cut, or ambient completeness witness.*

Proof. Project Definition 1543.1. The located cell row L is paired with the rational refinement ledger R, and the carrier definition states that R includes endpoint order, containment, and width-budget rows for those cells.

Apply Definition 1543.2. Its refinement-stability clause keeps every $\mathsf{RationalInterval}^{\uparrow}$ refinement row attached to its transported $\mathsf{LocatedInterval}^{\uparrow}$ cell and its transported window data.

Finally use Definition 1543.3. The Real-facing route reads $\mathsf{LocatedInterval}^{\uparrow}$ and $\mathsf{RationalInterval}^{\uparrow}$ before $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$, so no consumer can bypass endpoint order through host intervals, selected endpoints, quotient cuts, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainFiniteEndpointOrder`

Theorem 1543.7 (IntervalDomain dyadic endpoint coverage)**.** *Every accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet* $D = (L, R, N, W, Q, E, H, C, P, A)$ *whose* $\mathsf{RationalInterval}^{\uparrow}$ *ledger exposes endpoint order also exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows used by the endpoint windows before any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer reads the approximation. The coverage row is a finite dependency of the interval-domain packet through chapter 354 and chapter 291; it does not select endpoints, identify quotient cuts, assert host extensional equality, or close ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 1543.1. The rational refinement row R is the endpoint-order, containment, and width-budget ledger attached to the located cells in L.

Read R through the rational-interval dependency named in the chapter introduction. Endpoint order is accepted only together with the tolerance budget that makes the endpoint windows readable, and that budget is supplied by the dyadic-rational core route cited in chapter 291.

Now apply the endpoint-window transport clause of Definition 1543.2. The stream windows W and regular rational readbacks Q may replay an endpoint request only after the same transported rational refinement row has been displayed.

Finally use Definition 1543.3. Since $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are downstream of L, R, N, every completion-facing read first sees the dyadic tolerance support carried by R. The statement therefore records finite endpoint-window coverage only, excluding selected endpoints, quotient cuts, host extensional equality, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDyadicEndpointCoverage`

Theorem 1543.8 (IntervalDomain rational-width monotonicity)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. If a displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *cell is refined through the* $\mathsf{NestedInterval}^{\uparrow}$ *row N, then the* $\mathsf{RationalInterval}^{\uparrow}$ *width-budget row in R is monotonically tightened along the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route before any* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer reads the seal. The monotonicity is a finite relation among the accepted carrier rows L, R, N, H, C, P, A, not a host metric-width comparison, quotient-cut equality, selected endpoint oracle, or ambient completeness claim.*

Proof. Project the carrier of Definition 1543.1. The located cells are carried by L, the rational endpoint-order, containment, and width-budget ledger is carried by R, and the displayed refinement relation is carried by N.

Use Definition 1543.6 and Definition 1543.7. The first keeps endpoint order and containment inside the finite rational-interval row, while the second supplies the dyadic tolerance support needed to compare successive endpoint windows without selecting external endpoints.

Now apply Definition 1543.12. A later nested cell remains inside the same finite route through $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the later width budget can only be read as the transported tightening of the earlier displayed budget.

Consequently every stream, regular-rational, or Real-seal consumer sees the tightened rational-width row before it reads the seal. The statement records this monotone finite budget discipline and exports no host comparison or completeness principle. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainRationalWidthMonotonicity`

Theorem 1543.9 (IntervalDomain regular-Cauchy directed width)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. If a directed refinement through N tightens the* $\mathsf{RationalInterval}^{\uparrow}$ *width budget recorded in R, then the same refinement preserves the paired* $\mathsf{StreamName}^{\uparrow}$ *window row W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q before any* $\mathsf{Real}^{\uparrow}$ *seal consumer may inspect E. Thus rational-width monotonicity supplies a regular-Cauchy directed readback route inside the displayed packet, not a host metric-width comparison, quotient cut, endpoint selector, or ambient completeness principle.*

Proof. Project the accepted carrier. The located cells are read from L, the endpoint order, containment, and width-budget ledger from R, the directed refinement row from N, and the paired stream and regular rational observations from W, Q.

Use Definition 1543.6 and Definition 1543.7. These keep endpoint order, dyadic tolerance support, and width comparisons inside the finite rational-interval route attached to the displayed located cells.

Apply Definition 1543.8. Along a nested refinement, the later width budget is the transported tightening of the earlier displayed budget. Then apply Definition 1543.12: the same later cell is read through the common $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observation surface before the Real seal is available.

Finally use Definition 1543.3. The seal row E lies downstream of L, R, N, W, Q and the structural rows H, C, P, A, so the directed-width route is exactly the regular-Cauchy readback route of the packet. No carrier coordinate supplies a host metric-width comparison, quotient cut, endpoint selector, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainRegularCauchyDirectedWidth`

Theorem 1543.10 (IntervalDomain directed width non-completion)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. The rational-width monotonicity row and regular-Cauchy*

directed-width row expose only finite directed approximation through $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *They do not supply quotient cuts, selected endpoints, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1543.8. It reads width tightening only from the displayed located cell, rational refinement ledger, nested refinement row, dyadic tolerance support, and structural rows of the accepted packet.

Next apply Definition 1543.9. The directed-width readback keeps the same refinement inside the paired $\mathsf{StreamName}^{\uparrow}$ window row W and $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q before the $\mathsf{Real}^{\uparrow}$ seal E is inspected.

Finally use Definition 1543.14. That theorem records the complete completion-facing route as the finite BEDC surface through $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the structural rows. Since none of the cited rows contains quotient cuts, selected endpoints, trichotomy, host equality, or ambient completeness, directed width remains a finite approximation route and not a completion principle. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDirectedWidthNoncompletion`

Theorem 1543.11 (IntervalDomain directed approximation induction)**.** *Let* $D = (L, R, N, W, Q, E, H, C, P, A)$ *be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet, and let a finite displayed chain of nested refinements be read from the rows* L, R, N. *Induction on the accepted refinement rows gives a stable route through* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any completion-facing consumer reads the seal row* E. *The induction exports no quotient cuts, selected endpoints, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the base refinement row, use the finite endpoint order theorem and the dyadic endpoint coverage theorem, Definition 1543.6 and Definition 1543.7. They place endpoint order, containment, rational width, and dyadic tolerance support inside the displayed $\mathsf{LocatedInterval}^{\uparrow}$ and $\mathsf{RationalInterval}^{\uparrow}$ rows before any stream or seal read occurs.

For the induction step, apply rational-width monotonicity, Definition 1543.8. A later nested row can only be read as the transported tightening of the earlier displayed rational-width budget along the same $\mathsf{NestedInterval}^{\uparrow}$ route.

Next apply regular-Cauchy directed width, Definition 1543.9. The tightened rational-width row preserves the paired $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the $\mathsf{Real}^{\uparrow}$ seal is inspected.

Finally use directed width non-completion, Definition 1543.10. It identifies the resulting chain as a finite approximation route through the seven displayed faces and excludes quotient cuts, selected endpoints, trichotomy, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness at every induction stage. □

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDirectedApproximationInduction`

Theorem 1543.12 (IntervalDomain directed refinement covers)**.** *Let* $D = (L, R, N, W, Q, E, H, C, P, A)$ *be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. Any two accepted interval-domain cells whose displayed* $\mathsf{Real}^{\uparrow}$ *seal readbacks overlap admit a finite directed refinement row through the existing* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces. The refinement is read only as a displayed later cell with common stream and regular-rational observations; it does not assert quotient real equality, choose a limit representative, or use ambient completeness.*

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDirectedRefinementCovers`

Proof. Project the carrier rows of Definition 1543.1. The located cells are read from L, their rational containment and width ledgers from R, and their directed nesting relation from N.

Replay the nested-window refinement using the directedness clause of Definition 1543.2. Two cells admitted for a common completion-facing read must pass through a later displayed $\mathsf{NestedInterval}^{\uparrow}$ row before the Real seal can be inspected.

Now read the common observation surface. The $\mathsf{StreamName}^{\uparrow}$ windows W and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks Q expose the shared endpoint observations, while Definition 1543.5 keeps the refinement inside the regular Cauchy window route.

Finally use Definition 1543.3. The $\mathsf{Real}^{\uparrow}$ seal row E is downstream of the displayed located, rational, nested, stream, and regular-rational rows, so the directed refinement covers the overlapping readback without exporting quotient real equality, selected limits, or ambient completeness. □

Theorem 1543.13 (IntervalDomain directed-refinement obligation scope)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. For any two overlapping interval-domain cells, the directed refinement row must cite* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *as its complete finite scope before any* $\mathsf{Real}^{\uparrow}$ *consumer reads the seal row E. The obligation exports no quotient cuts, selected limits, host equality, trichotomy, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDirectedRefinementObligationScope`

Proof. Project $D = (L, R, N, W, Q, E, H, C, P, A)$. The carrier rows place located cells in L, rational refinement data in R, directed nesting in N, stream windows in W, regular rational readbacks in Q, the terminal seal in E, and the structural transport, replay, provenance, and naming rows in H, C, P, A.

Apply Definition 1543.12. For two overlapping cells, the common later cell is read only through the displayed route over $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 1543.16. Any consumer of E still factors through the finite route and the structural BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so the refinement row is the complete obligation scope before the seal is read.

Since neither the carrier nor the two cited theorems supplies quotient cuts, selected limits, host equality, trichotomy, or ambient completeness, those objects remain outside the directed-refinement obligation. □

Theorem 1543.14 (IntervalDomain directed completion scope)**.** *Let $D = (L, R, N, W, Q, E, H, C, P, A)$ be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. Any directed-refinement read from D that is consumed by* $\mathsf{Real}^{\uparrow}$ *or by a completion-facing chapter must pass through the complete finite route*

$$\mathsf{LocatedInterval}^{\uparrow}, \mathsf{RationalInterval}^{\uparrow}, \mathsf{NestedInterval}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{C}$$

The handoff is exactly a displayed interval-domain completion route over BEDC rows. It exports no quotient cuts, selected endpoints, trichotomy, host equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainDirectedCompletionScope`

Proof. First read the directed-refinement witness through Definition 1543.12. The common later cell is available only through the located interval, rational interval, nested interval, stream-window, regular-rational, and Real seal surfaces already carried by D.

Next apply Definition 1543.13. That theorem records the complete obligation scope of the same refinement row, adding the structural BHist, hsame, Cont, Pkg, and NameCert rows before any $\mathsf{Real}^{\uparrow}$ consumer can inspect the seal.

Finally use Definition 1543.16. A completion-facing consumer of E receives the directed route only after the displayed approximation and structural rows have been read. The dyadic tolerance support is the same endpoint-budget surface named by the rational-refinement route through chapter 291, so the handoff includes $\mathsf{DyadicRatCore}^{\uparrow}$ without adding a new host principle.

The excluded objects require coordinates absent from the carrier and from the three cited theorems. Thus quotient cuts, selected endpoints, trichotomy, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the completion-facing directed-refinement read. □

Theorem 1543.15 (Interval-domain endpoint directedness scope)**.** *Every completion-facing consumer of an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet* $D = (L, R, N, W, Q, E, H, C, P, A)$ *must expose the directed endpoint rows, rational width monotonicity, dyadic endpoint coverage, directed refinement covers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal route before reading a completion consumer. The scope is the displayed finite route over* $L, R, N, W, Q, E, H, C, P, A$ *and exports no quotient cuts, selected endpoints, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainEndpointDirectednessScope`

Proof. Project the accepted carrier. Endpoint data enters through the located cell row L and rational refinement ledger R, while directedness is carried by the nested refinement row N.

Apply Definition 1543.8, Definition 1543.9, and Definition 1543.7. These bind endpoint order, dyadic tolerance support, and rational width tightening to the same displayed cell route before stream or regular-rational reads are available.

Next use Definition 1543.12 and Definition 1543.13. They require every completion-facing directed refinement to pass through the located, rational, nested, stream-window, regular-rational, Real-seal, and structural rows.

Finally apply Definition 1543.14 and Definition 1543.16. The completion consumer can read the terminal route only after $L, R, N, W, Q, E, H, C, P, A$ have been displayed, so the endpoint-directedness scope remains a finite L10 completion route and not a host completion principle. □

Theorem 1543.16 (IntervalDomain Real seal nonescape)**.** *Let* $D = (L, R, N, W, Q, E, H, C, P, A)$ *be an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *packet. A consumer of the* $\mathsf{Real}^{\uparrow}$ *seal row* E *receives only the finite route through located cells, rational refinements, nested directedness, stream windows, regular rational readbacks, transport, replay, provenance, and local naming. The packet exports no host completeness, selected endpoints, trichotomy, quotient real equality, or ambient interval compactness.*

Lean4 ✓ `BEDC.Derived.IntervalDomainUp.IntervalDomainRealSealNonescape`

Proof. Use the real-seal non-escape clause of Definition 1543.2. It places E after L, R, N, W, Q and after the structural rows H, C, P, A.

The completion approximation scope theorem then identifies the whole Real-facing path as the finite chain through $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The sibling anchors in the chapter introduction supply those displayed surfaces.

Since Definition 1543.1 contains no row for host completeness, endpoint selection, trichotomy, quotient real equality, or interval compactness, none of those principles can be exported by consuming E. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalDomain}^{\uparrow}$ packet is generated from finite LocatedIntervalUp cells, RationalIntervalUp refinement ledgers, a NestedIntervalUp directed nesting row, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1543.1, Definition 1543.2, Definition 1543.3, Definition 1543.14, and Definition 1543.16 close the interval-domain route from located cells, rational refinements, nested directedness, stream windows, regular rational readbacks, and the finite $\mathsf{Real}^{\uparrow}$ seal through the displayed hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, host real equality, open-cover compactness, selected limiting representatives, ambient RealUp completeness, or bridge checking.

Upgrade path: Bridge checking remains the separate formal-axis obligation for the same finite interval-domain packet.

Chapter 1544

A Concrete Naming Certificate for $\mathsf{RealSequentialCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley-style sequential completeness, the $\mathsf{RealSequentialCompleteness}^{\uparrow}$ packet records the real-line sequential-completeness face as finite NameCert data. It reads a regular Cauchy sequence of real names through the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ surfaces of chapter 301 and chapter 126, carries the real Cauchy modulus of chapter 1423, and exposes the displayed limit only through the $\mathsf{Real}^{\uparrow}$ surface of chapter 38. The chapter is a real-facing sibling of the metric sequence bridge in chapter 1515; it does not claim quotient completion, countable choice, open-cover compactness, or a classical ambient completeness principle.

Definition 1544.1 (RealSequentialCompleteness carrier)**.** *A* $\mathsf{RealSequentialCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, S, M, L, D, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row naming the real surface on which the sequence and limit are displayed.*
2. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *sequence data read through* $\mathsf{StreamName}^{\uparrow}$ *finite windows for the real names under consideration.*
3. *M is the displayed real Cauchy modulus row, assigning each requested real-facing tolerance a late window for the sequence.*
4. *L is a displayed* $\mathsf{Real}^{\uparrow}$ *limit row, available to consumers only as a named real surface rather than as a host real or selected quotient representative.*
5. *D is the late-distance ledger; for every tolerance request admitted by M, it records the sufficiently late* $\mathsf{Real}^{\uparrow}$ *distance bounds from the rows of S to L.*
6. *H records componentwise* hsame *transport for R, S, M, L, D, the replay row, the provenance row, and the local naming row.*
7. *C records the displayed* Cont *replay from real-source admission to stream windows, regular rational readbacks, modulus thresholds, late-distance bounds, and the real-limit handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RealSequentialCompleteness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSequentialCompleteness}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, countable choice, open-cover compactness, a selected host limit, or a classical completeness theorem for the ambient real line.

Theorem 1544.2 (RealSequentialCompleteness NameCert obligations)**.** *For an accepted* $\mathsf{RealSequentialCompletene}$ *carrier* $Q = (R, S, M, L, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealSequentialCompleteness}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed* $\mathsf{Real}^{\uparrow}$ *source, regular Cauchy real-name sequence, real Cauchy modulus, displayed limit, late-distance ledger, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *classifier stability, requiring any accepted comparison of carriers to transport* R, S, M, L, D *componentwise by* H *before the local classifier identifies the two packets;*
3. *regular-Cauchy convergence, requiring each tolerance request to read a late threshold from* M *and then read the corresponding late-distance rows from* D *through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *sequence surface;*
4. *real-limit handoff, requiring the same finite rows* $R, S, M, L, D, H, C, P, N$ *to present* L *as the real-facing limit surface for the displayed sequence;*
5. *ledger non-escape, stating that no quotient completion, countable-choice schedule, open-cover compactness principle, selected host limit, or ambient completeness proof is exported by the packet.*

Proof. Carrier admission is projection from Definition 1544.1. The packet exposes exactly the real source, sequence row, modulus, limit row, late-distance ledger, transport, replay, provenance, and local name listed there.

Classifier stability is componentwise. A comparison of two accepted packets must first transport the real source, stream windows, regular rational readbacks, modulus thresholds, displayed limit rows, and late-distance ledger by H; the local classifier then reads only the transported rows.

Regular-Cauchy convergence is the joint content of S, M, D. The sequence data is observed through $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the modulus row supplies the late threshold for each tolerance, and the ledger row supplies the corresponding real-facing distance bounds to L.

The real-limit handoff uses no second limit object. The replay row C presents the same rows R, S, M, L, D to the real-facing consumer, while P and N record that the route is sourced and named by this finite packet.

The non-escape clause follows because the displayed rows are exhausted by $R, S, M, L, D, H, C, P, N$. None stores quotient completion equality, a countable-choice schedule, open-cover compactness, a selected host limit, or an ambient completeness proof. □

Theorem 1544.3 (RealSequentialCompleteness regular-Cauchy handoff)**.** *Let* $Q = (R, S, M, L, D, H, C, P, N)$ *be an accepted* $\mathsf{RealSequentialCompleteness}^{\uparrow}$ *packet. If the real source* R*, the sequence data* S*, the modulus* M*, the displayed limit* L*, and the late-distance ledger* D *are displayed, then the same finite packet supplies the real-facing limit surface for the regular Cauchy sequence.*

The handoff route is

$$R \longmapsto S \longmapsto M \longmapsto L \longmapsto D \longmapsto H, C, P, N.$$

It exports sequential completeness only as the displayed $\mathsf{Real}^{\uparrow}$ *row* L *reached from regular Cauchy real-name data, not as quotient completion, countable choice, open-cover compactness, selected host limits, or a classical ambient completeness theorem.*

Proof. Start with the accepted carrier and project R. The real-facing classifier and observation surface used by the handoff are read from this displayed $\mathsf{Real}^{\uparrow}$ row, so the limit claim remains internal to the named real surface.

Next read the sequence and modulus rows. The row S supplies the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks for the regular Cauchy real-name sequence, while M supplies the late threshold requested by each tolerance.

Now read L and D. The row L is already a displayed $\mathsf{Real}^{\uparrow}$ limit row, and D records the late-distance bounds that connect sufficiently late sequence windows to L under the thresholds supplied by M.

Finally replay the route through C and attach H, P, N. These rows transport, source, and name exactly the data required for the real-facing limit surface, and they introduce no coordinate for quotient completion, countable choice, open-cover compactness, selected host limits, or ambient completeness. □

Theorem 1544.4 (RealSequentialCompleteness CauchyCriterion handoff)**.** *Let K be an accepted* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *packet and let $Q = (R, S, M, L, D, H, C, P, N)$ be an accepted* $\mathsf{RealSequentialCompleteness}^{\uparrow}$ *packet. Suppose the two packets expose the same displayed* $\mathsf{Real}^{\uparrow}$ *source, the same* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and Cauchy ledgers, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed limit row L.*

Then the Cauchy-criterion certificate of K determines one finite BEDC route to the displayed sequential-completeness limit in Q:

$$K \longmapsto R, S \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto L, D, H, C, P, N.$$

The route consumes the Cauchy-criterion certificate only through the matching finite rows and exports no quotient streams, selected host limits, choice principle, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the Cauchy-criterion certificate. By Definition 1590.2, the accepted $\mathsf{RealCauchyCriterion}^{\uparrow}$ packet exposes exactly the carrier admission, window-readback compatibility, dyadic exactness, transport and replay stability, and provenance exhaustion needed for its finite certificate surface.

Next follow the readback and seal rows. Apply Definition 1590.3 to obtain the $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and Cauchy ledgers from the same certificate. Then use Definition 1590.4 to factor the terminal real seal through those rows rather than through an independent completion object.

Now compare the resulting rows with the sequential-completeness packet. The hypotheses identify the real source, stream windows, regular rational readbacks, dyadic ledgers, and terminal real seal of K with the corresponding rows of Q, so Definition 1544.2 supplies the accepted $\mathsf{RealSequentialCompleteness}^{\uparrow}$ admission, classifier stability, regular-Cauchy convergence, real-limit handoff, and ledger non-escape clauses for the same finite data.

Finally apply Definition 1544.3. It reads the displayed limit row L and the late-distance ledger D from Q and replays them through H, C, P, N, giving the advertised finite route from the Cauchy-criterion certificate to the displayed sequential-completeness limit.

The non-export claim is inherited from both packets' exhaustion clauses. Neither cited certificate adds quotient streams, selected host limits, choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness to the displayed BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequentialCompleteness}^{\uparrow}}$.

Constructive story: A RealSequentialCompleteness$^{\uparrow}$ packet is generated from a displayed Real$^{\uparrow}$ source, RegSeqRat$^{\uparrow}$ sequence data read through StreamName$^{\uparrow}$ windows, a RealCauchyModulus$^{\uparrow}$ row, a displayed Real$^{\uparrow}$ limit row, late-distance bounds, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealSequentialCompleteness}^{\uparrow}}$, seed)

Scope closed: Definition 1544.1, Definition 1544.2, and Definition 1544.3 seed the finite bridge from regular Cauchy real-name data to the displayed Real$^{\uparrow}$ limit surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealSequentialCompleteness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, countable choice, open-cover compactness, selected host limits, or classical ambient completeness for Real$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, regular-Cauchy convergence, real-limit handoff, and ledger non-escape for the same finite packet.

Chapter 1545

A Concrete Naming Certificate for $\mathsf{IntervalDomainWayBelow}^{\uparrow}$

Following Scott's finite-information order and the Gierz–Hofmann–Keimel–Lawson–Mislove–Scott account of continuous domains, with Bishop–Bridges located intervals as the constructive endpoint ground, the $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ packet records the finite way-below relation used by the L10 interval-domain route. It refines the carrier of chapter 1543 by naming when one displayed approximation cell sits compactly inside another before the $\mathsf{Real}^{\uparrow}$ seal is read. The route is grounded in the sibling certificates for chapter 394, chapter 320, chapter 354, chapter 126, chapter 301, chapter 291, and chapter 38. It is only the finite Scott-domain approximation relation; it is not quotient real equality, host real equality, open-cover compactness, a selected limit, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1545.1 (IntervalDomainWayBelow carrier)**.** *An* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (O, I, M, N, S, Q, E, H, C, P, A)$$

with the following visible rows:

1. *O is the coarser* $\mathsf{IntervalDomain}^{\uparrow}$ *cell whose displayed window is being approximated.*
2. *I is the inner cell, recorded simultaneously as* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint data and a* $\mathsf{RationalInterval}^{\uparrow}$ *containment ledger.*
3. *M is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *margin row witnessing that the inner rational interval lies strictly inside the coarser interval cell.*
4. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement route carrying later cells from O toward I without leaving the displayed interval-domain packet.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which finite endpoint requests for O and I are inspected.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the same windows with regular rational observations.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the coarser cell, inner cell, positive margin, nested route, stream windows, and regular readbacks have been displayed.*
8. *H records componentwise* hsame *transport for O, I, M, N, S, Q, E and the structural rows.*
9. *C records displayed* Cont *replay for reading the coarser cell, inner cell, margin, nesting route, windows, readbacks, and seal boundary in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *A is the local* $\mathsf{NameCert}_{\mathsf{IntervalDomainWayBelow}^{\uparrow}}$ *evidence row.*

The intended reading is $I \ll O$: the inner located rational cell is compactly contained in the coarser interval-domain cell by the displayed positive dyadic margin and can be replayed through the finite L10 observation route before any real seal is exposed. The carrier has no coordinate for quotient real equality, host real equality, open-cover compactness, selected limits, or ambient completeness.

Theorem 1545.2 (IntervalDomainWayBelow NameCert obligations)**.** *For an accepted* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *carrier $W = (O, I, M, N, S, Q, E, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{IntervalDomainWayBelow}^{\uparrow}}$ *surface consists exactly of carrier admission, strict-margin evidence, nested-route compatibility, observation replay, transport stability, and seal non-escape:*

1. *carrier admission exposes precisely the coarser interval-domain cell, inner located rational cell, positive dyadic margin, nested route, stream windows, regular rational readbacks, seal boundary, transports, continuations, provenance, and local naming row;*
2. *strict-margin evidence requires M to be positive and to certify that both rational endpoints of I lie inside the displayed bounds of O with that margin;*
3. *nested-route compatibility requires every refinement consumer of O that asks for the inner cell to pass through the displayed* $\mathsf{NestedInterval}^{\uparrow}$ *route before reading I;*
4. *observation replay requires the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks to serve the same endpoint requests on both sides of the way-below comparison;*
5. *transport stability identifies transported carriers only through the componentwise* hsame *row and the displayed* Cont *replay route;*
6. *seal non-escape states that any* $\mathsf{Real}^{\uparrow}$ *consumer of E must first read $O, I, M, N, S, Q, H, C, P, A$.*

No obligation exports quotient real equality, host real equality, open-cover compactness, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 1545.1. The tuple lists the whole visible surface: coarser cell, inner cell, positive margin, nested route, observation windows, rational readbacks, seal boundary, transport, replay, provenance, and local naming evidence.

Strict-margin evidence is read from I and M. The inner cell carries located endpoints and a rational interval ledger, while the positive dyadic margin records a strict separation from the coarser endpoint bounds named by O.

Nested-route compatibility is read from N. A consumer that starts with the coarser $\mathsf{IntervalDomain}^{\uparrow}$ cell can request the inner cell only by following the displayed $\mathsf{NestedInterval}^{\uparrow}$ route, so the way-below comparison is a finite refinement relation rather than an ambient order assertion.

Observation replay uses S and Q as a paired window/readback layer. The same endpoint request is served through the stream-name window and the regular rational observation row, so replay cannot change which finite data witnesses the comparison.

Transport stability follows from H and C. Componentwise hsame moves each row of the carrier, and the displayed continuation route replays the same reads after transport.

Finally, seal non-escape follows because E is downstream of all approximation rows. Since the carrier has no quotient, host-equality, compactness, selected-limit, or completeness coordinate, none of those principles can be read from the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.IntervalDomainWayBelowUp.IntervalDomainWayBelowCarrier namecert obligations`

Theorem 1545.3 (IntervalDomainWayBelow approximation route)**.** *Let* $W = (O, I, M, N, S, Q, E, H, C, P, A)$ *be an accepted* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *carrier. Every L10 completion-facing consumer of the way-below comparison factors through the finite route*

$$\mathsf{IntervalDomain}^{\uparrow} \longmapsto (\mathsf{LocatedInterval}^{\uparrow}, \mathsf{RationalInterval}^{\uparrow}) \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}$$

Thus the relation $I \ll O$ *is available as finite BEDC approximation data for interval-domain refinement. It is not quotient real equality, host real equality, open-cover compactness, a selected limit, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntervalDomainWayBelowUp.IntervalDomainWayBelowApproximationRoute`

Proof. Begin with the coarser approximation cell. The row O supplies the public $\mathsf{IntervalDomain}^{\uparrow}$ boundary, and the row I supplies the inner located rational cell to be compared with it.

The margin row M is then read as a positive $\mathsf{DyadicRatCore}^{\uparrow}$ witness. It is the finite separation datum that turns containment into a way-below comparison rather than a bare subset relation.

Next the nested route N carries the comparison through the directed interval-domain layer. The route forces later finite approximants of O to encounter the displayed inner cell before the seal boundary is available.

The observation layer is read through S and Q. Stream-name windows and regular rational readbacks supply the endpoint observations for the same finite route, and H, C, P, A transport, replay, source, and name it.

The seal row E is reached only at the end of this chain. Therefore every completion-facing consumer factors through the displayed BEDC data and receives no quotient, host-equality, open-cover, selected-limit, or ambient-completeness principle. □

Theorem 1545.4 (IntervalDomainWayBelow obligation-closure package)**.** *For an accepted* IntervalDomainWayBelo *carrier* $W = (O, I, M, N, S, Q, E, H, C, P, A)$*, the carrier admission, strict-margin evidence, nested-route compatibility, observation replay, transport stability, seal non-escape, and completion-consumer factorization jointly supply the full finite way-below obligation surface for the displayed tuple* W*.*

Proof. Apply Definition 1545.1. The tuple $W = (O, I, M, N, S, Q, E, H, C, P, A)$ fixes the coarser interval-domain cell, the inner located rational cell, the positive dyadic margin, the nested route, stream windows, regular rational readbacks, the seal boundary, and the structural rows.

Use Definition 1545.2. It supplies carrier admission, strict-margin evidence, nested-route compatibility, observation replay, transport stability, and seal non-escape as the exact local NameCert surface.

Then apply Definition 1545.3. Every completion-facing consumer factors through the same finite Scott-domain route before the $\mathsf{Real}^{\uparrow}$ seal is read.

Thus the package remains a BHist/Cont/NameCert comparison route. It does not export quotient real equality, host equality, open-cover compactness, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.IntervalDomainWayBelowUp.IntervalDomainWayBelowObligationClosurePackage`
↪ variant `BEDC.Derived.IntervalDomainWayBelowUp.IntervalDomainWayBelowCarrier obligation closure package`

Theorem 1545.5 (IntervalDomainWayBelow strict-margin obligation scope)**.** *Every accepted* IntervalDomainWayB *carrier must expose the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *margin row before any* $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$,

$\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer may read the way-below comparison. The accepted route is therefore a strict-margin route through the displayed finite carrier, not a quotient-real comparison, host equality test, open-cover compactness proof, selected limit, or ambient completeness principle.*

Proof. Project the carrier of Definition 1545.1. The row M is the positive dyadic margin, and it sits before the nested route N, stream windows S, regular readbacks Q, and seal boundary E in the displayed tuple.

Use Definition 1545.2. Its strict-margin clause requires M to certify that the inner rational interval lies strictly inside the coarser interval cell before the local NameCert accepts the comparison.

Apply Definition 1545.3. The completion-facing route factors through $\mathsf{DyadicRatCore}^{\uparrow}$ before it reaches $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$, so every downstream consumer receives the margin row first.

The exclusions follow from the same carrier projection. Since the carrier has no quotient-real equality, host-equality, open-cover compactness, selected-limit, or ambient-completeness coordinate, none of those principles can be supplied by the strict-margin obligation surface. □

Theorem 1545.6 (IntervalDomainWayBelow consumer boundary)**.** *For every accepted* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *carrier* $W = (O, I, M, N, S, Q, E, H, C, P, A)$*, every* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumer must read the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *margin row* M *and the nested route* N *before the seal row* E *is available. The consumer boundary is therefore the displayed strict-margin route through* $O, I, M, N, S, Q, E, H, C, P, A$*, not a quotient-real comparison, host-equality test, selected-limit witness, open-cover compactness argument, or ambient completeness principle.*

Proof. Project the carrier of Definition 1545.1. The positive margin row M precedes the nested route N, the stream windows S, the regular readbacks Q, and the seal boundary E in the displayed packet.

Use Definition 1545.2. Its local NameCert clauses accept the way-below comparison only after the margin row certifies strict inclusion and the nested route records where the comparison is consumed.

Apply Definition 1545.3 together with Definition 1545.5. They force the completion-facing approximation route to pass through M and N before any $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read can reach the seal row.

Finally inspect the remaining rows H, C, P, A. They transport, replay, source, and name the same strict-margin packet; none supplies a bypass around M, N or an alternate seal. Thus the stated consumers meet exactly the displayed boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalDomainWayBelow}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ packet is generated from a coarser IntervalDomainUp cell, an inner LocatedIntervalUp/RationalIntervalUp cell, a positive DyadicRatCore margin, a NestedIntervalUp refinement route, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntervalDomainWayBelow}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1545.1, Definition 1545.2, Definition 1545.3, Definition 1545.4, Definition 1545.5, and Definition 1545.6 close the finite strict-margin scope for L10 interval-domain way-below approximation.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntervalDomainWayBelow}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.IntervalDomainWayBelowUp.IntervalDomainWayBelowCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, host real equality, open-cover compactness, selected limits, ambient RealUp completeness, public export, or bridge checking.

Upgrade path: Public closure requires an exported way-below approximation certificate consumable by the IntervalDomainUp and RealUp routes without leaving the displayed strict-margin packet.

$\mathsf{Cauchy}^{\uparrow}$ is an L10 route whose regular-sequence, finite-window, dyadic-tolerance, and terminal seal reads are supplied through chapter 301, chapter 126, chapter 291, and chapter 38.

Chapter 1546

A Concrete Naming Certificate for $\mathsf{CauchyRealLocator}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRealLocator}^{\uparrow}$ packet records the finite locator surface by which a displayed Cauchy real answers Real-facing precision and side-location requests. It refines the modulus route of chapter 1423 and chapter 292, reads finite observations through chapter 126, uses the regular rational handoff of chapter 301, records dyadic tolerances through chapter 291, and reaches the terminal seal of chapter 38. The packet is a traditional constructive-analysis locator object reconstructed as finite NameCert data; it does not select a host limit, identify quotient streams, invoke countable choice, decide trichotomy, use open-cover compactness, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1546.1 (Cauchy real locator carrier)**.** *A* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row. It records the displayed RealCauchyModulus and CauchyModulus threshold data used for every locator request.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the locator at the requested precision and side test.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the positive dyadic scale, comparison cells, and slack budget for the displayed windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows into regular rational data before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *locator seal. It records only the Real-facing locator boundary delivered after M, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, stream windows, dyadic ledger, regular readback, terminal locator seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a locator request through M, S, D, Q, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$*, RealCauchyModulus, CauchyModulus,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $M, S, D, Q, R, H, C, P, N$. It has no coordinate for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Theorem 1546.2 (Cauchy real locator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier*

$$L = (M, S, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the modulus schedule, finite stream windows, dyadic tolerance ledger, regular rational readback, terminal Real locator seal, transport, replay, provenance, and local naming;*
2. *modulus exactness, requiring every locator request to use the displayed row M rather than an independent threshold, host convergence theorem, or selected limit;*
3. *window and tolerance compatibility, requiring the inspected windows in S to be compared only through the dyadic ledger D;*
4. *RegSeqRat readback, requiring the rational data consumed by the locator seal to pass through the displayed row Q;*
5. *route ordering, requiring R to be read only after M, S, D, Q have been displayed;*
6. *nonescape, excluding host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, and bridge checking.*

No local locator obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3410.1. The accepted packet displays exactly the modulus schedule, finite windows, dyadic ledger, regular readback, terminal locator seal, and structural rows.

Modulus exactness is forced by the single coordinate M. Every locator request reads its threshold from this row, so the packet has no second convergence witness, hidden host completeness theorem, or selected limit coordinate.

Window and tolerance compatibility are supplied by S and D. The stream row exposes only finite windows, while the dyadic row records the positive scale, comparison cells, and slack budget used to interpret those windows.

The readback and ordering clauses follow from Q and R. The regular rational row is the only rational readback coordinate, and the terminal Real locator seal occurs downstream of M, S, D, Q.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory contains no row for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 1546.3 (Cauchy real locator modulus route)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier factors each locator request through the displayed finite route*

$$M \longmapsto S, D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

Thus the request reaches the $\mathsf{Real}^{\uparrow}$ *locator seal only through the visible modulus schedule, finite stream windows, dyadic tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*

Proof. Begin with an accepted carrier $L = (M, S, D, Q, R, H, C, P, N)$ and a displayed locator request. The only threshold coordinate available to the request is M, so the modulus schedule is read first.

The finite observation step is next. The request opens the window row S and interprets its tolerance through D, whose dyadic ledger records the positive scale and comparison cells.

The rational handoff is then forced through Q. No independent stream or host rational approximation is present in the carrier, so the locator request reaches the Real-facing boundary only after the regular rational readback has been displayed.

Finally the terminal row R is consumed and the structural rows H, C, P, N preserve the same route. This proves the stated factorization and excludes a bypass through selected limits, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. □

Theorem 1546.4 (Cauchy real locator Real seal nonescape)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *locator-seal read reaches* R *only after the displayed rows* M, S, D, Q *have been consumed. The seal exports no host Real equality, quotient stream representative, selected limit, countable-choice selector, trichotomy branch, open-cover compactness witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Inspect the terminal coordinate of the carrier. The only Real-facing locator seal is R, and it is listed after the modulus schedule, stream-window, dyadic-ledger, and regular-readback rows.

Apply the obligation surface of Definition 3410.2. It requires route ordering through M, S, D, Q before R can be read by a Real-facing consumer.

The structural rows preserve this boundary. The hsame transports and Cont replay keep the same displayed packet, while Pkg provenance and local naming record only that route.

Because no excluded coordinate appears in L, the terminal seal cannot export host Real equality, quotient representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. Any consumer asking for one of those principles must leave the local carrier. □

Theorem 1546.5 (Cauchy real locator four-object exit)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *Real-facing locator read factors through exactly the four L10 exit objects named by Definition 3412.8: the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *locator seal. In carrier coordinates, any accepted read of* $L = (M, S, D, Q, R, H, C, P, N)$ *uses* S, D, Q, R *as the four object faces and uses* M, H, C, P, N *only as the modulus schedule, transport, replay, provenance, and local naming support. It exports no quotient stream equality, host Real equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier tuple. The row S is the finite $\mathsf{StreamName}^{\uparrow}$ window, D is the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, Q is the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and R is the terminal $\mathsf{Real}^{\uparrow}$ locator seal.

The modulus route theorem Definition 3410.3 fixes the order of consumption. A locator request reads the schedule M, opens the finite windows S, interprets them through the dyadic ledger D, passes through the regular readback Q, and only then reaches R.

The Real-seal nonescape theorem Definition 3410.4 supplies the boundary condition for the terminal read. It rules out every Real-facing bypass that would identify quotient streams, appeal to host Real equality, choose a limit, branch by trichotomy, use open covers, or import ambient completeness.

Finally compare this carrier projection with Definition 3412.8. The four object faces are exactly S, D, Q, R, while M, H, C, P, N supply only schedule, transport, replay, provenance, and naming support. Hence an accepted locator read has the claimed four-object L10 exit route and no additional exported coordinate. □

Theorem 1546.6 (Cauchy real locator induction route)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every locator-side read available to induction is obtained by the finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

The induction step reads finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal rows without deciding trichotomy and without choosing a host limit.*

Proof. Project the carrier of Definition 3410.1. The modulus schedule M is the only threshold source, so a locator-side induction step begins by reading the same schedule used in the modulus route.

The finite observation is then S interpreted through D. The stream row exposes only bounded windows, while the dyadic row supplies the tolerance scale and comparison cells needed to use those windows.

The rational and Real-facing parts follow through Q and R. The modulus route theorem Definition 3410.3 fixes this order, and the four-object exit theorem Definition 3410.5 identifies S, D, Q, R as the four L10 exit faces.

Finally H, C, P, N preserve the route by transport, replay, provenance, and local naming. Since the carrier has no coordinate for trichotomy or selected host limits, the induction route cannot decide a side by trichotomy or choose a limit outside the displayed locator data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3410.1, Definition 3410.2, Definition 3410.3, Definition 3410.4, Definition 3410.5, and Definition 3410.6 seed the finite locator route over Cauchy modulus schedules, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, and the Real locator seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, window and tolerance compatibility, RegSeqRat readback, route ordering, nonescape, and local NameCert registration for BEDC.Derived.CauchyRealLocatorUp.

Constructive story: A $\mathsf{CauchyRealLocator}^{\uparrow}$ packet is generated from a RealCauchyModulusUp and CauchyModulusUp schedule row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a terminal RealUp locator seal, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1547

A Concrete Naming Certificate for CauchyRealLocatorPointwiseInduction$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet records the finite-window induction route used by Cauchy real locators. It is a sibling of the locator surface of chapter 3410 and the finite schedule discipline of chapter 126: a pointwise induction step opens one displayed stream window, reads its dyadic tolerance ledger, passes through the regular rational readback of chapter 301, and returns to the same Real-facing locator seal of chapter 38. The packet is not an induction principle over all host streams, a quotient-real equality theorem, a countable-choice selector, or an ambient completeness assertion.

The dependency route is substantive: before the packet exports pointwise locator induction, it consumes the rational interval enclosure surface of chapter 4202 together with the RegSeqRat window handoff of chapter 301. Thus each pointwise branch is read as rational interval enclosure plus regular Cauchy window data, not as a decorative citation to neighboring chapters.

Definition 1547.1 (Cauchy real locator pointwise induction carrier)**.** *A* CauchyRealLocatorPointwiseInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* CauchyRealLocator$^{\uparrow}$ *row, carrying the locator modulus, finite-window, dyadic, regular-rational, and Real seal data.*
2. *W is the* StreamName$^{\uparrow}$ *pointwise window row selected for the current locator request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the pointwise window with the requested side test.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the window and dyadic tolerance have been displayed.*
5. *R is the terminal* Real$^{\uparrow}$ *locator seal reached by the pointwise readback.*
6. *B is the finite induction-branch ledger, recording the base window and successor-window handoff over the displayed rows W, D, Q, R.*
7. *H records componentwise* hsame *transport for the locator source, window, dyadic tolerance, regular readback, Real seal, branch ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for each pointwise induction step.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1547.2 (Cauchy real locator pointwise induction regularity-witness route)**.** *Every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier consumes the finite regularity-witness surface of chapter 1158 before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the pointwise branch first opens the displayed $\mathsf{StreamName}^{\uparrow}$ *window W, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q through the regularity-witness route, and only then reaches the terminal Real locator seal R.*

Proof. Project the carrier. The only rows available before the Real seal are the locator source L, the displayed window W, the dyadic tolerance D, and the regular-rational readback Q.

Now use the sibling regularity-witness surface. Its displayed route supplies the same finite window, tolerance ledger, and RegSeqRat readback before the Real seal handoff, so the pointwise branch can inspect regularity evidence without opening a host stream representative.

Finally read R and the structural rows B, H, C, P, N. These rows record, transport, replay, source, and name the already displayed route, so the pointwise induction packet depends on the regularity witness before it reaches the Real-facing locator seal. □

Theorem 1547.3 (Cauchy real locator pointwise window induction)**.** *For every accepted* CauchyRealLocatorPointwi *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

each pointwise locator step factors through the finite route

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B, H, C, P, N.$$

The base and successor cases of the induction ledger B may inspect only the displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *locator seal supplied by the same* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row.*

Proof. Project the accepted carrier. The source row L is the only Cauchy real locator coordinate, so every pointwise step begins by reading the displayed locator packet of chapter 3410.

The induction window is then opened through W. The dyadic tolerance row D is the only comparison surface attached to that window, and the regular rational readback Q is available only after the window and dyadic rows have been displayed.

The terminal read reaches R and is then recorded by the branch ledger B. The base branch and each successor branch therefore preserve the same finite route rather than selecting a host stream representative.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, the displayed route exhausts the pointwise induction surface. □

Theorem 1547.4 (Cauchy real locator pointwise induction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *obligations are exactly carrier admission for the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row* L*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *window admission for* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility for* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for* Q*,* $\mathsf{Real}^{\uparrow}$ *locator-seal ordering for* R*, finite base and successor branch admission for* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4225.1. The tuple displays the locator source, pointwise window, dyadic tolerance, regular-rational readback, real seal, branch ledger, and structural rows.

The source and window obligations are read from L and W. The dyadic tolerance row D is the only comparison surface attached to that pointwise window, and the readback row Q can be inspected only after those rows are displayed.

The real-seal ordering obligation is the row R, downstream of Q. The branch ledger B records the finite base and successor handoff over the same displayed rows rather than over a host stream representative.

The rows H, C, P, N transport, replay, source, and name the packet. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 1547.5 (Cauchy real locator pointwise window stability)**.** *Let*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier. Replacing the locator source,* $\mathsf{StreamName}^{\uparrow}$ *pointwise window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible pointwise induction route*

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B.$$

Thus the base and successor branches of the finite induction ledger remain attached to the same locator source and cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and use Definition 4225.3. Every pointwise step already factors through the displayed locator source, window, dyadic tolerance, regular-rational readback, real seal, and branch ledger.

The componentwise replacement is recorded by H. It transports the locator source, window, tolerance, readback, seal, branch ledger, replay, provenance, and local name without adding another induction coordinate.

The replay row C then carries the transported rows through the same pointwise route. The branch ledger B therefore continues to read the base window and successor-window handoff over W, D, Q, R.

The carrier has no row for any excluded host or quotient object, so row exhaustion shows that the transported packet preserves exactly the admissible pointwise induction route. □

Theorem 1547.6 (Cauchy real locator pointwise branch exhaustion)**.** *For every accepted* CauchyRealLocatorPointw *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

every base or successor branch read in B is exhausted by the displayed rows $L, W, D, Q, R, H, C, P, N$. Such a branch read cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The branch ledger B is downstream of the locator source L, pointwise window W, dyadic tolerance row D, regular-rational readback Q, and terminal real seal R.

Use pointwise window induction from Definition 4225.3. It forces both the base branch and each successor branch to read the same finite route $L \longmapsto W, D \longmapsto Q \longmapsto R$ before B records the branch.

Use window stability from Definition 4225.5. The transport row H and replay row C preserve that route under displayed componentwise replacement, while P, N only source and name the packet.

Row exhaustion completes the claim. No coordinate of I stores host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no base or successor branch can export any of those objects. □

Theorem 1547.7 (Cauchy real locator pointwise induction sibling route)**.** *Every accepted* CauchyRealLocatorPointw *read must pass through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38 before the branch ledger is public. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the rows L, W, D, Q, R are exactly that sibling route, and B, H, C, P, N can only record, transport, replay, source, and name the displayed route.

Proof. Project the carrier rows $L, W, D, Q, R, B, H, C, P, N$ from Definition 4225.1. The source row L is read through the Cauchy real locator certificate, while W is the finite StreamName window attached to the current pointwise request.

The dyadic tolerance row D is then consumed through the DyadicRatCore certificate, and Q is the RegSeqRat readback of that displayed window and tolerance data. The terminal row R is the Real-facing locator seal reached after those rows are visible.

Apply Definition 4225.3 and Definition 4225.4. They force the pointwise induction route and the local NameCert obligations to use exactly the rows L, W, D, Q, R before the branch ledger can be inspected.

Finally use Definition 4225.5 and Definition 4225.6. The transport, replay, provenance, and local naming rows preserve the same sibling route and exhaust the branch surface, so the public branch ledger has no alternate dependency edge outside the listed chapters. □

Not claimed: This chapter does not claim host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window induction, dyadic tolerance compatibility, RegSeqRat readback, Real seal ordering, and local NameCert registration for BEDC.Derived.CauchyRealLocatorPointwiseInductionUp.

Constructive story: A CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet is generated from a CauchyRealLocator source row, one StreamName pointwise window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp locator seal, a finite induction-branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1548

A Concrete Naming Certificate for $\mathsf{CauchySequenceAlgebra}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ packet records the finite algebra route by which two regular rational Cauchy source rows are added or multiplied before any $\mathsf{Real}^{\uparrow}$ consumer reads the sealed result. It sits between the regular source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic ledger of chapter 291, the addition route of chapter 1695, the product route of chapter 461, and the terminal real-name seal of chapter 38. The packet gives later Real algebra and CauchyRealField consumers one BEDC-native finite dependency for binary Cauchy algebra; it does not import quotient Cauchy classes, host real arithmetic, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1548.1 (CauchySequenceAlgebra carrier)**.** *A* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations supply the left and right inputs.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite window pairs in which the two source rows are inspected at the same requested tolerance scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row. It stores the displayed endpoint arithmetic, slack conversions, tolerance comparisons, addition-budget entries, and product-budget entries used by the accepted binary operation request.*
4. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the summed endpoint row, finite addition ledger, and resulting regular readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the product endpoint row, product-error ledger, magnitude-budget entries, and resulting regular readback.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after the chosen operation row A or M has displayed its regular readback.*
7. *H records componentwise* hsame *transport for the two source rows, synchronized windows, dyadic budgets, operation rows, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a binary algebra request through $X, Y, W, D, A, M, S, H, P, N$.*
9. *P is the* Pkg *provenance over* CauchySequenceAlgebra$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, A, M, S, H, C, P, N$. The carrier has no coordinate for quotient-stream equality, host real addition or multiplication, a selected limit, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 1548.2 (CauchySequenceAlgebra NameCert obligations)**.** *For every accepted* CauchySequenceAlgebra$^{\uparrow}$ *carrier*

$$G = (X, Y, W, D, A, M, S, H, C, P, N),$$

the local NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* RegSeqRat$^{\uparrow}$ *sources, synchronized* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *operation budgets,* RegularCauchyAddition$^{\uparrow}$ *route,* RegularCauchyProduct$^{\uparrow}$ *route,* Real$^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *source-window synchronization, requiring every operation request to inspect X and Y through the same displayed window row W before any endpoint arithmetic is read;*
3. *dyadic-budget exactness, requiring every addition or product endpoint row to consume only the displayed tolerance, slack, comparison, and magnitude-budget entries of D;*
4. *operation-route separation, requiring A to carry only the addition route and M to carry only the product route, while both routes consume the same source, window, and dyadic-budget rows;*
5. *Real seal handoff, requiring S to be exposed only after the selected operation route has produced its* RegSeqRat$^{\uparrow}$ *readback;*
6. *transport and replay stability, requiring H and C to preserve the full route $X, Y, W, D, A, M, S, P, N$ without adding a quotient stream, host operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.*

No CauchySequenceAlgebra NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 3708.1. The displayed coordinates are exactly the two source rows X, Y, synchronized windows W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Source-window synchronization is forced by the single window coordinate W. Both source reads must pass through that coordinate before the dyadic operation budget is available, so the carrier has no second window service for either input.

Dyadic-budget exactness and operation-route separation are read from D, A, M. The row D supplies the finite arithmetic budgets, the row A consumes those budgets for addition, and the row M consumes those budgets for product. Since A and M are distinct rows with the same upstream inputs, neither route can borrow an unrecorded host operation.

Finally, the Real seal and structural rows close the finite route. The seal S is downstream of the operation readback, while H, C, P, N only transport, replay, package, and name the displayed rows. The excluded quotient, host arithmetic, selected-limit, choice, trichotomy, and ambient-completeness data have no carrier coordinate. □

Theorem 1548.3 (CauchySequenceAlgebra Real-field handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *binary algebra read reaches field-facing data only through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *routes, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In particular the handoff exports regular Cauchy addition and multiplication readbacks before the final Real seal, and it exports no quotient stream, host real arithmetic, selected limit, trichotomy, countable-choice datum, or ambient completeness principle.*

Proof. Project the carrier of Definition 3708.1. The only field-facing source data are the two regular rational Cauchy rows X, Y, the synchronized window W, and the dyadic operation budget D.

Read the operation rows before the final Real seal. The addition route is A, the product route is M, and both routes consume the same source, window, and budget rows named in Definition 3708.2.

The terminal consumer then reads S only after one of those operation routes has produced its $\mathsf{RegSeqRat}^{\uparrow}$ readback. Transport, replay, provenance, and local naming in H, C, P, N preserve that route. Since the carrier has no coordinate for quotient streams, host arithmetic, selected limits, trichotomy, countable choice, or ambient completeness, no Real-field handoff can export any of those objects. □

Theorem 1548.4 (CauchySequenceAlgebra operation route)**.** *Every* $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProdu}$ $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier reads binary algebra data only through the displayed route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N.$$

Consequently the consumer obtains the two regular source rows, synchronized stream windows, dyadic operation budgets, the addition route, the product route, the terminal Real seal handoff, transport, replay, provenance, and local naming, and obtains no quotient Cauchy class, host real operation, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a downstream algebra request. By Definition 3708.1, the only source coordinates are X and Y, and the only synchronized window coordinate available to both sources is W.

The operation budget is then forced through D. Addition reads the route row A, product reads the route row M, and both rows are displayed downstream of the same sources, windows, and dyadic budgets named in Definition 3708.2.

The Real-facing handoff is last. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyRealField}^{\uparrow}$ consumer can read the seal S only after an operation route has produced its regular readback, and the rows H, C, P, N preserve that same finite route. No coordinate remains from which a quotient Cauchy class, host operation, selected limit, countable choice, trichotomy, or ambient completeness principle could be exported. □

Theorem 1548.5 (CauchySequenceAlgebra route non-escape)**.** *Let* $G = (X, Y, W, D, A, M, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier. Any algebraic fact exported from* G *is a rowwise consequence of the displayed regular source rows, synchronized windows, dyadic operation budgets, operation routes, Real seal, transport, replay, provenance, and local naming rows. It is not a quotient Cauchy class, host real addition, host real multiplication, selected limit, countable-choice datum, trichotomy datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly X, Y, W, D, A, M, S, and the structural coordinates are exactly H, C, P, N.

An exported addition fact must use A after the source, window, and dyadic-budget rows have been displayed. An exported product fact must use M after the same upstream rows have been displayed. A Real-facing algebra fact must then pass through the seal row S.

The structural rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot create a host operation or a quotient relation, while provenance and local naming record only the finite packet. Thus every exported algebraic fact is confined to the listed rows, and each excluded principle has no entry point. □

Theorem 1548.6 (CauchySequenceAlgebra remainder-estimate handoff)**.** *Let*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

be an accepted CauchySequenceAlgebra$^{\uparrow}$ *carrier. Any downstream* CauchyRemainderEstimate$^{\uparrow}$ *read for an addition or product result factors first through the same finite binary-algebra route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N$$

and then through the finite tail-estimate rows of chapter 3991. The handoff exports the displayed source rows, synchronized windows, dyadic operation budgets, selected addition or product route, terminal Real seal, transport, replay, provenance, local naming, finite tail threshold, admitted tail windows, regular readback, and tail-diameter boundary rows. It exports no quotient Cauchy class, host real operation, selected limit, countable-choice datum, trichotomy datum, or ambient Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier G. By Definition 3708.2, every binary algebra read exposes only the source rows X, Y, synchronized window W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Apply Definition 3708.4 to the downstream addition or product request. The result route must pass through A for addition or M for product, and in either case it uses the same upstream X, Y, W, D rows before reaching the seal S.

Now apply Definition 3708.5. No part of that binary-algebra route can introduce a quotient Cauchy class, host real operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.

The remainder-estimate consumer therefore begins from the regular readback already displayed by the operation route and then uses the sibling surface chapter 3991. That surface supplies the finite threshold, admitted tail windows, regular readback, tail-diameter boundary, transport, replay, provenance, and local naming rows for CauchyRemainderEstimate$^{\uparrow}$. Composing these two finite routes gives the stated handoff and leaves every excluded principle without a carrier coordinate. □

Closure status for NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 3708.1, Definition 3708.2, Definition 3708.3, Definition 3708.4, Definition 3708.5, and Definition 3708.6 seed the finite binary algebra route over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyRemainderEstimate$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host real operations, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-window synchronization, dyadic-budget exactness, operation-route separation, Real seal handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceAlgebraUp.

Constructive story: A CauchySequenceAlgebra$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, one DyadicRatCore$^{\uparrow}$ operation-budget ledger, RegularCauchyAddition$^{\uparrow}$ and RegularCauchyProduct$^{\uparrow}$ route rows, a Real$^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The Cauchy$^{\uparrow}$ gateway reads its completion-facing source through chapter 126, chapter 301, chapter 291, and chapter 38 before any terminal seal is public.

Theorem 1548.7 (Cauchy L10 sibling route)**.** *The Cauchy packet family exported by this hub is consumed through the L10 route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}.$$

Concretely, the finite-window surface of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the completion boundary of chapter 1506 are sibling inputs to the Cauchy carriers rather than hidden ambient structure.

Proof. Read any Cauchy carrier exported by the hub through its finite observation rows. The stream coordinate supplies the inspected windows, the regular-rational coordinate supplies the numerical readback, and the dyadic coordinate supplies the tolerance budget.

The Real-facing seal is reached only after those rows have been displayed. When a completion consumer is present, it receives the same displayed route through the metric-completion boundary.

Thus the hub's Cauchy packet family is attached to the Real and MetricCompletion siblings by visible L10 rows, with no quotient representative, selected limit, countable-choice schedule, host real equality, or ambient completeness coordinate added by the route. □

The Cauchy$^{\uparrow}$ route consumes the L10 sibling chapters before the real locator and sequence algebra inputs are read. In particular, the regular-rational source of chapter 301, the finite stream windows of chapter 126, and the terminal seal of chapter 38 are already part of the displayed dependency spine for every downstream Cauchy locator or algebra consumer. The completion-side consumer in chapter 1937 reads the same RegSeqRat, StreamName, and RealUp spine before exposing its functorial completion route.

Theorem 1548.8 (Cauchy L10 four-object seal route)**.** *Every accepted* Cauchy$^{\uparrow}$ *Real-facing seal route used by the current L10 phase factors through the four displayed sibling faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Concretely, the finite window family of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38 are the only Real-facing sibling rows exported by the route. The supporting rows are the displayed BHist *carrier data, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *registration.*

Proof. Read the route through the existing CauchyRealLocator carrier and its Real-seal nonescape theorem. The carrier exposes a finite StreamName window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, and a terminal RealUp locator seal before any Real-facing consumer can read the packet.

Project those four named faces. The StreamName row supplies only inspected finite windows, the DyadicRatCore row supplies the tolerance and comparison budget, the RegSeqRat row supplies the rational readback, and the RealUp row supplies the terminal seal.

The structural rows preserve this factorization. The BHist data name the carried packet, hsame transports the displayed coordinates, Cont replays the same route, Pkg records provenance, and NameCert records the local accepted surface.

Since the carrier has no coordinate for quotient streams, host equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the Cauchy Real-facing seal route. □

Chapter 1549

A Concrete Naming Certificate for $\mathsf{Cauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{Cauchy}^{\uparrow}$ packet records the ordinary constructive Cauchy-real carrier as finite BEDC naming data. It sits above the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational sequence surface of chapter 301, and the terminal seal of chapter 38. The packet is not a quotient construction of reals; it is a finite route by which a modulus, rational readback, transport, replay, provenance, and local naming row become visible before any $\mathsf{Real}^{\uparrow}$ consumer can read the Cauchy object.

Definition 1549.1 (Cauchy carrier)**.** *A* $\mathsf{Cauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, recording the finite windows of rational approximants inspected by the carrier.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the positive dyadic scale, comparison cells, and slack conversions used to interpret each requested window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence row, exposing the rational readback consumed downstream.*
4. *M is the modulus row, recording the displayed threshold assignment used by Cauchy requests and refusing any hidden convergence theorem.*
5. *Q is the modulus/readback compatibility row, requiring the stream window, dyadic tolerance, regular rational sequence, and modulus rows to agree at every displayed precision request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, exposed only after S, D, R, M, Q have been displayed.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-sequence, modulus, compatibility, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Cauchy request through $S, D, R, M, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $S, D, R, M, Q, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyUp.CauchyCarrier`

Theorem 1549.2 (Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *carrier*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 3413.1.*

Proof. Carrier admission is projection from Definition 3413.1. The accepted packet displays precisely the stream, dyadic, regular-sequence, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

The stability and exactness obligations are rowwise. The stream row supplies only finite windows, the dyadic row supplies only displayed tolerance cells, the regular-sequence row supplies only rational readback, and the modulus row supplies only the visible threshold assignment.

The compatibility row Q binds these four data rows before any $\mathsf{Real}^{\uparrow}$ seal can be consumed. The structural rows H, C, P, N then transport, replay, source, and name the same route without adding quotient equality, selected limits, host real equality, choice, trichotomy, compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCarrier namecert obligations`

Theorem 1549.3 (Cauchy modulus readback route)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *consumer route factors through the displayed path*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a precision request reads finite $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the explicit modulus row, the compatibility row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the* $\mathsf{Real}^{\uparrow}$ *seal-facing boundary.*

Proof. Begin with an accepted carrier $X = (S, D, R, M, Q, E, H, C, P, N)$ and a displayed precision request. The only finite observations available to the request are the windows in S, and their tolerance scale is read through D.

The request next reads the explicit modulus row M. The compatibility row Q is the only coordinate that relates the chosen window, tolerance, threshold, and regular-rational readback, so the route cannot bypass it.

After Q is displayed, the consumer may read the $\mathsf{RegSeqRat}^{\uparrow}$ row R and then the terminal $\mathsf{Real}^{\uparrow}$ seal-facing row E. The rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming.

Since the carrier has no quotient, selected-limit, host equality, countable-choice, trichotomy, open-cover, or ambient-completeness coordinate, the displayed route is the whole public Cauchy readback surface. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusReadbackRoute`

Theorem 1549.4 (Cauchy StreamName RegSeqRat window)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet exposes its* $\mathsf{RegSeqRat}^{\uparrow}$ *row only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and modulus/readback compatibility row. Thus a regular rational read of* $X = (S, D, R, M, Q, E, H, C, P, N)$ *must factor through* S, D, M, Q *before it can inspect* R*.*

Proof. Project the carrier of Definition 3413.1. The row S is the only finite observation surface, D is the only displayed tolerance surface, and M is the only modulus row available to the packet.

Apply Definition 3413.2 to identify Q as the compatibility row binding stream windows, dyadic tolerances, regular rational readback, and modulus data. Then apply Definition 3413.3: the displayed route reads S, D, M and Q before R.

The carrier has no quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient completeness coordinate. Hence the stated window and compatibility rows exhaust the public access path to $\mathsf{RegSeqRat}^{\uparrow}$. □

Theorem 1549.5 (Cauchy finite-tail criterion)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

be an accepted $\mathsf{Cauchy}^{\uparrow}$ *carrier. Suppose every displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window admitted by* S *and every dyadic tolerance cell admitted by* D *satisfy the tail bound named by the modulus row* M*, and suppose the compatibility row* Q *identifies those windows with the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of* X *is routed through the same finite tail ledger*

$$S, D, M \longmapsto Q \longmapsto R$$

before the $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed. The criterion exports no selected limit, quotient stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows available for a tail read are the finite StreamName window row S, the DyadicRatCore tolerance row D, the modulus row M, the compatibility row Q, the RegSeqRat readback row R, and the terminal seal row E.

Induct over the displayed window list retained by S. The empty window has no readback outside the recorded tolerance ledger. In the successor step, the new inspected position is checked against the dyadic cell in D and the threshold supplied by M, so the same finite tail bound remains attached to the extended window.

Apply Definition 3413.4. It forces any access to R through the displayed S, D, M, Q route. Apply Definition 3413.3 to identify Q as the point where the window, tolerance, modulus, and readback rows are jointly inspected.

Finally use Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal E is downstream of the regular rational readback, so no Real-facing consumer can bypass the finite tail ledger. Since the carrier has no selected-limit, quotient-stream, countable-choice, trichotomy, or ambient-completeness coordinate, the displayed finite induction exhausts the criterion. □

Definition 1549.6 (Cauchy finite-window modulus carrier)**.** *The finite-window modulus carrier associated to an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet is the displayed handoff surface*

$$W = (S, D, M, Q, R, E, H, C, P, N)$$

read from the carrier of Definition 3413.1. Its rows have the following roles:

1. *S records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by a tail request.*

2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells and slack conversions attached to those windows.*
3. *M records the explicit modulus threshold row used to accept later-window requests.*
4. *Q records the compatibility row tying each displayed window, dyadic tolerance, modulus threshold, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
5. *R records the regular-rational readback exposed only after S, D, M, Q have been displayed.*
6. *E records the downstream* $\mathsf{Real}^{\uparrow}$ *seal-facing row.*
7. *H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *naming for the same finite route.*

The carrier admits only these displayed coordinates. It has no coordinate for quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1549.7 (Cauchy finite-window tail induction)**.** *Let $W = (S, D, M, Q, R, E, H, C, P, N)$ be the finite-window modulus carrier of Definition 3413.6. Every accepted tail request obtained by extending the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row preserves the dyadic tolerance row D, the modulus threshold row M, the compatibility row Q, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. Thus the induction route is*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E$$

with H, C, P, N transporting, replaying, sourcing, and naming the same displayed handoff.

Proof. Project the underlying accepted Cauchy carrier through Definition 3413.1 and read it in the window/modulus order specified by Definition 3413.6. The only tail-request rows available are $S, D, M, Q, R, E, H, C, P, N$.

Induct over the displayed $\mathsf{StreamName}^{\uparrow}$ windows retained by S. The empty window has no tolerance request outside D and no readback outside the route named by Definition 3413.4.

For the successor step, the new inspected window is accepted only through the dyadic cell in D and the threshold supplied by M. Apply Definition 3413.5 to keep the same finite tail ledger attached to the extended request.

The compatibility row Q is then the unique displayed row where the window, dyadic tolerance, modulus threshold, and regular readback are jointly inspected. Apply Definition 3413.3 to place R after Q and E after R.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Since none of the rows supplies quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the induction cannot expose any such principle. □

Theorem 1549.8 (Cauchy RegSeqRat handoff obligation)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the finite-window modulus carrier of Definition 3413.6 and the tail-induction route of Definition 3413.7. In particular, the consumer reads S, D, M, Q before R, and any Real-facing use reads E only after that* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Begin with an accepted Cauchy packet and project its rows by Definition 3413.1. The carrier supplies finite stream windows, dyadic tolerances, a modulus row, a compatibility row, regular-rational readback, a terminal Real-facing seal, and structural transport, replay, provenance, and naming rows.

Apply Definition 3413.4. It forces access to the $\mathsf{RegSeqRat}^{\uparrow}$ row through the displayed S, D, M, Q route, so no consumer can inspect R independently of the finite window and tolerance data.

Next apply Definition 3413.5 and Definition 3413.7. These identify the finite tail ledger and show that accepted extensions preserve the dyadic tolerance, modulus threshold, compatibility, and regular readback rows before the Real seal is exposed.

Finally use Definition 3413.3. The structural rows H, C, P, N transport and name the same handoff, while the carrier contains no quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every $\mathsf{RegSeqRat}^{\uparrow}$ consumer factors through the stated finite-window induction surface. □

Theorem 1549.9 (Cauchy RegSeqRat Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the terminal real seal. In the notation of Definition 3413.1, the seal-facing route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

It does not expose quotient streams, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project $X = (S, D, R, M, Q, E, H, C, P, N)$ from Definition 3413.1. The seal row E is declared terminal and seal-facing; it is not an independent source of Cauchy data.

Use Definition 3413.3 to order the displayed read. The route reaches R after S, D, M, Q and reaches E only after R has been displayed.

Finally apply Definition 3413.2. The rows H, C, P, N transport, replay, source, and name the same route, so they cannot insert quotient representatives, selected limits, host equality, countable choice, trichotomy, or ambient completeness between $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. □

Theorem 1549.10 (Cauchy modulus transport stability)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

and

$$X' = (S', D', R', M', Q', E', H', C', P', N')$$

be accepted $\mathsf{Cauchy}^{\uparrow}$ *packets. Suppose the stream row, dyadic tolerance row, modulus row, modulus/readback compatibility row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, replay row, provenance row, and local naming row are transported componentwise by the displayed* hsame *data in* H *and* H'*, and suppose both packets are replayed through the same displayed* Cont *route. Then the public Cauchy readback route*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

is the same BEDC route as

$$S', D', M' \longmapsto Q' \longmapsto R' \longmapsto E' \longmapsto H', C', P', N'.$$

In particular, componentwise transport of the modulus/readback surface cannot introduce quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, or ambient completeness.

Proof. Project both accepted packets through Definition 3413.1. The only visible coordinates are the stream, dyadic tolerance, regular-rational readback, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

Apply Definition 3413.3 to X and to X'. The two projected routes must read their displayed stream, dyadic, and modulus rows before their compatibility rows, and the shared Cont replay identifies these reads through the componentwise hsame data.

Next use Definition 3413.4. Access to R and R' is forced through the transported S, D, M, Q and S', D', M', Q' rows, so no other regular-rational readback path is available.

Finally apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal remains downstream of the transported $\mathsf{RegSeqRat}^{\uparrow}$ rows, and the structural rows H, C, P, N and H', C', P', N' only transport, replay, source, and name that path. Since neither carrier contains quotient streams, selected limits, host equality, choice, trichotomy, or ambient completeness, the two displays name the same BEDC route. □

Theorem 1549.11 (Cauchy uniform-modulus Real seal)**.** *For an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

any uniform-modulus consumer of the explicit modulus row M *that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must read* S, D, M, Q *before* R*, and* R *before* E*. The route contains no quotient stream equality, selected limit, countable choice, trichotomy, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet through Definition 3413.1. The explicit modulus row M is packaged with the finite stream window S, the dyadic tolerance row D, the compatibility row Q, the regular rational readback R, and the terminal seal-facing row E.

Apply Definition 3413.3. It forces a precision request to read S, D, M and then Q before any regular-rational row can be inspected.

Next apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal row E is downstream of R, so a uniform-modulus consumer cannot reach the seal before the regular rational readback has been displayed.

Finally use Definition 3413.10. Componentwise transport and the displayed Cont replay preserve the same route for every accepted consumer, and the carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, metric-completeness data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1549.12 (Cauchy root filter-completion anchor)**.** *Every Cauchy root consumer that first reaches the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *surface of chapter 1569 must already have read the Cauchy core route, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route remains inside componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

Proof. Project the root hub through its Cauchy core child. The core route exposes the stream-window, tolerance, readback, transport, replay, provenance, and naming rows before any completion-facing consumer can inspect the root packet.

Now read the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ chapter. Its completion handoff consumes the same finite windows and regular rational readback before the terminal Real seal is visible, so the root consumer cannot enter through a detached filter object.

The structural rows preserve the path. Componentwise hsame transport and displayed Cont replay keep the consumer inside the Cauchy root packet, while Pkg provenance and the local $\mathsf{NameCert}$ row record that no quotient filter, selected limit, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported. □

Theorem 1549.13 (Cauchy L10 child dependency route)**.** *Every finite-window read exported by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by sibling L10 chapters only after it passes through the child routes displayed in this chapter. The regular-rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-facing route of chapter 1569 read the* $\mathsf{Cauchy}^{\uparrow}$ *packet through finite stream windows, dyadic tolerance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. No child route exports quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the hub through its child files. The core carrier in chapter 3413 displays the stream-window, dyadic tolerance, regular readback, transport, replay, provenance, and naming rows before any downstream consumer can inspect a Cauchy object.

The sibling dependency spine then sends those rows to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The cited regular-rational and Real chapters consume only the displayed finite route; they do not receive a quotient stream, selected limit, choice schedule, trichotomy oracle, host equality coordinate, or ambient completeness proof.

The completion-facing consumer follows the same rows through the Cauchy-filter completion surface. Because the hub contains only child inputs and each child route exposes finite BHist and NameCert data, the L10 dependency path is connected through sibling chapters rather than through an unstated top-level object. □

Theorem 1549.14 (Cauchy RegSeqRat and completion forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *finite-window packet consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *factors through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route exports no quotient streams, selected limits, choice schedules, host equality, or ambient completeness.*

Proof. Start with the child dependency route above. It already displays the finite stream-window, dyadic tolerance, regular readback, Real-seal, transport, replay, provenance, and naming rows before any L10 consumer reads a Cauchy packet.

The regular rational and Real consumers are the first forward users. The chapters chapter 301 and chapter 38 read only the displayed finite windows, readback rows, tolerance rows, and terminal seal.

The completion consumer reads the same route through chapter 1506. A metric-completion request can inspect Cauchy data only after the finite windows, tolerances, readbacks, Real seal, transport, replay, provenance, and local naming rows have been displayed.

The excluded objects have no row in this finite route. Thus quotient streams, selected limits, choice schedules, host equality, and ambient completeness cannot be exported by the forward handoff. □

The L10 route consumes $\mathsf{Cauchy}^{\uparrow}$ through the finite-window surface of chapter 126, the regular readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal seal rows of chapter 38. These four child dependencies keep the Cauchy packet attached to finite stream windows, regular rational evidence, dyadic budgets, and the Real seal before any L10 consumer may read it.

Every $\mathsf{Cauchy}^{\uparrow}$ read used by Real and completion consumers factors through the same horizontal lattice: finite observation windows from chapter 126, regular-rational readback from chapter 301, dyadic tolerance rows from chapter 291, and the terminal seal of chapter 38. Downstream

consumers therefore receive a displayed finite-window route before they may treat the packet as Real-facing Cauchy data.

Theorem 1549.15 (Cauchy finite-window modulus pullback)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *modulus read pulls back to the same finite* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row of chapter 291, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any consumer can inspect a Cauchy value. In the notation of Definition 3413.1, the pullback route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No quotient stream equality, selected limit, host real equality, countable-choice coordinate, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row is available along this route.*

Proof. Project the accepted carrier through Definition 3413.1. The finite stream window S, dyadic tolerance row D, modulus row M, compatibility row Q, regular-rational readback R, and terminal Real seal E are the only rows available before the structural rows are read.

Apply Definition 3413.2. It identifies the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ surface with stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility, Real seal ordering, transport, replay, provenance, and local naming.

Now use Definition 3413.3. A precision request first reads S, D, M, Q, then reaches R, and only then reaches E. The route is sharpened by Definition 3413.4, which keeps the $\mathsf{RegSeqRat}^{\uparrow}$ row behind the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, modulus, and compatibility rows.

Finally apply Definition 3413.9. The terminal Real seal is reached only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback has been displayed. Thus every accepted modulus read pulls back to the same four L10 sibling rows before a consumer sees a Cauchy value, and none of the excluded quotient, selected-limit, choice, order, compactness, or completeness coordinates can be inserted. □

Theorem 1549.16 (Regular-Cauchy modulus pullback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of the* $\mathsf{Cauchy}^{\uparrow}$ *finite-window modulus route obtains a dyadic tolerance schedule that is cofinal with the route displayed in Definition 3413.15. In the notation of Definition 3413.1, the consumer may read*

$$S, D, M, Q \longmapsto R \longmapsto E$$

only as a regular-rational handoff: the $\mathsf{Real}^{\uparrow}$ *seal is reached after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, not before it. The route exports no quotient stream equality, selected limit, host real equality, choice principle, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 3413.15. It fixes the finite route from the StreamName window S, dyadic tolerance row D, modulus row M, and compatibility row Q into the regular-rational readback R, and only then into the terminal Real seal E.

Project the route at the $\mathsf{RegSeqRat}^{\uparrow}$ boundary. A RegSeqRat-facing consumer reads the dyadic tolerance row D through the same finite windows S and compatibility row Q, so its tolerance requests are bounded by a cofinal schedule already displayed by the Cauchy modulus route.

Transport the schedule through the regular-rational classifier row. The readback row R is the first row that presents the schedule as regular-rational data, and the Real seal E is reachable only after that readback has been displayed.

Thus the pullback is cofinal at the RegSeqRat surface and terminal at the Real seal. Since the carrier has no coordinate for quotient stream equality, selected limits, host equality, choice,

trichotomy, or Real completeness, none of those principles can be inserted into the consumer route. □

Theorem 1549.17 (Cauchy finite-window pullback uniqueness)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing Cauchy modulus consumer accepted by the* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the same finite route*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

displayed in Definition 3413.15. The consumer cannot replace this route by quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows visible to a modulus consumer are the finite StreamName window, dyadic tolerance ledger, modulus row, compatibility row, RegSeqRat readback, Real seal, and the structural rows.

Apply Definition 3413.2. It identifies the local NameCert surface with precisely those rows, so there is no second carrier coordinate from which an alternative Real-facing route could be read.

Use Definition 3413.3. A precision request reaches R only after S, D, M, Q have been displayed, and it reaches the terminal seal E only after the regular-rational readback has been displayed.

Finally apply Definition 3413.15 and Definition 3413.16. The first theorem fixes the finite pullback route to the L10 sibling rows, while the second shows that every RegSeqRat-facing consumer receives the same cofinal handoff. Hence any Real-facing Cauchy modulus consumer factors through the displayed route and gains no quotient, selected-limit, choice, host-equality, or completeness coordinate. □

Every completion-facing consumer of the $\mathsf{Cauchy}^{\uparrow}$ hub reads the finite Cauchy packet through chapter 301 and chapter 38 before any Real seal is exposed to completion rows. The route first displays the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the dyadic tolerance ledger, then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal, and only then lets Cauchy completion consumers inspect the same BHist, hsame, Cont, Pkg, and local NameCert rows. Thus the hub records a structural dependency route, not quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness.

Theorem 1549.18 (Cauchy RegSeqRat Real forward dependency)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *source-window read consumed by a Real-facing downstream chapter must pass through the regular rational readback of chapter 301 and the terminal real-name seal of chapter 38 before any* $\mathsf{Real}^{\uparrow}$*-facing seal is exposed. The route reads only displayed finite windows, regular rational tail data, componentwise transport, replay, provenance, and local naming; it exports no selected limit, quotient stream equality, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Cauchy carrier route in Definition 3413.1. Its source-window reads are displayed before the regular rational readback and terminal real seal rows are available.

Use the regular readback and real-seal routes already named by the Cauchy child files. They order downstream consumption through $\mathsf{RegSeqRat}^{\uparrow}$ and then $\mathsf{Real}^{\uparrow}$, with the structural rows transporting and naming the same finite windows.

Since the hub exposes only child-file surfaces and no independent carrier coordinate, a Real-facing consumer can cite $\mathsf{Cauchy}^{\uparrow}$ only through that forward dependency route. The read therefore reaches chapter 301 and chapter 38 before any Real-facing seal is exposed. □

Theorem 1549.19 (Cauchy located-uniform filter forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *route whose explicit modulus row is consumed by a located or uniform Cauchy filter completion must pass through the displayed carrier route*

$$S, D, M, Q, R, E, H, C, P, N$$

of Definition 3413.1, then through chapter 1661 or chapter 1694, before any $\mathsf{Real}^{\uparrow}$ *seal-facing completion row is exported. The forward route has no quotient stream equality, selected limit, countable choice, metric-completeness datum, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host equality.*

Proof. Start with the explicit modulus readback of the Cauchy carrier. By Definition 3413.3, a precision request reads the finite StreamName row S, the DyadicRatCore row D, the explicit modulus row M, and the compatibility row Q before it can inspect the regular rational row R.

Apply Definition 3413.9. The seal-facing row E is downstream of R, so a Real-facing completion consumer cannot bypass the regular rational readback.

Now use Definition 3413.11. Any uniform-modulus consumer of M that reaches a $\mathsf{Real}^{\uparrow}$ seal preserves the same ordering S, D, M, Q before R and R before E.

The remaining completion-neighbour branch is supplied only by the sibling chapters chapter 1661 and chapter 1694. These chapters consume the already displayed Cauchy route as located or uniform filter evidence; neither adds quotient stream equality, selected limits, choice, metric-completeness data, ambient completeness, or host equality to the core Cauchy carrier. □

Theorem 1549.20 (Cauchy route to CauchyCriterion)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *hub's finite route is consumed by chapter 392 through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route exports no detached completion carrier, quotient sequence equality, selected modulus outside the displayed rows, countable-choice schedule, or host completeness principle.*

Proof. Read the hub through its existing finite siblings. The $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows provide the only Cauchy data visible to downstream criteria.

The structural rows hsame, Cont, Pkg, and NameCert transport, replay, source, and name that same finite route. Therefore the Cauchy criterion consumer receives exactly the displayed BEDC rows and no external completion or choice object. □

Theorem 1549.21 (Cauchy hub Bishop completion forward route)**.** *The regular-source material routed by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by chapter 1639 through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The forward route exports no detached Cauchy representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness principle.*

Proof. Read the Cauchy hub through its regular-source children. Those children expose dyadic tolerance arithmetic, finite stream windows, regular rational readback, and the terminal real seal as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The Bishop regular Cauchy completion chapter consumes exactly that L10-facing route. Its completion read is mediated by the same finite BHist carrier discipline, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Since the hub route contains no detached representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness coordinate, the forward edge to the Bishop completion packet is precisely the displayed finite dependency route. □

Chapter 1550

A Concrete Naming Certificate for $\mathsf{IntegerRealEmbedding}^{\uparrow}$

Following Bishop and Bridges on integers as exact rational constants inside constructive real analysis, the $\mathsf{IntegerRealEmbedding}^{\uparrow}$ packet records the finite route by which an $\mathsf{Int}^{\uparrow}$ signed-pair row becomes a $\mathsf{Real}^{\uparrow}$ name. The route does not ask the real layer to forget the integer source: it passes first through the integer certificate of chapter 31, then the rational source surface of chapter 37, the rational-to-real route of chapter 1491, the stationary diagonal route of chapter 362, the constant stream surface of chapter 126, the regular-rational handoff of chapter 301, the dyadic tolerance row of chapter 291, and the terminal real seal of chapter 38.

Definition 1550.1 (IntegerRealEmbedding carrier)**.** *An* $\mathsf{IntegerRealEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (z, q, S, R, D, E, H, C, P, N)$$

with the following displayed coordinates:

1. z *is the* $\mathsf{Int}^{\uparrow}$ *signed-pair row naming the integer source;*
2. q *is the induced* $\mathsf{Rat}^{\uparrow}$ *row obtained by reading* z *as the rational constant* $z/1$*;*
3. S *is the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule whose admitted finite windows all read the same rational row* q*;*
4. R *is the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff obtained from the constant schedule* S*;*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and observation row used to compare the stationary rational reads at the displayed finite precisions;*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the rows* z, q, S, R, D *have been exposed;*
7. H *records componentwise* hsame *transports for the integer source, rational image, constant schedule, stationary readback, dyadic tolerance row, real seal, package provenance, and local naming row;*
8. C *records the visible* Cont *routes from* z *to* q*, from* q *to* S*, from* S *to* R*, from* R *to* D*, and from* D *to* E*;*
9. P *is the* Pkg *provenance over* $\mathsf{Int}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}$ *row.*

The carrier is finite data for integer constants as real names. It contains no quotient stream, no host integer equality oracle, no host real equality row, no selected limit, no trichotomy principle, and no ambient completeness coordinate.

Definition 1550.2 (IntegerRealEmbedding classifier)**.** *The* $\mathsf{IntegerRealEmbedding}^{\uparrow}$ *classifier compares two accepted carriers*

$$K = (z, q, S, R, D, E, H, C, P, N), \qquad K' = (z', q', S', R', D', E', H', C', P', N')$$

only through the displayed route rows. It first compares the $\mathsf{Int}^{\uparrow}$ *signed-pair sources* z, z' *by the integer classifier, then compares the induced* $\mathsf{Rat}^{\uparrow}$ *rows* q, q' *by the rational classifier, then compares the constant* $\mathsf{StreamName}^{\uparrow}$ *schedules, stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *handoffs, dyadic tolerance rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows through their visible* hsame *and* Cont *transports. The provenance rows* P, P' *and local certificate rows* N, N' *must name the same finite dependency surface.*

Theorem 1550.3 (IntegerRealEmbedding NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier: the finite packet of Definition 1550.1;*
2. *classifier: comparison through the* $\mathsf{Int}^{\uparrow}$ *source, the induced* $\mathsf{Rat}^{\uparrow}$ *row, the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule, the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and the* $\mathsf{Real}^{\uparrow}$ *seal;*
3. *stability: componentwise* hsame *transport preserves the integer source, rational image, constant schedule, stationary readback, dyadic observations, and real seal;*
4. *exactness/readback: every real-facing read factors through* z, q, S, R, D *before consulting* E*;*
5. *ledger: the* Pkg *and local* $\mathsf{NameCert}$ *rows expose only* $\mathsf{Int}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local certificate coordinates.*

No row of the surface is a quotient stream, host integer equality oracle, host real equality, trichotomy principle, selected limit, or ambient completeness principle.

Proof. Project the carrier of Definition 1550.1. Its visible coordinates already name the integer source, rational image, constant stream schedule, stationary regular-rational readback, dyadic observation row, real seal, transports, continuation routes, package provenance, and local certificate row.

The classifier row is fixed by Definition 1550.2. It never compares real names directly before the displayed integer-to-rational and rational-to-stationary route has been read.

Stability follows by transporting each listed coordinate through the stored hsame row and using the displayed Cont route for the corresponding handoff. Exactness is then forced because the only route to E is the route through z, q, S, R, D.

The ledger is exhausted by P and N. Since the carrier has no coordinate for quotient streams, host integer equality, host real equality, trichotomy, selected limits, or ambient completeness, none of those objects can be exported by the local certificate. □

Theorem 1550.4 (IntegerRealEmbedding stationary stream route)**.** *Every accepted* $\mathsf{IntegerRealEmbedding}^{\uparrow}$ *carrier routes its* $\mathsf{Int}^{\uparrow}$ *source row* z *through the induced rational row* q *and the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *before any regular-rational or real-facing coordinate is available. Every admitted stream window therefore reads the same rational constant induced by* z*.*

Proof. Read the continuation coordinates of the carrier. The first displayed handoff is z to q, and the next displayed handoff is q to the constant schedule S.

The schedule S has no independent stream seed. Each admitted finite window is generated from the same rational row q, so the stream route is stationary at the rational constant induced by the integer source.

Only after this constant schedule is displayed can the packet expose the regular-rational handoff R and the later real-facing rows. Thus every consumer that reaches those later rows has already passed through z, q, S. □

Theorem 1550.5 (IntegerRealEmbedding RegSeqRat handoff)**.** *For every accepted* $\mathsf{IntegerRealEmbedding}^{\uparrow}$ *carrier* $K = (z, q, S, R, D, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is the stationary regular-rational readback of the constant stream schedule* S*. The dyadic tolerance row* D *can inspect only finite precision reads of that stationary row before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is opened.*

Proof. Apply Definition 1550.4. It identifies every admitted stream window of S with the same rational row q obtained from z.

The handoff coordinate R is reached from S by the displayed continuation route and has no independent sequence source. Its readback is therefore stationary at the same rational row.

The dyadic row D is downstream from R in the carrier. It records only the finite tolerance and observation data attached to that stationary readback, so it cannot inspect an unrelated regular sequence before the real seal is reached. □

Theorem 1550.6 (IntegerRealEmbedding RealUp seal nonescape)**.** *For every accepted* $\mathsf{IntegerRealEmbedding}^{\uparrow}$ *carrier* $K = (z, q, S, R, D, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the displayed dependency chain*

$$\mathsf{Int}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}.$$

The seal exports only the local rows $z, q, S, R, D, H, C, P, N$ *as boundary data. It does not export quotient-stream equality, host integer equality, host real equality, trichotomy, selected limits, or ambient completeness.*

Proof. Start with a read of the real seal E. By the carrier definition, E is reachable only through the displayed predecessor D, whose predecessor is R, whose predecessor is S, whose predecessor is q, whose source is z.

Use Definition 1550.5. It shows that the regular-rational row and dyadic observation row are attached to the stationary constant readback induced by the integer source.

The remaining rows H, C, P, N provide transport, continuation, provenance, and local naming for the same finite route. Since the carrier contains no coordinate for quotient-stream equality, host integer equality, host real equality, trichotomy, selected limits, or ambient completeness, the real seal cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}$.

Constructive story: An $\mathsf{IntegerRealEmbedding}^{\uparrow}$ packet is generated from an IntUp signed-pair source row, induced RatUp constant row, constant StreamName schedule, stationary RegSeqRat handoff, DyadicRatCore tolerance row, RealUp seal, componentwise transports, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 1550.1, Definition 1550.2, Definition 1550.3, Definition 1550.4, Definition 1550.5, and Definition 1550.6 seed the finite integer-constant route from $\mathsf{Int}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntegerRealEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient-stream equality, host integer equality, trichotomy, selected limits, ambient completeness, or a checked Lean certificate.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, stationary StreamName routing, RegSeqRat handoff, DyadicRatCore observation exactness, RealUp seal factorization, and nonescape.

Chapter 1551

A Concrete Naming Certificate for $\mathsf{IsometryExtension}^{\uparrow}$

Following Bishop and Bridges constructive completion and the standard extension theorem for isometries on dense subspaces, the $\mathsf{IsometryExtension}^{\uparrow}$ packet records the finite BEDC surface by which a dense isometric embedding extends across an L10 completion route. It sits after the dense completion entry of chapter 1512, the displayed distance-reflection route of chapter 439, the extension-and-uniqueness surface of chapter 397, and the unit boundary of chapter 1527. The packet also fixes the finite name route through chapter 126, chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38; it is a named obligation surface, not a quotient-completion construction.

Definition 1551.1 (IsometryExtension carrier)**.** *An* $\mathsf{IsometryExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, J, I, U, W, R, S, A, L, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row together with the dense source reads admitted by the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *packet.*
2. *Y is the target completion-facing metric row whose target reads are reached through displayed completion evidence.*
3. *J is the dense completion embedding row, read through* $\mathsf{CompletionEmbedding}^{\uparrow}$ *rather than through a host inclusion map.*
4. *I is the distance-preserving graph row supplied by* $\mathsf{IsometricEmbedding}^{\uparrow}$*.*
5. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension-and-uniqueness row attached to the same dense source and target route.*
6. *W is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *unit row that admits source points into the completion-facing surface.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row used by the source completion read.*
8. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row used to inspect the displayed regular Cauchy name.*
9. *A is the* $\mathsf{Real}^{\uparrow}$ *distance and seal row reached after the stream-window and regular-rational rows have been read.*

10. *L records componentwise* hsame *transport for the source, target, dense embedding, isometry, universal-property, unit, stream, regular-rational, and real-seal rows.*
11. *C records displayed* Cont *replay through $X, Y, J, I, U, W, R, S, A, L$.*
12. *P is the* Pkg *provenance over* CompletionEmbedding$^{\uparrow}$, IsometricEmbedding$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\mathsf{IsometryExtension}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, or completeness of Real$^{\uparrow}$.

Theorem 1551.2 (IsometryExtension NameCert obligations)**.** *For an accepted* IsometryExtension$^{\uparrow}$ *carrier $E = (X, Y, J, I, U, W, R, S, A, L, C, P, N)$, the local* NameCert$_{\mathsf{IsometryExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source, target, dense embedding, isometry, universal-property, unit, stream-window, regular-rational, real-seal, transport, continuation, provenance, and local naming rows;*
2. *dense-source compatibility, requiring every extension read to enter through J and the unit row W before any target completion-facing row is consumed;*
3. *isometric distance preservation, requiring each source-distance read to pass through I and then through the* Real$^{\uparrow}$ *row A;*
4. *universal-property extension, requiring the extension candidate and its uniqueness ledger to be read only through U over the same dense isometric route;*
5. *finite-name handoff, requiring stream windows S and regular rational names R to be displayed before the real-seal row A is consumed;*
6. *ledger non-escape, stating that L, C, P, N expose no quotient completion equality, selected representatives, countable choice, open-cover compactness, or completeness of* Real$^{\uparrow}$.

Proof. Carrier admission is projection from Definition 1551.1. The tuple lists exactly the source and target rows, dense embedding row, isometry row, universal-property row, unit row, finite-name rows, real-seal row, and structural BEDC rows available to the certificate.

Dense-source compatibility is read from J and W. The completion embedding supplies the dense source image, and the unit row is the only admission route from a displayed source point into the completion-facing surface.

Distance preservation is then forced by I and A. The isometry row records the distance-reflection route, while the real-seal row records the terminal distance observation after the source stream and regular-rational names have been displayed.

The universal-property obligation is local to U. Since U is attached to the same J, I, W, R, S, A route, extension existence and uniqueness can be read only as a ledger over those displayed rows.

Finally inspect L, C, P, N. Transport is componentwise, replay follows the displayed route, and provenance names only the listed sibling packets. Hence the excluded quotient, representative-choice, countability, compactness, and real-completeness principles have no row from which a consumer could read them. □

Theorem 1551.3 (IsometryExtension completion handoff)**.** *Every completion-facing consumer of an accepted* IsometryExtension$^{\uparrow}$ *carrier factors through the displayed route*

$$X, J, W \longmapsto R, S \longmapsto I, A \longmapsto U \longmapsto Y.$$

Thus the extension reaches the target completion-facing row only after the dense completion embedding, unit admission, finite stream and regular-rational name rows, real-distance seal, and universal-property extension ledger have been replayed inside the same packet.

Proof. Begin with the source side. The source metric row X reaches a completion-facing read only through the dense embedding row J and the unit row W, so no detached source completion point is exposed.

Next read the finite name route. The regular rational row R and stream-window row S display the source Cauchy evidence before any real-distance seal is available.

Apply the isometry route through I and A. The distance-preserving graph transports the displayed source evidence to the target side, and the real-seal row records the resulting distance observation.

The universal-property row U then supplies the extension and uniqueness ledger for the same dense isometric route. Only after this ledger is displayed can a consumer read the target row Y as the completion-facing endpoint of the extension.

The structural rows L, C, P, N preserve the same ordered route and add no quotient completion equality, selected representative, countable-choice schedule, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$. □

Theorem 1551.4 (IsometryExtension Real seal boundary)**.** *For every accepted* $\mathsf{IsometryExtension}^{\uparrow}$ *carrier* $E = (X, Y, J, I, U, W, R, S, A, L, C, P, N)$*, each* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by the extension is determined by the displayed chain*

$$J, W, R, S, I, A, U.$$

The seal cannot be read as a quotient-completion equality, a selected representative, a countable-choice selection, an open-cover compactness witness, or a proof of completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier and isolate the real-seal coordinate A. It appears only after the dense embedding row J, unit row W, regular-rational row R, stream-window row S, and isometry row I have been displayed.

Use the completion handoff of Definition 1551.3. Any completion-facing consumer reaches the target side by replaying the same J, W, R, S, I, A, U route before reading Y.

The universal-property row U keeps the extension ledger attached to that real-seal route. A second seal, a selected representative, or a quotient equality would require a carrier coordinate outside the displayed chain.

No such coordinate exists in E. Transport, continuation, provenance, and local naming preserve the listed rows componentwise, so every $\mathsf{Real}^{\uparrow}$ read remains bounded by $J, W, R, S, I, A, U, L, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{IsometryExtension}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IsometryExtension}^{\uparrow}$ packet is generated from source and target metric rows, a CompletionEmbedding row, an IsometricEmbedding row, a CompletionUniversalProperty row, a CauchyCompletionUnit row, StreamName and RegSeqRat finite-name rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IsometryExtension}^{\uparrow}}$, seed)

Scope closed: Definition 1551.1, Definition 1551.2, Definition 1551.3, and Definition 1551.4 seed the finite isometry-extension surface for L10 completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IsometryExtension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-source compatibility, isometric distance preservation, universal-property extension, finite-name handoff, Real-seal boundary, and ledger non-escape for BEDC.Derived.IsometryExtensionUp.

Chapter 1552

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySubsequenceCriterion}^{\uparrow}$ packet records the finite route by which a displayed source sequence is accepted as having a Cauchy subsequence before any completion-facing consumer reads it. It sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the inspected fast-subsequence route of chapter 1518, the monotone-cofinal regular-subsequence surface of chapter 381, and the terminal real-name boundary of chapter 38. The packet is a finite criterion surface for downstream Bolzano–Weierstrass and completion consumers; it does not select an infinite subsequence by choice, identify quotient streams, compare host real equalities, or assert completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1552.1 (CauchySubsequenceCriterion carrier)**.** *A* $\mathsf{CauchySubsequenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, W, Q, D, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row whose finite* $\mathsf{StreamName}^{\uparrow}$ *windows are inspected before any subsequence is accepted;*
2. *T is the monotone subsequence schedule, recorded as a finite unary reindexing ledger with visible order and later-index comparisons on inspected indices;*
3. *W records the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows before and after applying the displayed schedule T;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and no independent rational stream;*
5. *D is the dyadic tolerance ledger tying the selected windows to the requested Cauchy radii and pointwise comparison rows;*
6. *F is the* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *witness that the selected windows satisfy the displayed fast-Cauchy bounds;*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row that repacks the same schedule, windows, dyadic tolerance ledger, and regular-rational readback for downstream consumers;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after Q, F, R and the tolerance ledger have been displayed;*

9. *H records componentwise* hsame *transport for the source row, schedule, window rows, regular-rational readback, dyadic ledger, fast witness, regular-subsequence handoff, real seal, and support rows;*

10. *C records displayed* Cont *replay from source inspection through schedule selection, finite windows, tolerance ledger, fast-Cauchy witness, regular-rational readback, regular-subsequence handoff, and real-seal delivery;*

11. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FastCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceCriterion}^{\uparrow}}$ *row.*

The carrier stores no selected infinite subsequence object, arbitrary choice functional, quotient stream, host real equality, independent real carrier, or completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 1552.2 (CauchySubsequenceCriterion NameCert obligations)**.** *For an accepted* CauchySubsequenceCrite *carrier $K = (S, T, W, Q, D, F, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source row, monotone schedule, inspected window rows, regular-rational readback, dyadic tolerance ledger, fast-Cauchy witness, regular-subsequence handoff, real seal, transport, replay, provenance, and local naming row;*

2. *schedule monotonicity for T, requiring each displayed later index to be read from the finite unary order ledger rather than from a host-level selector;*

3. *window transport, requiring every selected* $\mathsf{StreamName}^{\uparrow}$ *window in W to be transported from an inspected source window along T;*

4. *fast-Cauchy handoff, requiring the witness F to consume exactly the transported windows and dyadic tolerance rows displayed by W and D;*

5. *regular-rational readback, requiring Q to be obtained from the same selected windows and not from an independent rational sequence;*

6. *Real seal non-escape, requiring E to be reached only through the displayed fast witness, regular-rational readback, and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff;*

7. *ledger exactness for D, H, C, P, N, requiring dyadic tolerance, transport, replay, package provenance, and local naming to mention only the rows of the carrier.*

No obligation row exports a selected infinite subsequence, arbitrary choice functional, quotient stream, host real equality, independent real carrier, or completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier. The tuple displays exactly the source row, monotone schedule, inspected windows, regular-rational readback, dyadic tolerance ledger, fast witness, regular-subsequence handoff, real seal, componentwise transport, continuation replay, package provenance, and local naming row.

Read the schedule and window rows first. The row T supplies only finite monotone later-index comparisons, and W records only the source and selected windows transported along that ledger. Thus the criterion has no coordinate from which an arbitrary subsequence selector could be read.

Use the analytic handoff rows next. The row D records the dyadic tolerances, F verifies the fast-Cauchy subsequence route over those same rows, Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and R repacks the displayed data as a $\mathsf{RegularCauchySubsequence}^{\uparrow}$ consumer surface.

Finally the real seal and structural rows preserve the same dependency order. The row E sits downstream of Q, F, R and D, while H, C, P, N transport, replay, source, and name only the displayed coordinates. Since the carrier is exhausted by $S, T, W, Q, D, F, R, E, H, C, P, N$, the excluded choice, quotient, host-equality, independent-real, and completeness data have no row. □

Theorem 1552.3 (CauchySubsequenceCriterion fast-subsequence handoff)**.** *Every accepted* CauchySubsequenceCri *packet hands any downstream* BolzanoWeierstrass$^{\uparrow}$, Real$^{\uparrow}$, *or completion-facing consumer only the displayed subsequence schedule, finite windows, dyadic tolerance rows, fast-Cauchy witness,* RegSeqRat$^{\uparrow}$ *handoff,* RegularCauchySubsequence$^{\uparrow}$ *route, and real seal. In the notation of Definition 1552.1, every such read factors through*

$$S, T, W, D, F, Q, R, E, H, C, P, N.$$

The consumer receives no selected infinite subsequence, arbitrary choice functional, quotient stream, host real equality, independent real carrier, or Real$^{\uparrow}$ *completeness principle.*

Proof. Start with a downstream read of an accepted criterion packet. The only exposed source of subsequence data is the schedule row T together with the selected window row W.

The dyadic tolerance ledger D is read before the fast witness F, so the Cauchy assertion is witnessed by finite radius and comparison rows. The readback row Q and the regular-subsequence row R consume the same selected windows, preventing any independent rational stream or separate subsequence route from entering the handoff.

The real seal E is reached only after those rows have been displayed. Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite route for equivalent packets.

No other coordinate exists in the carrier. Hence every Bolzano–Weierstrass, real-name, or completion-facing consumer receives exactly the displayed finite subsequence criterion package and cannot read a selected infinite subsequence, choice functional, quotient stream, host real equality, independent real carrier, or completeness field. □

Closure status for NameCert$_{\text{CauchySubsequenceCriterion}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchySubsequenceCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 1552.1, Definition 1552.2, and Definition 1552.3 seed the finite criterion route from inspected source windows to fast subsequence evidence, regular rational readback, regular-subsequence handoff, and the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{CauchySubsequenceCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, arbitrary choice, quotient streams, host real equality, independent real carriers, Real$^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Formal closure requires checked carrier admission, schedule monotonicity, window transport, fast-Cauchy handoff, regular-rational readback, Real seal non-escape, and ledger exactness for BEDC.Derived.CauchySubsequenceCriterionUp.

Constructive story: A CauchySubsequenceCriterion$^{\uparrow}$ packet is generated from a source sequence row, a monotone finite subsequence schedule, inspected StreamName windows, RegSeqRat readback, dyadic tolerance rows, a FastCauchySubsequence witness, a RegularCauchySubsequence handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1553

A Concrete Naming Certificate for $\mathsf{Liminf}^{\uparrow}$

Following Hardy and Bishop–Bridges, $\mathsf{Liminf}^{\uparrow}$ records the finite tail-lower-cut companion to the tail-upper-cut surface of chapter 768. The packet consumes the bounded sequence rows of chapter 1415, the lower-cut observation discipline of chapter 1440, the upper-cut comparison discipline of **??**, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It gives Real-and-Completion consumers a finite lower-tail boundary for bounded real sequences without importing Real completeness, trichotomy, a host infimum, quotient stream equality, selected subsequences, or open-cover compactness.

The lower-tail rows are consumed together with the bounded upper-envelope data of chapter 7101 in Real sequence oscillation packets. In that route, tail-cut lower envelope rows from $\mathsf{Liminf}^{\uparrow}$ pair with bounded upper envelope rows from $\mathsf{BoundedRealLimsup}^{\uparrow}$ before any gap-width or zero-gap convergence certificate is exported.

Definition 1553.1 (Liminf carrier)**.** *A* $\mathsf{Liminf}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, L, D, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row whose finite windows, bound ledger, and displayed* $\mathsf{Real}^{\uparrow}$ *entries are being inspected.*
2. *L is the tail lower-cut schedule, recording for each displayed tail index the bounded lower-cut observations read through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*.*
3. *D is the dyadic tolerance ledger, recording the finite rational tolerances used to compare tail lower cuts with the upper observation surface.*
4. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row named as the liminf candidate exposed by the packet.*
5. *H records componentwise* hsame *transports for S, L, D, T and the structural rows.*
6. *C records the displayed* Cont *routes by which consumers replay the bounded sequence row, tail lower-cut schedule, dyadic tolerance ledger, terminal real seal, transports, provenance, and local naming row.*
7. *P is the* Pkg *provenance over* $\mathsf{Liminf}^{\uparrow}$*,* $\mathsf{BoundedRealSequence}^{\uparrow}$*,* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*,* $\mathsf{BoundedRealUpperCut}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Liminf}^{\uparrow}}$ *row.*

The carrier stores a finite lower-tail cut surface for a bounded real sequence. It has no coordinate for Real completeness, trichotomy, a host infimum, quotient stream equality, selected subsequences, or open-cover compactness.

Lean4 (definition) `BEDC.Derived.LiminfUp.LiminfCarrier`

Lemma 1553.2 (Liminf carrier route rows)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *carrier of Definition 1553.1 projects the three route rows*

$$\mathsf{Cont}(S, L, D), \qquad \mathsf{Cont}(D, T, C), \qquad \mathsf{Pkg}^{\mathrm{sig}}(B, P, \mathsf{pkg}),$$

namely bounded-sequence to lower-cut to dyadic replay, dyadic to terminal-real to continuation replay, and bundle provenance through the displayed package row.

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfCarrier route rows`

Proof. Project the displayed carrier rows of Definition 1553.1. The route coordinate C contains the bounded sequence, lower-cut, dyadic, terminal, and replay continuations, while the provenance row P supplies the package signature.

Thus the accepted carrier exposes exactly the two Cont rows and the $\mathsf{Pkg}^{\mathrm{sig}}$ provenance row named above, without adding a lower-envelope theorem or a host infimum. □

Definition 1553.3 (Liminf classifier)**.** *Two* $\mathsf{Liminf}^{\uparrow}$ *carriers*

$$I = (S, L, D, T, H, C, P, N) \qquad \text{and} \qquad I' = (S', L', D', T', H', C', P', N')$$

are classified as the same displayed liminf packet exactly when the bounded sequence rows match componentwise, the tail lower-cut schedules expose the same finite tail observations, the dyadic tolerance ledgers carry the same rational comparison budgets, the terminal $\mathsf{Real}^{\uparrow}$ *seals are transported by the displayed* hsame *data, the continuation replays preserve the same consumer routes, and the provenance and local NameCert rows name the same* $\mathsf{Liminf}^{\uparrow}$ *surface. The classifier is therefore rowwise over* S, L, D, T, H, C, P, N *and does not identify carriers by host sequence equality, quotient streams, selected cofinal subsequences, or a completed infimum construction.*

Lean4 (definition) `BEDC.Derived.LiminfUp.LiminfClassifier`

Theorem 1553.4 (Liminf NameCert obligations)**.** *For an accepted* $\mathsf{Liminf}^{\uparrow}$ *carrier* $I = (S, L, D, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Liminf}^{\uparrow}}$ *surface consists of six finite obligation rows:*

1. *carrier formation for the bounded real sequence row, tail lower-cut schedule, dyadic tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transports, continuations, provenance, and local naming data;*
2. *classifier stability for the componentwise comparison of Definition 1553.3;*
3. *lower-tail exactness, stating that every lower observation in* L *is read from a finite tail of* S *through the bounded lower-cut surface;*
4. *upper-cut compatibility, stating that every tolerance row in* D *compares the same tail data against the bounded upper-cut observation surface;*
5. *terminal seal routing, stating that the candidate row* T *is consumed only as a* $\mathsf{Real}^{\uparrow}$ *seal after the displayed tail-cut checks have been replayed;*
6. *ledger non-escape, excluding Real completeness, trichotomy, host infimum selection, quotient stream equality, selected subsequences, and open-cover compactness.*

Proof. Carrier formation is projection from Definition 1553.1. The packet displays exactly the bounded sequence row, tail lower-cut schedule, dyadic tolerance ledger, terminal real seal, componentwise transports, continuation routes, provenance, and local name.

Classifier stability is the componentwise comparison of Definition 1553.3. Transport along H may replace the visible rows only by rows with the same scheduled tail observations, the same dyadic budgets, and the same terminal seal route, while C preserves the consumer replay order.

Lower-tail exactness is supplied by L together with the bounded sequence row S. Each accepted lower observation names the finite tail index, the inspected sequence windows, and the bounded lower-cut certificate through which the read is made.

Upper-cut compatibility is supplied by D and the sibling bounded upper-cut discipline. The tolerance ledger records only finite dyadic comparisons between the same tail data and the upper observation surface, so it does not become a host supremum or a completeness witness.

Terminal seal routing is the role of T. A consumer may read the candidate liminf only after the sequence tail, lower-cut, upper-cut, and tolerance rows have been replayed; the terminal coordinate remains a $\mathsf{Real}^{\uparrow}$ seal rather than a completed infimum object.

The non-escape row follows from the carrier inventory. No displayed field carries Real completeness, trichotomy, a host infimum, quotient stream equality, selected subsequences, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfNameCertObligations`

Theorem 1553.5 (Liminf tail-cut route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto L \longmapsto D \longmapsto T \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before using the displayed liminf surface.

Proof. Begin with the bounded sequence row S. It supplies the only displayed source of sequence entries, finite windows, and boundedness evidence available to the packet.

The tail lower-cut schedule L then names which tails and lower observations are inspected. The dyadic ledger D records the tolerance comparisons that align those tail-lower observations with the bounded upper-cut surface.

Only after those rows are replayed can a consumer inspect the terminal real seal T. The structural rows H, C, P, N then transport, replay, source, and name the same finite route, so the consumer cannot bypass the tail-cut surface by reading a host infimum or a selected subsequence. □

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfTailCutRoute`

Theorem 1553.6 (Liminf tail lower-envelope compatibility)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *packet*

$$I = (S, L, D, T, H, C, P, N)$$

whose bounded sequence row S is paired with the bounded upper-envelope surface of $\mathsf{BoundedRealLimsup}^{\uparrow}$ *factors its lower-tail schedule through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *and its dyadic tolerance ledger through* $\mathsf{BoundedRealUpperCut}^{\uparrow}$ *before any gap-width or zero-gap convergence consumer reads the terminal* $\mathsf{Real}^{\uparrow}$ *seal T.*

Proof. Project the accepted carrier into its displayed rows S, L, D, T, H, C, P, N. The row S is the bounded sequence source described in Definition 1553.1, and the paired upper-envelope data is read through the sibling $\mathsf{BoundedRealLimsup}^{\uparrow}$ chapter rather than through an ambient supremum.

Apply the tail-cut route of Definition 1553.5. That route forces every consumer to replay S before L, and L is exactly the finite lower-tail schedule whose observations are certified by the bounded lower-cut chapter. Thus the lower-envelope half of the paired liminf–limsup surface reaches the consumer only through $\mathsf{BoundedRealLowerCut}^{\uparrow}$.

The dyadic tolerance row D is then replayed before the terminal seal T. By the upper-cut compatibility row in Definition 1553.4, those tolerances compare the same tail data against the bounded upper-cut surface, so the upper comparison half factors through $\mathsf{BoundedRealUpperCut}^{\uparrow}$.

The structural rows H, C, P, N only transport, replay, source, and name this ordered route. Hence a later gap-width or zero-gap convergence certificate can read T only after the bounded sequence row, lower-cut schedule, upper-cut tolerance ledger, and limsup sibling surface have all been exposed as finite certificate data. □

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfTailLowerEnvelopeCompatibility`

Theorem 1553.7 (Liminf RegSeqRat lower-cut public export)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or Real-and-Completion consumer of an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet receives the lower-envelope claim only after the displayed route exposes the bounded sequence row* S*, the* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *tail schedule* L*, the* $\mathsf{BoundedRealUpperCut}^{\uparrow}$ *tolerance comparison through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*. The public export is the finite packet*

$$S, L, D, T, H, C, P, N$$

read through BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it does not export a host infimum, selected tail subsequence, quotient stream equality, trichotomy decision, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfRegSeqRatLowerCutPublicExport`

Proof. Project the accepted carrier of Definition 1553.1. Its public read surface is exactly the row family S, L, D, T, H, C, P, N, where S is the bounded sequence source, L is the finite lower-tail schedule, D is the dyadic tolerance ledger, and T is the terminal Real seal.

Apply the route theorem Definition 1553.5. It orders every consumer read through S, L, D, T before the structural rows H, C, P, N can transport, replay, source, and name the packet.

Use the lower-envelope compatibility theorem, Definition 1553.6. It identifies the lower side with $\mathsf{BoundedRealLowerCut}^{\uparrow}$ and the comparison side with $\mathsf{BoundedRealUpperCut}^{\uparrow}$ through the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before any Real-and-Completion consumer may inspect T.

The export is therefore public only as a finite RegSeqRat-facing handoff. Since no carrier row stores a host infimum, selected subsequence, quotient stream equality, trichotomy decision, open-cover compactness, or ambient completeness principle, the lower-envelope claim cannot be strengthened beyond those displayed rows. □

Theorem 1553.8 (Liminf tail-envelope monotone refinement)**.** *Let an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet* $I = (S, L, D, T, H, C, P, N)$ *be paired with bounded upper-envelope data from* $\mathsf{BoundedRealLimsup}^{\uparrow}$*. If the displayed tail schedule* L *is refined by a later monotone tail schedule while preserving the same bounded sequence row* S*, lower-cut route through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*, upper-cut tolerance ledger* D*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*, then every gap-width or zero-gap convergence consumer reads the refined packet through the same bounded-sequence, lower-envelope, upper-tolerance, and terminal-seal route.*

Proof. Project the carrier and classifier. The bounded sequence row S is unchanged, and the classifier of Definition 1553.3 permits only rowwise comparison of the displayed tail schedule, dyadic ledger, terminal seal, replay, provenance, and local name.

Refine the tail schedule monotonically. The new lower observations remain lower-cut reads through $\mathsf{BoundedRealLowerCut}^{\uparrow}$, and the tolerance row D still compares the same bounded-sequence data against the upper-cut surface before the terminal seal is visible.

Apply the lower-envelope compatibility theorem above. It already forces every liminf–limsup consumer to expose S, L, D, T in that order, with the bounded upper-envelope surface present before any gap-width or zero-gap convergence certificate can inspect T.

The structural rows H, C, P, N transport, replay, source, and name the refined route. Since the refinement changes only the displayed tail schedule and preserves the bounded sequence row, lower-cut route, upper-cut tolerance ledger, and terminal Real seal, no zero-gap consumer can bypass the finite envelope or read a host infimum, selected subsequence, quotient stream equality, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfTailEnvelopeMonotoneRefinement`

Theorem 1553.9 (Liminf–limsup zero-gap convergence)**.** *Let an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet*

$$I = (S, L, D, T, H, C, P, N)$$

be paired with an accepted $\mathsf{BoundedRealLimsup}^{\uparrow}$ *packet whose bounded sequence row is the same displayed S, whose tail schedule is the same displayed L, and whose gap-width ledger is displayed as zero along the same dyadic tolerance row D. Then every convergence consumer that treats the lower and upper envelopes as coincident must first read the terminal* $\mathsf{Real}^{\uparrow}$ *seal through the shared route*

$$S, L, D, T, H, C, P, N$$

before exporting the convergence result.

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfLimsupZeroGapConvergence`

Proof. Start with the lower envelope. Theorem 1553.6 forces the $\mathsf{Liminf}^{\uparrow}$ half of the pair to expose the bounded sequence row S, the lower-tail schedule L, and the dyadic tolerance row D before the terminal seal T can be consumed.

Next use the monotone refinement theorem, Definition 1553.8. It keeps later tail reads on the same bounded-sequence, lower-envelope, upper-tolerance, and terminal-seal route whenever the displayed schedule is refined without changing S, D, T.

Now attach the sibling $\mathsf{BoundedRealLimsup}^{\uparrow}$ packet. Its upper-envelope surface is paired with the same S, the same tail schedule L, and the same zero gap-width ledger over D, so a convergence consumer has no separate upper route from which to read a different terminal value.

Therefore the zero-gap read can only identify the two envelope surfaces after the common route S, L, D, T, H, C, P, N has been displayed. The packet exports no Real completeness principle, trichotomy, selected subsequence, quotient stream equality, host infimum, or host supremum as a substitute for that finite route. □

Theorem 1553.10 (Liminf tail lower-upper gap width)**.** *Let an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet*

$$I = (S, L, D, T, H, C, P, N)$$

be paired with a $\mathsf{BoundedRealLimsup}^{\uparrow}$ *upper-envelope packet over the same bounded sequence row* S*. Any zero-gap or convergence-facing read from the pair is exposed only after the shared bounded sequence row* S*, lower-cut schedule* L*, upper-cut comparison surface, dyadic tolerance ledger* D*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*, and structural rows* H, C, P, N *have been displayed. The resulting gap-width handoff is a finite dyadic envelope route, not a Real completeness principle, host infimum or supremum, selected subsequence, or quotient stream equality.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfTailLowerUpperGapWidth`

Proof. Start with lower-tail compatibility, Definition 1553.6. It forces the $\mathsf{Liminf}^{\uparrow}$ half of the pair to expose S, L, D, T before any lower-envelope consumer can inspect the terminal seal.

Next apply monotone refinement, Definition 1553.8. It keeps later tail reads on the same bounded-sequence, lower-cut, upper-comparison, dyadic-tolerance, and terminal-seal route whenever the schedule is refined without changing S, D, T.

Finally use zero-gap convergence, Definition 1553.9. Once the $\mathsf{BoundedRealLimsup}^{\uparrow}$ packet is paired with the same S and dyadic tolerance row D, a convergence-facing read can only pass through the shared finite gap-width route.

The structural rows H, C, P, N transport, replay, source, and name that route. Since the proof uses only the displayed lower envelope, upper comparison surface, dyadic ledger, and Real seal, it introduces no Real completeness, host infimum, host supremum, selected subsequence, or quotient stream equality. □

Theorem 1553.11 (Liminf Real seal non-escape)**.** *An accepted* $\mathsf{Liminf}^{\uparrow}$ *packet exposes its candidate value only as the terminal* $\mathsf{Real}^{\uparrow}$ *row* T *reached through the displayed tail-cut route. In particular, it does not export Real completeness, trichotomy, a host infimum, quotient stream equality, selected subsequences, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfRealSealNonescape`

Proof. The only value-facing coordinate in the carrier is T. All sequence-facing information is confined to S, L, D, and all structural access is confined to H, C, P, N.

A consumer that asks for the candidate value must therefore follow the continuation replay from the bounded sequence row through the tail lower-cut and tolerance ledgers before reaching T. The replay exposes a sealed real name, not a construction by infimum, compactness, or subsequence selection.

Since no carrier field stores the excluded principles, componentwise transport and continuation replay cannot introduce them. The $\mathsf{Real}^{\uparrow}$ seal remains terminal for the packet, and the liminf surface remains a finite tail-cut certificate. □

Theorem 1553.12 (Liminf tail-infimum obligation route)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *obligation read must expose the rows*

$$S, L, D, T, H, C, P, N$$

before any tail-infimum consumer can read the packet. The source row S*, tail lower-cut schedule* L*, dyadic tolerance ledger* D*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *are therefore the whole tail-infimum surface visible to the consumer.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfObligationTailInfimumRoute`

Proof. Project the accepted carrier of Definition 1553.1. Its tuple already orders the bounded sequence source, lower-tail schedule, dyadic ledger, terminal seal, transport, replay, provenance, and local naming rows.

Apply the route theorem Definition 1553.5. It forces every Real-and-Completion consumer to replay S, L, D, T, H, C, P, N before using the displayed liminf surface.

A tail-infimum consumer is such a value-facing consumer, so it receives no additional row. The read is exhausted by the displayed carrier route and cannot bypass it through a host infimum or selected subsequence. □

Theorem 1553.13 (Liminf bounded-cut compatibility obligation)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *obligation read that compares lower-cut and upper-cut data must use the same bounded sequence row* S *and the same dyadic tolerance ledger* D*. The lower-cut observations in* L *and the upper-cut comparison surface are compatible only as finite reads from that shared bounded sequence and shared tolerance ledger before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T *is consumed.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfBoundedCutCompatibilityObligation`

Proof. Read the carrier rows S, L, D, T, H, C, P, N. The row S is the only bounded sequence source, and D is the only displayed tolerance ledger available to comparisons.

Use Definition 1553.4. Its lower-tail exactness row routes lower observations through the finite tail data of S, while its upper-cut compatibility row uses D to compare that same tail data against the bounded upper-cut surface.

The structural rows H, C, P, N preserve this common source and tolerance ledger under transport, replay, provenance, and local naming. Thus a consumer cannot pair the lower cut with a different bounded sequence, a different dyadic budget, a host supremum, or ambient completeness data. □

Theorem 1553.14 (Liminf Real-seal exhaustion obligation)**.** *Every value-facing read of an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet ends at the displayed* $\mathsf{Real}^{\uparrow}$ *seal* T*. It cannot expose a host infimum, selected subsequence, trichotomy, quotient stream equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness beyond the finite route* S, L, D, T, H, C, P, N*.*

Proof. Start from Definition 1553.11. The theorem identifies T as the only value-facing coordinate and places it after the bounded sequence, lower-cut, and tolerance rows.

The obligation route of Definition 1553.12 gives the complete list of rows a value-facing consumer may read. The bounded-cut compatibility obligation keeps lower-cut and upper-cut reads on the same S, D route before T is reached.

No carrier row remains after T except the structural transport, replay, provenance, and local naming rows already listed. Hence the displayed Real seal exhausts the value-facing surface and the excluded host principles are not exported by the packet. □

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfRealSealExhaustionObligation`

Theorem 1553.15 (Liminf lower-cut readback scope)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *lower-tail read must expose the bounded sequence source* S*, the finite lower-cut schedule* L*, the dyadic tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T *before any lower-cut readback is consumed. The source row is read through* $\mathsf{BoundedRealSequence}^{\uparrow}$*, the lower observations through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*, the comparison rows through* $\mathsf{BoundedRealUpperCut}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal value only as the* $\mathsf{Real}^{\uparrow}$ *seal named in Definition 1553.1, Definition 1553.4, Definition 1553.5, and Definition 1553.11.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfLowerCutReadbackScope`

Proof. Project the carrier $I = (S, L, D, T, H, C, P, N)$ of Definition 1553.1. The source row S is the displayed bounded real sequence, and the schedule L is the finite lower-cut ledger attached to tails of that same source.

Use the NameCert obligations of Definition 1553.4. Their lower-tail exactness row routes each accepted lower observation through $\mathsf{BoundedRealLowerCut}^{\uparrow}$, while the upper-cut compatibility row routes comparisons through $\mathsf{BoundedRealUpperCut}^{\uparrow}$ using the dyadic tolerance ledger D.

Apply the tail-cut route of Definition 1553.5. It orders the read as S, L, D, T, H, C, P, N, so the terminal value cannot be inspected before the bounded source, lower schedule, and dyadic comparison rows have been displayed.

Finally use the Real-seal non-escape theorem, Definition 1553.11. The endpoint is only the row T, not a host infimum, trichotomy decision, selected subsequence, quotient stream equality, or ambient completeness principle. □

Theorem 1553.16 (Liminf scoped tail envelope)**.** *Every accepted* $\mathsf{Liminf}^{\uparrow}$ *consumer must route lower-tail data through the shared* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row, the* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{BoundedRealUpperCut}^{\uparrow}$ *comparison surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any tail-envelope read is public. The scoped route is the finite envelope*

$$S, L, D, T, H, C, P, N$$

read through $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows; it exports no host infimum, trichotomy decision, selected subsequence, quotient stream equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfScopedTailEnvelope`

Proof. Start with the NameCert obligations of Definition 1553.4. They identify the accepted packet as the finite row family S, L, D, T, H, C, P, N and place lower-tail exactness, upper-cut compatibility, terminal sealing, transport, replay, provenance, and local naming in that family.

Use the tail-cut route of Definition 1553.5. It orders every value-facing read through the bounded sequence row, lower-tail schedule, dyadic tolerance ledger, and terminal Real seal before the structural rows can replay the packet to a consumer.

Apply the bounded-cut compatibility obligation, Definition 1553.13. It forces lower-cut and upper-cut comparisons to use the same source row S and the same tolerance ledger D, so the lower envelope cannot be paired with an unrelated upper surface.

Finally read the lower-cut scope theorem, Definition 1553.15. It identifies the public lower-tail readback as a route through $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{BoundedRealUpperCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal, with BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserving the same displayed rows. □

Theorem 1553.17 (Liminf lower-cut readback)**.** *Every lower-tail observation exposed by an accepted* $\mathsf{Liminf}^{\uparrow}$ *carrier*

$$I = (S, L, D, T, H, C, P, N)$$

is read through the $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *row* L*, compared through the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and sealed only at the terminal* $\mathsf{Real}^{\uparrow}$ *row* T*. The readback may cite the bounded source* S *and the upper comparison surface, but it does not expose a host infimum, a selected subsequence, trichotomy, quotient stream equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfLowerCutReadback`

Proof. Project the carrier of Definition 1553.1. The source S is the bounded sequence row, L is the finite lower-tail schedule, D is the dyadic tolerance ledger, and T is the only terminal Real seal.

Use Definition 1553.15. It already forces public lower-tail readback to pass through $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{BoundedRealUpperCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal in that same displayed packet.

The present readback only isolates the lower-cut side of that route. Every lower observation is therefore a read from L compared against D, and the value-facing endpoint remains T rather than a host infimum, selected subsequence, trichotomy decision, quotient stream equality, or ambient completeness principle. □

Theorem 1553.18 (Liminf regular-sequence route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{Liminf}^{\uparrow}$ *packet must pass through*

$$\mathsf{BoundedRealSequence}^{\uparrow},\quad \mathsf{BoundedRealLowerCut}^{\uparrow},\quad \mathsf{BoundedRealUpperCut}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{R}$$

before reading the liminf surface S, L, D, T, H, C, P, N*. The route exposes finite regular-sequence and cut data only; it does not claim Real completeness, an actual infimum object, a quotient-real equality, a selected tail subsequence, or an open-cover compactness principle.*

Lean4 ✓ `BEDC.Derived.LiminfUp.LiminfRegularSequenceRoute`

Proof. Begin with Definition 1553.16. The scoped envelope names the bounded sequence, lower-cut schedule, dyadic tolerance ledger, upper comparison surface, and terminal Real seal as the public order of the liminf packet.

Next read the regular-sequence-facing part of the route. The bounded source row S is interpreted through $\mathsf{BoundedRealSequence}^{\uparrow}$, its lower and upper observations pass through $\mathsf{BoundedRealLowerCut}^{\uparrow}$ and $\mathsf{BoundedRealUpperCut}^{\uparrow}$, and all finite comparisons use the common $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D.

The consumer may then pass through $\mathsf{RegSeqRat}^{\uparrow}$ and only finally through the $\mathsf{Real}^{\uparrow}$ seal T. The support rows H, C, P, N transport, replay, source, and name the same finite packet, so the route supplies no host infimum, selected subsequence, quotient equality, Real-completeness principle, or compactness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{Liminf}\uparrow}$**.**

Constructive story: A $\mathsf{Liminf}^{\uparrow}$ packet is generated from a bounded RealUp sequence row, a finite tail lower-cut schedule, a dyadic tolerance ledger, a terminal RealUp seal, componentwise hsame transports, Cont replay routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Liminf}\uparrow}$, scopedClosed)

Scope closed: Definition 1553.1, Definition 1553.3, Definition 1553.4, Definition 1553.5, Definition 1553.11, Definition 1553.15, and Definition 1553.16 scope the finite tail-cut liminf surface for bounded real sequences.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Liminf}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, a host infimum, quotient stream equality, selected subsequences, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Public closure requires checked carrier formation, classifier stability, lower-tail exactness, upper-cut compatibility, terminal seal routing, tail-cut route ordering, lower-cut readback, and Real seal non-escape for the displayed packet.

Chapter 1554

A Concrete Naming Certificate for $\mathsf{RegulatedRealFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegulatedRealFunction}^{\uparrow}$ packet names a real-valued function on a closed interval by a finite ledger of dyadic step approximations together with a uniform tail route, rather than by a host function-space object.

The packet sits after four visible neighbours: the dyadic step-function approximation surface of chapter 428, the uniform-limit route of chapter 463, the closed interval domain row of chapter 1448, and the endpoint seal surface of chapter 1454. It exposes the approximation and seal rows needed by later integration-facing work, but it does not supply integration, open-cover compactness, or ambient completeness.

Definition 1554.1 (Regulated real function NameCert surface)**.** *A* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, A, T, U, E, H, C, P, N)$$

with the following displayed coordinates:

1. *I is a* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *domain row naming the source interval and its endpoint order data;*
2. *A is a finite ledger of* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation rows, indexed by displayed dyadic tolerances and read through chapter 428;*
3. *T is the uniform tail and modulus ledger recording the common threshold beyond which the approximants are uniformly close;*
4. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *route that consumes A and T through chapter 463;*
5. *E is the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *endpoint seal row, read only after the closed interval and uniform-limit routes of chapter 1448 and chapter 1454;*
6. *H stores componentwise* hsame *transports for the interval row, approximation ledger, tail ledger, uniform-limit route, endpoint seal, provenance, and local name;*
7. *C stores the displayed* Cont *continuations that read a domain request, choose the approximation threshold, replay the step-function ledger, pass through U, and expose E;*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedUnitInterval}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{RegularLocatedCauchyRea}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed interval row, the finite dyadic step-function ledger, the uniform tail ledger, the uniform-limit route, the endpoint seal row, and the visible transport, continuation, provenance, and naming rows.

Lean4 ✓ `BEDC.Derived.RegulatedRealFunctionUp.RegulatedRealFunctionTasteGate single carrier alignment`

Theorem 1554.2 (Regulated real function NameCert obligations)**.** *For the carrier of Definition 1554.1, the local* $\mathsf{NameCert}_{\mathsf{RegulatedRealFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for* $G = (I, A, T, U, E, H, C, P, N)$*, interval-domain admission through chapter 1448, finite step-approximation admission through chapter 428, uniform-tail routing through chapter 463, endpoint sealing through chapter 1454, componentwise transport, continuation replay, provenance, local naming, and non-escape from hidden function-space equality.*

Lean4 ✓ `BEDC.Derived.RegulatedRealFunctionUp.RegulatedRealFunctionCarrier namecert obligations`

Proof. Project the accepted carrier. The interval row I, approximation ledger A, uniform tail ledger T, uniform-limit route U, endpoint seal row E, transports H, continuations C, provenance P, and local name N are the only public coordinates.

The source side is finite. The closed interval is read through I using chapter 1448, and each displayed approximant in A is a dyadic step-function row governed by chapter 428.

The limiting side is also routed. The ledger T selects common thresholds for the step approximants, then U consumes that ledger through chapter 463, and only then can the endpoint seal E be read through chapter 1454. The rows H, C, P, N preserve this same route under transport, replay, package provenance, and local naming. □

Theorem 1554.3 (Regulated real function step-approximation coverage)**.** *Every accepted* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *carrier exposes each domain-facing request as a finite approximation read over the* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *row of chapter 1448 and the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *ledger of chapter 428. The selected approximation row is then checked against the uniform tail ledger and passed to the* $\mathsf{UniformLimit}^{\uparrow}$ *route of chapter 463 before any* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *endpoint seal from chapter 1454 is exposed.*

Proof. Begin with a domain-facing consumer request. The continuation row C first sends the request to I, so the request is scoped by the closed interval surface and its displayed endpoint order data.

Next choose the displayed tolerance row named by the request. The ledger A supplies a dyadic step-function approximant for that tolerance, and the dyadic step-function certificate supplies finite cell coverage, endpoint transport, and carried-value reads.

The approximation is not an endpoint by itself. The uniform tail ledger T records the threshold at which later approximants remain uniformly close, and U is the route that repacks the same ledger as a uniform limit. The endpoint seal E can therefore be read only after the closed interval, step approximation, and uniform-limit rows have all been consumed. □

Theorem 1554.4 (Regulated real function uniform-limit seal nonescape)**.** *For an accepted* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *carrier, every endpoint-facing read factors through the finite route*

$$I, A, T \longmapsto U \longmapsto E$$

using the closed interval row of chapter 1448, the dyadic step-function ledger of chapter 428, the uniform-limit route of chapter 463, and the regular located Cauchy real seal of chapter 1454. The packet exports no Riemann integration row, host function-space limit, quotient function equality, open-cover compactness, or ambient Real completeness.

Proof. Inspect the carrier coordinates. The only endpoint-facing row is E, and the continuation data reaches it by replaying the interval, approximation, tail, and uniform-limit rows in order.

Apply Definition 1554.3. Any consumer read first lands on the closed interval row and a displayed dyadic step approximant, then reads the uniform tail ledger before reaching the uniform-limit route.

Finally use the carrier and NameCert obligations of Definition 1554.2. They exhaust the visible rows $I, A, T, U, E, H, C, P, N$, so a consumer has no coordinate for integration, host function-space limits, quotient equality of functions, open-cover compactness, or a completeness theorem outside the displayed seal route. □

Theorem 1554.5 (Regulated real function integration-facing handoff boundary)**.** *Every later Darboux, Riemann, or regulated-integral consumer of an accepted* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *packet must first read the* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *row I, the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation ledger A, the uniform tail ledger T, the* $\mathsf{UniformLimit}^{\uparrow}$ *route U, and the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *endpoint seal E, with transport, replay, provenance, and naming carried by H, C, P, N. The packet exports no integration row, host function quotient, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegulatedRealFunctionUp.RegulatedRealFunctionCarrier integration facing handoff boundary`

↪ variant `BEDC.Derived.RegulatedRealFunctionUp.RegulatedRealFunction integration facing handoff boundary`

Proof. Begin with Definition 1554.2. It identifies the accepted carrier rows as exactly $I, A, T, U, E, H, C, P, N$ and places the interval, step-ledger, uniform-limit, endpoint-seal, transport, replay, provenance, and local naming obligations on that same finite packet.

Apply Definition 1554.3. A consumer request first enters through the closed interval row and a displayed dyadic step-function approximation before the uniform tail ledger and uniform-limit route can be read.

Finally apply Definition 1554.4. Endpoint-facing data is exposed only through the route from I, A, T to U and then to E. Since the carrier has no integration, quotient-function, compactness, or ambient-completeness coordinate, later integration-facing chapters may cite this handoff boundary without importing integration into the seed packet. □

Theorem 1554.6 (Regulated real function obligation closure)**.** *For the carrier of Definition 1554.1, the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *obligation surface is closed by carrier admission, dyadic step-approximation coverage, uniform-tail routing,* $\mathsf{UniformLimit}^{\uparrow}$ *nonescape, and* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *endpoint sealing. Equivalently, every accepted packet $G = (I, A, T, U, E, H, C, P, N)$ exposes the route*

$$\mathsf{ClosedUnitInterval}^{\uparrow},\ \mathsf{DyadicStepFunction}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{RegularLocatedCauchyReal}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{N}$$

and no integration row, host function-space limit, quotient function equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Carrier admission and local naming are supplied by Definition 1554.2. They identify the visible rows as $I, A, T, U, E, H, C, P, N$ and keep every read on the same finite packet.

Step-approximation coverage is supplied by Definition 1554.3. Each domain-facing read first passes through the closed interval row and a displayed dyadic step-function approximation before the uniform tail ledger is inspected.

The tail and endpoint boundary is supplied by Definition 1554.4. It places endpoint-facing reads on the route from I, A, T to U and then to E, excluding host limits, quotient equality, compactness, and ambient completeness.

Finally use Definition 1554.5. Later Darboux, Riemann, or regulated-integral consumers may consume the displayed interval, approximation, uniform-tail, uniform-limit, and endpoint rows, but they do not add an integration coordinate to the regulated-function packet. These four rows close the obligation surface exactly at the stated boundary. □

Theorem 1554.7 (Regulated real function uniform step route)**.** *Every consumer of an accepted* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *packet reads the* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *row, the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation ledger, the* $\mathsf{UniformLimit}^{\uparrow}$ *route, and the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *endpoint seal in that order. The supporting* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows are preserved componentwise along the same route, so no consumer can reach an endpoint, integration-facing handoff, or local certificate row without first replaying the closed-domain and dyadic-step data.*

Proof. Start with the NameCert obligations of Definition 1554.2. They identify the only public rows as $I, A, T, U, E, H, C, P, N$, with I carrying the closed interval, A the dyadic step approximations, T the uniform tail ledger, U the uniform-limit route, and E the endpoint seal.

Apply Definition 1554.3. A consumer request first enters through the $\mathsf{ClosedUnitInterval}^{\uparrow}$ row and then chooses a displayed $\mathsf{DyadicStepFunction}^{\uparrow}$ approximant; the approximation ledger cannot be bypassed because the request is scoped by I and A before T is inspected.

Next use Definition 1554.4. The tail ledger feeds the $\mathsf{UniformLimit}^{\uparrow}$ route, and endpoint-facing data appears only after that route reaches the $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ seal.

Finally combine Definition 1554.5 with Definition 1554.6. Integration-facing reads and local certificate reads consume the same ordered surface, while H, C, P, N preserve transport, replay, provenance, and naming without adding any alternate endpoint or integration coordinate. □

Theorem 1554.8 (Regulated real function scope)**.** *Every Darboux, Riemann, or regulated-integral consumer of an accepted* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *packet must read the scoped route*

$$\mathsf{ClosedUnitInterval}^{\uparrow} \longmapsto \mathsf{DyadicStepFunction}^{\uparrow} \longmapsto \mathsf{UniformLimit}^{\uparrow} \longmapsto \mathsf{RegularLocatedCauchyReal}^{\uparrow} \longmapsto (H, C, P, N)$$

before any integration-facing handoff is available. The route is exactly the interval row I, approximation ledger A, uniform tail ledger T, uniform-limit row U, endpoint seal E, and structural rows H, C, P, N of Definition 1554.1; it does not add an integration row to the packet.

Proof. Begin with the uniform step route. It sends every consumer through the closed-domain row, dyadic step approximation ledger, uniform-limit route, and regular located Cauchy endpoint seal in that order.

Apply the integration-facing handoff boundary. Darboux, Riemann, and regulated-integral consumers are permitted to consume the same displayed route, but the packet exports no integration coordinate, quotient function, compactness row, or ambient Real-completeness object.

Thus the stated route is the scoped consumer surface. The structural rows preserve transport, replay, provenance, and local naming without opening a second handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedRealFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegulatedRealFunction}^{\uparrow}$ packet is generated from a ClosedUnitInterval domain row, a finite DyadicStepFunction approximation ledger, a uniform tail and modulus ledger, a UniformLimit route, a RegularLocatedCauchyReal endpoint seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedRealFunction}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1554.1, Definition 1554.2, Definition 1554.3, Definition 1554.4, Definition 1554.5, Definition 1554.6, Definition 1554.7, and Definition 1554.8 export the regulated-function interface over interval, step-approximation, uniform-tail, UniformLimit, endpoint-seal, transport, replay, provenance, naming, and integration-facing consumer rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegulatedRealFunction}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.RegulatedRealFunctionUp.RegulatedRealFunctionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Riemann integration, host function-space limits, quotient function equality, open-cover compactness, or ambient Real completeness.

Upgrade path: No further theory-axis upgrade is pending for the displayed regulated-function interface; bridge checking remains a separate formal-axis and bridge task.

Chapter 1555

A Concrete Naming Certificate for $\mathsf{UniformCauchyFamily}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformCauchyFamily}^{\uparrow}$ packet records the finite NameCert surface for a displayed finite family of regular Cauchy rational names whose Cauchy control is witnessed by one shared threshold schedule. It sits between the stream-window source of chapter 126, the regular rational readbacks of chapter 301, the dyadic tolerance ledger of chapter 291, the shared-tail criterion of chapter 435, the Cauchy-name consumer surface of chapter 406, and the terminal real-name boundary of chapter 38. The packet names the family-level carrier consumed by uniform-tail and completion routes; it does not select a limit, quotient streams, host real equality, countable choice, or an ambient completeness principle.

Definition 1555.1 (UniformCauchyFamily carrier)**.** *A* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, \sigma, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family row, listing the inspected family members and their visible component identifiers;*
2. *σ is the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule that selects one threshold window surface for the whole family;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *family readback row, assigning to each displayed component the rational readbacks inspected at the scheduled windows;*
4. *D is the single* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every componentwise comparison in the family;*
5. *T is an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row whose shared threshold consumes the same family row, schedule, regular readbacks, and dyadic tolerance ledger;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after the shared-threshold criterion and regular readbacks have been displayed;*
7. *H records componentwise* hsame *transport for the family row, shared schedule, regular readbacks, dyadic ledger, uniform criterion row, real seal, replay row, provenance row, and local naming row;*

8. *C records displayed* Cont *replay from family inspection through the shared schedule, regular readbacks, dyadic tolerance ledger, uniform Cauchy criterion, and real-seal delivery;*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}$ *row.*

The carrier stores no separate threshold per component, no quotient stream, no selected host limit, no host equality of real names, no countable-choice selector, and no ambient completeness field.

Theorem 1555.2 (UniformCauchyFamily NameCert obligations)**.** *For an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier $U = (F, \sigma, R, D, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed family row, shared stream schedule, regular rational readbacks, dyadic tolerance ledger, accepted uniform Cauchy criterion row, real seal, transports, replay route, provenance, and local naming row;*
2. *shared-threshold exactness, requiring every componentwise Cauchy comparison to use the same* $\mathsf{StreamName}^{\uparrow}$ *schedule σ and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D;*
3. *readback compatibility, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *rows in R to be the only rational names consumed by the shared criterion T;*
4. *criterion transport, requiring T to remain attached to F, σ, R, D under the componentwise* hsame *row H and displayed* Cont *replay C;*
5. *real-seal non-escape, requiring the handoff E to be reached only after T and the componentwise readbacks in R have been displayed;*
6. *CauchySequenceSpace compatibility, requiring any* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *consumer to read the family through the same $F, \sigma, R, D, T, E, H, C, P, N$ route;*
7. *ledger exhaustion, stating that no per-component hidden threshold, quotient stream, selected host limit, host real equality, countable-choice selector, or ambient completeness principle is exported.*

Proof. Carrier admission is projection from Definition 1555.1. The tuple displays the finite family row, shared schedule, regular rational readbacks, dyadic tolerance ledger, uniform criterion row, real seal, transport, replay, provenance, and local name.

Shared-threshold exactness is forced by the single schedule coordinate σ and the single tolerance coordinate D. Every componentwise comparison named by the packet must therefore read the same window and tolerance ledger before consulting the uniform criterion row.

Readback compatibility and criterion transport are the role of R, T, H, C. The criterion row T consumes the displayed regular readbacks in R, while H and C move and replay only those rows together with the family and tolerance data.

The real-seal and CauchySequenceSpace boundaries are downstream of the same route. Since E and any $\mathsf{CauchySequenceSpace}^{\uparrow}$ consumer are named after $F, \sigma, R, D, T, H, C, P, N$ have been displayed, neither can import a selected limit, a quotient stream, host real equality, countable choice, or an ambient completeness principle. □

Theorem 1555.3 (UniformCauchyFamily common-window extraction)**.** *Let $U = (F, \sigma, R, D, T, E, H, C, P, N)$ be an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *packet. Every componentwise Cauchy comparison extracted from U factors through the same finite route*

$$F, \sigma, R, D, T, H, C, P, N.$$

In particular, the extracted comparison cannot replace the shared $\mathsf{StreamName}^{\uparrow}$ *schedule by a component-specific threshold, cannot replace the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks by an independent rational stream, and cannot replace the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger by a hidden host tolerance.*

Proof. Project the accepted carrier. The family row F has only one schedule row σ, one regular readback family R, and one dyadic tolerance ledger D.

Use the shared-threshold and readback clauses of Definition 1555.2. They force each componentwise comparison to read σ, R, D before it reaches the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row T.

Transport and replay do not add coordinates. The rows H, C, P, N preserve the same finite route, so the extracted comparison has no access to a component-specific threshold, independent rational stream, or hidden host tolerance. □

Theorem 1555.4 (UniformCauchyFamily RegSeqRat handoff)**.** *Let* $U = (F, \sigma, R, D, T, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *packet. Every shared threshold window extracted from* U *produces a rowwise* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for each displayed family member before any* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal consumer may read the family. The handoff uses the same family row* F*, shared* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*, dyadic tolerance ledger* D*, accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row* T*, and transport route* H, C, P, N*.*

Proof. Project the accepted carrier. The finite family row F lists the displayed members, the shared schedule σ names the threshold window, and the row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ family readback coordinate.

Apply common-window extraction from Definition 1555.3. Each componentwise comparison factors through $F, \sigma, R, D, T, H, C, P, N$, so the same extracted window supplies the regular rational readback row for every displayed member.

Use shared-threshold transport from Definition 1555.6. The rows H and C move the schedule σ and tolerance ledger D together with F, R, T, preventing a transported component from acquiring a hidden threshold or an independent rational stream.

The downstream boundary is therefore ordered. A $\mathsf{CauchySequenceSpace}^{\uparrow}$ consumer or a $\mathsf{Real}^{\uparrow}$ seal consumer may read the family only after the rowwise $\mathsf{RegSeqRat}^{\uparrow}$ readbacks in R have been displayed over the shared window and criterion route. □

Theorem 1555.5 (UniformCauchyFamily Real seal boundary)**.** *For an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier* $U = (F, \sigma, R, D, T, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read and every completion-facing consumer read of the family reaches* E *only after passing through the finite family row* F*, shared* $\mathsf{StreamName}^{\uparrow}$ *schedule* σ*,* $\mathsf{RegSeqRat}^{\uparrow}$ *family readbacks* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row* T*. The boundary exports no quotient stream, selected host limit, host real equality, countable choice, or ambient completeness row.*

Proof. Begin with a real-seal or completion-facing read of U. By the carrier definition, the only terminal seal coordinate is E.

The NameCert obligations place E downstream of the shared-threshold criterion T and the regular readback row R. Hence the read must first traverse F, σ, R, D, T.

Finally, H, C, P, N preserve the same displayed route for equivalent packets and consumer replays. The carrier lists no quotient stream, selected host limit, host real equality, countable-choice selector, or ambient completeness coordinate, so the real seal boundary is exhausted by the stated finite packet. □

Theorem 1555.6 (UniformCauchyFamily shared-threshold transport)**.** *Let $U = (F, \sigma, R, D, T, E, H, C, P, N)$ be an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier. The transport rows H and C move the single shared* $\mathsf{StreamName}^{\uparrow}$ *schedule σ and the single* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D together with the displayed family row F and the accepted criterion row T. Thus a transported component cannot acquire its own hidden threshold, tolerance ledger, or per-component Cauchy witness outside the route*

$$F, \sigma, R, D, T, H, C, P, N.$$

Proof. Project the carrier coordinates. The only schedule coordinate available to the family is σ, and the only tolerance ledger coordinate available to componentwise comparisons is D.

The transport row H is componentwise hsame over the displayed family row, shared schedule, regular readbacks, dyadic ledger, criterion row, real seal, replay row, provenance row, and local naming row. It therefore transports the criterion surface with σ and D still attached.

The replay row C follows the same displayed route from family inspection through the shared schedule, regular readbacks, dyadic tolerance ledger, uniform criterion, and real seal. Since neither H nor C adds a threshold coordinate, every transported component remains bound to the shared schedule and ledger. □

Theorem 1555.7 (UniformCauchyFamily Real seal factorization)**.** *For an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier $U = (F, \sigma, R, D, T, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$ *seal read factors through the finite packet*

$$F, \sigma, R, D, T, E, H, C, P, N.$$

The seal coordinate E is therefore readable only as the terminal handoff of the displayed family row, shared $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *family readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row, transport rows, replay row, provenance, and local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}$ *row.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ seal read of U. By the carrier definition, the only seal coordinate is E, and it is listed after the family row, schedule, readbacks, tolerance ledger, and accepted criterion row.

The NameCert obligations require real-seal non-escape. Thus the read cannot reach E before the shared criterion T and the regular readback family R have been displayed over F, σ, D.

Transport and replay preserve the factorization. The rows H and C move the same displayed data, while P and N record provenance and local naming for the packet; no extra seal source is available. □

Theorem 1555.8 (UniformCauchyFamily CauchySequenceSpace compatibility)**.** *Let $U = (F, \sigma, R, D, T, E, H, C, P$ be an accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *carrier. Any* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *consumer of the family receives exactly the finite route*

$$F, \sigma, R, D, T, E, H, C, P, N$$

through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces. Such a consumer cannot import quotient streams, selected limits, countable choice, host real equality, or ambient completeness.*

Proof. Read the consumer through the compatibility clause of Definition 1555.2. The clause names the same carrier route $F, \sigma, R, D, T, E, H, C, P, N$ for every $\mathsf{CauchySequenceSpace}^{\uparrow}$ consumer.

The upstream rows are finite and displayed. They pass through the $\mathsf{StreamName}^{\uparrow}$ schedule σ, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks R, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row T, and the $\mathsf{Real}^{\uparrow}$ handoff E.

The exclusion follows from ledger exhaustion. Since the carrier has no quotient-stream coordinate, selected-limit coordinate, countable-choice selector, host real equality, or ambient completeness row, the consumer cannot import any of those structures. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1555.1, Definition 1555.2, Definition 1555.3, Definition 1555.5, Definition 1555.6, Definition 1555.7, and Definition 1555.8 seed the shared-threshold family packet over StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerances, UniformCauchyCriterion rows, CauchySequenceSpace consumers, and Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close per-component hidden thresholds, quotient streams, selected host limits, host real equality, countable choice, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, shared-threshold exactness, readback compatibility, criterion transport, Real seal non-escape, CauchySequenceSpace compatibility, and ledger exhaustion for BEDC.Derived.UniformCauchyF

Constructive story: A $\mathsf{UniformCauchyFamily}^{\uparrow}$ packet is generated from a finite family row, a shared $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ family readbacks, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1556

A Concrete Naming Certificate for $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ packet records the finite NameCert surface for constructive metric completion as a route through located metric data, regular Cauchy names, dyadic tolerances, filter bases, separated equality, dense embedding, and uniformly continuous extension. It reads the metric-completion packet of chapter 1506, the located-metric source of chapter 1533, the Cauchy-filter basis row of the completion interface, the separated regular-Cauchy route of chapter 1513, the embedding handoff of chapter 1512, the extension surface of chapter 769, and the naming spine of chapter 126, chapter 301, chapter 291, and chapter 38. The packet is a finite completion certificate for displayed Cauchy-filter reads; it is not a quotient construction, a selected host limit, a countable-choice schedule, an open-cover compactness principle, or a full completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1556.1 (Constructive metric completion carrier)**.** *A* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, A, D, F, E, S, U, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{LocatedMetric}^{\uparrow}$ *row, including the displayed* $\mathsf{Met}^{\uparrow}$ *distance witness and the finite locatedness route used by completion-facing consumers.*
2. *A is the regular Cauchy name family row. It stores the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks by which a completion point is inspected at finite precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the windows of A, including the monotone tolerance requests used to compare finite prefixes.*
4. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row, recording the Cauchy-filter neighborhoods generated by the same regular names and dyadic tolerances.*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that embeds source observations densely into the displayed completion route.*
6. *S is the* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *row, exposing separated completion equality only through the displayed regular-Cauchy and zero-distance comparison route.*
7. *U is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff row for uniformly continuous consumers of the dense source.*

8. *H records componentwise* hsame *transport for the located source, regular Cauchy names, dyadic ledger, Cauchy filter basis, completion embedding, separated equality row, extension handoff, replay row, provenance row, and local naming row.*

9. *C records the displayed* Cont *replay from located-metric observations to regular Cauchy windows, dyadic tolerances, Cauchy-filter neighborhoods, embedding reads, separated comparisons, and uniformly continuous extension reads.*

10. *P is the* Pkg *provenance over* ConstructiveMetricCompletion$^{\uparrow}$, LocatedMetric$^{\uparrow}$, MetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, RegularCauchyCompleti UniformContinuousExtension$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ConstructiveMetricCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient representatives, host-selected limits, countable choice, open-cover compactness, detached Real$^{\uparrow}$ *completeness, or an ambient complete metric space.*

Theorem 1556.2 (ConstructiveMetricCompletion NameCert obligations)**.** *For an accepted* ConstructiveMetricCom *carrier $K = (X, A, D, F, E, S, U, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveMetricCompletion}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed located metric source, regular Cauchy name family, dyadic tolerance ledger, Cauchy filter basis, completion embedding, separated equality row, uniformly continuous extension handoff, transports, replay route, provenance, and local naming row;*

2. *classifier stability, requiring two accepted completion reads to be compared only through the same ordered route $X, A, D, F, E, S, U, H, C, P, N$ after componentwise* hsame *transport;*

3. *embedding coverage, requiring each source observation used by the completion packet to enter through the dense* CompletionEmbedding$^{\uparrow}$ *row E;*

4. *separatedness exactness, requiring every equality judgement between completion reads to pass through S and hence through the displayed regular-Cauchy separated route;*

5. *universal handoff, requiring each uniformly continuous consumer of the dense source to read the completion point through F, S, U before any exported value is named;*

6. *transport replay, requiring H and C to preserve the located source, regular names, dyadic tolerances, filter basis, embedding row, separated row, and extension row as one packet;*

7. *ledger non-escape, stating that no quotient representative, host-selected limit, countable-choice selector, open-cover compactness principle, detached* Real$^{\uparrow}$ *completeness theorem, or ambient complete metric space is exported.*

Proof. Carrier admission is projection from Definition 1556.1. The tuple displays the located source, regular Cauchy name family, dyadic ledger, Cauchy-filter basis, completion embedding, separated equality row, extension handoff, and structural support rows.

Classifier stability is componentwise. The transport row H moves each displayed coordinate in the same order, and the replay row C forces any accepted comparison to traverse the located source, regular names, dyadic tolerances, filter basis, embedding row, separated row, and extension row before the local name is read.

Embedding coverage is the role of E. A source observation becomes completion-facing data only through the dense embedding row, so no selected representative or host completion point can be substituted for it.
