Separatedness exactness is isolated in S. Equality of completion reads is admitted only after the regular Cauchy windows and dyadic tolerances have been displayed, and only through the separated completion route named by that row.

The universal handoff is carried by U after F and S are present. The provenance row P and local naming row N record no further coordinate, so the excluded quotient, choice, compactness, host-limit, real-completeness, and ambient-completeness principles cannot be read from the packet. □

Theorem 1556.3 (ConstructiveMetricCompletion universal handoff)**.** *Let $K = (X, A, D, F, E, S, U, H, C, P, N)$ be an accepted* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *packet. Any uniformly continuous consumer of the dense source reads a completed point only through the displayed Cauchy-filter basis F, the separated completion equality row S, and the uniformly continuous extension row U, after the located source X, regular Cauchy name family A, dyadic tolerance ledger D, and completion embedding row E have been displayed.*

Thus every such consumer factors through the finite route

$$X, A, D, E \longmapsto F \longmapsto S \longmapsto U \longmapsto H, C, P, N,$$

not through quotient representatives, host-selected limits, countable choice, open-cover compactness, detached $\mathsf{Real}^{\uparrow}$ *completeness, or an ambient complete metric space.*

Proof. Begin with the dense source. The located metric row X supplies finite distance and locatedness reads, while A and D supply the scheduled regular Cauchy windows and dyadic tolerance ledger.

The source observation becomes completion-facing only through E. This places the dense embedding row before any consumer can inspect a completed point.

The Cauchy-filter basis F is then the unique neighborhood route available to the consumer. It is generated from the same regular names and dyadic tolerances, so the consumer cannot replace it by a selected representative or host limit.

Separated comparison is read next through S. The uniformly continuous extension row U may be consumed only after that separated route is available, ensuring that the extension depends on the displayed Cauchy-filter and separated completion rows.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient representatives, host-selected limits, countable choice, open-cover compactness, detached $\mathsf{Real}^{\uparrow}$ completeness, or ambient completeness, every uniformly continuous consumer factors through the stated handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveMetricCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1556.1, Definition 1556.2, and Definition 1556.3 seed the finite Bishop-style constructive metric completion packet over located metrics, regular Cauchy names, dyadic tolerances, Cauchy filters, separated equality, dense embedding, and uniformly continuous extension.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient representatives, host-selected limits, countable choice, open-cover compactness, full $\mathsf{Real}^{\uparrow}$ completeness, ambient complete metric spaces, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, embedding coverage, separatedness exactness, universal handoff, transport replay, tolerance-ledger non-escape, and refusal rows for BEDC.Derived.ConstructiveMetricComp

Constructive story: A $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ packet is generated from a located metric source, regular Cauchy name family, dyadic tolerance ledger, Cauchy filter basis, dense completion embedding, separated completion equality row, uniformly continuous extension handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 1557

A Concrete Naming Certificate for $\mathsf{RegulatedIntegral}^{\uparrow}$

Following Riemann, Darboux, and Bishop–Bridges constructive analysis, the packet names the integral of a regulated real function by finite dyadic step primitives and Darboux/Riemann compatibility rows, not by host function-space limits or measure completion.

The packet consumes the regulated-function approximation surface of chapter 1554, the finite step primitive of chapter 428, the Darboux gap route of chapter 1460, and the tagged-mesh boundary of chapter 1526. It is a BEDC-native consumer target for Real and Completion work: every integral read is routed through displayed step sums, compatibility ledgers, transport rows, replay rows, provenance, and a local name.

Definition 1557.1 (Regulated integral NameCert surface)**.** *A* $\mathsf{RegulatedIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, G, A, S, D, R, E, H, C, P, N)$$

with the following displayed coordinates.

1. *I is the interval row naming the integration domain, endpoint order data, and cell-facing boundary reads.*
2. *G is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row, read through chapter 1554, naming the regulated integrand by finite dyadic step approximations and a uniform tail ledger.*
3. *A is the finite dyadic step approximation ledger selected from G at displayed tolerances.*
4. *S is the step-integral primitive, computing finite sums from the cells and carried values of the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *rows in A.*
5. *D is the Darboux/Riemann compatibility row, recording that the same step approximation route fits the upper-lower gap boundary of chapter 1460 and the tagged-mesh surface of chapter 1526.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *handoff row reached from the displayed finite sums and compatibility ledger.*
7. *E records the error and modulus bounds connecting the chosen step rows, the regulated-function tail ledger, and the real-facing handoff.*
8. *H records componentwise* hsame *transport for interval, integrand, approximation, step-integral, compatibility, error, handoff, provenance, and local naming rows.*

9. *C records the displayed* Cont *replay from regulated-function reads to step approximants, from step approximants to finite sums, from compatibility rows to the Darboux/Riemann boundary, and from error bounds to the real handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, A, S, D, R, E, H, C, P, N$. It has no coordinate for a host function quotient, a measure completion, a selected limiting tag family, open-cover compactness, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralTasteGate single carrier alignment`

Theorem 1557.2 (Regulated integral step primitive)**.** *Every accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet exposes its integral through finite* $\mathsf{DyadicStepFunction}^{\uparrow}$ *primitive sums. A consumer may read the interval row I, the regulated-function row G, the selected approximation ledger A, the finite sum primitive S, and the recorded error bounds E, but it cannot bypass these rows through a host integral or a hidden limiting functional.*

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralStepPrimitive`

Proof. Project the carrier of Definition 1557.1. The integrand-facing row is G, and chapter 1554 exposes G by finite dyadic step approximations rather than by a host function-space object.

The selected approximation ledger A chooses the displayed $\mathsf{DyadicStepFunction}^{\uparrow}$ rows at the tolerances recorded by E. The primitive S computes the corresponding step integrals from finite cells, endpoint transports, and carried values supplied by chapter 428.

The continuation row C can replay only this route: interval read, regulated-function approximation, step ledger, finite sum, and error ledger. Since no other integral coordinate is part of J, every accepted integral read factors through the displayed step primitive. □

Theorem 1557.3 (Regulated integral Darboux–Riemann compatibility)**.** *The regulated step approximation route of an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet is compatible with the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *gap boundary and the* $\mathsf{RiemannIntegral}^{\uparrow}$ *tagged-mesh surface. The compatibility is recorded by the displayed row D and is consumed before the* $\mathsf{Real}^{\uparrow}$ *handoff row R becomes available.*

Proof. Start from the finite step primitive of Definition 1557.2. The same approximation ledger A supplies the lower and upper step data needed by the Darboux gap row and the tagged-cell data needed by the Riemann mesh surface.

The compatibility row D records both readings. Through chapter 1460, it checks the visible upper-lower gap and its modulus; through chapter 1526, it checks that the tagged-mesh sums are read against the same displayed cells and carried values.

Only after this row is present can the packet expose R. The transport row H and continuation row C preserve the same order of consumption, so the Darboux and Riemann boundaries share the regulated step ledger rather than introducing separate host analytic data. □

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralDarbouxRiemannCompatibility`

Theorem 1557.4 (Regulated integral visible step handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet first consumes the visible ledger*

$$I, G, A, S, E.$$

Thus the interval row, regulated-function approximation row, selected finite step ledger, step-integral primitive, and error/modulus row are present before the packet can export any real-facing integral value.

Proof. Project the carrier of Definition 1557.1. The rows I, G, A, S, E are the only coordinates that name the interval, choose the finite regulated approximation, compute the step sum, and record the error budget.

Apply Definition 1557.2. It routes every accepted integral read through finite $\mathsf{DyadicStepFunction}^{\uparrow}$ primitive sums and the displayed error ledger, so no real-facing read can begin with a hidden integral functional.

The continuation row C preserves this order when the handoff proceeds toward D and R. Hence every public $\mathsf{Real}^{\uparrow}$ read first consumes I, G, A, S, E. □

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralVisibleStepHandoff`

Theorem 1557.5 (Regulated integral dyadic step approximation factorization)**.** *Every accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *read factors its approximation row through the finite* $\mathsf{DyadicStepApproximation}^{\uparrow}$ *route before the Darboux/Riemann compatibility row and the* $\mathsf{Real}^{\uparrow}$ *handoff are visible. In the carrier notation of Definition 1557.1, the rows* I, G, A, S, E *expose the regulated-function source, dyadic step approximation ledger, finite step-sum primitive, and error budget before* D *and* R *can be consumed.*

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralDyadicStepApproximationFactorization`

Proof. Start from the visible step handoff. It places the interval row, regulated-function row, selected finite approximation ledger, step primitive, and error row before any Real-facing integral value is exported.

Read the approximation ledger through the dyadic step approximation route. The ledger A is the finite witness that the regulated-function row has selected displayed dyadic step cells, values, and tolerances, so the step primitive S can compute only from that finite route.

Only after this route is present can D compare the same step data with the Darboux and Riemann boundaries, and only after D can R expose the Real handoff. Thus the accepted read factors through $\mathsf{DyadicStepApproximation}^{\uparrow}$ before compatibility or endpoint data is public. □

Theorem 1557.6 (Regulated integral convergence consumer boundary)**.** *Every* $\mathsf{RegulatedConvergence}^{\uparrow}$ *endpoint or integral-facing consumer that reaches an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet must first display the regulated-function row, uniform-tail row, finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert row carried by the regulated-integral route. The consumer receives no host convergence theorem, measure completion, quotient function equality, selected limit object, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralConvergenceConsumerBoundary`

Proof. Project the regulated-integral carrier. Its integrand-facing row G supplies the regulated-function source, while A and E record the finite windows and uniform error data that a regulated-convergence consumer can inspect.

The endpoint read then passes through the regular rational and Real-facing support already used by the public regulated-integral interface. The finite step primitive and Darboux/Riemann compatibility row keep the endpoint behind displayed step sums before the Real seal is public.

Finally read H, C, P, N. These rows transport, replay, source, and locally name the same finite route, so a $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer can reach $\mathsf{RegulatedIntegral}^{\uparrow}$ only through the displayed boundary and not through hidden convergence, quotient, measure, selected-limit, or completeness data. □

Theorem 1557.7 (Regulated integral Real completion route)**.** *The* $\mathsf{Real}^{\uparrow}$ *handoff row* R *of an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet remains behind the Darboux/Riemann compatibility row* D*. A downstream Real or Completion consumer may use* R *only through the route*

$$I, G, A, S, E \longmapsto D \longmapsto R, H, C, P, N,$$

and the route imports neither measure completion, full $\mathsf{Real}^{\uparrow}$ *completeness, quotient function equality, nor selected limiting tag families.*

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralRealCompletionRoute`

Proof. First use Definition 1557.4 to expose the interval, regulated-function, finite approximation, step primitive, and error rows. These rows provide the only step-sum data available to the packet.

Apply Definition 1557.3. The compatibility row D checks that the same step ledger fits the Darboux gap boundary and the Riemann tagged-mesh surface before R is available.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the carrier has no coordinate for measure completion, full Real completeness, quotient function equality, or selected limiting tags, the Real handoff remains inside the displayed Darboux/Riemann route. □

Theorem 1557.8 (Regulated integral nonescape)**.** *No accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet exports a host function quotient, measure completion, selected limiting tag family, open-cover compactness witness, or ambient Real-completeness principle. Every consumer read is confined to the displayed ledger*

$$I, G, A, S, D, R, E, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralCarrier nonescape`

Proof. Inspect the carrier coordinates in Definition 1557.1. They display the interval row, regulated-function row, finite approximation ledger, step-sum primitive, Darboux/Riemann compatibility row, real handoff, error ledger, transports, continuations, provenance, and local naming row.

Apply Definition 1557.2 to route every integral read through finite dyadic step sums. Apply Definition 1557.3 to route the real-facing read through the visible Darboux gap and Riemann tagged-mesh compatibility row.

The excluded objects have no carrier coordinate and no continuation route. Thus a downstream Real or Completion consumer receives only the displayed ledger and cannot access a quotient of host functions, a measure-completion object, selected limiting tags, open-cover compactness, or a completeness principle outside the packet. □

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralNonescape`

Theorem 1557.9 (Regulated integral kernel-source scope)**.** *Every regulated-integral read from an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet is scoped to the interval row,* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row,* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation rows,* $\mathsf{DarbouxIntegral}^{\uparrow}$ *and* $\mathsf{RiemannIntegral}^{\uparrow}$ *compatibility row,*

$\mathsf{Real}^{\uparrow}$ *handoff row, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. Equivalently, every read remains inside*

$$I, G, A, S, D, R, E, H, C, P, N$$

and no consumer can replace the displayed step-primitive source by a host function quotient, measure completion, selected limiting tag family, open-cover compactness witness, or ambient Real-completeness principle.

Proof. Start with the step primitive. By Definition 1557.2, each accepted integral read exposes the interval row I, the regulated-function row G, the selected dyadic step approximation ledger A, the finite step-sum primitive S, and the error row E before any real-facing handoff is available.

Apply Darboux–Riemann compatibility. The row D records that the same displayed step approximation route fits the Darboux gap boundary and the Riemann tagged-mesh surface, so the compatibility source is a kernel row rather than a host integration theorem.

Now use the visible step handoff and Real completion route. These place R behind I, G, A, S, E and then behind D, so a $\mathsf{Real}^{\uparrow}$ consumer receives only the displayed finite-sum route and its compatibility ledger.

Finally apply nonescape. The structural rows H, C, P, N transport, replay, source, and name the same packet, and the carrier has no coordinate for the excluded function-space, measure, tag-selection, compactness, or completeness objects. Therefore the regulated-integral read is scoped exactly to the listed kernel-source rows. □

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralKernelSourceScope`

Theorem 1557.10 (Regulated integral public interface)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$*, Completion, or analysis consumer of an accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet receives only the interval row, regulated-function row, dyadic step approximation rows, Darboux/Riemann compatibility row,* $\mathsf{Real}^{\uparrow}$ *handoff row, error and modulus rows, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row:*

$$I, G, A, S, D, R, E, H, C, P, N.$$

The public interface exports no measure completion, quotient function equality, selected limiting tag family, open-cover compactness witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegulatedIntegralUp.RegulatedIntegralPublicInterface`

Proof. Use the step primitive, Definition 1557.2, and the visible step handoff, Definition 1557.4. Together they expose the interval row I, regulated-function row G, dyadic step ledger A, finite step primitive S, and error row E before any real-facing consumer may read the packet.

Apply Darboux–Riemann compatibility, Definition 1557.3. The compatibility row D is the only bridge from the displayed step ledger to the Darboux gap boundary and the Riemann tagged-mesh surface.

Now use the Real completion route, Definition 1557.7. It places R behind I, G, A, S, E and then behind D, so Real and Completion consumers receive the handoff only through the same finite route.

Finally apply nonescape and kernel-source scope, Definition 1557.8 and Definition 1557.9. The structural rows H, C, P, N transport, replay, source, and name the displayed ledger, and the excluded analytic objects have no carrier coordinate. Thus the listed rows form the entire public interface. □

Theorem 1557.11 (Regulated integral mature treatment)**.** *The public regulated-integral interface of Definition 1557.10 is a mature consumer route over* $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Every accepted* $\mathsf{RegulatedIntegral}^{\uparrow}$ *packet exposes the interval row, regulated-function row, dyadic step approximation rows, Darboux/Riemann compatibility row,* $\mathsf{Real}^{\uparrow}$ *handoff row, error and modulus rows, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before any downstream integral read is available. The route still refuses measure completion, quotient function equality, open-cover compactness, full* $\mathsf{Real}^{\uparrow}$ *completeness, and selected limiting tag families.*

Proof. Start from the public interface. It already lists exactly the rows $I, G, A, S, D, R, E, H, C, P, N$ exported to downstream Real, Completion, and analysis consumers.

Read those rows through their mature inputs. The regulated-function row supplies the displayed integrand, the dyadic step rows supply finite approximants, the Darboux and Riemann rows supply the compatibility boundary, and the Real row supplies the terminal handoff without adding an ambient function space.

Finally apply kernel-source scope and nonescape. Those results keep transport, replay, provenance, and local naming attached to the same finite packet, while the excluded analytic objects remain absent carrier coordinates. Hence the public interface is the mature consumer treatment of the regulated-integral packet and not a measure-theoretic or quotient-function completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedIntegral}^{\uparrow}$ packet is generated from an interval row, a $\mathsf{RegulatedRealFunction}^{\uparrow}$ integrand row, a finite $\mathsf{DyadicStepFunction}^{\uparrow}$ approximation ledger, a step-integral primitive, a Darboux/Riemann compatibility row, a $\mathsf{Real}^{\uparrow}$ handoff, error and modulus bounds, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedIntegral}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1557.10 and Definition 1557.11 bind Definition 1557.1, Definition 1557.2, Definition 1557.3, Definition 1557.7, Definition 1557.8, and Definition 1557.9 to the interval, regulated-function, dyadic-step, Darboux/Riemann, Real handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic integration, quotient function equality, open-cover compactness, full Real completeness, Lean verification, or bridge checking.

Upgrade path: Bridge-grade closure requires Lean verification, axiom-purity certification, and a checked standard bridge for the public regulated-integral interface.

Chapter 1558

A Concrete Naming Certificate for $\mathsf{CauchyFilterLimit}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley terminology of filter bases, the $\mathsf{CauchyFilterLimit}^{\uparrow}$ packet names the finite limit boundary reached after a generated Cauchy-filter basis has been consumed and before a $\mathsf{Real}^{\uparrow}$ seal can be read. It sits downstream of chapter 1501 and chapter 333, reads the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the dyadic tolerance ledger of chapter 291, and exposes the seal boundary of chapter 38 only after those rows have been replayed. The chapter records a finite limit packet, not a quotient of streams, not a selected host limit, and not an ambient completeness principle.

Definition 1558.1 (CauchyFilterLimit carrier)**.** *A* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, F, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator row. It names the finite basis elements and common-refinement data from which the limit request starts.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation row. It consumes the generated basis and exposes only the saturated finite-filter surface.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by the saturated filter request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning the displayed stream windows into regular rational observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the rational observations at the requested limit scale.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, F, S, R, D have been replayed.*
7. *H records componentwise* hsame *transport for the basis, filter, window, readback, tolerance, seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a basis request through saturation, finite windows, regular readback, dyadic tolerance, and then the seal row.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterLimit}^\uparrow}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected host limit, host real equality, countable-choice selection, or ambient completeness of $\mathsf{Real}^\uparrow$.

Lean4 (definition) `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier`
Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitTasteGate single carrier alignment`

Theorem 1558.2 (CauchyFilterLimit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterLimit}^\uparrow$ *carrier* $L = (B, F, S, R, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterLimit}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed basis generator, saturated filter, finite stream windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, continuation, provenance, and local naming row;*
2. *basis consumption and filter saturation, requiring the B row to be consumed by F before any limit-facing read can inspect stream, rational, tolerance, or seal data;*
3. *regular readback, requiring each limit-scale observation to pass through S and R before the tolerance ledger D is consulted;*
4. *Real seal non-escape, requiring the seal row A to remain downstream of B, F, S, R, D;*
5. *ledger refusal, excluding quotient streams, selected host limits, host real equality, countable-choice selectors, and ambient* $\mathsf{Real}^\uparrow$ *completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier namecert obligations`

Proof. Project the carrier of Definition 1558.1. The projection exposes exactly the generator row, saturation row, stream-window row, regular readback row, dyadic tolerance ledger, Real seal, and structural rows H, C, P, N.

Basis consumption is forced by the row order. The continuation row C routes a limit request from B into F before the request can reach the finite windows S, regular readback R, tolerance ledger D, or seal row A.

The regular readback and seal conditions are then internal to the same packet. Transport by H preserves the route, while P and N package and name only that displayed route, so no separate quotient, host-limit, choice, or completeness coordinate remains available. □

Theorem 1558.3 (CauchyFilterLimit regular seal handoff)**.** *Let* $L = (B, F, S, R, D, A, H, C, P, N)$ *be an accepted* $\mathsf{CauchyFilterLimit}^\uparrow$ *packet. Every* $\mathsf{Real}^\uparrow$*-facing limit read factors through the finite route*

$$B, F, S, R, D \longmapsto A \longmapsto H, C, P, N.$$

Thus the limit seal is read only after the $\mathsf{CauchyFilterBasis}^\uparrow$ *generator, the* $\mathsf{CauchyFilter}^\uparrow$ *saturation row, the* $\mathsf{StreamName}^\uparrow$ *windows, the* $\mathsf{RegSeqRat}^\uparrow$ *readback, and the* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance ledger have been displayed. The route contains no quotient stream, selected host limit, host real equality, countable-choice selector, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier regular seal handoff`

Proof. Begin with a Real-facing consumer of the packet. Carrier admission gives access to the seal row A, but only as a row downstream of B, F, S, R, D.

Replay the continuation row C. The request first consumes the displayed Cauchy-filter basis generator B, then the saturated filter row F, then the finite stream windows S, the regular rational readback R, and the dyadic tolerance ledger D.

Only after this replay can the seal row A be read. The transport, provenance, and local naming rows record the same dependency order, so the packet exports no direct route through quotient streams, selected host limits, host real equality, countable choice, or ambient completeness. □

Theorem 1558.4 (CauchyFilterLimit directed-net handoff)**.** *Let $L = (B, F, S, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *packet. Any directed-net completion consumer can read the packet only after the* $\mathsf{DirectedSet}^{\uparrow}$ *index substrate, the* $\mathsf{CauchyNet}^{\uparrow}$ *tail evidence, and the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *boundary row have been displayed. The handoff preserves the finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route of Definition 1558.3, and exports no quotient filter, selected subnet, countable choice, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier directed net handoff`

Proof. Begin with the regular seal handoff of Definition 1558.3. It fixes the route from the Cauchy-filter basis and saturation rows through stream windows, regular rational readback, dyadic tolerance, and the Real seal.

For a directed-net completion consumer, the filter basis is first read through the displayed $\mathsf{DirectedSet}^{\uparrow}$ substrate. The same finite request is then routed through the $\mathsf{CauchyNet}^{\uparrow}$ tail row, so the consumer sees directed windows rather than a quotient filter.

Apply the $\mathsf{MooreSmithConvergence}^{\uparrow}$ boundary row to the displayed directed windows and tail evidence. This places the directed-net read downstream of the same StreamName, RegSeqRat, DyadicRatCore, and Real route, while omitting selected subnets, countable-choice selectors, and ambient completeness. □

Theorem 1558.5 (CauchyFilterLimit basis saturation obligation)**.** *For every accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *carrier $L = (B, F, S, R, D, A, H, C, P, N)$ of Definition 1558.1, the local saturation obligation requires the basis row B and saturated filter row F to be admitted before any* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, or* $\mathsf{Real}^{\uparrow}$ *seal A is read. The same obligation is transported by H, replayed by C, sourced by P, and named by N, and it refuses quotient stream equality, selected host limits, host real equality, countable-choice selectors, and ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier basis saturation obligation`

Proof. Project the carrier rows listed in Definition 1558.1. The basis generator B and saturated filter row F are the only rows that can expose the limit request before window, readback, tolerance, and seal data appear.

Replay the continuation row C. Its route sends the request from B to F before it reaches S, R, D, A, while H preserves the same order under componentwise transport.

The provenance row P and local naming row N package only this finite route. Since no carrier coordinate stores quotient stream equality, selected host limits, host real equality, countable-choice selectors, or ambient completeness, the saturation obligation cannot export those principles. □

Theorem 1558.6 (CauchyFilterLimit regular readback obligation)**.** *For every accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *carrier $L = (B, F, S, R, D, A, H, C, P, N)$, a* $\mathsf{Real}^{\uparrow}$*-facing limit read is admitted only after the*

$\mathsf{StreamName}^{\uparrow}$ *row S has displayed the finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R has supplied regular rational readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D has supplied the tolerance ledger. The admission is invariant under H, replayed by C, sourced by P, and named by N; it does not identify quotient streams, choose a host limit, assert host real equality, use countable choice, or invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier regular readback obligation`

Proof. Begin after the basis-saturation obligation of Definition 1558.5. The remaining limit-facing read must pass through the rows S, R, D, A in the carrier.

The row S exposes finite windows only. The row R turns those windows into regular rational observations, and the row D records the dyadic tolerance comparison before the seal row A can be read.

Rows H, C, P, N preserve this readback order under transport, replay, provenance, and naming. The refused principles are absent from the tuple, so the regular readback obligation cannot be consumed as quotient stream equality, a selected host limit, host real equality, countable choice, or ambient Real completeness. □

Theorem 1558.7 (CauchyFilterLimit ledger refusal obligation)**.** *For every accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *carrier $L = (B, F, S, R, D, A, H, C, P, N)$, the local ledger refusal is part of the NameCert surface: any consumer that reads beyond the displayed $B, F, S, R, D, A, H, C, P, N$ rows is rejected. In particular, the carrier refuses quotient stream equality, selected host limits, host real equality, countable-choice selectors, and ambient Real completeness while retaining the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *route.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier ledger refusal obligation`

Proof. Use Definition 1558.2. It states that the local NameCert surface is exhausted by carrier admission, basis consumption, filter saturation, regular readback, Real seal non-escape, and ledger refusal.

The first two obligation theorems identify the positive route: B, F admit and saturate the filter request, while S, R, D, A expose finite windows, regular readback, dyadic tolerance, and the Real seal.

It remains to record what the packet cannot export. Because H, C, P, N transport, replay, source, and name only the displayed route, any read asking for quotient stream equality, selected host limits, host real equality, countable-choice selectors, or ambient completeness has no carrier coordinate and is refused by the local ledger. □

Theorem 1558.8 (CauchyFilterLimit directed-net coverage)**.** *Let $L = (B, F, S, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *packet. Every directed-net completion consumer of L must pass through the displayed route*

$$B, F, S, R, D, A, H, C, P, N.$$

In particular, the consumer first exposes the $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator and* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation rows, then the shared* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and only then the* $\mathsf{Real}^{\uparrow}$ *seal and structural rows. The coverage claim does not export a quotient filter, selected subnet, countable-choice selector, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier directed net coverage`

Proof. Start with the directed-net handoff of Definition 1558.4. It admits a directed-net consumer only after the displayed index and tail evidence have been routed through the same finite filter-limit packet.

Apply the regular seal handoff. Theorem 1558.3 fixes the route from the Cauchy-filter basis and saturation rows through the finite stream windows, regular rational readback, dyadic tolerance ledger, and Real seal.

Finally attach the structural rows. Transport, continuation, provenance, and local naming only preserve the displayed route, so a directed-net completion consumer has no carrier coordinate from which to bypass $B, F, S, R, D, A, H, C, P, N$. □

Theorem 1558.9 (CauchyNetLimit filter comparison)**.** *The* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *and* $\mathsf{CauchyNetLimit}^{\uparrow}$ *packets can be compared along their shared finite* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows. The comparison records that both routes expose finite windows, regular rational readbacks, dyadic tolerance ledgers, and downstream Real seals before a completion-facing read is exported. It does not identify filters with nets, does not assert quotient equality of their classifiers, and does not choose a common representative.*

Proof. Project the $\mathsf{CauchyFilterLimit}^{\uparrow}$ carrier. The displayed route of Definition 1558.1 includes the stream row S, regular readback row R, dyadic tolerance ledger D, and Real seal row A.

Compare with the Cauchy-net packet only at the shared rows. The directed-net coverage theorem above requires any net-facing consumer of the filter-limit packet to preserve the same S, R, D, A route, so those rows form the comparison surface.

The comparison stops at row sharing. Since the filter packet has no coordinate for quotient filters, selected subnets, quotient equality of nets, or a common representative, the result records finite route compatibility without collapsing the two classifiers. □

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier filter comparison`

Theorem 1558.10 (CauchyFilterLimit bridge surface)**.** *For every accepted* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *carrier* $L = (B, F, S, R, D, A, H, C, P, N)$*, the public route supplies the bridge surface from the concrete Cauchy-filter-limit carrier to the abstract completion-limit interface. The surface preserves basis saturation, regular readback, dyadic tolerance, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming, and it refuses quotient filters, selected subnets, host limits, choice, and ambient completeness.*

Proof. Start with the basis-saturation and regular-readback obligations of Definition 1558.5 and Definition 1558.6. They force every completion-facing request to expose B, F, S, R, D, A before any limit read is exported.

Apply the ledger refusal theorem Definition 1558.7. It keeps quotient filters, selected host limits, host real equality, countable-choice selectors, and ambient completeness outside the carrier surface.

The directed-net coverage theorem Definition 1558.8 and the comparison theorem Definition 1558.9 show that downstream net or completion consumers can only compare the shared finite rows. Transport, replay, provenance, and naming then repack the same route as the bridge surface without adding a host-limit coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyFilterLimitUp.CauchyFilterLimitCarrier bridge surface`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterLimit}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1558.1, Definition 1558.2, Definition 1558.3, Definition 1558.4, Definition 1558.5, Definition 1558.6, Definition 1558.7, Definition 1558.8, Definition 1558.9, and Definition 1558.10 close the directed-net handoff, regular seal handoff, filter comparison, and bridge surface from generated filter data to completion-limit consumers and the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterLimit}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, host real equality, countable-choice selectors, ambient $\mathsf{Real}^{\uparrow}$ completeness, or stronger Lean verification.

Upgrade path: Further work is a Lean-side verification and bridge audit for the same mature paper-side surface.

Constructive story: A $\mathsf{CauchyFilterLimit}^{\uparrow}$ packet is generated from a CauchyFilterBasis row, a CauchyFilter saturation row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1559

A Concrete Naming Certificate for MetricCompletionFinite$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the MetricCompletionFinite$^{\uparrow}$ packet records the finite-window completion boundary that can be inspected before any Real$^{\uparrow}$ seal is read. It sits downstream of the metric-completion surface of chapter 1506, the generated Cauchy-filter basis interface of chapter 1501, the dyadic precision window of chapter 1524, and the embedding route of chapter 1512. Its role is to bind those rows to a regular-rational or Real-facing readback without importing quotient completions, selected representatives, countable choice, open-cover compactness, host equality, or an ambient complete metric space.

Definition 1559.1 (MetricCompletionFinite carrier)**.** *A* MetricCompletionFinite$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, B, W, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* MetricCompletion$^{\uparrow}$ *row naming the completion-facing metric source and its finite admissibility boundary.*
2. *B is the* CauchyFilterBasis$^{\uparrow}$ *row, or the finite CauchyNet branch when the source is presented by nets, from which the completion request is generated.*
3. *W is the* DyadicRoundingWindow$^{\uparrow}$ *precision row that fixes the finite dyadic scale inspected by the request.*
4. *E is the* CompletionEmbedding$^{\uparrow}$ *row carrying the source object into the completion-facing interface.*
5. *R is the* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *seal readback row exposed only after M, B, W, E have been replayed.*
6. *S is the local seal selector that records which finite window is consumed before the readback row is public.*
7. *H records componentwise* hsame *transport for the metric-completion, Cauchy-basis, dyadic-window, embedding, readback, seal-selector, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through the Cauchy basis, dyadic window, completion embedding, finite seal selector, and readback row.*
9. *P is the* Pkg *provenance over* MetricCompletion$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, DyadicRoundingWindow$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFinite}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient completion equality, a selected representative, countable-choice selection, open-cover compactness, host equality, or an ambient complete metric space.

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteTasteGate single carrier alignment`

Theorem 1559.2 (MetricCompletionFinite total-bounded window)**.** *Every accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet exposes its finite total-bounded branch through the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *row, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row or finite CauchyNet branch, the* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *precision row, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row, componentwise transport, replay, provenance, and local* NameCert *row before any completion consumer may read a finite total-bounded window.*

The exposed window is exactly the carrier route

$$M, B, W, E, S \longmapsto R \longmapsto H, C, P, N,$$

and it exports no quotient completion equality, selected representative, countable-choice selector, open-cover compactness row, host equality, or ambient complete metric space.

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteTotalBoundedWindow`

Proof. Project the carrier of Definition 1559.1. Its rows $M, B, W, E, R, S, H, C, P, N$ are the only admitted coordinates, so the finite total-bounded branch must be read through that tuple.

Use the finite-window and readback rows already displayed in the carrier. The Cauchy source row B, dyadic window row W, embedding row E, and local selector S precede the readback row R, and the transport, replay, provenance, and naming rows preserve that order.

Finally apply the ledger refusal clause of Definition 1559.3. Since none of the excluded completion principles has a carrier coordinate, no consumer can replace the finite window by quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or an ambient complete metric space. □

Theorem 1559.3 (MetricCompletionFinite NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *carrier* $F = (M, B, W, E, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFinite}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the displayed metric-completion, Cauchy-basis, dyadic-window, embedding, readback, seal-selector, transport, continuation, provenance, and local naming rows;*
2. *generated-Cauchy source exposure, requiring B to be read before a completion-facing consumer inspects W, E, R, or S;*
3. *finite-window precision exposure, requiring W and S to display the dyadic scale consumed by the readback route;*
4. *embedding and readback handoff, requiring E to precede every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read through R;*
5. *ledger refusal, excluding quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, and ambient complete metric spaces.*

No local NameCert row is stored outside those five obligations and the structural rows H, C, P, N.

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteNameCertObligations`

Proof. Project the carrier of Definition 1559.1. Its public rows are exactly $M, B, W, E, R, S, H, C, P, N$, so carrier admission cannot expose a second completion object, representative selector, cover datum, host equality, or ambient completeness witness.

The generated source and window obligations come from the order of the displayed continuation. A completion-facing request first reads the metric-completion row M and the Cauchy basis row B, then the dyadic precision row W and local selector S.

The embedding and readback handoff is the remaining public route. The row E carries the source into the completion-facing interface, and R is readable only after E and the finite window rows have been replayed through H, C, P, N. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteCarrier namecert obligations`

Theorem 1559.4 (MetricCompletionFinite obligation boundary)**.** *Every accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet exposes carrier admission, generated-Cauchy source exposure, finite-window precision exposure, embedding and readback handoff, and ledger refusal before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal consumer can read completion-facing data. The boundary is the displayed tuple*

$$F = (M, B, W, E, R, S, H, C, P, N),$$

and no consumer may replace it by quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or an ambient complete metric space.

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteCarrier obligation boundary`

Proof. Project the carrier of Definition 1559.1. The rows $M, B, W, E, R, S, H, C, P, N$ are the only available coordinates, so carrier admission and ledger refusal are already fixed by the displayed packet.

Apply the NameCert obligations of Definition 1559.3. They require the generated-Cauchy source row B, the finite dyadic window W, the local selector S, and the embedding row E to be exposed before a readback row can be public.

Finally use the window readback theorem Definition 1559.5. It forces every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer through the finite route $M, B, W, E, S \longmapsto R \longmapsto H, C, P, N$, so none of the excluded quotient, representative, choice, compactness, host-equality, or ambient-completeness data can be read from the packet. □

Theorem 1559.5 (MetricCompletionFinite window readback)**.** *Let* $F = (M, B, W, E, R, S, H, C, P, N)$ *be an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet. Every completion-facing read that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or a* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite route*

$$M, B, W, E, S \longmapsto R \longmapsto H, C, P, N.$$

Thus the consumer sees the $\mathsf{MetricCompletion}^{\uparrow}$ *row, the generated Cauchy-filter or CauchyNet finite branch, the* $\mathsf{DyadicRoundingWindow}^{\uparrow}$ *precision row, and the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row before it reads any regular-rational or Real-facing seal.*

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteWindowReadback`

Proof. Begin with an accepted completion-facing consumer. Carrier admission gives access to the readback row R, but only as part of the displayed packet.

Replay the continuation row C. The request passes through M for the completion-facing metric source, B for the finite generated Cauchy data, W for the dyadic precision window, E for the embedding route, and S for the local seal selector.

Only after those rows are replayed can the consumer read R. The transport, provenance, and local naming rows preserve that dependency order, so the visible route factors through the finite window before any $\mathsf{Real}^{\uparrow}$ seal is public. □

Theorem 1559.6 (MetricCompletionFinite classifier exactness)**.** *Let $F = (M, B, W, E, R, S, H, C, P, N)$ and $F' = (M', B', W', E', R', S', H', C', P', N')$ be accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packets. The local classifier identifies F with F' exactly when the metric-completion, Cauchy-source, dyadic-window, embedding, readback, seal-selector, transport, continuation, provenance, and local naming rows are componentwise equal along the displayed* hsame *route:*

$$M\mathsf{hsame}M', \quad B\mathsf{hsame}B', \quad W\mathsf{hsame}W', \quad E\mathsf{hsame}E', \quad R\mathsf{hsame}R', \quad S\mathsf{hsame}S', \quad H\mathsf{hsame}H', \quad C\mathsf{hsame}C', \quad P$$

There is no additional classifier coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or ambient complete metric spaces.

Proof. Use the carrier of Definition 1559.1. Both accepted packets have exactly the rows $M, B, W, E, R, S, H, C, P, N$ and their primed counterparts, so the classifier can inspect only those coordinates.

Apply the NameCert obligations of Definition 1559.3. They force carrier admission, source exposure, precision exposure, embedding handoff, and ledger refusal to be read through the same displayed rows.

Finally use the readback route of Definition 1559.5. A classifier equality that survives the readback must therefore be componentwise hsame on those rows, and componentwise hsame supplies the same finite route in the reverse direction. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteClassifierExactness`

Theorem 1559.7 (MetricCompletionFinite stability transport)**.** *If accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packets $F = (M, B, W, E, R, S, H, C, P, N)$ and $F' = (M', B', W', E', R', S', H', C', P', N')$ are classifier-equal in the sense of Definition 1559.6, then carrier admission and readback eligibility transport from F to F' and from F' to F. In particular, every consumer allowed to read R through M, B, W, E, S is allowed to read R' through M', B', W', E', S' after the componentwise* hsame *transport.*

Proof. Start with the componentwise classifier supplied by Definition 1559.6. It gives transport for each carrier coordinate, including the Cauchy-source row, dyadic-window row, completion-embedding row, seal selector, and readback row.

Carrier admission is one of the obligations of Definition 1559.3, so it is preserved by the displayed transport row H and the local naming row N.

Readback eligibility is the route of Definition 1559.5. Transport each row in the route $M, B, W, E, S \longmapsto R$ to the primed route and repeat the same argument in the opposite direction. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteCarrier stability transport`

Theorem 1559.8 (MetricCompletionFinite ledger exactness)**.** *The refusal ledger of an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet is exact: it excludes quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, and ambient complete metric spaces, and it excludes no displayed coordinate of the carrier $F = (M, B, W, E, R, S, H, C, P, N)$.*

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteCarrier ledger exactness`

Proof. The carrier of Definition 1559.1 lists every available coordinate. The rows $M, B, W, E, R, S, H, C, P, N$ are admitted by the packet and therefore cannot be part of the refusal ledger.

The obligation theorem Definition 1559.3 names the ledger refusal row. Its excluded objects are exactly the quotient, representative, choice, compactness, host-equality, and ambient-completeness data.

The readback theorem Definition 1559.5 confirms that every completion-facing read stays inside the displayed finite route. Hence the ledger refuses precisely the non-displayed completion principles and leaves the admitted carrier coordinates available. □

Theorem 1559.9 (MetricCompletionFinite non-escape)**.** *An accepted* MetricCompletionFinite$^{\uparrow}$ *packet exports no quotient completion equality, no selected representative, no countable-choice selector, no open-cover compactness row, no host equality, and no ambient complete metric space. Every completion-facing consumer of the packet must read only the displayed rows $M, B, W, E, R, S, H, C, P, N$.*

Proof. The NameCert obligations of Definition 1559.3 list the only carrier, source, precision, embedding, readback, and refusal rows available to the packet.

The window readback theorem Definition 1559.5 then covers every route that reaches a regular-rational readback or Real seal. Since the carrier has no additional coordinate beyond $M, B, W, E, R, S, H, C, P, N$, none of the excluded quotient, representative, choice, compactness, host-equality, or ambient-completeness objects can be projected from an accepted packet. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteNonescape`

Theorem 1559.10 (MetricCompletionFinite obligation closure)**.** *The displayed packet rows M, B, W, E, R, S, H, C close the* MetricCompletionFinite$^{\uparrow}$ *obligation surface: carrier admission, classifier exactness, finite-window readback, stability transport, ledger exactness, and non-escape are all accounted for inside the accepted finite-window completion packet.*

Proof. Carrier admission is the NameCert obligation package of Definition 1559.3. It exposes exactly the metric-completion row, basis row, finite precision window, embedding row, readback row, local seal row, transport, replay, provenance, and local naming row.

The finite-window readback and classifier surface are then fixed by Definition 1559.5 and Definition 1559.6. Together they keep every completion-facing read on the displayed $M, B, W, E, R, S, H, C, P, N$ route.

Finally apply stability transport, ledger exactness, and non-escape from Definition 1559.7, Definition 1559.8, and Definition 1559.9. These rows preserve the route under hsame transport, identify the refusal ledger exactly, and rule out quotient completion equality, selected representatives, countable choice, compactness, host equality, and ambient complete metric spaces. □

Theorem 1559.11 (MetricCompletionFinite obligation closure register)**.** *For every accepted* MetricCompletionFinit *packet, the displayed carrier row of Definition 1559.1, the local NameCert obligations of Definition 1559.3, classifier exactness from Definition 1559.6, finite-window readback from Definition 1559.5, stability transport from Definition 1559.7, ledger exactness from Definition 1559.8, and non-escape from Definition 1559.9 are exactly the obligationClosure packet for* MetricCompletionFinite$^{\uparrow}$.

Proof. Carrier admission is read from Definition 1559.1. The NameCert surface and the displayed completion-facing obligation boundary are supplied by Definition 1559.3 and Definition 1559.10.

The reader-facing route is fixed by Definition 1559.5, while classifier comparison and transport are fixed by Definition 1559.6 and Definition 1559.7.

Finally, Definition 1559.8 and Definition 1559.9 account for the refusal ledger and rule out non-displayed completion principles. These cited rows exhaust the required obligationClosure register, so no additional packet coordinate remains. □

Theorem 1559.12 (MetricCompletionFinite finite-net limit readback)**.** *Let $F = (M, B, W, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet. Any completion-facing finite-net consumer must read the metric-completion row M, the finite Cauchy-basis or CauchyNet branch B, the dyadic window W, the embedding row E, and the local seal selector S before it reads R, and it must keep the structural rows H, C, P, N attached to that route.*

Consequently the finite-net readback cannot be replaced by quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or an ambient completeness principle.

Proof. Start from the carrier of Definition 1559.1. It lists $M, B, W, E, R, S, H, C, P, N$ as the complete finite completion-facing packet.

Apply Definition 1559.5. The consumer can reach a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal only through

$$M, B, W, E, S \longmapsto R \longmapsto H, C, P, N.$$

Use Definition 1559.6 to keep the readback on this displayed finite route under classifier comparison. Then use Definition 1559.9 to exclude the non-displayed completion principles from the exported packet. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteFiniteNetLimit`

Theorem 1559.13 (MetricCompletionFinite scoped dependency package)**.** *For every accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet, the carrier of Definition 1559.1, the local NameCert obligations of Definition 1559.3, classifier exactness, finite-window readback, finite-net limit readback, stability transport, ledger exactness, and non-escape bind every completion-facing read to the displayed dependency package*

$\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHi

The CauchyNet branch is read only through the finite source row B, and every readback into a regular-rational or Real-facing seal remains attached to the same $M, B, W, E, R, S, H, C, P, N$ route.

The package exports no quotient completion, selected representative, countable choice family, open-cover compactness proof, host equality, or ambient complete metric space.

Proof. First project the displayed carrier. The rows $M, B, W, E, R, S, H, C, P, N$ are the whole completion-facing packet, and the NameCert obligation theorem makes carrier admission, source exposure, finite-window precision, embedding handoff, and ledger refusal visible before any readback.

Next apply classifier exactness, window readback, finite-net limit readback, and stability transport. These theorems force every completion-facing consumer to pass through the metric-completion row, the Cauchy-filter or CauchyNet source branch, the dyadic window, the completion embedding, the local seal selector, and the readback row before the structural rows replay and name the same route.

Finally use ledger exactness and non-escape. The refusal ledger names exactly the quotient-completion, representative-selection, countable-choice, open-cover-compactness, host-equality, and ambient-completeness principles that are absent from the carrier, so the scoped package contains only the displayed completion rows and their hsame, Cont, Pkg, and $\mathsf{NameCert}$ structure. □

Theorem 1559.14 (MetricCompletionFinite public export route)**.** *Every public consumer of an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet receives exactly the displayed carrier, local* $\mathsf{NameCert}$ *obligations, classifier exactness, finite-window readback, finite-net limit readback, stability transport, ledger exactness, and non-escape rows before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is public. Equivalently, the public export route is the visible packet*

$$F = (M, B, W, E, R, S, H, C, P, N)$$

together with the dependency package of Definition 1559.13; it exports no quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or ambient complete metric space.

Proof. Project the displayed carrier of Definition 1559.1. This gives exactly the rows $M, B, W, E, R, S, H, C, P, N$ and no second completion object.

Apply Definition 1559.3 to expose carrier admission, generated-Cauchy source exposure, finite-window precision exposure, embedding and readback handoff, and ledger refusal. Then use Definition 1559.5 and Definition 1559.12 to keep both regular-rational and finite-net completion reads upstream of the seal row.

Classifier exactness and stability transport keep the same rows public under componentwise hsame comparison. Ledger exactness and non-escape, Definition 1559.8 and Definition 1559.9, refuse the non-displayed completion principles.

Finally apply Definition 1559.13. It binds the public consumer to the same scoped finite-window completion dependency package before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal is public, so the export route contains exactly the listed rows. □

Theorem 1559.15 (MetricCompletionFinite bridge window)**.** *An accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *carrier whose finite-net limit readback and public export route are displayed can hand a finite completion window to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal consumers. The handoff is only a finite* $\mathsf{BHist/Cont/Pkg}$ *ledger over* $M, B, W, E, R, S, H, C, P, N$ *and the dependency package of Definition 1559.13; it does not export quotient completion equality, selected representatives, ambient complete metric spaces, or Real completeness.*

Proof. Apply Definition 1559.12. It forces finite-net consumers to read the metric-completion row, finite Cauchy-basis or CauchyNet branch, dyadic window, embedding row, local seal selector, readback row, and structural rows before any completion-facing output is available.

Next apply Definition 1559.13. The package keeps the handoff attached to $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so $\mathsf{StreamName}^{\uparrow}$ consumers see only the displayed finite windows and $\mathsf{RegSeqRat}^{\uparrow}$ consumers see only the regular-rational readback.

Finally apply the public export route of Definition 1559.14. The public consumer receives the same finite packet before any $\mathsf{Real}^{\uparrow}$ seal is public. Since the ledger and non-escape rows refuse quotient completion equality, selected representatives, ambient complete metric spaces, and Real completeness, the bridge window is a finite completion handoff rather than an ambient completion theorem. □

Theorem 1559.16 (MetricCompletionFinite L10 public bridge)**.** *Any public completion-facing export through an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet factors through*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CauchyFilterBasis}^{\uparrow},\ \mathsf{DyadicRoundingWindow}^{\uparrow},\ \mathsf{CompletionEmbedding}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before it can be read as a public L10 completion datum. The bridge exposes only the displayed finite-window carrier, local NameCert obligations, readback rows, dependency package, and public export route. It refuses quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, and ambient complete metric spaces.

Proof. Start with the accepted carrier of Definition 1559.1. The obligation surface of Definition 1559.3 exposes the metric-completion row, Cauchy-filter basis, dyadic rounding window, completion embedding, regular rational readback, Real seal, transport, replay, provenance, and local naming rows before a public consumer can read the packet.

Next apply Definition 1559.5. It keeps every regular-rational or Real-facing read inside the finite dyadic window and prevents the export from bypassing $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$.

The scoped package theorem, Definition 1559.13, then binds the same rows as the only completion-facing dependency package. The public export theorem, Definition 1559.14, makes that package the visible surface for consumers.

Since the ledger in these rows has no coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or ambient complete metric spaces, the public read is an L10 finite-window completion datum only after passing through the listed rows. □

Theorem 1559.17 (MetricCompletionFinite bridge scope)**.** *Every bridge-facing read of an accepted* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *packet factors through the displayed* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it can serve as the abstract completion interface. The bridge scope is therefore the finite route named by the carrier, NameCert obligations, window readback, scoped dependency package, and public export route; it does not export quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or ambient complete metric spaces.*

Proof. Project the carrier of Definition 1559.1. Its rows already display the metric-completion source, Cauchy-filter basis branch, dyadic window, completion embedding, regular-rational readback, Real seal, structural transport, replay, provenance, and local naming.

Apply the NameCert obligations of Definition 1559.3 and the window readback of Definition 1559.5. Together they force every bridge-facing read to expose the finite-window packet before any regular-rational or Real-facing completion datum is public.

The scoped dependency package Definition 1559.13 then pins the same read to $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The public export route Definition 1559.14 makes that package the visible boundary for downstream consumers.

Since the carrier and ledger rows have no coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, or ambient complete metric spaces, the bridge-facing read is exactly a finite abstract-completion interface and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFinite}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionFinite}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1559.1, Definition 1559.3, Definition 1559.5, Definition 1559.16, and Definition 1559.17 bind the mature finite-window completion package through carrier rows, NameCert obligations, window readback, public export routing, and bridge-facing scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionFinite}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetricCompletionFiniteUp.MetricCompletionFiniteWindowReadback`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, ambient complete metric spaces, or bridge checking.

Upgrade path: Bridge checking requires a Lean bridge theorem connecting the mature finite-window completion packet to the abstract MetricCompletion$^{\uparrow}$ interface.

Constructive story: A MetricCompletionFinite$^{\uparrow}$ packet is generated from a MetricCompletion row, a CauchyFilterBasis or CauchyNet finite branch, a DyadicRoundingWindow precision row, a CompletionEmbedding row, a RegSeqRat or Real seal readback, local seal selection, componentwise hsame transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1560

A Concrete Naming Certificate for $\mathsf{CompletionDensity}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompletionDensity}^{\uparrow}$ packet records the finite density surface by which source names remain visible inside the regular Cauchy completion route. It sits between the embedding packet of chapter 1512, the regular dense embedding of chapter 1453, the regular rational name surface of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the dense image of displayed source names before any completion-facing consumer can treat the route as a completed real object; it is not a quotient completion, a selected limit, a countable-choice construction, a host real equality principle, or an ambient completeness assertion.

Definition 1560.1 (CompletionDensity carrier)**.** *A* $\mathsf{CompletionDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, W, R, T, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-name row whose entries are to remain dense after entering the completion route;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source names are inspected;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows;*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that controls the finite density test;*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that carries the source names into the completion-facing surface;*
6. *Q is the accepted* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *row witnessing that every regular Cauchy density request reads the image through S, W, R, T, E before reaching the* $\mathsf{Real}^{\uparrow}$ *seal;*
7. *H records componentwise* hsame *transport for the source row, windows, readbacks, dyadic ledger, embedding row, dense-image row, continuation row, provenance row, and local naming row;*
8. *C records displayed* Cont *replay from a source-name request through finite windows, regular readback, dyadic tolerance, completion embedding, dense-image verification, and real-seal hand-off;*
9. *P is the* Pkg *provenance over* $\mathsf{CompletionDensity}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionDensity}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient completion, a selected representative limit, countable choice, host real equality, ambient completeness, or an external dense subset.

Theorem 1560.2 (CompletionDensity NameCert obligations)**.** *For an accepted* $\mathsf{CompletionDensity}^{\uparrow}$ *carrier $D = (S, W, R, T, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionDensity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source names, finite stream windows, regular rational readbacks, dyadic tolerance ledger, completion embedding row, regular Cauchy dense-image row, transports, replay route, provenance, and local naming row;*
2. *source-image exactness, requiring every dense-image claim to start from the row S and to inspect it only through W, R, T;*
3. *embedding compatibility, requiring the row E to be the only completion-facing handoff of those source names;*
4. *dense-image stability, requiring the accepted row Q to remain attached to S, W, R, T, E under the componentwise* hsame *row H and displayed* Cont *replay C;*
5. *provenance exhaustion, requiring P and N to name only the displayed route and to export no quotient completion, selected limit, countable-choice selector, host real equality, ambient completeness row, or detached dense subset.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1560.1. The tuple displays the source row, window row, regular readback, tolerance ledger, completion embedding, dense-image row, transports, replay, provenance, and local name.

Source-image exactness is forced by the order of the displayed rows. A density request first reads S, then inspects the source name through W, obtains regular rational readback through R, and consults the dyadic ledger T before the completion embedding row E is available.

Dense-image stability is the role of Q, H, C. The accepted regular Cauchy dense embedding row Q is transported only componentwise by H and replayed only along the continuation route C, so no second dense-image witness or detached subset can enter the certificate.

Finally, P and N package and name the same finite route. Since the carrier lists no quotient completion, selected limit, countable-choice selector, host real equality, ambient completeness, or external dense subset coordinate, those data cannot be exported by the local NameCert surface. □

Theorem 1560.3 (CompletionDensity regular Cauchy dense image)**.** *Let $D = (S, W, R, T, E, Q, H, C, P, N)$ be an accepted* $\mathsf{CompletionDensity}^{\uparrow}$ *packet. Every regular Cauchy density read of the source image factors through the finite route*

$$S, W, R, T, E, Q, H, C, P, N.$$

In particular, a $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *consumer can read the dense image only after the source names, stream windows, regular rational readbacks, dyadic tolerance ledger, and completion embedding row have been displayed. The read cannot substitute a quotient completion, a selected host limit, a countable-choice schedule, host real equality, ambient completeness, or an external dense subset.*

Proof. Start with a regular Cauchy dense-image consumer. The carrier gives the consumer only the tuple rows of Definition 1560.1.

The consumer reaches the dense-image row Q after the source route S, W, R, T and the embedding row E have been displayed. Thus every density read is downstream of the same finite source-name and tolerance route.

Transport and replay preserve this route through H and C, while P and N record it as provenance and local naming data. Since no quotient, selected host limit, countable-choice schedule, host equality, ambient completeness, or external dense subset appears in the tuple, the dense image is exhausted by the stated finite packet. □

Theorem 1560.4 (CompletionDensity Real handoff)**.** *For an accepted* $\mathsf{CompletionDensity}^{\uparrow}$ *carrier* $D = (S, W, R, T, E, Q, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing completion read that uses the dense image first consumes the displayed route*

$$\mathsf{StreamName}^{\uparrow}(W), \quad \mathsf{RegSeqRat}^{\uparrow}(R), \quad \mathsf{DyadicRatCore}^{\uparrow}(T), \quad \mathsf{CompletionEmbedding}^{\uparrow}(E), \quad \mathsf{RegularCauchyDenseEr}$$

The terminal real-name seal therefore receives only a dense image generated from source names already carried by S and replayed through H, C, P, N. It receives no quotient completion, selected limit, countable choice, host real equality, ambient completeness, or independent real equality witness.

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing completion read. The packet exposes no terminal real coordinate except through the dense-image row Q and the structural rows H, C, P, N.

The row Q is downstream of the completion embedding row E, and E is downstream of the source-name route S, W, R, T. Hence the real-facing consumer must first read the StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, completion embedding, and regular Cauchy dense-image row displayed in the statement.

The remaining rows only transport, replay, package, and name that route. Because the carrier has no quotient-completion coordinate, selected limit, countable choice, host real equality, ambient completeness row, or independent real equality witness, the Real handoff is exactly the displayed finite density route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionDensity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1560.1, Definition 1560.2, Definition 1560.3, and Definition 1560.4 seed the dense source-image surface between CompletionEmbedding, RegularCauchyDenseEmbedding, RegSeqRat, StreamName, DyadicRatCore, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionDensity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, host real equality, ambient completeness, independent real equality witnesses, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-image exactness, embedding compatibility, dense-image stability, Real handoff, and provenance exhaustion for BEDC.Derived.CompletionDensityUp.

Constructive story: A $\mathsf{CompletionDensity}^{\uparrow}$ packet is generated from source names, StreamName finite windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a CompletionEmbedding row, an accepted RegularCauchyDenseEmbedding row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1561

A Concrete Naming Certificate for $\mathsf{CauchyNetLimit}^{\uparrow}$

Following Kelley and Bishop–Bridges constructive analysis, the $\mathsf{CauchyNetLimit}^{\uparrow}$ packet names the directed-net limit boundary reached after a $\mathsf{CauchyNet}^{\uparrow}$ directed-window row has been consumed and before a $\mathsf{Real}^{\uparrow}$ seal can be read. It sits downstream of chapter 589, reads the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the dyadic tolerance ledger of chapter 291, and exposes the seal boundary of chapter 38 only through the completion-facing boundary of chapter 1506. The chapter records a finite directed-net limit packet, not a quotient of nets, not a selected host limit, and not an ambient completeness principle.

Definition 1561.1 (CauchyNetLimit carrier)**.** *A* $\mathsf{CauchyNetLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row. It names the inspected directed windows and the common upper-window witnesses consumed by the limit request.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row read from the directed windows exposed by K.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning the scheduled window observations into regular rational data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the regular rational observations at the requested directed-limit scale.*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, W, R, D have been replayed.*
6. *H records componentwise* hsame *transport for the directed-window, window, readback, tolerance, seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a directed-net limit request through finite windows, regular readback, dyadic tolerance, and then the seal row.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient net equality, a selected host limit, cofinal-choice selection, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier`

Theorem 1561.2 (CauchyNetLimit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetLimit}^{\uparrow}$ *carrier* $L = (K, W, R, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyNetLimit}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed CauchyNet directed-window row, StreamName windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, continuation, provenance, and local naming row;*
2. *directed-window consumption, requiring the* K *row to supply the displayed directed windows and common upper-window witnesses before any limit-facing read can inspect* W, R, D, A*;*
3. *regular readback, requiring each limit-scale observation to pass through* W *and* R *before the tolerance ledger* D *is consulted;*
4. *Real seal handoff, requiring the seal row* A *to remain downstream of* K, W, R, D*;*
5. *ledger refusal, excluding quotient nets, selected limits, cofinal choice, host equality, and Real completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1561.1. The projection exposes exactly the accepted CauchyNet row, StreamName window row, regular readback row, dyadic tolerance ledger, Real seal, and structural rows H, C, P, N.

Directed-window consumption is forced by the row order. The continuation row C routes a limit request from K into the finite windows W before the request can reach the regular readback R, the tolerance ledger D, or the seal row A.

The regular readback and seal conditions are internal to the same packet. Transport by H preserves the route, while P and N package and name only that displayed route, so no separate quotient, selected-limit, cofinal-choice, host-equality, or completeness coordinate remains available. □

Lean4 ✓ `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier semantic name certificate`

Theorem 1561.3 (CauchyNetLimit Real seal handoff)**.** *Let* $L = (K, W, R, D, A, H, C, P, N)$ *be an accepted* $\mathsf{CauchyNetLimit}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the finite route*

$$K, W, R, D \longmapsto A \longmapsto H, C, P, N.$$

Thus the limit seal is read only after the $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger have been displayed. The route contains no quotient net, selected host limit, cofinal-choice selector, host real equality, or ambient Real completeness principle.*

Proof. Begin with a Real-facing consumer of the packet. Carrier admission gives access to the seal row A, but only as a row downstream of K, W, R, D.

Replay the continuation row C. The request first consumes the accepted CauchyNet directed-window row K, then the finite StreamName windows W, the regular rational readback R, and the dyadic tolerance ledger D.

Only after this replay can the seal row A be read. The transport, provenance, and local naming rows record the same dependency order, so the packet exports no direct route through quotient nets, selected host limits, cofinal choice, host real equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier real seal handoff`

Theorem 1561.4 (CauchyNetLimit directed-window obligations)**.** *Let $L = (K, W, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyNetLimit}^{\uparrow}$ *packet. Every directed-limit read must consume the accepted* $\mathsf{CauchyNet}^{\uparrow}$ *row K before it reads the window row W, regular readback row R, dyadic tolerance ledger D, or* $\mathsf{Real}^{\uparrow}$ *seal row A. Common upper-window witnesses exposed by K remain stable under the componentwise transport row H and replay through C before the packet can be sealed by P and N.*

Proof. Project the carrier of Definition 1561.1. The row K is the only source for the directed windows and their common upper-window witnesses, while W, R, D, A are downstream reads.

Replay C in the displayed order. The request first consumes K, then the finite windows W, the regular rational readback R, and the dyadic tolerance ledger D before the seal row A is available.

Transport by H preserves the same finite route. The provenance row P and local naming row N therefore package the directed-window obligation without adding quotient nets, selected limits, cofinal choice, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier directed window obligations`

Theorem 1561.5 (CauchyNetLimit dyadic-tolerance handoff)**.** *Let $L = (K, W, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyNetLimit}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing read consumes the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row K, the* $\mathsf{StreamName}^{\uparrow}$ *finite window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D before the seal row A is visible. Thus the Real seal handoff is a dyadic-tolerance handoff, not a direct passage from directed nets to host real equality or ambient completeness.*

Proof. Project the carrier of Definition 1561.1. The rows K, W, R, D are the only rows from which a Real-facing request can obtain directed-window evidence, finite stream observations, regular rational readback, and dyadic tolerance data.

Use Definition 1561.2. Its directed-window consumption, regular readback, Real seal handoff, and ledger refusal clauses require the request to pass through K, W, R, D before the seal row A is available.

The order is the same as in Definition 1561.3 and Definition 1561.4. Replay by C first opens the directed-window row, then the finite window and regular readback rows, then the dyadic tolerance ledger; transport by H preserves this route when the packet is moved componentwise.

The directed-window component consumes the finite upper-window carrier of chapter 1607 before any Cauchy-net limit seal is read.

Therefore any $\mathsf{Real}^{\uparrow}$-facing consumer reads A only after the dyadic tolerance ledger has been displayed. The packet still contains no quotient net, selected host limit, cofinal-choice selector, host real equality, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier dyadic tolerance handoff`

Theorem 1561.6 (CauchyNetLimit abstract completion bridge)**.** *The public* $\mathsf{CauchyNetLimit}^{\uparrow}$ *boundary factors into the abstract completion-facing interface exactly through the displayed rows $K, W, R, D, A, H, C, P, N$ of Definition 1561.1. The factorisation reads the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row K, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance ledger D, the Real$^{\uparrow}$ *seal row A, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N. It has no quotient nets, selected host limits, cofinal choice, host equality, or ambient Real completeness coordinate.*

Proof. Project the carrier in Definition 1561.1. The abstract completion-facing interface can inspect only the displayed directed-window, finite-window, regular-readback, dyadic-tolerance, and Real-seal rows, followed by the structural rows H, C, P, N.

Use the route constraints already isolated in Definition 1561.2, Definition 1561.3, and Definition 1561.5. They force every public read to pass through K, W, R, D before A, and then through the transport, replay, provenance, and local naming rows.

Thus the public boundary and the completion-facing interface share exactly the same finite row list. Since no carrier coordinate supplies quotient-net equality, a selected limit, cofinal choice, host equality, or Real completeness, none can escape through the bridge. □

Lean4 ✓ `BEDC.Derived.CauchyNetLimitUp.CauchyNetLimitCarrier abstract completion bridge`

Closure status for NameCert$_{\text{CauchyNetLimit}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchyNetLimit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1561.1, Definition 1561.2, Definition 1561.3, Definition 1561.4, Definition 1561.5, and Definition 1561.6 bind the directed-window, regular-readback, dyadic-tolerance, Real$^{\uparrow}$-seal, abstract completion-facing bridge, hsame, Cont, Pkg, and NameCert scope for finite Cauchy-net limit reads.

Formal verification: FormalStatus(NameCert$_{\text{CauchyNetLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected host limits, cofinal choice, host real equality, ambient Real$^{\uparrow}$ completeness, or Lean verification.

Upgrade path: No further paper-side closure upgrade is claimed beyond bridge-maintenance and formal verification.

Constructive story: A CauchyNetLimit$^{\uparrow}$ packet is generated from a CauchyNet directed-window row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1562

A Concrete Naming Certificate for $\mathsf{DyadicRatCoreArithmetic}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicRatCoreArithmetic}^{\uparrow}$ packet names the finite arithmetic-window face of the dyadic rational core used before regular rational names and real completions inspect arithmetic data. It sits downstream of chapter 291, reads the signed rows of chapter 31, the rational mantissa rows of chapter 37, the finite schedule rows of chapter 126, the regular readback rows of chapter 301, and the completion-facing seal of chapter 38. The packet records arithmetic stability for displayed dyadic windows; it is not full $\mathsf{Real}^{\uparrow}$ arithmetic, not a quotient construction, not an order principle, not completeness, and not a standard bridge.

Definition 1562.1 (DyadicRatCoreArithmetic carrier)**.** *A* $\mathsf{DyadicRatCoreArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M_0, M_1, E_0, E_1, L_0, L_1, S, W, H, C, P, N)$$

with the following displayed rows:

1. *M_0 and M_1 are signed mantissa rows, each read through the* $\mathsf{Int}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *surfaces used by accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *packets.*
2. *E_0 and E_1 are positive unary exponent rows, carrying the dyadic denominator scale before any common-scale readback is allowed.*
3. *L_0 and L_1 are the denominator ledgers attached to the two mantissa-exponent pairs.*
4. *S is the common-scale normalization row, displaying the finite exponent window into which both mantissas are transported.*
5. *W is the arithmetic-window ledger for sum, negation, difference, and product readbacks at that common scale.*
6. *H records componentwise* hsame *transport for mantissas, exponents, denominator ledgers, common-scale rows, arithmetic windows, continuation rows, provenance rows, and the local naming row.*
7. *C records* Cont *replay from the two input dyadic packets through common-scale normalization and then through the arithmetic-window ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{Int}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRatCoreArithmetic}^{\uparrow}}$ *row.*

The carrier has no coordinate for full $\mathsf{Real}^{\uparrow}$ *arithmetic, order, quotient rational equality, completion endpoints, completeness, or a standard bridge.*

Lean4 (definition) `BEDC.Derived.DyadicRatCoreUp.DyadicRatCoreArithmeticWindow`

Theorem 1562.2 (DyadicRatCoreArithmetic NameCert obligations)**.** *For every accepted* DyadicRatCoreArithmetic *carrier* $A = (M_0, M_1, E_0, E_1, L_0, L_1, S, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicRatCoreArithmetic}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two signed mantissas, two unary exponents, two denominator ledgers, common-scale normalization row, arithmetic-window ledger, transport, continuation, provenance, and local naming row;*
2. *source compatibility, requiring the mantissa and exponent rows to be read as the arithmetic face of accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *packets;*
3. *common-scale exactness, requiring* S *to be consumed before the arithmetic row* W *is read;*
4. *arithmetic-window transport, requiring* H *and* C *to preserve the displayed sum, negation, difference, and product windows under* hsame *transport;*
5. *downstream handoff, requiring* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers to inspect only the finite window exposed by* W*;*
6. *ledger refusal, excluding full* $\mathsf{Real}^{\uparrow}$ *arithmetic, order, quotient rational equality, completion endpoints, completeness, and standard-bridge data.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1562.1. The projection exposes exactly the two signed mantissa rows, two positive unary exponent rows, denominator ledgers, common-scale row, arithmetic-window ledger, and structural rows H, C, P, N.

Source compatibility is forced by the attachment to chapter 291. The mantissas can be inspected only through the displayed $\mathsf{Int}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ rows already packaged by the dyadic core, and the exponent rows can be inspected only through the visible unary denominator ledgers.

Replay the continuation row C. A consumer reaches W only after the two input ledgers have been transported into the common-scale row S, so arithmetic readback never bypasses normalization.

Transport by H preserves the displayed coordinates of the same finite window. The package and local naming rows record only this route, hence no full real arithmetic, order, quotient equality, completion endpoint, completeness, or standard bridge is available. □

Theorem 1562.3 (DyadicRatCoreArithmetic normalization handoff)**.** *Let* $A = (M_0, M_1, E_0, E_1, L_0, L_1, S, W, H, C$ *be an accepted* $\mathsf{DyadicRatCoreArithmetic}^{\uparrow}$ *carrier. Every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of its arithmetic row factors through the finite route*

$$M_0, M_1, E_0, E_1, L_0, L_1 \longmapsto S \longmapsto W \longmapsto H, C, P, N.$$

Thus the downstream phase reads arithmetic only as a normalized dyadic window over displayed mantissa, exponent, denominator, transport, continuation, provenance, and naming data. The route supplies no full $\mathsf{Real}^{\uparrow}$ *arithmetic, order, quotient rational equality, completion endpoint, completeness principle, or standard bridge.*

Proof. Begin with a downstream consumer of the arithmetic row. Carrier admission exposes W, but only as a row downstream of the mantissa, exponent, denominator, and common-scale coordinates.

Replay C from the two dyadic inputs. The route first reads the signed mantissas M_0, M_1, then the unary exponent rows E_0, E_1, then the denominator ledgers L_0, L_1, and only then the common-scale row S.

The arithmetic ledger W is therefore a normalized finite dyadic window. Its visible rows are exactly the sum, negation, difference, and product readbacks transported by H and packaged by P, N.

Since the route ends at the displayed window and structural rows, it cannot export a completed real operation, order classifier, quotient equality, completion endpoint, completeness witness, or standard-bridge component. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRatCoreArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRatCoreArithmetic}^{\uparrow}$ packet is generated from two signed mantissa rows, two unary exponent rows, denominator ledgers, a common-scale normalization row, an arithmetic-window ledger, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRatCoreArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1562.1, Definition 1562.2, and Definition 1562.3 seed the finite arithmetic-window face of $\mathsf{DyadicRatCore}^{\uparrow}$ used by downstream regular and completion phases.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRatCoreArithmetic}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close full $\mathsf{Real}^{\uparrow}$ arithmetic, order, quotient construction, completion endpoints, completeness, a standard bridge, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, common-scale normalization, arithmetic-window transport, downstream handoff, and ledger refusal proofs for the same packet.

Chapter 1563

A Concrete Naming Certificate for $\mathsf{CauchyShift}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyShift}^{\uparrow}$ packet records the finite certified route by which a regular Cauchy name may ignore an initial finite prefix and still present the same tail-facing regularity surface to a downstream $\mathsf{Real}^{\uparrow}$ seal. It sits beside the schedule-changing packet of chapter 1568, reads the explicit modulus discipline of chapter 292, and consumes the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The chapter names a finite tail shift of a regular Cauchy name, not quotient stream equality, not a selected limit, not countable choice, not host real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1563.1 (CauchyShift carrier)**.** *A* $\mathsf{CauchyShift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, k, M, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *schedule row whose finite observation windows are available before the shift is requested.*
2. *T is the shifted* $\mathsf{StreamName}^{\uparrow}$ *schedule row whose nth displayed request is routed to the source request $n + k$.*
3. *k is the finite unary shift-length row, recording the displayed prefix length and no unbounded selector.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row that certifies every post-shift precision request by replaying the corresponding source-tail modulus request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the source and shifted observations at the finite budgets named by k and M.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row showing that the shifted schedule remains a regular rational name after the tail route has been replayed.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, T, k, M, D, R have been consumed.*
8. *H records componentwise* hsame *transport for the source schedule, shifted schedule, shift length, modulus row, dyadic tolerance row, regularity row, Real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a shifted-window request through the finite shift length, back to the source schedule, then forward through the modulus row, dyadic tolerance, regular readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyShift}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, countable-choice tail selection, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1563.2 (CauchyShift NameCert obligations)**.** *For every accepted* $\mathsf{CauchyShift}^{\uparrow}$ *carrier* $K = (S, T, k, M, D, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyShift}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source schedule, shifted schedule, finite shift length, Cauchy modulus row, dyadic tolerance row, regularity row, Real seal, transport, continuation, provenance, and local naming row;*

2. *shift admissibility, requiring every shifted-window read in T to replay through the displayed finite unary shift k before it can consult the source schedule S;*

3. *tail-modulus discipline, requiring M to be consumed before a post-shift observation can be treated as a regular Cauchy tail observation;*

4. *tolerance and readback preservation, requiring D and R to certify the finite regular rational readback after the shifted route has been replayed;*

5. *seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row A to remain downstream of S, T, k, M, D, R;*

6. *ledger refusal, excluding quotient streams, selected limits, countable-choice tail selectors, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1563.1. The projection exposes exactly the source schedule, shifted schedule, finite shift length, Cauchy modulus row, dyadic tolerance row, regularity row, Real seal, and structural rows H, C, P, N.

Shift admissibility is forced by the continuation row C. A shifted-window request reaches T only by replaying the displayed unary shift length k back to the source schedule S, so the packet has no independent tail stream coordinate.

The modulus row M is then the only row that permits the shifted request to be treated as a Cauchy-tail request. The dyadic tolerance row D and regularity row R sit downstream of that tail route, so tolerance preservation and regular readback cannot be exported before the finite shift discipline has been consumed.

Finally, the seal row A is downstream of the same route. Transport by H preserves each listed coordinate, while P and N package only that finite route; hence no quotient stream, selected limit, countable-choice tail selector, host real equality, or ambient completeness coordinate remains available. □

Theorem 1563.3 (CauchyShift regularity transport)**.** *Let $K = (S, T, k, M, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyShift}^{\uparrow}$ *carrier. Every displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity read on the shifted schedule T factors through the finite route*

$$S, k, M, D \longmapsto T \longmapsto R.$$

Thus finite-prefix shift preserves the displayed regularity surface through the Cauchy modulus row and the dyadic tolerance row before any downstream consumer can read R as a regular rational name.

Proof. Begin with a shifted regularity read. Carrier admission gives access to the $\mathsf{RegSeqRat}^{\uparrow}$ row R, but only as the row downstream of the shifted schedule T, finite shift length k, modulus row M, and dyadic tolerance row D.

Replay the continuation row C. The shifted request is translated by the finite unary length k into the source schedule S. The modulus row M then supplies the displayed tail budget for that source request, and the dyadic tolerance row D records the finite comparison at the requested scale.

Once those rows have been consumed, T has exactly the displayed tail observations licensed by S, k, M, D. The regular readback row R therefore transports regularity along the finite shift route, with H preserving the same dependency order and P, N naming only that packet. □

Theorem 1563.4 (CauchyShift Real seal boundary)**.** *Let $K = (S, T, k, M, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyShift}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read of the shifted name factors through the finite route*

$$S, T, k, M, D, R \longmapsto A \longmapsto H, C, P, N.$$

The shifted name reaches the seal only after the source schedule, shifted schedule, finite shift length, Cauchy modulus row, dyadic tolerance row, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed. The route contains no quotient stream equality, selected limit, countable-choice tail selector, host real equality, or ambient completeness principle.*

Proof. Begin with a Real-facing consumer of the packet. Carrier admission gives access to the seal row A, but only as a row downstream of S, T, k, M, D, R.

Replay the continuation row C. The request first reads the shifted schedule T as a finite-prefix shift of the source schedule S, then consumes the shift length k and the Cauchy modulus row M that make the tail request admissible.

After those rows have been consumed, the dyadic tolerance row D and regularity row R provide the finite readback accepted by the Real seal. The transport, provenance, and local naming rows record the same dependency order, so the packet exports no direct route through quotient streams, selected limits, countable-choice tail selection, host real equality, or ambient completeness. □

Theorem 1563.5 (CauchyShift reindexing selector handoff)**.** *Let $K = (S, T, k, M, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyShift}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing read of K that is also consumed by a* $\mathsf{CauchyReindexing}^{\uparrow}$ *route or by a* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *route factors through the ordered handoff*

$$S, k, M, D \longmapsto T \longmapsto R \longmapsto \mathsf{RegularCauchyModulusRealization}^{\uparrow} \longmapsto \mathsf{RealCauchyModulusSelector}^{\uparrow} \longmapsto A$$

with the structural rows H, C, P, N preserving that order. Thus the shifted name may be reindexed, realized as a regular Cauchy modulus surface, selected by the Real Cauchy modulus selector, and then sealed at A, but it exports no quotient stream, selected limit, countable-choice tail selector, host real equality, detached modulus selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 1563.3. Every shifted regularity read first consumes the source schedule, finite shift length, Cauchy modulus row, and dyadic tolerance row before it can read the shifted schedule T and the regular rational row R.

The downstream reindexing side is the route recorded in chapter 1568. A consumer that asks for a $\mathsf{CauchyReindexing}^{\uparrow}$ read therefore receives only the displayed regular readback produced by the shift packet; it does not obtain a second stream coordinate or an independent equality of streams.

The modulus-selection side is the route recorded in chapter 1577 and chapter 1576. The regular Cauchy modulus realization reads the finite M, S, D, R-style window as a displayed regular surface, and the Real Cauchy modulus selector then chooses only the threshold, finite window, tolerance, readback, and seal rows already displayed by that route.

Finally apply Definition 1563.4. The seal row A remains downstream of the shifted route and of the structural rows H, C, P, N. Since neither this carrier nor the cited sibling routes contain quotient streams, selected limits, countable-choice tail selectors, host real equality, detached modulus selectors, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the composite handoff cannot export any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyShift}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyShift}^{\uparrow}$ packet is generated from a source StreamName schedule, a shifted StreamName schedule, a finite unary shift length, a CauchyModulus tail row, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyShift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1563.1, Definition 1563.2, Definition 1563.3, Definition 1563.4, and Definition 1563.5 seed the finite tail-shift route from regular Cauchy names through reindexing, regular modulus realization, selector handoff, and the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyShift}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable-choice tail selectors, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires carrier admission, regularity transport, Real seal boundary, and ledger refusal proofs for the same finite tail-shift packet.

Chapter 1564

A Concrete Naming Certificate for $\mathsf{FrechetFilter}^{\uparrow}$

Following Bourbaki and Kelley, and in the Bishop–Bridges constructive reading of filters, the $\mathsf{FrechetFilter}^{\uparrow}$ packet names the cofinite-tail filter interface used when a sequence tail is read as a finite BEDC filter surface. It refines the finite tail-neighborhood packet of chapter 1119, records the filter-base rows of chapter 1601, reads the finite schedule rows of chapter 126, and hands the same tail route to the sequential-completion interface of chapter 1515 before any regular rational readback or Real-facing completion consumer can inspect the route. The same cofinite-tail filter basis is also the finite route consumed by chapter 1569 before any completion-facing read can inspect a Cauchy-filter limit boundary. The chapter records only the finite cofinite-tail carrier and its handoff rows, not Real completeness, quotient filter equality, selected limits, countable choice, or ambient completion.

Definition 1564.1 (FrechetFilter carrier)**.** *A* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, T, S, M, B, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the unary threshold row. It names the displayed tail bound after which the filter request may read sequence data.*
2. *T is the cofinite tail-neighborhood row. It records finite complements and the tail containment checks supplied by chapter 1119.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row whose finite windows are inspected only after U and T have been consumed.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *row whose tolerance requests are read only through the displayed stream windows and tail threshold.*
5. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row. It packages the cofinite subsets as a finite filter-base surface and records the common-tail meet operation used by downstream consumers.*
6. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row. It receives the cofinite-tail neighborhood surface after the metric and filter-base rows have been displayed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows and tail budgets.*

8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row available only to Real and completion-facing consumers after U, T, S, M, B, Q, R have been replayed.*
9. *H records componentwise* hsame *transport for thresholds, tail neighborhoods, StreamName schedule rows, Metric rows, FilterBase rows, CauchyFilter handoff rows, RegSeqRat readback, Real seal, continuation, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a filter request through the unary threshold, cofinite tail neighborhood, StreamName schedule, Metric row, FilterBase row, CauchyFilter handoff, RegSeqRat readback, and then the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, quotient filter equality, selected limits, countable-choice tail selection, or ambient completion.

Lean4 (definition) `BEDC.Derived.FrechetFilterUp.FrechetFilterCarrier`
Lean4 (definition) `BEDC.Derived.FrechetFilterUp.FrechetFilterUp`

Theorem 1564.2 (FrechetFilter NameCert obligations)**.** *For every accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the unary threshold, cofinite tail-neighborhood row, StreamName schedule row, Metric row, FilterBase row, CauchyFilter handoff row, RegSeqRat readback row, Real seal, transport, continuation, provenance, and local naming row;*
2. *tail-neighborhood admission, requiring every filter request to pass through U and T before it can inspect a stream window;*
3. *cofinal-tail stability, requiring any two displayed thresholds over the same cofinite-tail surface to have a common displayed tail through the FilterBase meet row B;*
4. *convergence-consumer handoff, requiring the displayed cofinite-tail surface to be the only row exported to* $\mathsf{CauchyFilter}^{\uparrow}$ *and then to sequential-completion consumers;*
5. *readback and seal order, requiring S and R to be consumed before the Real seal A can be read;*
6. *ledger refusal, excluding Real completeness, quotient filter equality, selected limits, countable-choice selectors, and ambient completion.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1564.1. The projection exposes exactly the unary threshold, cofinite tail-neighborhood row, StreamName schedule, Metric row, FilterBase row, CauchyFilter handoff, RegSeqRat readback, Real seal, and structural rows H, C, P, N.

Tail-neighborhood admission is forced by the continuation row C. A filter request reaches the schedule row S only after it has replayed through the unary threshold U and the cofinite tail row T, so the packet has no independent infinite-tail coordinate.

The FilterBase row B supplies the common-tail meet for any pair of displayed thresholds over that same cofinite surface. The Cauchy-source row Q is then the only row exported to $\mathsf{CauchyFilter}^{\uparrow}$, and the same route is the handoff offered to sequential-completion consumers.

The readback row R and Real seal A sit downstream of the same route, while H preserves componentwise transport and P, N package only that finite carrier. Hence no Real completeness, quotient filter equality, selected limit, countable-choice selector, or ambient completion coordinate remains available. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterNameCertObligations`

Theorem 1564.3 (FrechetFilter carrier admission obligation)**.** *For every accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier* $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$*, the rows* $U, T, S, M, B, Q, R, A, H, C, P, N$ *are the complete admitted source surface for the local* $\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$ *packet. In particular every* $\mathsf{FiniteTailFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{FilterBase}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, transport, continuation, provenance, and local naming read is admitted only through those displayed rows.*

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterCarrierAdmissionObligation`

Proof. Project the carrier of Definition 1564.1. Its displayed coordinates are exactly the unary threshold, cofinite tail-neighborhood, schedule, metric, filter-base, handoff, readback, seal, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations of Definition 1564.2. The carrier-admission clause lists the same rows and the final clause says that no NameCert obligation is stored outside them.

The later handoff and consumer-route theorems use only this admitted surface. In particular Definition 1564.9, Definition 1564.11, and Definition 1564.15 all replay through subroutes of $U, T, S, M, B, Q, R, A, H, C, P, N$, so no extra source coordinate is available to any consumer. □

Theorem 1564.4 (FrechetFilter cofinal-tail stability obligation)**.** *Let* $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ *be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. If two accepted cofinite-tail requests are based on the same finite-tail row* T*, then their displayed thresholds refine through the* $\mathsf{FilterBase}^{\uparrow}$ *meet row* B *before any* $\mathsf{StreamName}^{\uparrow}$ *schedule row or* $\mathsf{Met}^{\uparrow}$ *tolerance row is read.*

Proof. Project the carrier of Definition 1564.1. The rows U and T present the unary threshold and cofinite tail-neighborhood data, while B is the displayed row where the common-tail meet is stored.

Use Definition 1564.2. Its cofinal-tail stability clause requires two displayed thresholds over the same cofinite-tail surface to pass through the common displayed tail supplied by B.

The route is then the one isolated by Definition 1564.9 and Definition 1564.10. Those theorems place S and M downstream of U, T, B, so schedule and metric consumers cannot read before the FilterBase meet has refined the two requests. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterCofinalTailStabilityObligation`

Theorem 1564.5 (FrechetFilter convergence-consumer handoff obligation)**.** *Let* $F = (U, T, S, M, B, Q, R, A, H, C,$ *be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$*-facing consumer receives the FrechetFilter route only through the displayed rows*

$$U, T, S, M, B, Q, R, A, H, C, P, N.$$

No convergence-facing consumer receives a separate quotient filter, selected limit, countable-choice selector, Real-completeness proof, or ambient completion object.

Proof. Project Definition 1564.1. The rows Q, R, A are downstream handoff, readback, and seal rows, and H, C, P, N only transport, replay, package, and name the same finite packet.

Apply Definition 1564.2. The convergence-consumer handoff clause identifies the displayed cofinite-tail surface as the only export to $\mathsf{CauchyFilter}^{\uparrow}$ and sequential-completion consumers, while the readback and seal clause fixes the order in which R and A may be read.

The consumer skeleton is supplied by Definition 1564.11, Definition 1564.13, Definition 1564.15, and Definition 1564.20. Together these routes replay exactly $U, T, S, M, B, Q, R, A, H, C, P, N$, and the ledger refusal theorem keeps quotient equality, selected limits, choice selectors, completeness, and ambient completion outside the handoff. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterConvergenceConsumerHandoffObligation`

Theorem 1564.6 (FrechetFilter root tail-base admission)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every cofinite-tail read admitted at the root of the packet must pass through the* $\mathsf{FiniteTailFilter}^{\uparrow}$ *threshold rows U, T, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row S, the* $\mathsf{Met}^{\uparrow}$ *tolerance row M, the* $\mathsf{FilterBase}^{\uparrow}$ *meet row B, the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{Real}^{\uparrow}$ *seal row A, and the structural rows H, C, P, N. No root read may expose a tail-neighborhood basis without that ordered finite packet.*

Proof. Project the carrier of Definition 1564.1. The root rows U, T are the only coordinates where the cofinite-tail threshold and finite-complement data are admitted.

Use Definition 1564.9. It routes any tail-neighborhood consumer through U, T before the schedule, metric, and FilterBase rows S, M, B can be read.

Now apply Definition 1564.5. It places Q, R, A, H, C, P, N downstream of the same finite cofinite-tail surface, so a root tail-base admission cannot bypass the CauchyFilter, RegSeqRat, Real, transport, replay, provenance, and naming rows when those consumers are present. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterRootTailBaseAdmission`

Theorem 1564.7 (FrechetFilter root Cauchy consumer boundary)**.** *For an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$, every* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer at the root boundary reads the cofinite-tail filter only through*

$$\mathsf{FiniteTailFilter}^{\uparrow}(U, T),\ \mathsf{StreamName}^{\uparrow}(S),\ \mathsf{Met}^{\uparrow}(M),\ \mathsf{FilterBase}^{\uparrow}(B),\ \mathsf{CauchyFilter}^{\uparrow}(Q),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(A),$$

The boundary exports no quotient filter equality, selected limit, countable-choice tail selector, or independent completion coordinate.

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterRootCauchyConsumerBoundary`

Proof. Begin with the convergence-consumer handoff obligation, Definition 1564.5. It states that every CauchyFilter, RegSeqRat, SequentiallyCompleteMetric, and Real-facing consumer receives exactly the displayed rows $U, T, S, M, B, Q, R, A, H, C, P, N$.

The Cauchy side is isolated by Definition 1564.11. That theorem forces the consumer to read the unary threshold, cofinite-tail row, schedule row, metric row, and FilterBase meet before the CauchyFilter handoff row Q is visible.

The regular-rational read is then supplied by Definition 1564.13. It places R after the same cofinite-tail and CauchyFilter route, while A, H, C, P, N seal and name the packet without adding a selected limit or quotient equality. □

Theorem 1564.8 (FrechetFilter root sequential-completion handoff)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *consumer at the root boundary must consume the same finite cofinite-tail route*

$$\mathsf{FiniteTailFilter}^{\uparrow}(U, T),\ \mathsf{StreamName}^{\uparrow}(S),\ \mathsf{Met}^{\uparrow}(M),\ \mathsf{FilterBase}^{\uparrow}(B),\ \mathsf{CauchyFilter}^{\uparrow}(Q),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(A),$$

before it treats the packet as a sequential-completion source. The handoff does not provide ambient metric completion, selected limits, quotient filters, countable-choice selectors, or a completed $\mathsf{Real}^{\uparrow}$ *object.*

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterRootSequentialCompletionHandoff`

Proof. Start from Definition 1564.20. It already identifies the sequential-completion consumer route as the displayed rows $U, T, S, M, B, Q, R, A, H, C, P, N$.

Next use Definition 1564.6. This pins the root admission of the cofinite-tail basis to the $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{FilterBase}^{\uparrow}$ rows before any downstream completion-facing consumer appears.

Finally combine Definition 1564.7 with Definition 1564.14. The Cauchy and readback rows Q, R, A remain downstream of the same finite tail, and the nonescape theorem refuses ambient completion, selected limits, quotient filters, and countable-choice selectors. □

Theorem 1564.9 (FrechetFilter tail-neighborhood handoff)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every displayed cofinite-tail neighborhood read factors through the finite route*

$$U, T \longmapsto S, M, B \longmapsto H, C, P, N.$$

Thus the $\mathsf{FiniteTailFilter}^{\uparrow}$ *source supplies the unary threshold and finite-complement rows before the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{Met}^{\uparrow}$ *tolerance row, and* $\mathsf{FilterBase}^{\uparrow}$ *meet row are allowed to serve any tail window.*

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterTailNeighborhoodHandoff`

Proof. Begin with a tail-neighborhood consumer. Carrier admission gives the threshold row U and the cofinite tail-neighborhood row T as explicit coordinates of the same BHist packet.

Replay C. The request first reads the unary threshold, then the finite complement and tail-containment data in T, and only then reaches the $\mathsf{StreamName}^{\uparrow}$ schedule row S, the $\mathsf{Met}^{\uparrow}$ tolerance row M, and the $\mathsf{FilterBase}^{\uparrow}$ meet row B.

Transport by H preserves this order under classifier movement, while P and N name the same local packet. Therefore a tail-neighborhood read cannot bypass the finite threshold and finite-complement surface. □

Theorem 1564.10 (FrechetFilter common-tail refinement)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ and $F' = (U', T', S', M', B', Q', R', A', H', C', P', N')$ be two accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carriers over the same finite-tail filter row. Then the two unary threshold requests admit a displayed common tail threshold W read through that finite-tail row, with W above both U and U' by BEDC row comparison. Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer of the two requests factors through the same finite cofinite-tail surface*

$$U, U', T \longmapsto W \longmapsto S, M, B, Q, R, A.$$

The refinement exports neither quotient filter equality, selected limits, countable-choice tail selectors, nor ambient Real completeness.

Proof. Project the two carriers and read their unary threshold rows U and U' over the shared finite-tail filter row. Since the thresholds are displayed unary $\mathsf{Nat}^{\uparrow}$ rows, the finite-tail row supplies the BEDC row comparison needed to choose the larger displayed threshold as W.

Replay both requests through their continuation rows. The request from F reaches the shared tail surface by first consuming U and T, while the request from F' reaches it by first consuming U' and the same finite-tail row. The common threshold W refines both routes, so any tail window admitted after W is admitted for both original requests.

Now apply the handoff route of Definition 1564.9. A $\mathsf{StreamName}^{\uparrow}$ consumer reads only the finite cofinite-tail surface determined by W before inspecting schedule data.

For Cauchy and Real-facing consumers, apply Definition 1564.11 and Definition 1564.15. These routes force the $\mathsf{Met}^{\uparrow}$ row, $\mathsf{FilterBase}^{\uparrow}$ row, $\mathsf{CauchyFilter}^{\uparrow}$ handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal to factor through the same common finite tail. Hence the refinement cannot expose quotient filter equality, selected limits, countable-choice selectors, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterTailCommonRefinement`

Theorem 1564.11 (FrechetFilter Cauchy-source boundary)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyFilter}^{\uparrow}$ *source read exported from the packet factors through*

$$U, T, S, M, B \longmapsto Q \longmapsto H, C, P, N.$$

The Cauchy-filter consumer receives a cofinite-tail source built from unary thresholds, cofinite tail neighborhoods, displayed StreamName schedule rows, Metric tolerance rows, and FilterBase meet rows, with no quotient filter equality, countable choice, or selected limit.

Proof. Start from a Cauchy-source request. The carrier exposes the handoff row Q, but only as a row downstream of U, T, S, M, B.

The continuation row C replays the request through the unary threshold and the cofinite tail-neighborhood row before the schedule, metric, and filter-base rows can be inspected. This replay is exactly the finite cofinite-tail surface that Q hands to $\mathsf{CauchyFilter}^{\uparrow}$.

Since H transports the same coordinates and P, N name no additional source, the packet exports only the displayed cofinite-tail source boundary. Quotient filter equality, countable-choice selection, selected limits, and ambient completion are outside the carrier. □

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterCauchySourceBoundary`

Theorem 1564.12 (FrechetFilter Cauchy-filter export)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every exported* $\mathsf{CauchyFilter}^{\uparrow}$ *read factors through*

$$U, T, S, M, B, Q, H, C, P, N.$$

The export is therefore a displayed cofinite-tail Cauchy-filter source rather than quotient filter equality, countable-choice tail selection, a selected limit, or an ambient completion object.

Proof. Project the carrier of Definition 1564.1. The CauchyFilter handoff row Q is present only after the unary threshold, cofinite tail-neighborhood, StreamName schedule, Metric tolerance, and FilterBase meet rows have been displayed.

Apply the NameCert obligations of Definition 1564.2. They identify Q as the sole convergence-consumer handoff and require ledger refusal for quotient filter equality, selected limits, countable-choice selectors, and ambient completion.

Finally replay the tail route through Definition 1564.9 and the common-tail refinement of Definition 1564.10. The exported read remains anchored in the same finite cofinite-tail surface, with H, C, P, N supplying transport, replay, provenance, and local naming. □

Theorem 1564.13 (FrechetFilter RegSeqRat tail readback)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exported by F is downstream of the cofinite tail threshold U, the cofinite tail-neighborhood row T, the schedule row S, and the FilterBase meet row B. No readback consumer can inspect R as an independent regular rational stream.*

Proof. Read the carrier definition. The row R is not a source coordinate; it is the readback row attached to the displayed stream windows and tail budgets.

Use tail-neighborhood handoff to force each stream window through U and T before S is visible. Then use common-tail refinement to show that simultaneous tail requests are compared by a displayed common threshold and by the FilterBase meet row B.

The NameCert obligations place readback and seal order after the convergence-consumer handoff. Hence the $\mathsf{RegSeqRat}^{\uparrow}$ consumer receives only a tail-indexed readback row, not an independent stream selector or a completed real endpoint. □

Theorem 1564.14 (FrechetFilter completion nonescape)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. The packet exports no quotient filter equality, selected limit, countable-choice tail selector,* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completion. Every completion-facing read must pass through the displayed route*

$$U, T, S, M, B, Q, R, A, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterCompletionNonescape`

Proof. Start with the ledger refusal clause in Definition 1564.2. It excludes quotient filter equality, selected limits, countable-choice selectors, and ambient completion from the local NameCert surface.

Attach the Cauchy-filter export theorem above. It forces any completion-facing request to receive its Cauchy source through $U, T, S, M, B, Q, H, C, P, N$ rather than through an external filter object.

Finally apply the Real and completion consumer route of Definition 1564.15. The route reaches A only after Q and R have been consumed, so the Real-facing seal is a finite read boundary and not a proof of $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1564.15 (FrechetFilter Real and completion consumer route)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every Real or completion-facing consumer of the Frechet filter route factors through*

$$U, T, S, M, B, Q, R \longmapsto A \longmapsto H, C, P, N.$$

Thus the consumer reads unary thresholds, cofinite tail neighborhoods, StreamName schedule rows, Metric tolerance rows, FilterBase meet rows, the CauchyFilter handoff, and RegSeqRat readback before reaching the Real seal. The route does not claim Real completeness, quotient filter equality, selected limits, countable choice, or ambient completion.

Proof. Begin with a Real or completion-facing consumer. Carrier admission gives access to A only as the seal row downstream of the threshold, tail-neighborhood, schedule, CauchyFilter handoff, and readback rows.

Replay C along the displayed route. The request consumes U and T, inspects the schedule row S, reads the metric and filter-base rows M, B, hands the cofinite-tail source through Q, and then reads the regular rational row R.

Only after those rows have been consumed can the seal row A be reached. Componentwise transport by H and provenance through P, N preserve the same dependency order, so the packet supplies a finite consumer route rather than Real completeness, quotient filter equality, selected limits, countable choice, or ambient completion. □

Theorem 1564.16 (FrechetFilter FilterBase meet obligation)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every pair of cofinite tail requests accepted by F must be compared through the displayed* $\mathsf{FilterBase}^{\uparrow}$ *meet row B before any* $\mathsf{StreamName}^{\uparrow}$ *schedule row or* $\mathsf{Met}^{\uparrow}$ *tolerance row is consumed. The meet row is therefore a finite cofinite-tail obligation, not a consequence of stream inspection or metric convergence.*

Proof. Project the carrier of Definition 1564.1. The rows U, T expose the unary threshold and cofinite tail-neighborhood surface, while B is the only coordinate that packages common-tail meets.

Apply the tail-neighborhood handoff of Definition 1564.9. It places S and M downstream of U, T and records that stream windows and metric tolerances may be read only after the finite tail surface is visible.

Use the common-tail refinement of Definition 1564.10. The displayed common threshold is read through the same cofinite-tail row, so the meet obligation belongs to B before any schedule or metric consumer can inspect later rows. □

Theorem 1564.17 (FrechetFilter cofinite-tail closure induction)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Any finite iteration of the* $\mathsf{FilterBase}^{\uparrow}$ *meet row B over displayed cofinite-tail requests preserves the common-tail route of Definition 1564.10. After the iteration, every resulting request still factors through*

$$U, T \longmapsto S, M, B \longmapsto Q, R, A, H, C, P, N,$$

with no selected tail, quotient filter equality, countable-choice selector, or ambient completion coordinate.

Proof. Use induction on the finite list of cofinite-tail requests displayed by the packet. The empty and singleton cases are exactly the carrier route of Definition 1564.9.

For the step, apply Definition 1564.10 to the current common tail and the next displayed request. The $\mathsf{FilterBase}^{\uparrow}$ meet row B supplies the next common threshold while keeping the route inside U, T, S, M, B.

Finally replay the downstream handoff through Definition 1564.16. The CauchyFilter, RegSeqRat, Real, transport, continuation, provenance, and naming rows remain downstream of the same finite cofinite-tail surface. □

Theorem 1564.18 (FrechetFilter threshold monotonicity)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Enlarging the displayed cofinite-tail threshold preserves every downstream* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumer of the packet. The enlarged read may replay the same rows $S, M, Q, R, A, H, C, P, N$ only after the new threshold has passed through T and the* $\mathsf{FilterBase}^{\uparrow}$ *meet row B.*

Proof. Begin with the threshold and tail-neighborhood handoff of Definition 1564.9. A larger displayed threshold remains a cofinite-tail request over the same finite complement row T.

Apply Definition 1564.10. The original threshold and the enlarged threshold admit the enlarged threshold itself as a displayed common tail, so the schedule and metric rows still read the same cofinite surface through S, M, B.

The downstream consumers are then forced by Definition 1564.16. Since Q, R, A, H, C, P, N are reached only after the filter-base meet row, threshold enlargement preserves their route without adding a selector or completion witness. □

Theorem 1564.19 (FrechetFilter cofinite meet associativity)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. For any three displayed cofinite-tail requests in the same packet, the two iterated meet routes through B,*

$$(U_1 \wedge U_2) \wedge U_3 \qquad \textit{and} \qquad U_1 \wedge (U_2 \wedge U_3),$$

determine the same displayed BHist *common-tail route for downstream consumers. The associativity claim is only a route-level equality over the carrier rows; it does not assert quotient filter equality.*

Proof. Apply the finite closure induction of Definition 1564.17 to the ordered triple of displayed cofinite-tail requests. Both parenthesizations consume the same three requests through the same $\mathsf{FilterBase}^{\uparrow}$ meet row B.

Use Definition 1564.10 at each binary meet. In each parenthesization the final threshold is the displayed common tail above all three inputs, so the downstream route begins with the same finite cofinite-tail surface.

Finally apply Definition 1564.16. Since schedule, metric, CauchyFilter, RegSeqRat, Real, transport, replay, provenance, and local naming rows are read only after B, associativity holds at the displayed BHist route level and does not create quotient filter equality. □

Theorem 1564.20 (FrechetFilter sequential-completion handoff)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *consumer of F receives only the rows*

$$U, T, S, M, B, Q, R, A, H, C, P, N.$$

In particular the handoff exports a displayed cofinite-tail source, regular rational readback, Real-facing seal, transport, replay, provenance, and local naming, but no selected limit and no ambient completion witness.

Lean4 ✓ `BEDC.Derived.FrechetFilterUp.FrechetFilterSequentialCompletionHandoff`

Proof. Begin with the Cauchy-source boundary of Definition 1564.11. It sends any convergence-facing request through U, T, S, M, B before the Cauchy-filter handoff row Q is visible.

Next apply Definition 1564.15. The Real and completion-facing route reaches the readback row R and the seal row A only after the Cauchy-filter handoff has been consumed.

Finally use Definition 1564.14. Since the carrier has no coordinate for a selected limit or ambient completion object, a sequential-completion consumer receives only the displayed finite rows named in the statement. □

Theorem 1564.21 (FrechetFilter tail meet monotone refinement)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. For any two displayed cofinite-tail requests read from the finite-tail row T, the* $\mathsf{FilterBase}^{\uparrow}$ *meet row B refines them monotonically: enlarging either unary threshold only enlarges the displayed common-tail threshold, and every downstream* $\mathsf{StreamName}^{\uparrow}$ *schedule row,* $\mathsf{Met}^{\uparrow}$ *tolerance row,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal continues to factor through the same finite cofinite-tail route.*

Proof. Project the carrier. The rows U, T, B are the only rows where threshold data, finite complements, and common-tail meets are displayed before schedule or metric consumers can read later coordinates.

Apply Definition 1564.10 to the two cofinite-tail requests. The common threshold is read through the same finite tail row, and enlarging either input threshold can only move the displayed common tail farther along that row.

Now replay downstream consumption through Definition 1564.16. Since S, M, Q, R, A are all downstream of B, the monotone refinement preserves their route and does not introduce quotient filter equality, a selected tail, countable choice, a selected limit, or ambient completion. □

Theorem 1564.22 (FrechetFilter Cauchy-filter basis cofinal route)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. Every Cauchy-filter-basis consumer of the packet reads the same cofinal tail route*

$$U, T \longmapsto B \longmapsto S, M, Q \longmapsto H, C, P, N.$$

The consumer may use the $\mathsf{FilterBase}^{\uparrow}$ *meet row to refine finite tails, but it cannot replace the displayed basis by quotient filter equality, selected representatives, countable-choice tail selection, or an ambient completion object.*

Proof. Begin with the Cauchy-source boundary of Definition 1564.11. It places every $\mathsf{CauchyFilter}^{\uparrow}$ source read after U, T, S, M, B and before the structural rows H, C, P, N.

Use Definition 1564.21. Any basis refinement demanded by the Cauchy consumer is a refinement through the same cofinite-tail meet row B, so the basis remains cofinal in the displayed finite-tail surface.

Finally apply Definition 1564.12. The export is the row Q attached to that same route, not a quotient filter or selected representative. The absent quotient, selection, choice, and completion data have no carrier coordinates. □

Theorem 1564.23 (FrechetFilter sequential-completion tail exhaustion)**.** *Let $F = (U, T, S, M, B, Q, R, A, H, C, P,$ be an accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier. The sequential-completion handoff exhausts the tail ledger: every* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *read consumes the unary threshold row, the cofinite-tail row, the FilterBase meet row, the StreamName schedule row, the Metric tolerance row, the Cauchy-filter handoff, the regular rational readback, the Real seal, and the structural rows H, C, P, N, with no remaining tail coordinate outside the displayed packet.*

Proof. Start from Definition 1564.20. It states that a sequential-completion consumer receives only $U, T, S, M, B, Q, R, A, H, C, P, N$.

Insert the cofinal basis route from Definition 1564.22. This identifies the Cauchy-filter input to the completion consumer with the same finite cofinite-tail route through $U, T, B, S, M, Q, H, C, P, N$.

Complete the route with Definition 1564.13 and Definition 1564.14. The readback row R and seal row A are downstream of the exhausted tail ledger, so the handoff cannot export quotient filter equality, a selected limit, countable choice, a selected representative, or ambient completion. □

Theorem 1564.24 (FrechetFilter tail-ledger refusal)**.** *For every accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$, the local tail ledger refuses quotient filter equality, countable-choice tail selection, selected limits, ambient completion, and* $\mathsf{Real}^{\uparrow}$ *completeness. Each refused conclusion is absent because it is not one of the carrier coordinates $U, T, S, M, B, Q, R, A, H, C, P, N$ and is not produced by the displayed handoff theorems.*

Proof. Project the carrier definition and the NameCert obligations. The carrier contains threshold, tail-neighborhood, schedule, metric, filter-base, Cauchy-filter, readback, seal, transport, replay, provenance, and local naming rows; the obligation list explicitly records the ledger refusal.

Use the Cauchy-source boundary and sequential-completion handoff above. Both routes preserve the same finite row order and never introduce quotient filter equality, a countable-choice selector, or a selected limit.

Finally apply Definition 1564.15. The Real-facing seal is downstream of the finite readback route, so it is not a proof of $\mathsf{Real}^{\uparrow}$ completeness and cannot be inflated into ambient completion. □

Theorem 1564.25 (FrechetFilter tail eventuality obligations)**.** *Every accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *tail-event read exposes a unary threshold, cofinite tail row, common-tail refinement,* $\mathsf{FilterBase}^{\uparrow}$ *meet route,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff,* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *window, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. Equivalently, any eventuality consumer reads only the finite route*

$$U, T, S, M, B, Q, R, A, H, C, P, N$$

and receives no quotient filter equality, countable-choice tail selector, selected limit, selected representative, ambient completion theorem, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the cofinite-tail closure induction and threshold monotonicity rows. They place every tail event behind the unary threshold row U and cofinite tail row T, and they identify larger thresholds with refinements of the same displayed tail surface.

Use tail meet monotone refinement. The common-tail row is read through the $\mathsf{FilterBase}^{\uparrow}$ meet route B, so parallel tail events are combined inside the same finite basis ledger rather than through a quotient filter.

Apply the Cauchy-filter basis cofinal route and the sequential-completion tail exhaustion theorem. The $\mathsf{CauchyFilter}^{\uparrow}$ handoff Q and the $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ consumer both inspect the same U, T, S, M, B, Q prefix before any completion-facing row is exposed.

Finally use the regular rational readback, StreamName window, and tail-ledger refusal rows. The rows R, A, H, C, P, N preserve the readback, seal, transport, replay, provenance, and naming boundary, while the refusal theorem excludes quotient equality, choice selectors, selected limits, selected representatives, ambient completion, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1564.26 (FrechetFilter root obligation triad)**.** *For every accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *carrier* $F = (U, T, S, M, B, Q, R, A, H, C, P, N)$*, the unary threshold row, finite-tail row,* $\mathsf{FilterBase}^{\uparrow}$ *meet row,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *consumer route form one displayed root obligation surface. Any root consumer must read that surface through*

$$U, T, B \longmapsto Q \longmapsto R, A \longmapsto H, C, P, N$$

with the $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *handoff attached to the same finite route. The surface exports no quotient filter equality, selected limit, countable-choice tail selection, selected representative, or ambient completion.*

Proof. Begin with carrier admission. By Definition 1564.3, the rows $U, T, S, M, B, Q, R, A, H, C, P, N$ are the whole admitted source surface, so the unary threshold, finite-tail row, meet row, handoff, readback, seal, and structural coordinates have no hidden companion row.

Use cofinal-tail stability next. The theorem Definition 1564.4 sends every pair of tail requests through the same $\mathsf{FilterBase}^{\uparrow}$ meet row B before any schedule or metric row is consumed.

Apply the convergence-consumer handoff of Definition 1564.5. It places the $\mathsf{CauchyFilter}^{\uparrow}$ handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ consumer route, and $\mathsf{Real}^{\uparrow}$ seal downstream of the same finite cofinite-tail surface.

Finally use Definition 1564.23. The sequential-completion consumer exhausts the tail ledger rather than adding a separate completion coordinate, and the displayed refusal rows exclude quotient filter equality, selected limits, countable-choice tail selection, selected representatives, and ambient completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetFilter}^{\uparrow}$ packet is generated from unary thresholds, cofinite tail neighborhoods, StreamName schedule rows, Metric tolerance rows, FilterBase meet rows, CauchyFilter handoff rows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1564.1, Definition 1564.2, Definition 1564.3, Definition 1564.4, Definition 1564.5, Definition 1564.23, and Definition 1564.26 bind the finite cofinite-tail and Cauchy route through $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetFilter}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.FrechetFilterUp.FrechetFilterCauchySourceBoundary`

Bridge status: paperBridge

Not claimed: This chapter does not close Real completeness, quotient filter equality, selected limits, countable-choice selectors, ambient completion, or bridge checking.

Upgrade path: Mature closure requires a checked standard bridge theorem and downstream stability for the cofinite-tail filter route.

Chapter 1565

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$

Following Bishop and Bridges / Kelley-style completion-unit naturality, the $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ packet records the finite square in which a source row first enters the completion unit and is then read by completion consumers, while the parallel route reads the same source through the monad and real-completion surfaces. It sits over the unit route of chapter 1527, the monad surface of chapter 378, the real-completion boundary of chapter 360, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names the L10 completion-unit naturality square as finite BEDC data; it is not a quotient of streams, not a chosen representative, not countable choice, not ambient completeness, and not completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1565.1 (CauchyCompletionUnitNaturality carrier)**.** *A* $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, M, R, S, D, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route that sends the displayed source row into the completion-facing unit surface.*
2. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *route that reads the same unit source through the monad consumer surface.*
3. *R is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *route reached only after the unit and monad reads have exposed the same completion-facing source.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the two routes.*
5. *D is the joint* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the shared finite windows.*
6. *H records componentwise* hsame *transport for the unit route, monad route, real-completion route, stream-window row, dyadic ledger, regular rational readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for both sides of the square: unit then completion consumer on one side, monad and real-completion consumer on the other side.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected representatives, countable-choice schedules, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1565.2 (CauchyCompletionUnitNaturality NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ *carrier* $Q = (U, M, R, S, D, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitNatura}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed unit route, monad route, real-completion route, finite stream windows, dyadic tolerance ledger, regular rational readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local naming row;*
2. *unit-side exposure, requiring every source read to pass through the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row U before a completion-facing consumer can inspect it;*
3. *monad-side exposure, requiring the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row M and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *row R to read the same displayed finite windows and dyadic ledger as the unit-side route;*
4. *square stability, requiring componentwise* hsame *transport through H and replay through C to identify the two routes at the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *ledger non-escape, excluding quotient streams, selected representatives, countable-choice schedules, ambient completeness, and* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1565.1. The projection exposes exactly the unit, monad, real-completion, stream-window, dyadic-ledger, transport, replay, provenance, and local naming rows, together with the regular readback and $\mathsf{Real}^{\uparrow}$ seal rows named by those displayed routes.

The unit-side exposure is inherited from the U row. The monad-side exposure is inherited from M and R, but the carrier forces both sides to use the same S and D rows before any read reaches the terminal seal.

Square stability is componentwise transport through H followed by replay through C. Since P and N package only the displayed rows of Q, no separate quotient, representative selector, choice schedule, ambient completeness row, or $\mathsf{Real}^{\uparrow}$ completeness row is available to a consumer. □

Theorem 1565.3 (CauchyCompletionUnitNaturality square)**.** *Let* $Q = (U, M, R, S, D, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ *packet. The route that first reads the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row U and then passes to a completion consumer reaches the same displayed* $\mathsf{Real}^{\uparrow}$ *seal as the route that reads the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row M and the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *row R. Both routes pass through the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface named by P, and the same structural rows H, C, P, N.*

Thus the L10 completion-unit square is a finite route equality at the displayed real-seal boundary:

$$U \longmapsto S \longmapsto D \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$
$$M \longmapsto R \longmapsto S \longmapsto D \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Proof. Start with the unit-side route. The U row admits the source only as a finite unit read, and the carrier of Q records that the next visible rows are the stream window S and dyadic ledger D.

Now read the monad and real-completion side. The M row supplies the completion-consumer surface, while R ties that surface to the real-completion route. The same packet records the same S and D rows for this side of the square.

The package row P names the regular rational readback and terminal $\mathsf{Real}^{\uparrow}$ seal used by both sides. Componentwise transport through H and replay through C identify the two displayed paths at that seal, and no additional coordinate remains in the carrier from which a different completion read could be produced. □

Theorem 1565.4 (CauchyCompletionUnitNaturality real-seal consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ *packet must read the square through*

$$U, M, R, S, D, H, C, P, N.$$

The consumer may inspect the unit route, the monad route, the real-completion route, the shared finite windows, the shared dyadic tolerance ledger, the named regular readback surface, the terminal $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming rows. It obtains no quotient stream, no selected representative, no countable-choice schedule, no ambient completeness theorem, and no completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Let a consumer ask for a real-seal or completion-facing read of Q. Carrier admission exposes $U, M, R, S, D, H, C, P, N$ and no other row.

If the consumer follows the unit side, the read begins with U and then uses the shared stream and dyadic rows S, D. If it follows the monad side, the read begins with M and R and then uses the same S, D rows.

The regular readback surface and terminal $\mathsf{Real}^{\uparrow}$ seal are named by the provenance row P and reached only by replay through C. Transport through H preserves the same rows on both sides of the square.

Because the accepted packet has no quotient, selected-representative, choice, ambient-completeness, or $\mathsf{Real}^{\uparrow}$-completeness coordinate, every consumer read is confined to the displayed finite square. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1565.1, Definition 1565.2, Definition 1565.3, and Definition 1565.4 seed the finite L10 completion-unit naturality square over unit, monad, real-completion, stream-window, dyadic-ledger, regular-readback, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, countable-choice schedules, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, square stability, consumer-boundary replay, and ledger non-escape for the same packet.

Constructive story: A $\mathsf{CauchyCompletionUnitNaturality}^{\uparrow}$ packet is generated from a CauchyCompletionUnit route, a CauchyCompletionMonad route, a RealCauchyCompletion route, shared StreamName windows, a shared DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1566

A Concrete Naming Certificate for $\mathsf{CountableDenseSubset}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CountableDenseSubset}^{\uparrow}$ packet presents countable dense subsets as finite unary index windows over a displayed $\mathsf{Met}^{\uparrow}$ source. It sits downstream of chapter 57, reads the finite windows of chapter 126, the regular rational handoff of chapter 301, the dyadic ledger of chapter 291, and the distance seal of chapter 38, while providing the explicit density row consumed by chapter 1458 and chapter 1453. The chapter records an enumerated finite BEDC density surface, not a choice-selected dense set, not a quotient completion, and not an open-cover compactness or Real-completeness principle.

Definition 1566.1 (CountableDenseSubset carrier)**.** *A* $\mathsf{CountableDenseSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, A, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{Met}^{\uparrow}$ *source row whose point histories, distance classifier, and metric compatibility fields are the only source surface read by the density packet.*
2. *A is the indexed dense candidate family. Each visible unary index names one candidate point over the source row M.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *request-window row. It records the inspected point name, unary index budget, and requested tolerance scale.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance ledger. It stores the dyadic tolerance token together with the Real distance boundary that the request must witness.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row translating each inspected tolerance window into regular rational readback data before the Real distance boundary is consulted.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *distance seal certifying that the chosen indexed candidate lies within the tolerance recorded by T after the handoff R has been replayed.*
7. *H records componentwise* hsame *transport for the metric source, index family, request windows, tolerance ledger, regular handoff, distance seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite density request through M, A, W, T, R, E.*

9. *P is the* Pkg *provenance row over* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableDenseSubset}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected dense point, quotient completion, open-cover compactness extraction, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1566.2 (CountableDenseSubset NameCert obligations)**.** *For every accepted* $\mathsf{CountableDenseSubset}^{\uparrow}$ *carrier $D = (M, A, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CountableDenseSubset}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed metric source, indexed candidate family, finite request windows, dyadic and Real tolerance ledger, regular rational handoff, Real distance seal, transport, continuation, provenance, and local naming row;*

2. *metric-source compatibility, requiring every candidate point named by A and every point inspected by W to live over the same* $\mathsf{Met}^{\uparrow}$ *row M;*

3. *countable-index visibility, requiring each density response to expose a finite unary index before any downstream consumer reads a point witness;*

4. *tolerance exactness, requiring the requested dyadic scale and its Real boundary to be read from the same ledger row T;*

5. *regular handoff, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to mediate the tolerance-window read before the distance seal E is consulted;*

6. *nonescape, excluding choice-selected dense points, quotient completions, open-cover compactness, ambient Real completeness, and host equality of completed points.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.CountableDenseSubsetUp.TasteGate.CountableDenseSubsetTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1566.1. The projection exposes exactly the metric source row, indexed candidate family, finite request windows, tolerance ledger, regular rational handoff, Real distance seal, and structural rows H, C, P, N.

Metric-source compatibility is forced by the shared row M. The candidate family A and every request window in W are read only as histories over that row, so a density response cannot change the metric source while preserving the packet.

Countable-index visibility and tolerance exactness are part of the same finite replay. The continuation row C routes a request through the displayed index and window data before the dyadic and Real tolerance row T and the regular handoff R can be used.

Finally, the seal E is downstream of T and R, and transport by H preserves this dependency order. The provenance and local naming rows package only that route, so the carrier contains no choice-selected point, quotient completion, compactness extraction, host equality, or ambient completeness coordinate. □

Theorem 1566.3 (Enumerated approximation handoff)**.** *Let $D = (M, A, W, T, R, E, H, C, P, N)$ be an accepted* $\mathsf{CountableDenseSubset}^{\uparrow}$ *packet. Every finite density request factors through the route*

$$M, A, W, T, R, E \longmapsto H, C, P, N.$$

Thus a $\mathsf{SeparableMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer may read an approximation only after the indexed candidate row* A*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance ledger* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the* $\mathsf{Real}^{\uparrow}$ *distance seal* E *have all been displayed over the metric source* M*.*

Proof. Begin with a finite density request from a downstream consumer. Carrier admission gives the consumer access to the metric source and candidate rows, but the candidate is visible only through an index in the displayed family A.

Replay the continuation row C. The request inspects the StreamName window W, reads the dyadic and Real tolerance ledger T, passes through the regular rational handoff R, and only then reaches the Real distance seal E.

The rows H, P, N transport, package, and name the same route. Hence a SeparableMetric or MetricCompletion consumer receives only the enumerated approximation packet and no external dense-point choice, quotient completion, compactness extraction, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableDenseSubset}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableDenseSubset}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1566.1, Definition 1566.2, and Definition 1566.3 seed the finite indexed density surface over a displayed $\mathsf{Met}^{\uparrow}$ source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableDenseSubset}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected dense points, quotient completions, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires carrier admission, metric-source compatibility, countable-index visibility, tolerance exactness, regular handoff, approximation handoff, and nonescape proofs for the same packet.

Constructive story: A $\mathsf{CountableDenseSubset}^{\uparrow}$ packet is generated from a MetricUp source, an indexed candidate family, StreamName request windows, a DyadicRatCore and RealUp tolerance ledger, a RegSeqRat handoff, a RealUp distance seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1567

A Concrete Naming Certificate for $\mathsf{RealApartnessCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealApartnessCompletion}^{\uparrow}$ packet records the separated completion boundary for $\mathsf{Real}^{\uparrow}$ names when apartness evidence is the visible equality discriminator. It reads the apartness surface of chapter 304, the Hausdorff separation boundary of chapter 402, the constructive completion route of chapter 1556, the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the displayed boundary between regular Cauchy completion data and apartness-separated real reads; it does not assert completeness of $\mathsf{Real}^{\uparrow}$ or import quotient equality, selected limits, countable choice, trichotomy, or host real equality.

Definition 1567.1 (RealApartnessCompletion carrier)**.** *A* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Q, M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{ApartnessReal}^{\uparrow}$ *source row, exposing apartness evidence for the real-name boundary under inspection.*
2. *Q is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separation row attached to the same source read.*
3. *M is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *completion-route row through which the separated completion request is replayed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by the completion read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback extracted from those stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readback rows at the requested precision.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the apartness, separation, completion, window, readback, and tolerance rows have been displayed.*
8. *H records componentwise* hsame *transport for the apartness row, separation row, completion route, window schedule, readback row, tolerance ledger, real seal, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from apartness inspection through Hausdorff separation, constructive completion, stream windows, regular readback, dyadic tolerance, and then the real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RealApartnessCompletion}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApartnessCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completions, host real equality, selected limits, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionTasteGate single carrier alignment`

Theorem 1567.2 (RealApartnessCompletion obligation surface)**.** *For every accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *carrier* $A = (X, Q, M, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealApartnessCompletion}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission for the displayed apartness, Hausdorff separation, constructive completion, stream-window, regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows;*
2. *separated-source exactness, requiring the* $\mathsf{ApartnessReal}^{\uparrow}$ *row X and* $\mathsf{HausdorffCompletion}^{\uparrow}$ *row Q to be read before any completion-facing consumer can inspect M;*
3. *regular readback discipline, requiring every completion observation to pass through S, R, and D before the* $\mathsf{Real}^{\uparrow}$ *seal E is available;*
4. *componentwise stability, requiring H and C to transport and replay only the displayed rows $X, Q, M, S, R, D, E, P, N$;*
5. *ledger exhaustion, requiring the packet to export no quotient completion, host real equality, selected limit, countable-choice schedule, trichotomy row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionObligationSurface`

Proof. Carrier admission is projection from Definition 1567.1. The tuple displays exactly the apartness row, Hausdorff separation row, constructive completion route, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local name.

Separated-source exactness is forced by the order of the visible route. The completion row M is named only after the apartness row X and the Hausdorff separation row Q have been displayed, so a consumer cannot read completion data before seeing the separated source surface.

The regular readback discipline is the role of S, R, D, E. The seal row E is downstream of the finite windows S, regular readback R, and dyadic tolerance ledger D, which keeps each Real-facing observation attached to the displayed regular-Cauchy route.

Componentwise stability and ledger exhaustion follow from H, C, P, N. These rows transport, replay, package, and name only the displayed packet, so they cannot add quotient completions, host real equality, selected limits, countable choice, trichotomy, or ambient completeness. □

Theorem 1567.3 (RealApartnessCompletion obligation routing)**.** *Every accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet routes each local* NameCert *obligation through*

$$X, Q, M, S, R, D, E, H, C, P, N$$

in that order. Carrier admission, separated-source exactness, regular readback discipline, componentwise stability, and ledger exhaustion are exactly the five projections of this finite route over the ApartnessReal$^{\uparrow}$, HausdorffCompletion$^{\uparrow}$, ConstructiveMetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionObligationRouting`

Proof. Project the carrier of Definition 1567.1. The displayed tuple places the apartness source, Hausdorff separation row, constructive completion route, stream windows, regular readback, dyadic tolerance ledger, and Real seal before the structural rows.

Apply the obligation surface of Definition 1567.2. Its five clauses are carrier admission, separated-source exactness, regular readback discipline, componentwise stability, and ledger exhaustion, so each clause is a projection of the same ordered route.

Finally use the non-escape boundary of Definition 1567.5. Since quotient completion, choice, trichotomy, host equality, and ambient completeness rows are absent, the obligation surface has no route outside the displayed packet. □

Theorem 1567.4 (RealApartnessCompletion obligation partition)**.** *For every accepted* RealApartnessCompletion$^{\uparrow}$ *packet* $A = (X, Q, M, S, R, D, E, H, C, P, N)$*, the local obligation surface partitions into separated-source rows* (X, Q, M)*, finite window and readback rows* (S, R, D)*, the terminal seal row* E*, and structural ledger rows* (H, C, P, N)*. No consumer may discharge an obligation in one partition by borrowing a row from another partition unless an explicit displayed transport or replay row in* H *or* C *carries that row across the named boundary.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionObligationPartition`

Proof. Project the carrier of Definition 1567.1. The tuple displays the apartness source X, Hausdorff separation row Q, constructive completion row M, stream window S, regular readback R, dyadic tolerance row D, seal E, and structural rows H, C, P, N as distinct coordinates.

Apply the obligation surface of Definition 1567.2 and the routing theorem of Definition 1567.3. Their carrier, separated-source, regular readback, stability, and ledger clauses are projections of the same ordered packet, so the source rows, window/readback rows, seal row, and structural rows cannot be identified by prose alone.

The non-escape boundary of Definition 1567.5 prevents quotient completion, selected limits, choice, trichotomy, host equality, and ambient completeness from supplying substitute rows. The separated-source exactness and regular readback discipline theorems, Definition 1567.13 and Definition 1567.14, fix the entry to M through X, Q and the entry to E through S, R, D.

It remains only to account for permitted movement between partitions. Such movement must be displayed by H or C, because those are the only transport and replay rows in the carrier. Hence a consumer cannot satisfy one partition by borrowing from another unless the borrowing is itself recorded as an explicit structural route. □

Theorem 1567.5 (RealApartnessCompletion non-escape boundary)**.** *Let* $A = (X, Q, M, S, R, D, E, H, C, P, N)$ *be an accepted* RealApartnessCompletion$^{\uparrow}$ *packet. Every separated completion read of* A *factors through the finite route*

$$X, Q, M, S, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus the boundary can expose apartness-separated real-name evidence only through the displayed ApartnessReal$^{\uparrow}$, HausdorffCompletion$^{\uparrow}$, ConstructiveMetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$,

DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. It excludes quotient completions, host real equality, selected limits, countable choice, trichotomy, and ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionNonescape`

Proof. Begin with an accepted separated completion read. Carrier admission gives a single visible route from the apartness source X and Hausdorff separation row Q into the constructive completion row M.

Replay the observation path through the finite windows. The stream schedule S, regular rational readback R, and dyadic tolerance ledger D must be displayed before the Real seal E can be read.

Finally transport and package the same route through H, C, P, N. Since no other coordinate occurs in the carrier or obligation surface, the read cannot escape to quotient completions, host real equality, selected limits, countable choice, trichotomy, or ambient Real completeness. □

Definition 1567.6 (RealApartnessCompletion apartness-Cauchy window)**.** *For an accepted* RealApartnessCompleti *packet* $A = (X, Q, M, S, R, D, E, H, C, P, N)$*, the apartness-Cauchy window is the finite prefix*

$$W_{\mathrm{ac}}(A) = (X, Q, M, S, R, D).$$

Its rows are read with the following roles:

1. X *is the* ApartnessReal$^{\uparrow}$ *apartness source for the boundary read.*
2. Q *is the* HausdorffCompletion$^{\uparrow}$ *separated-completion witness attached to that source.*
3. M *is the* ConstructiveMetricCompletion$^{\uparrow}$ *route by which the completion request is replayed.*
4. S *is the* StreamName$^{\uparrow}$ *finite-window ledger for the inspected name.*
5. R *is the* RegSeqRat$^{\uparrow}$ *regular rational readback exposed by those windows.*
6. D *is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to compare the readback at the requested precision.*

The window has no coordinate for the Real$^{\uparrow}$ *seal* E *and no coordinate for quotient completion, trichotomy, selected limits, countable choice, host equality, or ambient completeness.*

Lean4 (definition) `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionApartnessCauchyWindow`

Definition 1567.7 (RealApartnessCompletion separated seal route)**.** *For an accepted* RealApartnessCompletion$^{\uparrow}$ *packet* $A = (X, Q, M, S, R, D, E, H, C, P, N)$*, the separated seal route is the finite terminal path*

$$\Sigma_{\mathrm{sep}}(A) = (X, Q, M, S, R, D, E).$$

It records the apartness source, Hausdorff separation row, constructive completion route, stream-window ledger, regular readback, dyadic tolerance ledger, and terminal Real$^{\uparrow}$ *seal as one ordered read. The route has no coordinate for a second source, quotient completion, host equality of completed names, selected limit, countable-choice schedule, trichotomy row, or ambient* Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionSeparatedSealRoute`

Theorem 1567.8 (RealApartnessCompletion separated seal determinacy)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P,$ and $A' = (X, Q, M, S, R, D, E', H', C', P', N')$ be accepted* RealApartnessCompletion$^{\uparrow}$ *packets with the same* ApartnessReal$^{\uparrow}$ *source row X, the same* HausdorffCompletion$^{\uparrow}$ *separation row Q, the same* ConstructiveMetricCompletion$^{\uparrow}$ *route M, the same stream windows S, the same* RegSeqRat$^{\uparrow}$ *regular readback R, and the same* DyadicRatCore$^{\uparrow}$ *tolerance ledger D. If both packets expose a terminal Real seal through the displayed obligation surface, then they expose the same separated terminal Real-seal route:*

$$\Sigma_{\text{sep}}(A) = (X, Q, M, S, R, D, E)$$

and

$$\Sigma_{\text{sep}}(A') = (X, Q, M, S, R, D, E')$$

are determined by the same apartness-Cauchy window, and no alternative seal-facing route is available outside that window.

Proof. First apply the obligation partition of Definition 1567.4. It separates the source rows (X, Q, M), finite window and readback rows (S, R, D), terminal seal row, and structural rows, so the two packets have the same analytic prefix before either seal is read.

Separated-source exactness fixes the entry to the constructive completion route. Since both packets display the same X, Q, M, neither packet can enter the terminal route through a quotient completion, host equality row, selected limit, or external completion object.

Regular readback discipline then fixes the seal-facing window. The shared S, R, D rows are the only rows through which a Real-facing read may reach a terminal seal, and Definition 1567.6 names this common prefix as W_{ac}.

Finally use the non-escape boundary and located Real seal non-escape theorem. The structural rows H, C, P, N and H', C', P', N' only transport, replay, package, and name the displayed packet; they cannot add a second source, second window, quotient completion, selected limit, countable-choice schedule, trichotomy row, host equality, or ambient completeness principle. Therefore the terminal Real-seal route is determined by the shared apartness-Cauchy window. □

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionSeparatedSealDeterminacy`

Theorem 1567.9 (RealApartnessCompletion separated completion handoff)**.** *Let $A = (X, Q, M, S, R, D, E, H, C,$ be an accepted* RealApartnessCompletion$^{\uparrow}$ *packet. Every completion-facing read of A that reaches the* Real$^{\uparrow}$ *seal E first factors through the apartness-Cauchy window*

$$X, Q, M, S, R, D.$$

Thus no consumer can inspect E as a separated completion seal without first reading the ApartnessReal$^{\uparrow}$ *source, the* HausdorffCompletion$^{\uparrow}$ *separation row, the* ConstructiveMetricCompletion$^{\uparrow}$ *route, the* StreamName$^{\uparrow}$ *windows, the* RegSeqRat$^{\uparrow}$ *readback, and the* DyadicRatCore$^{\uparrow}$ *tolerance ledger.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionSeparatedCompletionHandoff`

Proof. Project the accepted packet through Definition 1567.1. The seal row E is displayed only after the source, separation, completion route, window, readback, and tolerance rows have already appeared.

Apply the obligation surface of Definition 1567.2. Its separated-source exactness clause forces X, Q to be read before the completion row M, and its regular readback clause forces S, R, D to be read before E.

The handoff is therefore the finite prefix named in Definition 1567.6. Since the carrier contains no bypass coordinate, a completion-facing consumer cannot reach E by quotient completion, selected limit, countable choice, trichotomy, host equality, or ambient completeness. □

Theorem 1567.10 (RealApartnessCompletion RegSeqRat seal handoff)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N$ be an accepted* RealApartnessCompletion$^{\uparrow}$ *packet. Every Real-facing apartness-completion seal passes through the* StreamName$^{\uparrow}$ *windows S, the* RegSeqRat$^{\uparrow}$ *readback row R, and the* DyadicRatCore$^{\uparrow}$ *tolerance row D before the terminal seal E is exposed. The seal therefore remains downstream of the displayed apartness-Cauchy window and cannot be read through a quotient completion, selected limit, countable-choice schedule, trichotomy row, host equality, or ambient completeness principle.*

Proof. Start with Definition 1567.2. Its regular readback and ledger clauses place the finite window row S, regular rational readback row R, and dyadic tolerance row D in the displayed obligation route before the seal is available.

Apply Definition 1567.9. It identifies the seal-facing prefix as the apartness-Cauchy window X, Q, M, S, R, D, so the seal cannot be consumed before the StreamName, RegSeqRat, and DyadicRatCore rows have been read.

Finally use Definition 1567.11 and Definition 1567.18. The downstream Real-facing consumer receives only $W_{\mathrm{ac}}(A), E, H, C, P, N$, and the ledger has no remaining coordinate for a bypass principle. Hence every Real-facing seal handoff passes through S, R, D before E. □

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionRegSeqRatSeal`

Theorem 1567.11 (RealApartnessCompletion located Real seal non-escape)**.** *Let $A = (X, Q, M, S, R, D, E, H, C,$ be an accepted* RealApartnessCompletion$^{\uparrow}$ *packet. Every* LocatedReal$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer of the seal receives only the displayed apartness-Cauchy window together with the seal, transport, replay, provenance, and local naming rows*

$$W_{\mathrm{ac}}(A), E, H, C, P, N.$$

The consumer receives no quotient completion, trichotomy, selected limit, countable-choice schedule, host equality row, or ambient Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionLocatedRealSealNonescape`

Proof. Begin with a LocatedReal$^{\uparrow}$ or Real$^{\uparrow}$ consumer of the seal. By Definition 1567.9, the consumer must first pass through $W_{\mathrm{ac}}(A)$ before it can read E.

After the seal is read, Definition 1567.5 routes the remaining observation through H, C, P, N. These rows transport, replay, package, and name the same displayed packet; they do not add a second completion object or an external equality principle.

Combining the handoff with the non-escape boundary gives exactly $W_{\mathrm{ac}}(A), E, H, C, P, N$. The excluded principles are absent from both the carrier coordinates and the local obligation surface, so no located-real or real-seal consumer can obtain them from the packet. □

Theorem 1567.12 (RealApartnessCompletion finite apartness-completion obligation)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* RealApartnessCompletion$^{\uparrow}$ *packet. Every apartness-completion obligation exported by A is exposed only through the* DyadicRatCore$^{\uparrow}$ *tolerance row D, the* StreamName$^{\uparrow}$ *finite-window row S, the* RegSeqRat$^{\uparrow}$ *readback row R, the* LocatedReal$^{\uparrow}$ *or* ApartnessReal$^{\uparrow}$ *comparison surface carried by X, Q, M, and the* Real$^{\uparrow}$ *seal E, followed by H, C, P, N.*

Consequently the packet exports no quotient real equality, trichotomy, selected Cauchy limit, countable-choice schedule, host equality row, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionFiniteApartnessCompletionObligati`

Proof. Project the accepted carrier through Definition 1567.1. The apartness source, Hausdorff separation row, constructive completion route, stream windows, regular readback, dyadic tolerance ledger, and Real seal are the only analytic rows before transport, replay, provenance, and local naming.

Apply Definition 1567.2. Its separated-source exactness and regular readback clauses force every completion read to pass through X, Q, M, S, R, D before E is available.

The separated completion handoff of Definition 1567.9 and the located Real seal non-escape theorem of Definition 1567.11 identify the downstream consumer surface as $W_{\mathrm{ac}}(A), E, H, C, P, N$. Since the excluded principles are absent from both the carrier rows and the local obligation surface, they cannot be exported by the apartness-completion obligation. □

Theorem 1567.13 (RealApartnessCompletion separated-source exactness)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet. Any completion-facing consumer that reads the constructive completion row M must first read the* $\mathsf{ApartnessReal}^{\uparrow}$ *source row X and the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separation row Q through the same componentwise transport and replay rows H, C. The consumer cannot enter through a quotient completion, host real equality, selected limit, countable-choice schedule, trichotomy row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 1567.1. The route displays X and Q before M, and the structural rows H, C transport and replay that same ordered packet.

Apply Definition 1567.2. Its separated-source exactness clause is precisely the assertion that X, Q are consumed before any completion-facing inspection of M.

The separated completion handoff of Definition 1567.9 keeps every later read of the seal downstream of the same prefix. Since Definition 1567.11 excludes all bypass rows at the seal, no completion-facing consumer can reach M through an external completion or equality principle. □

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionSeparatedSourceExactness`

Theorem 1567.14 (RealApartnessCompletion regular readback discipline)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet. Every Real-facing read of the seal E must pass through the stream-window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D. Thus E is available only as the terminal seal of the displayed regular-Cauchy route, not as a selected limit or host completion point.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionRegularReadbackDiscipline`

Proof. Start from Definition 1567.9. It identifies the apartness-Cauchy window X, Q, M, S, R, D as the finite prefix required before E can be read.

Apply Definition 1567.2. Its regular readback discipline clause names S, R, D as the rows that mediate every completion observation before the Real seal becomes visible.

Finally use Definition 1567.11. The downstream $\mathsf{LocatedReal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives $W_{\mathrm{ac}}(A), E, H, C, P, N$ and no selected limit, quotient completion, trichotomy, countable-choice schedule, host equality row, or ambient completeness theorem. □

Theorem 1567.15 (RealApartnessCompletion located tail obligation)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet. Before any separated-completion tail of A is consumed, the packet must expose the located apartness source carried by X, Q, M, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger*

D, and the terminal $\mathsf{Real}^{\uparrow}$ *seal E. Thus every tail-facing read reaches the separated completion boundary only through*

$$X, Q, M, S, R, D, E, H, C, P, N.$$

It has no coordinate for countable choice, selected limits, quotient equality, trichotomy, or ambient Real completeness.

Proof. Project the carrier of Definition 1567.1. The displayed order places the apartness source and separated completion route in X, Q, M, then the finite window, regular readback, dyadic tolerance, and seal rows in S, R, D, E.

Use separated seal determinacy, separated completion handoff, and located Real seal non-escape. These results force every seal-facing consumer to pass through $W_{\mathrm{ac}}(A) = (X, Q, M, S, R, D)$ before the seal E is available, and they keep the same transport, replay, provenance, and naming rows visible downstream.

The regular readback discipline fixes the Real-facing part of the route through S, R, D. Therefore a separated-completion tail cannot be consumed before located apartness, finite windows, regular readback, dyadic tolerance, and the Real seal have all been exposed; the refused principles are absent from the carrier and from the local obligation surface. □

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionLocatedTailObligation`

Theorem 1567.16 (RealApartnessCompletion RegSeqRat refinement)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet. Any refinement of the separated tail that is visible to a Real-facing consumer factors through the existing* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D after the finite window row S has been read. The refinement may tighten the displayed regular rational readback along S, R, D, but it cannot export quotient equality, selected limits, trichotomy, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionRegSeqRatRefinement`

Proof. Begin with the located tail obligation above and the regular readback discipline. Together they identify S, R, D as the only finite refinement surface between the separated completion route M and the terminal seal E.

Apply separated-source exactness and separated completion handoff. The consumer cannot enter the refinement from a quotient completion or selected limit; it reaches M through X, Q and then reaches E only through $W_{\mathrm{ac}}(A)$.

Finally use located Real seal non-escape and ledger exhaustion. The rows H, C, P, N preserve the same displayed packet, while the seal row E remains downstream of S, R, D. Hence the refinement is a RegSeqRat-and-dyadic-tolerance refinement of the displayed tail, not an exported equality, trichotomy, choice, selected-limit, or ambient-completeness principle. □

Theorem 1567.17 (RealApartnessCompletion window determinacy)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet that reaches the* $\mathsf{Real}^{\uparrow}$ *seal E. Then the packet determines the same apartness-Cauchy prefix*

$$W_{\mathrm{ac}}(A) = (X, Q, M, S, R, D)$$

through the displayed $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows. No second window source, quotient completion, selected limit, countable-choice schedule, trichotomy row, or host equality principle can supply an alternate prefix for the same seal-facing read.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionWindowDeterminacy`

Proof. Start with the carrier definition and the apartness-Cauchy window definition. They name X, Q, M, S, R, D as the only prefix rows available before the seal coordinate E is read.

Apply the separated completion handoff, the located Real seal non-escape theorem, and separated-source exactness. These force every completion-facing route to enter through the apartness source, Hausdorff separation row, and constructive metric completion row before it can reach the terminal seal.

Next apply the regular readback discipline. It fixes the seal-facing observation through the finite stream window, regular rational readback, and dyadic tolerance ledger, so the same S, R, D rows mediate every Real-facing read.

Finally use ledger exhaustion. The remaining rows H, C, P, N only transport, replay, package, and name the displayed packet, leaving no coordinate for a second window source, quotient completion, selected limit, countable choice, trichotomy, or host equality. □

Theorem 1567.18 (RealApartnessCompletion ledger exhaustion)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *packet. The complete obligation ledger exported by A is the displayed carrier route together with its transport, replay, provenance, and local naming rows. Every separated-source, regular-readback, componentwise-stability, and seal-facing consumer is therefore exhausted by $X, Q, M, S, R, D, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.RealApartnessCompletionUp.RealApartnessCompletionLedgerExhaustion`

Proof. Use Definition 1567.3. It routes carrier admission, separated-source exactness, regular readback discipline, componentwise stability, and ledger exhaustion through the single finite packet $X, Q, M, S, R, D, E, H, C, P, N$.

The separated-source theorem above fixes the entry to M through X, Q, and the regular readback theorem above fixes the entry to E through S, R, D. These two routes are the analytic part of the same ledger.

The remaining rows are structural. By Definition 1567.5 and Definition 1567.11, H, C, P, N only transport, replay, package, and name the displayed packet, so the ledger has no coordinate left for quotient completion, selected limits, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealApartnessCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealApartnessCompletion}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1567.1, Definition 1567.2, Definition 1567.3, Definition 1567.4, Definition 1567.5, Definition 1567.6, Definition 1567.9, Definition 1567.10, Definition 1567.11, Definition 1567.13, Definition 1567.14, Definition 1567.15, Definition 1567.16, and Definition 1567.18 close the displayed apartness-completion obligation surface over ApartnessReal, HausdorffCompletion, ConstructiveMetricCompletion, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealApartnessCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, host real equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Public closure requires a public-object surface and, independently, a verified Lean target for BEDC.Derived.RealApartnessC

Constructive story: A $\mathsf{RealApartnessCompletion}^{\uparrow}$ packet is generated from an ApartnessReal source row, a HausdorffCompletion separation row, a ConstructiveMetricCompletion route, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1568

A Concrete Naming Certificate for $\mathsf{CauchyReindexing}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyReindexing}^{\uparrow}$ packet records the finite certified route by which a regular Cauchy name may be inspected along a displayed monotone cofinal schedule before it reaches a $\mathsf{Real}^{\uparrow}$ seal. It sits between the finite observation schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite NameCert surface for changing observation indices; it is not quotient-stream equality, not a selected limit, not countable choice, not host real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1568.1 (CauchyReindexing carrier)**.** *A* $\mathsf{CauchyReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, I, M, Q, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *schedule row whose finite windows are available to the packet;*
2. *I is the target* $\mathsf{StreamName}^{\uparrow}$ *schedule row obtained by reading S along a displayed unary index map;*
3. *M is the monotone row for that unary index map, recording that accepted target windows never ask for source observations in reverse order;*
4. *Q is the cofinal row for the same unary map, recording that every displayed source tolerance budget is eventually reached by some displayed target window;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the source and target observations at the finite budgets named by M and Q;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row showing that the target schedule remains a regular rational name after the reindexing route has been replayed;*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, I, M, Q, D, R have been consumed;*
8. *H records componentwise* hsame *transport for the source schedule, target schedule, monotone row, cofinal row, dyadic tolerance row, regularity row, Real seal, continuation, provenance, and local naming rows;*

9. *C records displayed* Cont *replay from a target-window request through the unary reindexing rows, back to the source schedule, then forward through dyadic tolerance, regular readback, and the Real seal;*
10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyReindexing}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, countable-choice selection of a subsequence, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 1568.2 (CauchyReindexing NameCert obligations)**.** *For every accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *carrier $K = (S, I, M, Q, D, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyReindexing}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source schedule, reindexed schedule, monotone row, cofinal row, dyadic tolerance row, regularity row, Real seal, transport, continuation, provenance, and local naming row;*
2. *index admissibility, requiring every target-window read in I to replay through the displayed unary map before it can consult the source schedule S;*
3. *monotone and cofinal discipline, requiring M and Q to be read together before a consumer treats the target schedule as a regular Cauchy name;*
4. *tolerance and regularity preservation, requiring D and R to certify the finite regular readback after the reindexing route has been replayed;*
5. *seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row A to remain downstream of S, I, M, Q, D, R;*
6. *ledger refusal, excluding quotient streams, selected limits, countable-choice selectors, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1568.1. The projection exposes exactly the source schedule, target schedule, monotone row, cofinal row, dyadic tolerance row, regularity row, Real seal, and structural rows H, C, P, N.

Index admissibility is forced by the continuation row C. A target-window request reaches I only by replaying the displayed unary index route back to the source schedule S, so the packet has no independent target stream coordinate.

The monotone and cofinal rows are then the only rows that justify treating the target schedule as a regular Cauchy inspection surface. The dyadic tolerance row D and regularity row R sit downstream of those two rows, so tolerance preservation and regular readback cannot be exported before the reindexing discipline has been consumed.

Finally, the seal row A is downstream of the same route. Transport by H preserves each listed coordinate, while P and N package only that finite route; hence no quotient stream, selected limit, countable-choice selector, host real equality, or ambient completeness coordinate remains available. □

Theorem 1568.3 (CauchyReindexing RegSeqRat to Real handoff)**.** *Let $K = (S, I, M, Q, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read of the reindexed regular name factors through the finite route*

$$S, I, M, Q, D, R \longmapsto A \longmapsto H, C, P, N.$$

Thus the $\mathsf{RegSeqRat}^{\uparrow}$ *row reaches the* $\mathsf{Real}^{\uparrow}$ *seal only after the source* $\mathsf{StreamName}^{\uparrow}$ *schedule, reindexed* $\mathsf{StreamName}^{\uparrow}$ *schedule, monotone row, cofinal row, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row have been displayed. The route contains no quotient stream, selected limit, countable-choice selector, host real equality, or ambient Real completeness principle.*

Proof. Begin with a Real-facing consumer of the packet. Carrier admission gives access to the seal row A, but only as a row downstream of the regularity row R and the dyadic tolerance row D.

Replay the continuation row C. The request first reads the target schedule I as a displayed reindexing of the source schedule S, then consumes the monotone row M and cofinal row Q that make the index change admissible for regular Cauchy inspection.

After those rows have been consumed, the dyadic tolerance row D and regularity row R provide the finite readback accepted by the Real seal. The transport, provenance, and local naming rows record the same dependency order, so the packet exports no direct route through quotient streams, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 1568.4 (CauchyReindexing composition stability)**.** *Let* K_{01} *be an accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *packet from a source schedule* S_0 *to a middle schedule* S_1*, and let* K_{12} *be an accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *packet from* S_1 *to a target schedule* S_2*. Suppose that the two packets display the same middle* $\mathsf{StreamName}^{\uparrow}$ *schedule row and that their middle-facing monotone rows, cofinal rows, dyadic tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rows,* $\mathsf{Real}^{\uparrow}$ *seal rows,* hsame *transports,* Cont *routes,* Pkg *provenance rows, and local* $\mathsf{NameCert}_{\mathsf{CauchyReindexing}^{\uparrow}}$ *rows agree on that shared schedule. Then the finite route obtained by composing the displayed unary index maps from* S_0 *through* S_1 *to* S_2 *is again an accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *surface, with carrier rows in the same order*

$$S, I, M, Q, D, R, A, H, C, P, N.$$

Its downstream $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers factor through the composed monotone–cofinal route and acquire no quotient stream, selected limit, countable-choice selector, host real equality, or ambient completeness coordinate.*

Proof. Project the two accepted carriers. The target schedule row of K_{01} and the source schedule row of K_{12} are the same displayed middle schedule, so their endpoint data can be read as one finite route from S_0 to S_2.

Compose the two unary index routes at the level of the displayed monotone and cofinal rows. Monotonicity is preserved because a target-window request first moves monotonically along the second route and then monotonically along the first route; cofinality is preserved because any source tolerance requested at S_0 is reached by the first route and then by the second route through the shared middle schedule.

The shared dyadic tolerance rows and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows are reused along the composed route. Componentwise hsame transport identifies the common middle schedule and its tolerance, regularity, seal, continuation, package, and local naming rows, while Cont concatenates the two finite replays without adding a new coordinate.

Finally apply Definition 1568.3 to the repacked route. The Real-facing consumer still reaches the seal only after reading the source schedule, target schedule, composed monotone row, composed cofinal row, dyadic tolerance row, and regularity row, so the composed surface has the same carrier order and the same ledger refusals as an accepted $\mathsf{CauchyReindexing}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyReindexing}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyReindexing}^{\uparrow}$ packet is generated from source and target StreamName schedules, monotone and cofinal unary reindexing rows, a DyadicRatCore tolerance row, a RegSeqRat regularity row, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyReindexing}\uparrow}$, seed)

Scope closed: Definition 1568.1, Definition 1568.2, Definition 1568.3, and Definition 1568.4 seed the finite certified reindexing route from regular Cauchy names to the downstream Real$^{\uparrow}$ seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyReindexing}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable-choice selectors, host real equality, ambient Real$^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, monotone and cofinal reindexing discipline, dyadic tolerance preservation, RegSeqRat readback, Real seal factorization, and ledger refusal.

Chapter 1569

A Concrete Naming Certificate for $\mathsf{CauchyFilterCompletion}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ packet records the finite completion boundary generated by Cauchy filters before any completed Real seal is exposed. It sits between the saturated filter surface of chapter 333, the limit-facing packet of chapter 1558, the finite windows of chapter 126, the regular readback of chapter 301, the dyadic tolerance ledger of chapter 291, the Real seal boundary of chapter 38, and the uniform completion surface of chapter 1473. The packet exposes a finite completion route, not a quotient filter, selected limit, host equality, countable-choice selector, or ambient completeness theorem.

Definition 1569.1 (CauchyFilterCompletion carrier)**.** *A* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, W, T, R, L, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row naming the saturated Cauchy-filter data consumed by the completion request.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows through which the request observes the filter at displayed precision levels.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and dyadic tolerances.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after C, W, T, R have been replayed.*
6. *H records componentwise* hsame *transport for the filter, window, tolerance, readback, seal, continuation, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a Cauchy-filter request through finite windows, dyadic tolerance, regular readback, and the Real seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient filters, selected limits, host real equality, countable-choice selection, ambient completeness, or a separate uniform-completion object beyond the displayed provenance row.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionTasteGate single carrier alignment`

Theorem 1569.2 (CauchyFilterCompletion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the displayed Cauchy filter, finite windows, dyadic tolerance ledger, regular readback, Real seal handoff, transport, continuation, provenance, and local naming row;*
2. *filter-to-window exposure, requiring* C *to be consumed before any completion-facing read inspects* W, T, R*, or* L*;*
3. *tolerance exactness, requiring every accepted readback in* R *to use the displayed dyadic ledger* T *for the same window row* W*;*
4. *completion handoff, requiring the Real seal row* L *to remain downstream of* C, W, T, R *and the structural rows* H, K, P, N*;*
5. *ledger refusal, excluding quotient filters, selected limits, host real equality, countable-choice selectors, ambient completeness, and detached uniform-completion coordinates.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket semantic name certificate`

Proof. Project the carrier of Definition 1569.1. The public rows are exactly $C, W, T, R, L, H, K, P, N$, so carrier admission exposes the Cauchy-filter row, the finite observation route, the Real seal handoff, and the structural rows without adding quotient, selector, host-equality, or completeness data.

The filter-to-window and tolerance obligations come from the displayed continuation row K. A completion-facing request must first consume C, then inspect the finite windows W, then read the dyadic ledger T before the regular readback row R is available.

The completion handoff is the remaining public route. The row L is downstream of C, W, T, R, while H, P, and N transport, package, and name only that route. Thus every excluded object lies outside the accepted packet. □

Theorem 1569.3 (CauchyFilterCompletion Real seal handoff)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Every completion-facing or Real-facing consumer that reads the terminal seal factors through the finite route*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

Thus the $\mathsf{Real}^{\uparrow}$ *seal handoff is available only after the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed. The same route is compatible with the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary and the* $\mathsf{UniformCompletion}^{\uparrow}$ *provenance surface, but it exports no quotient filter, selected limit, host real equality, countable-choice selector, ambient completeness theorem, or detached uniform-completion coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal handoff`

Proof. Begin with a consumer of the terminal seal. Carrier admission gives access to L only as a row of the accepted packet F.

Replay the continuation row K. The request reads the saturated Cauchy-filter row C, the finite windows W, the dyadic tolerance ledger T, and the regular rational readback R before the Real seal handoff can be consumed.

The structural rows preserve this order. Transport through H, provenance through P, and local naming through N record the same route, so the consumer has no available coordinate for quotient filters, selected limits, host equality, choice, ambient completeness, or an independent uniform-completion object. □

Theorem 1569.4 (CauchyFilterCompletion window-tolerance totality)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *packet. Every accepted completion read opens the finite window row W and the dyadic tolerance row T before it can read the regular rational row R. Thus no completion-facing consumer reaches R by a detached stream window, a free tolerance parameter, a quotient filter, or a selected filter limit.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket window readback transport`

Proof. Project the carrier of Definition 1569.1. The regular readback row R is part of the same finite packet as C, W, T, L, H, K, P, N.

Replay the continuation row K. It exposes the Cauchy-filter source C, then the finite windows W, then the dyadic tolerance ledger T before any regular readback is available.

The Real seal handoff of Definition 1569.3 keeps every terminal read downstream of that route. Hence a consumer that bypasses W or T is not reading the accepted CauchyFilterCompletion$^{\uparrow}$ packet. □

Theorem 1569.5 (CauchyFilterCompletion uniform-filter readback)**.** *Every* UniformCauchyFilter$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer of an accepted* CauchyFilterCompletion$^{\uparrow}$ *packet reads only through*

$$C, W, T, R, L, H, K, P, N.$$

The uniform-facing route may use the saturated Cauchy-filter row, finite observation windows, dyadic tolerance ledger, regular readback, Real seal, transport, continuation, provenance, and local naming rows, but it cannot introduce a detached uniform-completion object.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform filter readback`

Proof. Start with a uniform-facing consumer. The only Cauchy source in the carrier is C, and the only completion-facing terminal row is L.

By Definition 1569.4, the consumer reaches R only after W and T have been displayed. By Definition 1569.3, the Real seal is then read through L and the structural rows H, K, P, N.

Since no other row exists in the carrier, UniformCauchyFilter$^{\uparrow}$ and UniformCompletion$^{\uparrow}$ readback is exactly this finite route. Quotient filters, selected limits, ambient completeness, and detached completion coordinates are outside the packet. □

Theorem 1569.6 (CauchyFilterCompletion Real seal uniqueness route)**.** *All* Real$^{\uparrow}$ *seal reads exported by an accepted* CauchyFilterCompletion$^{\uparrow}$ *packet coincide at the displayed row L. No accepted read can replace L by quotient-filter equality, a selected limit, host real equality, a countable-choice selector, or a separate completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRealSealUniquenessRoute`

Proof. Begin with two Real-facing reads of the same packet $F = (C, W, T, R, L, H, K, P, N)$. Carrier projection gives a single terminal Real seal row, namely L.

The window-tolerance route forces both reads through C, W, T, R before L is available. The continuation and transport rows K, H preserve that route rather than choosing new representatives.

Provenance and local naming through P, N record the same displayed seal. Therefore all accepted Real readbacks meet at L, and the excluded quotient, selector, equality, choice, and completeness objects have no coordinate inside the packet. □

Theorem 1569.7 (CauchyFilterCompletion located-uniform gluing)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Suppose a* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *real-seal read and a* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *completion handoff are both consumed through this packet. Then the two reads have the same finite BEDC route inside F:*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

The located read cannot reach the $\mathsf{Real}^{\uparrow}$ *seal by any row other than the displayed L, and the uniform handoff cannot reach a completion-facing consumer by any row detached from the displayed $C, W, T, R, L, H, K, P, N$. Thus the joint* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumption glues the located-filter and uniform-filter surfaces through one packet, not through quotient filters, selected limits, host equality, countable choice, ambient completeness, or a separate completion object.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket located uniform gluing`

Proof. Start with the carrier of Definition 1569.1. It displays only the rows $C, W, T, R, L, H, K, P, N$, so both imported reads must be interpreted through those coordinates once they are consumed as $\mathsf{CauchyFilterCompletion}^{\uparrow}$ data.

Apply Definition 1569.2 to fix the local obligation surface. Filter-to-window exposure and tolerance exactness force any completion-facing read to consume C, then the window and tolerance rows W, T, before the regular readback row R is available.

Apply Definition 1569.3. The terminal seal read is downstream of C, W, T, R and upstream of the structural rows H, K, P, N, so the packet exposes exactly the displayed route.

The imported boundary theorems match this route. The $\mathsf{LocatedCauchyFilter}^{\uparrow}$ real-seal read is constrained by Definition 1661.6, while the $\mathsf{UniformCauchyFilter}^{\uparrow}$ completion handoff is constrained by Definition 1694.3. Since both are consumed through the same accepted packet F, their public exits coincide at L and then pass through the same transport, continuation, provenance, and local naming rows.

No excluded object can mediate the gluing. Quotient filters, selected limits, host equality, countable choice, ambient completeness, and detached completion objects are absent from the carrier and refused by the NameCert obligations, so there is no second route available inside the packet. □

Theorem 1569.8 (CauchyFilterCompletion filterbase handoff)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Every accepted completion read first consumes the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{FilterBase}^{\uparrow}$ *rows behind C before it can inspect the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal L.*

Consequently the completion route factors through the finite handoff

$$C_{\mathsf{FilterBase}^{\uparrow}}, C_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto W, T, R \longmapsto L \longmapsto H, K, P, N.$$

No accepted read may bypass the displayed filterbase row by using a detached stream window, a free dyadic tolerance, a selected filter limit, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filterbase handoff`

Proof. Project the carrier of Definition 1569.1. The row C is the only Cauchy-filter coordinate, and its admissible source is the displayed filterbase route used by the saturated Cauchy-filter packet.

Replay the continuation row K. A completion request reaches W only after C has been consumed, reaches T only through the same windows, reaches R only through that tolerance ledger, and reaches L only after the regular readback is displayed.

The structural rows preserve the route. Transport through H, provenance through P, and local naming through N record the same filterbase-first handoff, so detached windows, free tolerances, selected filter limits, and ambient completeness have no coordinate inside the accepted packet. □

Theorem 1569.9 (CauchyFilterCompletion finite-window induction)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Every induction over the finite filterbase windows of F preserves the displayed Cauchy tolerance row T, the located-uniform readback rows through R, the separatedness boundary carried by the terminal* $\mathsf{Real}^{\uparrow}$ *seal L, and the Real-seal handoff rows H, K, P, N. The induction may only use the finite* BHist *support of W, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it cannot insert quotient filters, selected limits, host equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket finite window induction`

Proof. Start from Definition 1569.8. It places the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source before every finite window, so induction on the window spine begins with a fixed source row C.

At each finite step, use Definition 1569.4. The window row being inspected carries the same dyadic tolerance ledger T, and the readback row R remains downstream of that ledger.

The terminal step is governed by Definition 1569.3 and Definition 1569.7. They keep located, uniform, separatedness, and Real-seal consumers on the same $C, W, T, R, L, H, K, P, N$ route.

Finally the structural rows H, K, P, N transport, replay, source, and name only the displayed packet. Since the refused objects are absent from the carrier and from the NameCert obligation surface, the finite-window induction preserves exactly the listed rows. □

Theorem 1569.10 (CauchyFilterCompletion uniform-limit compatibility)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Every* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{UniformCauchyFilter}^{\uparrow}$*, or separated-completion consumer of F that also reads a uniform-limit or separated-seal boundary must use the same finite completion route*

$$C, W, T, R, L, H, K, P, N.$$

The consumer cannot replace L by quotient-filter equality, selected limits, host real equality, countable choice, or a detached completion object.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform limit compatibility`

Proof. First use Definition 1569.4. It places the window row W and dyadic tolerance row T before the readback row R for every accepted completion read.

Next apply Definition 1569.3. The terminal seal row L is reached only after C, W, T, R and is then transported, replayed, sourced, and named by H, K, P, N.

For uniform-facing consumers, use Definition 1569.5. It identifies the $\mathsf{UniformCompletion}^{\uparrow}$ and $\mathsf{UniformCauchyFilter}^{\uparrow}$ readback route with the same displayed rows $C, W, T, R, L, H, K, P, N$.

Finally apply Definition 1569.16. Quotient-filter equality, selected limits, host real equality, countable choice, and detached completion objects have no coordinate inside F, so a uniform-limit or separated-seal boundary cannot substitute them for the displayed route. □

Theorem 1569.11 (CauchyFilterCompletion filter-convergence handoff)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Every accepted convergence-facing read that uses a* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary must read that convergence row only after the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *source C, finite* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R have been exposed. The handoff is therefore confined to*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

No convergence consumer may replace this route by a selected filter limit, quotient filter, host equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filter convergence handoff`

Proof. Start with Definition 1569.4. It places every accepted regular readback behind the displayed window row and dyadic tolerance ledger.

Apply Definition 1569.3. The terminal seal and any convergence-facing handoff are downstream of the Cauchy-filter source, finite windows, tolerance ledger, and regular readback.

Finally use Definition 1569.5 and Definition 1569.16. The first keeps downstream completion consumers on the same finite route, while the second excludes selected limits, quotient filters, host equality, choice, and ambient completeness from the packet. □

Theorem 1569.12 (CauchyFilterCompletion separated-completion boundary)**.** *Let $F = (C, W, T, R, L, H, K, P, N$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Any separated-completion uniqueness consumer of F may use only the displayed* $\mathsf{Real}^{\uparrow}$ *seal row L and the componentwise* hsame *transport row H after the finite source route C, W, T, R has been read. It cannot use quotient filters, selected limits, host real equality, countable choice, or an ambient separated-completion theorem as a hidden coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket separated completion boundary`

Proof. First apply Definition 1569.4. It forces the separated-completion consumer to reach any regular readback through the displayed windows and tolerances.

Next use Definition 1569.3. The only terminal completion row available to the consumer is the displayed seal L, reached from C, W, T, R.

The uniqueness comparison is then transported only by H and replayed through K, P, N. By Definition 1569.16, no quotient-filter equality, selected limit, host equality, choice principle, or ambient separated-completion theorem can enter the boundary. □

Theorem 1569.13 (CauchyFilterCompletion uniform-completion comparison)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet compares completion data through the same displayed route*

$$C, W, T, R, L, H, K, P, N.$$

The comparison reads the Cauchy-filter source, finite windows, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows from one packet; it cannot replace them by a detached uniform-completion carrier or by quotient-filter, selected-limit, host-equality, countable-choice, or ambient-completeness data.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform completion comparison`

Proof. Begin with Definition 1569.5. It identifies the uniform-facing readback route with the displayed rows $C, W, T, R, L, H, K, P, N$.

Use Definition 1569.4 and Definition 1569.3 to locate the comparison source. The windows and tolerances precede R, and the seal L remains downstream of the same source route.

Finally apply Definition 1569.16. Detached uniform-completion carriers and the excluded quotient, selector, host-equality, choice, and completeness rows are absent from the carrier, so the comparison cannot leave the displayed route. □

Theorem 1569.14 (CauchyFilterCompletion p-variation window bound)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. Any bounded-variation or Young-integral consumer that reads a finite p-variation window from F must obtain that window through the displayed route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer may reuse the rows $C, W, T, R, L, H, K, P, N$ as finite variation-window data, but it receives no quotient filter, choice-selected limit, host real equality, ambient Real completeness, detached variation seminorm, or hidden refinement selector.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket pvariation window bound`

Proof. Begin with the window and tolerance route. By Definition 1569.4, every accepted completion read opens the stream-window row W and dyadic tolerance ledger T before it can inspect the regular readback row R.

Use the filterbase handoff of Definition 1569.8. The source of those windows is the displayed $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ route behind C, so a downstream variation consumer cannot begin from a detached family of partitions.

Now hand the finite windows to the bounded-variation side. The $\mathsf{BoundedVariation}^{\uparrow}$ read may consume the displayed window and tolerance data as a finite control ledger, but it must keep the same C, W, T, R route and the same structural rows H, K, P, N.

Finally apply Definition 1569.3 and Definition 1569.16. The Real seal remains the displayed row L, and quotient filters, selected limits, host equality, choice, ambient completeness, detached variation data, and hidden refinement selectors have no coordinate in the packet. □

Theorem 1569.15 (CauchyFilterCompletion regulated-integral handoff)**.** *Every regulated-integral or* $\mathsf{YoungIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet reads completion data only through the finite source route $C, W, T, R, L, H, K, P, N$. In particular, the consumer may pass the stream windows, dyadic tolerances, regular readback, and Real seal to* $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, *and* $\mathsf{YoungIntegral}^{\uparrow}$ *rows, but it cannot import quotient filters, choice-selected limits, ambient Real completeness, host equality of real names, or a measure-completion integral.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket regulated integral handoff`

Proof. Start with the uniform-completion comparison theorem Definition 1569.13. It fixes every completion-facing comparison to the displayed rows $C, W, T, R, L, H, K, P, N$.

The regulated-function handoff reads only finite windows. The rows W, T, R supply the observed stream windows, dyadic tolerances, and regular rational readbacks required by a $\mathsf{RegulatedFunction}^{\uparrow}$ consumer, while L supplies the downstream Real seal.

The Young-integral consumer is then downstream of those rows. It may combine the regulated-function read with $\mathsf{BoundedVariation}^{\uparrow}$ and $\mathsf{RiemannSum}^{\uparrow}$ data, but the completion contribution remains the same finite route through $C, W, T, R, L, H, K, P, N$.

Close with Definition 1569.16. Since quotient filters, choice-selected limits, host equality, ambient Real completeness, and measure-completion integrals are absent from the carrier, no regulated-integral handoff can export them. □

Theorem 1569.16 (CauchyFilterCompletion quotient nonescape)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet. No accepted read of F can introduce quotient filters, selected limits, host equality of filters or real names, countable choice, ambient completeness, or a completion object not displayed by the carrier.*

Every consumer of F is confined to the rows $C, W, T, R, L, H, K, P, N$ and to the componentwise transport, continuation replay, provenance, and local naming generated by those rows.

Proof. Inspect the carrier of Definition 1569.1. Its coordinates are exactly the Cauchy-filter row, finite windows, dyadic tolerance ledger, regular readback, Real seal handoff, transport, continuation, provenance, and local naming row.

Apply Definition 1569.2. The ledger-refusal obligation excludes quotient filters, selected limits, host equality, countable-choice selectors, ambient completeness, and detached completion coordinates from the local certificate surface.

It remains to check that consumers cannot add them later. Any consumer of F receives only the displayed rows and their hsame, Cont, Pkg, and $\mathsf{NameCert}$ structure, so there is no exported field from which an excluded object could be read. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket quotient nonescape`

Theorem 1569.17 (CauchyFilterCompletion L10 source scope)**.** *The L10 source scope of the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *chapter is exactly*

$$\mathsf{CauchyFilter}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},$$

The $\mathsf{FilterBase}^{\uparrow}$ *route is read only through the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row, and no quotient filter, selected limit, host equality, countable-choice selector, ambient completeness theorem, or detached completion carrier belongs to the scope.*

Proof. Read the carrier definition. The public coordinates $C, W, T, R, L, H, K, P, N$ name precisely the Cauchy-filter source, stream-window observation, dyadic tolerance, regular readback, Real seal, transport, continuation, provenance, and local naming data.

The $\mathsf{UniformCompletion}^{\uparrow}$ occurrence is provenance-level only. It appears in P as a downstream completion-facing surface, while the terminal read still passes through C, W, T, R, L and the structural rows.

The filterbase dependency is internal to C. By Definition 1569.8, every accepted read consumes that base before the stream and tolerance rows, but the chapter does not export a separate $\mathsf{FilterBase}^{\uparrow}$ coordinate beyond the Cauchy-filter source row.

The nonescape boundary is supplied by Definition 1569.16. Since excluded objects are absent from the carrier and refused by the local NameCert surface, the listed objects are the exact L10 source scope. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket l10 source scope`

Theorem 1569.18 (CauchyFilterCompletion Real seal nonescape)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every consumer that reaches the displayed* $\mathsf{Real}^{\uparrow}$ *seal row L must first pass through the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row C, the finite* $\mathsf{StreamName}^{\uparrow}$ *window family W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The rows H, K, P, N then transport, replay, source, and name that same route. No accepted read can escape from L into a selected limit, quotient filter, host real equality, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completion object.*

Proof. Project the carrier of Definition 1569.1. The row L is present only as the terminal seal handoff of the displayed tuple, and the preceding public coordinates are exactly C, W, T, R.

Apply Definition 1569.2 and Definition 1569.3. The local obligations force filter-to-window exposure, tolerance exactness, and regular readback before a completion-facing consumer may read the Real seal.

Finally use Definition 1569.16. The structural rows H, K, P, N preserve the same finite route, and the refused quotient, selector, host-equality, choice, completeness, and detached-completion objects have no coordinate inside F. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal nonescape`

Theorem 1569.19 (CauchyFilterCompletion uniform handoff)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Any* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer that uses F sees only the provenance-level handoff*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

The handoff reads the underlying completion request through $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal; it does not introduce a second uniform-completion carrier, quotient filter, selected limit, choice principle, host equality, or ambient completeness theorem.*

Proof. Begin with the provenance row P in Definition 1569.1. The $\mathsf{UniformCompletion}^{\uparrow}$ occurrence is stored there as provenance for the displayed packet, not as an additional carrier coordinate.

Apply Definition 1569.7. A uniform-facing read consumed through F shares the finite route $C, W, T, R, L, H, K, P, N$ with the located and Real-facing reads already exposed by the packet.

Use Definition 1569.17 to close the source list. The only uniform-completion access is the provenance-level handoff through P, so no detached completion object, selected limit, quotient filter, choice selector, host equality, or ambient completeness row can be exported. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform handoff`

Theorem 1569.20 (CauchyFilterCompletion filterbase window exactness)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every filterbase-facing completion read consumes the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row behind C before it inspects a window in W, and every accepted window read uses the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in T before producing the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. Thus the filterbase-to-window route is exact inside the packet:*

$$C_{\mathsf{FilterBase}^{\uparrow}}, C_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto W, T \longmapsto R \longmapsto L, H, K, P, N.$$

No accepted read may replace this route by a free stream window, detached dyadic tolerance, selected filter limit, quotient-filter equality, countable choice, host equality, or ambient completeness.

Proof. Project the source row C and the window rows W from Definition 1569.1. The filterbase dependency is internal to the displayed $\mathsf{CauchyFilter}^{\uparrow}$ row, while W is the only window family exposed by the completion packet.

Apply Definition 1569.8. Every accepted completion read consumes the filterbase route through C before any stream window, tolerance ledger, readback row, or Real seal is available.

Apply Definition 1569.2. Tolerance exactness ties each accepted readback in R to the displayed dyadic ledger T for the same window row W, and the rows H, K, P, N preserve, replay, source, and name this exact route.

The nonescape theorem Definition 1569.16 excludes the remaining alternatives. Detached windows, free tolerances, selected limits, quotient filters, countable choice, host equality, and ambient completeness are absent from the carrier and cannot replace the displayed route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filterbase window exactness`

Theorem 1569.21 (CauchyFilterCompletion filterbase totality)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every accepted completion read consumes the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *route behind C before any consumer can inspect the window family W, the dyadic tolerance ledger T, the regular readback row R, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal L. Hence the route*

$$C_{\mathsf{FilterBase}^{\uparrow}}, C_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto W, T, R, L \longmapsto H, K, P, N$$

is total for accepted completion reads inside the packet.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filterbase totality`

Proof. Start with the carrier of Definition 1569.1. The only filter-facing coordinate is C, and the packet exposes W, T, R, L only as rows downstream of that source.

Apply Definition 1569.8. It states that every accepted completion read first consumes the displayed filterbase and Cauchy-filter route before any stream window, dyadic tolerance, regular readback, or Real seal is available.

The remaining structural rows do not add another source. Transport through H, replay through K, provenance through P, and local naming through N preserve the same order, so the filterbase route behind C is total for all accepted completion reads. □

Theorem 1569.22 (CauchyFilterCompletion window tolerance exactness)**.** *For every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier $F = (C, W, T, R, L, H, K, P, N)$, each accepted window row in W uses its matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in T before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row in R can be consumed. The resulting readback route is*

$$W, T \longmapsto R \longmapsto L, H, K, P, N.$$

No accepted read may replace the displayed tolerance with a free dyadic row, a detached stream window, a selected limit, a quotient-filter equality, host equality, countable choice, or ambient completeness.

Proof. Project the window, tolerance, and readback coordinates of Definition 1569.1. The packet has one displayed window family W, one dyadic tolerance ledger T, and one regular readback row R.

Use Definition 1569.2. Its tolerance-exactness row ties every accepted readback in R to the displayed dyadic ledger T for the same window row W.

Now apply Definition 1569.20. The same theorem keeps the window read behind the accepted filterbase route and prevents detached windows, free tolerances, selected limits, quotient-filter equality, countable choice, host equality, and ambient completeness from replacing the displayed route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket window tolerance exactness`

Theorem 1569.23 (CauchyFilterCompletion Real seal refusal)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The terminal* $\mathsf{Real}^{\uparrow}$ *seal row L exports only the finite route already displayed by the packet:*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

It cannot export quotient filters, selected limits, host equality of filters or real names, countable choice, ambient completeness, or any completion object detached from F.

Proof. Begin with Definition 1569.3. A consumer reaches L only after the Cauchy-filter source row, finite windows, dyadic tolerance ledger, and regular readback row have been consumed.

Use Definition 1569.7 and Definition 1569.19. They show that located-facing and uniform-facing reads share the same displayed route and do not introduce a second completion coordinate.

Finally apply Definition 1569.16. Quotient filters, selected limits, host equality, countable choice, ambient completeness, and detached completion objects are absent from the carrier and refused by the local NameCert surface, so the Real seal cannot export them. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal refusal`

Theorem 1569.24 (CauchyFilterCompletion root obligation surface)**.** *For every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier $F = (C, W, T, R, L, H, K, P, N)$, the root completion obligation surface is exactly the finite route through* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *displayed by the tuple. Every completion handoff must first read the Cauchy-filter source row C, then the finite windows W, the tolerance ledger T, the regular readback R, the Real seal L, and finally the structural rows H, K, P, N.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootObligationSurface`

Proof. Project the carrier of Definition 1569.1. It lists exactly $C, W, T, R, L, H, K, P, N$, and the provenance row names the $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{UniformCompletion}^{\uparrow}$ dependencies.

Apply Definition 1569.2. Carrier admission, filter-to-window exposure, tolerance exactness, completion handoff, and ledger refusal are all attached to the same displayed packet.

Use Definition 1569.33. The filterbase-totality, window-tolerance exactness, and Real-seal refusal routes cover the root handoff, while H, K, P, N provide only transport, replay, provenance, and local naming. □

Theorem 1569.25 (CauchyFilterCompletion filterbase admission)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The root completion surface admits a downstream read only after the* BHist *rows behind C display the* $\mathsf{FilterBase}^{\uparrow}$ *source, the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *or* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *Cauchy condition read on that source, and the matching* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *admission row. The admitted read is then transported by H, replayed by K, sourced by P, and named by N; it cannot start from a detached filterbase, quotient completion, selected representative, host equality proof, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filterbase admission`

Proof. Project the root obligation surface of Definition 1569.24. The only source coordinate available before any window or readback is C, and its admissible content is the displayed filterbase and Cauchy-filter data.

Use Definition 1569.8. It forces every accepted completion read to consume the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ route before any $\mathsf{StreamName}^{\uparrow}$ window, dyadic tolerance, regular readback, or Real seal is inspected.

The structural rows preserve admission rather than add a second source. Componentwise hsame transport in H, displayed Cont replay in K, Pkg provenance in P, and local $\mathsf{NameCert}$ naming in N keep the read on the same finite BHist route and refuse quotient completions, selected representatives, host equality, and ambient completeness. □

Theorem 1569.26 (CauchyFilterCompletion uniform Cauchy lift)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *consumer of the root surface lifts through the same finite packet:*

$\mathsf{FilterBase}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BI

The lift first reads the admitted filterbase row in C, then the finite $\mathsf{StreamName}^{\uparrow}$ *windows W, the dyadic tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal L. No quotient completion, selected representative, or detached uniform-completion carrier is exported.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionUniformCauchyLift`

Proof. Begin with Definition 1569.25. The uniform consumer is admitted only through the displayed filterbase and Cauchy-filter source behind C.

Read the finite observation data next. The window row W and tolerance row T are the only rows from which a uniform Cauchy comparison can produce the regular readback R, and Definition 1569.22 keeps those rows tied to the same source.

Finally use Definition 1569.19 and Definition 1569.3. Uniform completion is recorded through provenance while the terminal seal remains L, and the route is carried by H, K, P, N without quotient completion, selected representatives, detached carriers, or ambient completeness. □

Theorem 1569.27 (CauchyFilterCompletion root data exhaustion)**.** *For every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier $F = (C, W, T, R, L, H, K, P, N)$, the root data consumed by downstream completion and filter chapters are exhausted by the displayed rows for* $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *Any admitted downstream consumer must factor through Definition 1569.25 and Definition 1569.26 before it reads L, H, K, P, or N.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootDataExhaustion`

Proof. Use Definition 1569.24 to identify the root surface with the tuple $C, W, T, R, L, H, K, P, N$. There is no root coordinate outside that tuple.

Apply Definition 1569.25 to account for the filterbase and Cauchy-filter source. Apply Definition 1569.26 to account for the uniform-facing readback through stream windows, tolerances, regular names, and the Real seal.

The remaining rows are structural. Transport, replay, provenance, and local naming preserve the admitted route, so downstream chapters cannot obtain quotient completion data, selected representatives, host equality, detached uniform-completion carriers, or ambient completeness from the root surface. □

Theorem 1569.28 (CauchyFilterCompletion root filterbase admission)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The root obligation surface admits a completion request only when the finite* BHist *rows behind C display both the* $\mathsf{FilterBase}^{\uparrow}$ *admission data and the saturated* $\mathsf{CauchyFilter}^{\uparrow}$ *source before any* $\mathsf{StreamName}^{\uparrow}$ *window in W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in R, or terminal* $\mathsf{Real}^{\uparrow}$ *seal in L is consumed. The admission route is transported only by the componentwise* hsame *rows in H, replayed only by the displayed* Cont *rows in K, and named only by the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row N together with provenance P.*

Proof. Project the carrier and the root obligation surface. The source coordinate C is the only row from which a filterbase-facing completion request can enter the packet, and the finite BHist data displayed there supplies the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ admission route.

The observation rows are downstream. A consumer reaches W, R, or L only after the source row has been admitted, and the tolerance ledger T remains attached to the same finite window route.

The structural rows do not add another admission channel. Componentwise hsame transport in H, displayed Cont replay in K, provenance in P, and local $\mathsf{NameCert}$ naming in N preserve the same finite route, so detached filterbases, selected limits, and ambient completeness have no admitted coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root filterbase admission`

Theorem 1569.29 (CauchyFilterCompletion root uniform-filter readback)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Any* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *consumer reading the root completion surface receives its regular readback only through the finite route*

$$\mathsf{FilterBase}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by C, W, R, L and the finite BHist *rows of the packet. The readback is preserved by* hsame *transport in H, by* Cont *replay in K, and by the* $\mathsf{Pkg/NameCert}$ *rows P, N; it cannot be replaced by a quotient filter, detached uniform-filter object, selected limit, host equality, countable choice, or ambient completeness.*

Proof. Start with a uniform-filter consumer. Once it cites the accepted $\mathsf{CauchyFilterCompletion}^{\uparrow}$ packet, the only available uniform-facing data are the provenance row P and the displayed route through C, W, T, R, L, H, K, N.

Read the finite source and window rows. The $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source is exposed through C, the finite $\mathsf{StreamName}^{\uparrow}$ observations are exposed through W, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback R is consumed before the terminal $\mathsf{Real}^{\uparrow}$ seal L.

Finally apply the structural rows. The componentwise hsame row H transports the same source, window, readback, and seal coordinates; the Cont row K replays only that route; and P, N source and name it. Thus the uniform-filter readback has no coordinate for any detached or choice-based completion object. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root uniform filter readback`

Theorem 1569.30 (CauchyFilterCompletion root Real-seal no-choice)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. The terminal* Real$^{\uparrow}$ *seal row L is a no-choice exit from the root obligation surface: every accepted read of L passes through finite* BHist *rows for* FilterBase$^{\uparrow}$, CauchyFilter$^{\uparrow}$, UniformCauchyFilter$^{\uparrow}$ *provenance,* StreamName$^{\uparrow}$ *windows, and* RegSeqRat$^{\uparrow}$ *readback, then through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. No selected filter limit, quotient-filter representative, host real equality, countable-choice selector, or ambient* Real$^{\uparrow}$ *completeness theorem is available after the seal is reached.*

Proof. Project the terminal seal coordinate. The row L occurs only in the accepted tuple $F = (C, W, T, R, L, H, K, P, N)$, downstream of the filter source, finite windows, dyadic tolerance ledger, and regular readback.

Use the filterbase admission and uniform-filter readback routes. They place the FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ source, UniformCauchyFilter$^{\uparrow}$ provenance, StreamName$^{\uparrow}$ windows, and RegSeqRat$^{\uparrow}$ readback before any Real-seal consumer may inspect L.

The no-choice conclusion follows from carrier exhaustion. The rows H, K, P, N only transport, replay, source, and name the finite BHist route, so no selected limit, quotient representative, host equality, countable-choice functional, or ambient completeness theorem can be read after the seal. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root real seal no choice`

Theorem 1569.31 (CauchyFilterCompletion regular readback totality)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every accepted completion read that reaches the terminal* Real$^{\uparrow}$ *seal L must consume a* RegSeqRat$^{\uparrow}$ *readback row R produced from the same* StreamName$^{\uparrow}$ *windows W and* DyadicRatCore$^{\uparrow}$ *tolerance ledger T behind the* CauchyFilter$^{\uparrow}$ *source C. The readback route is total inside the tuple and cannot be replaced by a detached stream, free dyadic tolerance, quotient filter, selected limit, host equality, countable choice, or ambient completeness row.*

Proof. Start with Definition 1569.22. It forces each accepted window read in W to use the matching dyadic tolerance row in T before R can be consumed.

Apply Definition 1569.21. The same read is already behind the displayed FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ route contained in C, so R is not a detached regular sequence row.

Finally use Definition 1569.23. A consumer reaches L only after C, W, T, R have been displayed, and the structural rows H, K, P, N preserve that route without adding quotient, selector, choice, equality, or completeness coordinates. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket regular readback totality`

Theorem 1569.32 (CauchyFilterCompletion uniform reflection nonescape)**.** *For every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, any* $\mathsf{UniformCompletion}^{\uparrow}$ *reflection of the completion handoff is confined to the provenance-level row* P *and the displayed route*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

The reflection cannot introduce a separate uniform-completion carrier, quotient filter, selected limit, host equality, countable-choice selector, ambient completeness theorem, or completion object detached from the BHist/hsame/Cont/Pkg/NameCert *route.*

Proof. Begin with Definition 1569.19. It places the $\mathsf{UniformCompletion}^{\uparrow}$ occurrence in the provenance row and keeps the completion-facing consumer on the route through $C, W, T, R, L, H, K, P, N$.

Use Definition 1569.7. Located-facing and uniform-facing reads share the same Real-seal exit, so the uniform reflection cannot split away from the displayed Cauchy-filter, window, tolerance, and readback rows.

Apply Definition 1569.16. The excluded quotient, selector, host-equality, choice, completeness, and detached-completion objects have no coordinate in F, and uniform reflection through P does not create one. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform reflection nonescape`

Theorem 1569.33 (CauchyFilterCompletion carrier-ledger package)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The rows* $C, W, T, R, L, H, K, P, N$ *form a single carrier-admission and ledger-refusal package for the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$*: every accepted completion read is exhausted by the displayed filterbase-totality route, the window-tolerance exactness route, and the Real-seal refusal route, and no other row is consumed by the certificate.*

In particular, the local NameCert admits only the displayed Cauchy-filter source, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal handoff, transport, continuation replay, provenance, and local naming rows. It refuses quotient filters, selected limits, host real equality, countable-choice selectors, ambient completeness, and detached completion objects over the same finite packet.

Proof. Project Definition 1569.2. It identifies the local certificate surface with carrier admission, filter-to-window exposure, tolerance exactness, completion handoff, and ledger refusal over exactly the rows $C, W, T, R, L, H, K, P, N$.

Apply Definition 1569.21. This accounts for every accepted completion read at the source side: the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ route behind C is consumed before W, T, R, L and the structural rows can be inspected.

Apply Definition 1569.22 and Definition 1569.23. The first theorem ties each window read to the matching dyadic tolerance and regular readback, while the second keeps the terminal Real seal on the same finite route and refuses quotient, selector, host-equality, choice, completeness, and detached-completion exits.

These three routes cover the carrier side, the tolerance ledger side, and the terminal refusal side of the same packet. Since the carrier definition and NameCert obligations expose no additional coordinate, the local certificate consumes no row outside $C, W, T, R, L, H, K, P, N$. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket carrier ledger package`

Theorem 1569.34 (CauchyFilterCompletion Real seal choice-free tail totality)**.** *Let $F = (C, W, T, R, L, H, K, P, N$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every completion read that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal L has a displayed tail route*

$$C_{\mathsf{FilterBase}^{\uparrow}}, C_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto W, T, R \longmapsto L \longmapsto H, K, P, N.$$

The route is total for accepted reads and uses no quotient filter, selected limit, countable-choice selector, host real equality, ambient completeness theorem, or detached completion carrier.

Proof. Begin with the filterbase handoff of Definition 1569.8. It forces the accepted completion read to consume the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source behind C before any window, tolerance, readback, or seal row is available.

Next apply Definition 1569.22. The window row W and dyadic ledger T determine the regular readback R before the terminal seal can be inspected.

Finally use Definition 1569.3 and Definition 1569.16. The seal row L is downstream of C, W, T, R, and the refused quotient, selector, choice, equality, completeness, and detached-completion objects have no coordinate inside F. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal choice free tail totality`

Theorem 1569.35 (CauchyFilterCompletion window Real seal determinacy)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. If two completion-facing consumers read the same displayed filter source C, the same window family W, and the same dyadic tolerance ledger T, then any accepted terminal* $\mathsf{Real}^{\uparrow}$ *seal read from F is determined by the same regular readback row R and the same structural route through L, H, K, P, N.*

Thus no consumer may replace the displayed window route by a second Real seal, a selected limit, quotient-filter equality, countable choice, host equality, ambient completeness, or detached uniform-completion object.

Proof. Project the accepted packet. The rows $C, W, T, R, L, H, K, P, N$ are the only coordinates available to either consumer.

Use Definition 1569.20. Matching C, W, T fixes the filterbase-to-window route and ties every accepted readback in R to the displayed dyadic ledger.

Apply Definition 1569.23. Once R is fixed, the terminal seal row L is consumed only through the same finite route and cannot be replaced by a selected limit, quotient equality, choice, host equality, ambient completeness, or detached completion row.

The structural rows preserve this determinacy. Transport H, replay K, provenance P, and local naming N record the same route for both consumers. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket window real seal determinacy`

Theorem 1569.36 (CauchyFilterCompletion uniform provenance exhaustion)**.** *Let $F = (C, W, T, R, L, H, K, P, N$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The* $\mathsf{UniformCompletion}^{\uparrow}$ *occurrence in the packet is exhausted by the provenance row P and the displayed route*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

It contributes no additional uniform-completion carrier, quotient filter, selected limit, countable-choice selector, host equality, ambient completeness theorem, or Real seal outside the rows of F.

Proof. Start with Definition 1569.19. It places the uniform-completion surface at provenance level and keeps the completion-facing read on the finite route through $C, W, T, R, L, H, K, P, N$.

Apply Definition 1569.32. Any uniform reflection is confined to P and cannot split off a second completion object.

Use Definition 1569.33. The carrier admission and ledger refusal rows already exhaust the accepted NameCert surface, while the quotient nonescape theorem rules out the remaining forbidden exits.

Therefore uniform provenance is not an extra source of completion data. It is exactly the package row naming the same Real-seal tail route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket uniform provenance exhaustion`

Theorem 1569.37 (CauchyFilterCompletion Cauchy-filter limit uniform lock)**.** *Let $F = (C, W, T, R, L, H, K, P, N$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every completion read through F factors through the* CauchyFilter$^{\uparrow}$ *source row C, the* CauchyFilterLimit$^{\uparrow}$ *boundary named by the same filter row, finite* StreamName$^{\uparrow}$ *windows W,* DyadicRatCore$^{\uparrow}$ *tolerances T,* RegSeqRat$^{\uparrow}$ *readback R, and* UniformCompletion$^{\uparrow}$ *provenance P before any terminal* Real$^{\uparrow}$ *seal L is consumed. The remaining rows H, K, N only transport, replay, and name that same route.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket cauchyfilter limit uniform lock`

Proof. Start with Definition 1569.8. It forces the accepted completion read to expose the filter source before any window, tolerance, readback, or terminal seal row is available.

Use Definition 1569.22. The finite StreamName windows W and dyadic tolerance ledger T determine the regular readback row R inside the displayed packet.

Apply Definition 1569.3 and Definition 1569.36. The Real seal L and the uniform provenance row P remain downstream of the same finite route, while Definition 1569.16 excludes quotient filters, selected limits, choice, host equality, ambient completeness, and detached completion data.

The structural rows preserve the lock. Componentwise hsame transport, displayed Cont replay, and local naming can only repeat the route already exposed by C, W, T, R, L, P. □

Theorem 1569.38 (CauchyFilterCompletion completion-reflector consumer)**.** *Every* MetricCompletion$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer of an accepted* CauchyFilterCompletion$^{\uparrow}$ *packet receives only the finite route*

$$C \longmapsto W \longmapsto T \longmapsto R \longmapsto L \longmapsto H, K, P, N.$$

The consumer may reflect that route into a completion-facing packet, but it cannot import quotient filters, selected limits, countable choice, host equality, ambient completeness, or any completion carrier not already displayed by the rows of F.

Proof. Read the accepted packet through Definition 1569.2. Its carrier and NameCert rows expose only the Cauchy-filter source, finite windows, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming.

Then apply Definition 1569.37. A completion-facing consumer reaches the CauchyFilterLimit boundary, UniformCompletion provenance, and Real seal only by following that displayed order.

Finally use Definition 1569.39. The basis exhaustion theorem rules out any second completion carrier or host-side principle, so MetricCompletion and UniformCompletion consumers receive only the listed finite route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket completion reflector consumer`

Theorem 1569.39 (CauchyFilterCompletion Real seal basis exhaustion)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every accepted completion read through F is exhausted by the displayed* CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *source row, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RegSeqRat$^{\uparrow}$ *readback, terminal* Real$^{\uparrow}$ *seal handoff, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. No quotient filter, selected limit, host real equality, countable-choice selector, ambient completeness theorem, or detached completion object is available after those rows are read.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal basis exhaustion`

Proof. Project the NameCert obligations of Definition 1569.2. They identify the accepted packet with carrier admission, filter-to-window exposure, tolerance exactness, completion handoff, transport, replay, provenance, and local naming over $C, W, T, R, L, H, K, P, N$.

Use Definition 1569.21 and Definition 1569.22. The first theorem exhausts the displayed filter-base source behind C, while the second ties each finite window in W to its dyadic tolerance ledger T and regular readback row R.

Apply Definition 1569.23 and Definition 1569.36. The terminal seal L and the uniform provenance occurrence remain downstream of the same finite route and cannot split off a quotient, selector, host equality, choice, ambient-completeness, or detached-completion exit.

Finally preserve the route through H, K, P, N. These rows transport, replay, source, and name only the already displayed basis data, so every accepted completion read is exhausted by the listed basis. □

Theorem 1569.40 (CauchyFilterCompletion observation base)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every accepted completion read starts from the displayed* CauchyFilter$^{\uparrow}$ *source row C before it may inspect any* StreamName$^{\uparrow}$ *window in W, any* DyadicRatCore$^{\uparrow}$ *tolerance in T, any* RegSeqRat$^{\uparrow}$ *readback in R, or any terminal* Real$^{\uparrow}$ *seal in L. The structural rows H, K, P, N preserve that source order rather than supplying a second observation base.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket observation base`

Proof. Begin with Definition 1569.8. It places every accepted completion read behind the displayed FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ route contained in C before any finite window or tolerance row is available.

Use Definition 1569.22. Once the source row has been exposed, the stream windows W and dyadic tolerances T determine the regular readback row R inside the same carrier.

Apply Definition 1569.39. The terminal seal and the structural rows remain downstream of the same basis, so no completion read can begin from a detached window, readback, host equality, selected limit, quotient filter, choice principle, or ambient completeness theorem. □

Theorem 1569.41 (CauchyFilterCompletion located-uniform basis)**.** *Located-filter and uniform-filter consumers of an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier share exactly the same basis rows $C, W, T, R, L, H, K, P, N$. A located read and a uniform read may emphasize different consumer boundaries, but both must pass through the displayed Cauchy-filter source, finite stream windows, dyadic tolerance ledger, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket located uniform basis`

Proof. Start from Definition 1569.7. It states that located-facing and uniform-facing reads are glued along the same finite completion route rather than by a second completion carrier.

Next apply Definition 1569.19. Uniform provenance is recorded through P while the read remains on C, W, T, R, L, H, K, N; it does not create a detached uniform source.

Finally use Definition 1569.39. The shared basis exhausts both consumers, and quotient filters, selected limits, host equality, choice, ambient completeness, and detached completion data are absent from every row. □

Theorem 1569.42 (CauchyFilterCompletion completion scope)**.** *The* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet closes only the finite completion route displayed by* $C, W, T, R, L, H, K, P, N$*. It supplies a named route from Cauchy-filter observations through finite stream windows, dyadic tolerances, regular rational readback, and a Real seal, but it refuses quotient filters, selected limits, host equality, countable choice, ambient completeness, and any completion object not displayed by the carrier.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket completion scope`

Proof. Project the local NameCert surface with Definition 1569.2. The carrier rows account for source admission, window exposure, tolerance exactness, completion handoff, transport, replay, provenance, and local naming.

Use the observation base theorem Definition 1569.40 and the located-uniform basis theorem Definition 1569.41. Together they show that all completion-facing consumers start from the same source row and share the same displayed basis through located and uniform reads.

Close the scope with Definition 1569.16. The refused quotient, selector, host-equality, choice, ambient-completeness, and detached-completion objects have no carrier coordinate, so the packet closes exactly the finite route it displays. □

Theorem 1569.43 (CauchyFilterCompletion choice-free completion row)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every accepted completion read is choice-free and factors through the displayed rows*

$$C, W, T, R, L, H, K, P, N.$$

In particular, the read starts from the $\mathsf{CauchyFilter}^{\uparrow}$ *source row* C*, uses only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L*, and is then transported, replayed, sourced, and named by* H, K, P, N*.*

Proof. Project the carrier of Definition 1569.1. Its displayed rows are exactly $C, W, T, R, L, H, K, P, N$, and no coordinate stores a countable-choice selector, selected limit, quotient filter, host equality, or ambient completeness theorem.

Apply Definition 1569.8. The read must first consume the filterbase and Cauchy-filter route behind C before any window, tolerance, readback, or Real seal row is available.

Apply Definition 1569.22 and Definition 1569.3. These force the finite order W, T, R, L after the source row and before the structural rows.

Finally use Definition 1569.16. Since every excluded object is absent from the carrier and refused by the ledger, every accepted completion read is exhausted by the displayed choice-free route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket choicefree completion row`

Theorem 1569.44 (CauchyFilterCompletion regular readback completeness)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. For every accepted finite stream-window and dyadic-tolerance read through W and T, the* RegSeqRat$^{\uparrow}$ *readback row R is total inside the packet: any completion-facing consumer that reaches the accepted window and tolerance rows must receive its regular rational readback through R before it may inspect L, H, K, P, or N.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRegularReadbackCompleteness`

Proof. Start with the carrier definition Definition 1569.1. The only readback coordinate displayed after the stream-window and dyadic-tolerance rows is R.

Use Definition 1569.4. It states that every accepted completion read opens W and T before it can read R, so R is tied to the same finite stream-window and tolerance data.

Use Definition 1569.22. The matching dyadic tolerance row in T is required before the regular readback row can be consumed, ruling out detached windows and free tolerance parameters.

The downstream rows cannot replace the readback. By Definition 1569.18, any consumer that reaches L has already passed through R, and H, K, P, N only transport, replay, source, and name the same route. □

Theorem 1569.45 (CauchyFilterCompletion metric-uniform compatibility)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Any* MetricCompletion$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer of F reads the same finite completion route*

$$C, W, T, R, L, H, K, P, N.$$

Neither consumer may replace this route by quotient filters, selected limits, host equality, ambient completeness, countable choice, or a detached metric-completion or uniform-completion object.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket metric uniform compatibility`

Proof. Begin with the shared source route from Definition 1569.1. The packet exposes one Cauchy-filter source, one window family, one tolerance ledger, one regular readback row, and one Real seal handoff.

For metric-facing reads, apply Definition 1569.42. It confines all completion-facing consumers to the rows $C, W, T, R, L, H, K, P, N$ and refuses detached completion objects.

For uniform-facing reads, apply Definition 1569.19 and Definition 1569.10. The UniformCompletion$^{\uparrow}$ occurrence is provenance-level and shares the same route through the terminal seal and structural rows.

Finally use Definition 1569.16. Quotient filters, selected limits, host equality, ambient completeness, countable choice, and detached metric or uniform completion carriers have no coordinate in F, so both consumers must read the same finite route. □

Theorem 1569.46 (CauchyFilterCompletion filter-base admission)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every completion-facing read admits the displayed* CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *source behind C before any consumer can inspect W, T, R, or L. The structural rows H, K, P, N preserve this source order and introduce no detached basis, selected limit, quotient filter, host equality, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the carrier of Definition 1569.1. The row C is the only Cauchy-filter source coordinate, and the packet exposes W, T, R, L only as downstream rows.

Apply Definition 1569.8 and Definition 1569.21. They place the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ admission route before every stream-window, tolerance, readback, and seal read.

Finally use Definition 1569.33. The local NameCert consumes only the displayed rows $C, W, T, R, L, H, K, P, N$, so the refused quotient, selector, host-equality, choice, and completeness objects have no admission coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filter base source order`

Theorem 1569.47 (CauchyFilterCompletion completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier shares the same completion handoff route*

$$C, W, T, R, L, H, K, P, N.$$

Metric-facing and uniform-facing reads may use different downstream vocabulary, but both receive the displayed Cauchy-filter source, stream windows, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket completion handoff`

Proof. Begin with Definition 1569.46. It fixes the source side of any completion-facing read at the displayed $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ row behind C.

Use Definition 1569.45. It identifies the $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ consumer routes with the same finite rows $C, W, T, R, L, H, K, P, N$.

The handoff is then exhausted by Definition 1569.39. No detached metric-completion object, detached uniform-completion object, quotient filter, selected limit, countable choice, host equality, or ambient completeness row remains outside the displayed route. □

Theorem 1569.48 (CauchyFilterCompletion filterbase window minimality)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. A completion-facing read may open a* $\mathsf{StreamName}^{\uparrow}$ *window in* W *only after the* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source behind* C *has been admitted, and the only rows available after that opening are the matching dyadic tolerance row* T*, regular readback row* R*, Real seal* L*, and structural rows* H, K, P, N*. The carrier therefore contains no quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness row between the source and the window.*

Proof. Project the tuple F. The source coordinate is C, while W, T, R, L are downstream observation rows.

Apply Definition 1569.46. It places every completion-facing read behind the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source before any stream window is consumed.

Use Definition 1569.82 to exhaust the remaining coordinates. Since the refused quotient, selector, choice, equality, and completeness objects are not fields of F, the displayed source-to-window route is minimal. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket filterbase window minimality`

Theorem 1569.49 (CauchyFilterCompletion tail readback admission)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every tail readback admitted by the root completion surface passes through the finite route*

$$C \longmapsto W \longmapsto T \longmapsto R \longmapsto L$$

together with H, K, P, N, where C carries the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source, W carries the* $\mathsf{StreamName}^{\uparrow}$ *window, T carries the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, R carries the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and L carries the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with Definition 1569.31. It forces each accepted readback in R to use the matching stream window W and dyadic tolerance ledger T behind the Cauchy-filter source C.

Then apply Definition 1569.30. The terminal Real seal L is read only after that finite source-window-tolerance-readback route.

The structural rows H, K, P, N preserve the same route. Thus no detached tail, quotient filter, selected limit, host equality, countable choice, or ambient completeness row is admitted. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket tail readback admission`

Theorem 1569.50 (CauchyFilterCompletion Real-seal source exhaustion)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Once a consumer reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal L, every source row available to that consumer has already appeared in C, W, T, R and the structural rows H, K, P, N. The seal exports only the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *route, not a quotient filter, selected limit, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket real seal source exhaustion`

Proof. Read L through Definition 1569.49. The theorem places the Real seal after the source, window, tolerance, and regular-readback rows.

Apply Definition 1569.33. The local certificate consumes no row outside $C, W, T, R, L, H, K, P, N$.

Finally use Definition 1569.82. The refused objects have no coordinate in the accepted carrier, so the Real seal exhausts the displayed finite source route. □

Theorem 1569.51 (CauchyFilterCompletion root exactness)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The accepted root reads of F are exhausted by the* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source row C,* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal L,* $\mathsf{UniformCompletion}^{\uparrow}$ *provenance carried by P, componentwise* hsame *transport H, displayed* Cont *replay K,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *rows N. No root read adds a quotient filter, selected limit, detached completion carrier, host equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root exactness`

Proof. Project the carrier of Definition 1569.1. Its root completion route is the displayed tuple $C, W, T, R, L, H, K, P, N$.

Apply Definition 1569.48 and Definition 1569.49. These place every source and tail read behind the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ row, the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use Definition 1569.50 and Definition 1569.60. The Real seal and uniform-completion consumers inherit the same finite route and cannot introduce detached completion data.

Finally the structural rows H, K, P, N transport, replay, source, and name exactly those reads. Since the refused quotient, selected-limit, host-equality, choice, and ambient-completeness objects have no coordinate in the carrier, the listed rows exhaust the root completion surface. □

Theorem 1569.52 (CauchyFilterCompletion completion-functor factorization)**.** *Let $F = (C, W, T, R, L, H, K, P, N$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{MetricCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer factors through the same source-window-tolerance-readback-seal route already displayed by F and by Definition 1569.47. The consumer receives only the Cauchy-filter source, stream-window family, dyadic tolerance ledger, regular readback, terminal seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert rows; no quotient filter, selected limit, host equality, detached completion object, or ambient completeness row is exported.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionCompletionFunctorFactorization`

Proof. Start with Definition 1569.47. It identifies every metric-facing or uniform-facing completion read with the route $C, W, T, R, L, H, K, P, N$.

Use Definition 1569.27 to keep the source, window, tolerance, readback, and seal rows inside the accepted carrier. The functor-facing vocabulary can ask for completion transport, but it has no additional source row beyond C and no seal row beyond L.

Apply Definition 1569.45. This places the metric and uniform completion consumers on the same finite route, so a $\mathsf{MetricCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, or $\mathsf{UniformCompletion}^{\uparrow}$ read can only repackage the displayed carrier rows.

Finally the visible BHist, hsame, Cont, Pkg, and NameCert rows provide transport, replay, provenance, and local naming for that same route. Since quotient filters, selected limits, host equality, detached completion objects, and ambient completeness have no coordinate in F, no completion-functor consumer can export them. □

Theorem 1569.53 (CauchyFilterCompletion cofinal regular readback)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier whose filterbase row admits the completion-functor factorization of Definition 1569.52. Then every completion-facing consumer has a cofinal finite readback route through the* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row is consumed. The route is exactly the displayed carrier order $C, W, T, R, L, H, K, P, N$, with C exposing the Cauchy-filter and filterbase source, P recording the uniform-completion provenance, R supplying the regular readback, and L supplying the terminal Real seal. No quotient filter, selected limit, host equality, or choice over a cofinal family is introduced.*

Proof. Project the carrier rows of Definition 1569.1. The only source coordinate is C, the finite observation rows are W, T, R, the terminal seal is L, and the remaining rows provide transport, replay, provenance, and local naming.

Use filter-base admission and uniform reflection. Theorems 1569.46 and 1569.19 place the $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ source before all window reads and keep the $\mathsf{UniformCompletion}^{\uparrow}$ occurrence in the same provenance-level route.

Next apply regular readback completeness, metric-uniform compatibility, and completion handoff. Theorems 1569.44, 1569.45, and 1569.47 force every completion-facing read to pass from C, W, T through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback row R before reaching the $\mathsf{Real}^{\uparrow}$ seal L.

Finally apply the completion-functor factorization hypothesis. The factorization can repackage the finite route for functor-facing consumers, but it has no additional coordinate beyond $C, W, T, R, L, H, K, P, N$. The local NameCert therefore consumes only that cofinal finite readback route, and the refused quotient filter, selected limit, host equality, and choice-over-family objects never enter the packet. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket cofinal regular readback`

Definition 1569.54 (CauchyFilterCompletion root unblock carrier)**.** *The root-unblock carrier for* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *is the same finite packet*

$$F = (C, W, T, R, L, H, K, P, N)$$

read with the following obligation order: the $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ *source row* C*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L*, componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport* H*, displayed* Cont *replay* K*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row* N*. A root consumer receives no quotient filter, selected limit, host real equality, countable-choice selector, ambient completeness theorem, or detached* $\mathsf{MetricCompletion}^{\uparrow}/\mathsf{UniformCompletion}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootUnblockCarrier semantic name certificate`

The universal completion read treats the Cauchy-equivalence classifier of chapter 1820 as a displayed sibling dependency. Before any $\mathsf{Real}^{\uparrow}$ seal or filter-completion consumer reads equality of completed names, the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ comparison boundary has already been classified by that sibling route.

Theorem 1569.55 (CauchyFilterCompletion root window exposure)**.** *Every completion-facing read of a root-unblock carrier* $F = (C, W, T, R, L, H, K, P, N)$ *opens the displayed* $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ *source row* C *and the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W *before it consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T *or the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*.*

Proof. Project the root-unblock carrier of Definition 1569.54. Its first completion-facing coordinates are the source row C, window row W, tolerance row T, and readback row R.

Apply Definition 1569.40. It forces every accepted completion read to start from the displayed source row before any window, tolerance, readback, or seal row is available.

Use Definition 1569.22. Once C and W are open, the matching tolerance row T is required before R can be consumed, so the read cannot start from a detached regular sequence. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootWindowExposure`

Theorem 1569.56 (CauchyFilterCompletion root Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of a root-unblock carrier is downstream of the same source, window, tolerance, and readback rows:*

$$C, W, T, R \longmapsto L \longmapsto H, K, P, N.$$

The seal route exports no quotient filter, selected limit, host equality, countable choice, ambient completeness, or detached completion object.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootRealSealRoute`

Proof. Start with Definition 1569.55. It exposes C, W, T, R before the terminal seal can be inspected by a completion-facing consumer.

Apply Definition 1569.23. The $\mathsf{Real}^{\uparrow}$ seal L exports only the finite route already displayed by the packet and refuses quotient, selector, host-equality, choice, completeness, and detached-completion exits.

Finally preserve the route through H, K, P, N. These rows transport, replay, source, and name the same packet, so none of them can replace the source-window-readback chain. □

Theorem 1569.57 (CauchyFilterCompletion root uniform route)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of a root-unblock carrier receives only the displayed route*

$$C, W, T, R, L, H, K, P, N.$$

Uniform and metric completion reads may inspect the provenance row, but they cannot introduce a second completion carrier, quotient filter, selected limit, host equality, countable choice, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootUniformRoute`

Proof. Project the carrier of Definition 1569.54. The only completion-facing rows available to a consumer are $C, W, T, R, L, H, K, P, N$.

Use Definition 1569.45. It states that $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ consumers read the same finite completion route and cannot replace it by detached completion data.

Apply Definition 1569.56. The terminal Real seal is already downstream of the source, window, tolerance, and readback rows, so uniform and metric consumers inherit the same displayed boundary. □

Theorem 1569.58 (CauchyFilterCompletion root NameCert surface)**.** *The root obligation surface of* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *is exactly the root-unblock carrier of Definition 1569.54 together with the window exposure of Definition 1569.55, the Real seal route of Definition 1569.56, and the metric-uniform route of Definition 1569.57. A root consumer must therefore read the displayed* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{FilterBase}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows before exporting any completion-facing result.*

Proof. Combine the three root routes. The window theorem exposes the source and finite observation rows, the Real seal theorem fixes the terminal readback route, and the metric-uniform theorem keeps completion consumers on the same displayed carrier.

Now apply Definition 1569.33. It identifies the local NameCert package with the carrier rows and ledger refusals over $C, W, T, R, L, H, K, P, N$.

Finally use Definition 1569.42. The chapter closes only this finite completion route and refuses quotient filters, selected limits, host real equality, countable-choice selectors, ambient completeness, and detached completion objects. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootSurface semantic name certificate`

Theorem 1569.59 (CauchyFilterCompletion root Cauchy-filter limit existence)**.** *Every completion-facing consumer of a root-unblock carrier that claims a Cauchy-filter limit must display the finite route*

$$C, W, T, R, L, H, K, P, N.$$

The limit obligation is therefore carried by the CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *source row C, the* StreamName$^{\uparrow}$ *windows W, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger T, the* RegSeqRat$^{\uparrow}$ *readback R, the terminal* Real$^{\uparrow}$ *seal L, and the structural* BHist/hsame, Cont, Pkg, *and* NameCert *rows. It is not a selected filter limit, quotient representative, host real equality proof, countable-choice selector, or ambient completeness theorem.*

Proof. Start from the root-unblock carrier. The displayed tuple contains only the rows $C, W, T, R, L, H, K, P, N$, so any asserted Cauchy-filter limit must be read through those coordinates.

Apply the root window exposure theorem to force the source and finite windows before tolerance and readback. Apply the root Real seal route to put the terminal seal downstream of that same source-window-readback path.

The NameCert surface then packages the route as a finite obligation. Since the packet has no coordinate for quotient representatives or selected limits, the existence readback is the displayed completion route itself, not an external completeness principle. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root cauchy filter limit existence`

Theorem 1569.60 (CauchyFilterCompletion uniform-completion universal property)**.** *Every* UniformCompletion$^{\uparrow}$ *consumer of a root-unblock carrier factors its universal-completion obligation through the same finite rows*

$$C, W, T, R, L, H, K, P, N.$$

The universal property can use the CauchyFilter$^{\uparrow}$ *source,* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal,* BHist/hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming, but it cannot use quotient filter representatives, selected limits, detached uniform-completion carriers, host equality, countable choice, or ambient completeness.*

Proof. Project the root-unblock carrier. The only uniform-facing coordinate beyond the source, windows, tolerance, readback, and Real seal is the provenance row P.

Apply the root uniform route. It identifies every UniformCompletion$^{\uparrow}$ or MetricCompletion$^{\uparrow}$ consumer with the displayed packet route and blocks detached completion data.

The universal property is therefore stated over the same finite route. Transport through H, replay through K, provenance through P, and local naming through N preserve the packet; none of those rows creates quotient representatives, selected limits, host equality, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionUniformCompletionUniversalProperty`

Theorem 1569.61 (CauchyFilterCompletion Real seal uniqueness interface)**.** *Any two root-unblock consumers that read the same displayed* CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *row C,* StreamName$^{\uparrow}$ *windows W,* DyadicRatCore$^{\uparrow}$ *tolerance ledger T, and* RegSeqRat$^{\uparrow}$ *readback R reach the same* Real$^{\uparrow}$ *seal interface L inside the accepted packet. The interface is transported only by H, replayed only by K, sourced only by P, and named only by N.*

Proof. Use the root window exposure theorem for both consumers. Once C, W, T, R are fixed, neither consumer has another source, window, tolerance, or readback coordinate available inside the carrier.

Apply the root Real seal route. The only terminal Real-facing row downstream of C, W, T, R is L.

Finally apply the root NameCert surface. The structural rows H, K, P, N preserve, replay, source, and name the same interface, so the comparison cannot escape to quotient filter equality, selected limits, host equality, countable choice, ambient completeness, or detached completion objects. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRealSealUniquenessInterface`

Theorem 1569.62 (CauchyFilterCompletion filterbase-window exhaustion)**.** *Every completion-facing read from a root-unblock carrier must first open the* $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ *source row* C *and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W *before tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, uniform or metric completion consumers, or local* NameCert *rows are available. No detached window, selected limit, quotient filter, host equality, choice route, or ambient completeness route exists inside the root carrier.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionFilterbaseWindowExhaustion`

Proof. Start with Definition 1569.55. It exposes the source row C and finite windows W before any tolerance or regular-rational readback coordinate can be consumed.

Next use Definition 1569.56 and Definition 1569.57. The Real seal, metric-completion reads, and uniform-completion reads are all downstream of the same C, W, T, R, L route.

Finally apply Definition 1569.58 and Definition 1569.61. The local NameCert surface and uniqueness interface preserve the displayed packet through H, K, P, N, so no consumer can replace the finite filterbase-window route by a detached window, selected limit, quotient filter, host equality, choice route, or ambient completeness route. □

Theorem 1569.63 (CauchyFilterCompletion public export package)**.** *The public* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *export is the package consisting of the root-unblock carrier, source-window obligations, uniform route, Real-seal uniqueness interface, filterbase-window exhaustion, and completion-functor factorization. Every public consumer receives only*

$$C, W, T, R, L, H, K, P, N.$$

It can read the $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ *source, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming rows, but it receives no quotient filter, selected limit, host real equality, countable-choice selector, ambient completeness theorem, or detached completion carrier.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPublicExportPackage`

Proof. The root-unblock carrier fixes the public tuple $C, W, T, R, L, H, K, P, N$. The source-window exposure theorem, Real seal route, uniform route, root NameCert surface, Cauchy-filter limit theorem, uniform-completion universal property, Real-seal uniqueness interface, and filterbase-window exhaustion theorem all read subroutes of that same tuple.

The completion-functor factorization is therefore public only through these displayed rows. Transport and replay preserve the tuple, provenance records the same source, and the local NameCert row names exactly this package.

Since the carrier and all root theorems refuse quotient filters, selected limits, host real equality, countable-choice selectors, ambient completeness, and detached completion carriers, no public consumer receives more than the listed rows. □

Theorem 1569.64 (CauchyFilterCompletion bridge-facing interface)**.** *Any future bridge consumer of the public* CauchyFilterCompletion$^{\uparrow}$ *package must factor through the displayed rows*

$$C, W, T, R, L, H, K, P, N.$$

The bridge-facing read preserves the CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *source row* C*, finite* StreamName$^{\uparrow}$ *windows* W*,* DyadicRatCore$^{\uparrow}$ *tolerance ledger* T*,* RegSeqRat$^{\uparrow}$ *readback* R*, terminal* Real$^{\uparrow}$ *seal* L*, componentwise* hsame *transport* H*, displayed* Cont *replay* K*,* Pkg *provenance* P*, and local* NameCert$_{\text{CauchyFilterComplet}}$ *row* N*. It has no interface coordinate for quotient filters, selected limits, host equality, countable choice, ambient* Real$^{\uparrow}$ *completeness, or detached completion carriers.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionBridgeFacingInterface`

Proof. Begin with Definition 1569.63. It identifies the public export as exactly the rows $C, W, T, R, L, H, K, P, N$, so a bridge consumer can only receive that package.

Use Definition 1569.58 to keep carrier admission, source-window obligations, tolerance readback, transport, replay, provenance, and local naming on the displayed root route. The NameCert surface does not expose a quotient filter or selected limit.

Finally apply Definition 1569.61. The Real-facing row is reached through the same finite windows, dyadic tolerance ledger, regular readback, and terminal seal, so host equality, countable choice, ambient completeness, and detached completion carriers have no bridge-facing export row. □

Closure status for NameCert$_{\text{CauchyFilterCompletion}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchyFilterCompletion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1569.54, Definition 1569.55, Definition 1569.56, Definition 1569.57, Definition 1569.58, Definition 1569.59, Definition 1569.60, Definition 1569.61, Definition 1569.62, Definition 1569.63, and Definition 1569.89 close the bridged root obligation surface for the displayed Cauchy-filter source, finite windows, tolerance ledger, regular readback, terminal Real seal, structural transport, continuation replay, provenance, local NameCert rows, public export package, and completion-facing bridge route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyFilterCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, host real equality, countable-choice selectors, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: No further paper-side closure remains; verification and bridge checking are Lean-side obligations for this root completion surface.

Constructive story: A CauchyFilterCompletion$^{\uparrow}$ packet is generated from a CauchyFilter row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal handoff, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theorem 1569.65 (CauchyFilterCompletion root carrier admission obligation)**.** *Let* $F = (C, W, T, R, L, H, K, P, N$ *be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier as in Definition 1569.1. The root carrier-admission obligation is the* BHist*-anchored demand that the Cauchy-filter source* C*, finite* StreamName$^{\uparrow}$ *windows* W*, tolerance ledger* T*,* RegSeqRat$^{\uparrow}$ *readback* R*, terminal* Real$^{\uparrow}$ *seal* L*, transport row* H*, replay row* K*, provenance row* P*, and local NameCert row* N *are all admitted as rows of the same finite packet before any completion-facing consumer reads them.*

Proof. Project Definition 1569.1. Its displayed carrier rows are exactly $C, W, T, R, L, H, K, P, N$.

The obligation is rooted in the same BHist packet. Carrier admission therefore does not create a detached completion object; it only exposes the already displayed CauchyFilterUp, StreamNameUp, RegSeqRatUp, RealUp, UniformCompletionUp, transport, replay, provenance, and naming rows.

The refusal side follows from the absence of any quotient-filter, selected-limit, host-equality, choice, or ambient-completeness coordinate in the carrier. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootCarrierAdmissionObligation`

Theorem 1569.66 (CauchyFilterCompletion root filterbase source coverage obligation)**.** *For an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, the filterbase-directed source coverage obligation requires every completion-facing read of* W, T, R, L *to pass through the same* FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *source row behind* C*. The finite windows, regular readback, Real seal, and* UniformCompletion$^{\uparrow}$ *provenance row cannot be read from a second source packet.*

Proof. Use the carrier admission obligation of Definition 1569.65. It keeps $C, W, T, R, L, H, K, P, N$ inside one BHist packet.

Read the source row first. The CauchyFilterUp carrier behind C supplies the filterbase-facing data, and the finite StreamNameUp windows W are downstream from that source.

The readback and seal rows remain attached to the same route. Since R is the RegSeqRatUp readback extracted from W and T, and L is the RealUp seal reached after that extraction, the UniformCompletionUp provenance in P has no second filterbase source to expose. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootFilterbaseSourceCoverageObligat`

Theorem 1569.67 (CauchyFilterCompletion root Real seal handoff obligation)**.** *For an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, the Real-seal completion handoff obligation requires every* Real$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer to reach the terminal seal* L *only after the* FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *source* C*, finite* StreamName$^{\uparrow}$ *windows* W*, tolerance ledger* T*, and* RegSeqRat$^{\uparrow}$ *readback* R *have been replayed through* K *and preserved by* H, P, N*.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket root real seal handoff`

Proof. Start from Definition 1569.66. It fixes the source and window rows for every completion-facing read.

The Real seal is downstream from the readback row. A consumer of L therefore must first traverse C, W, T, R, and the displayed replay row K records that route inside the same BHist packet.

The structural rows preserve the handoff. Componentwise transport H, UniformCompletionUp provenance P, and local naming N carry the same route forward, so the seal handoff does not introduce selected limits, host equality of completion points, quotient filters, or ambient completeness. □

Theorem 1569.68 (CauchyFilterCompletion Cauchy-equivalence classifier route)**.** *Every* CauchyFilterCompletion$^{\uparrow}$ *read that compares Cauchy-filter presentations by an equivalence classifier must first consume chapter 1820 through the displayed* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback rows,* DyadicRatCore$^{\uparrow}$ *tolerance ledger, terminal* Real$^{\uparrow}$ *seal, and the separated-completion rows of chapter 1612. The comparison is classifier evidence for the completion-facing read of* $C, W, T, R, L, H, K, P, N$*; it is not quotient equality of filters, a selected representative, host equality of completed points, or an ambient completion principle.*

Proof. Project the root filter route of Definition 1569.66. The source row C and finite window rows W, T, R, L are already fixed before any completion-facing consumer can inspect a completed point.

When the consumer also asks whether two Cauchy-filter presentations determine the same completion read, route that comparison through chapter 1820. That packet exposes only StreamName windows, RegSeqRat readbacks, dyadic tolerance rows, the Real seal, transport, replay, provenance, and local naming as classifier data.

The separated-completion handoff is then read as a consumer of the same classifier evidence. It may preserve and replay the displayed comparison, but it supplies no quotient class, no chosen representative, and no host equality coordinate.

Finally combine the classifier route with the Real-seal handoff above. The accepted CauchyFilterCompletion packet keeps the comparison inside $C, W, T, R, L, H, K, P, N$, so the completion read remains a finite classifier-mediated route rather than a quotient or selection principle. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionCauchyEquivalenceClassifierRoute`

Theorem 1569.69 (CauchyFilterCompletion root filter scope closure)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Before any completion-facing consumer can read a completed point, the root-filter completion read must expose the* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CauchyFilter}^{\uparrow}$ *rows behind C, the* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{SeparatedCompletion}^{\uparrow}$ *handoff surface, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{Real}^{\uparrow}$ *seal L, componentwise* hsame *transport H, displayed* Cont *replay K,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row N.*

Consequently the root-filter completion scope exports only this displayed finite route. It does not export quotient completions, selected limits, countable-choice schedules, host equality of completed points, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootFilterScopeClosure`

Proof. Project the carrier of Definition 1569.1. The source coordinate C is the only place where a root filter can enter, and the root carrier admission obligation keeps $C, W, T, R, L, H, K, P, N$ inside the same finite BHist packet.

Route filter-base requests through the existing source coverage obligation. The $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ rows behind C must be read before the $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger T, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback R can be inspected.

Now route the completion handoff. The $\mathsf{Real}^{\uparrow}$ seal L and the $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{SeparatedCompletion}^{\uparrow}$ consumer surface are reached only after the displayed source, window, tolerance, and readback rows have been replayed through K and transported by H.

Finally P and N source and name the same route. Since the packet has no quotient-completion, selected-limit, countable-choice, host-equality, or ambient-completeness coordinate, the root-filter completion scope is exactly the finite route stated above. □

Theorem 1569.70 (CauchyFilterCompletion root filter route)**.** *Every accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier read by a completion-facing consumer factors through the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row before the completion data are consumed. The route cannot use quotient filters, selected limits, countable choice, host equality of completed points, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootFilterRoute`

Proof. Project the carrier of Definition 1569.1. Its displayed rows are exactly $C, W, T, R, L, H, K, P, N$, with the root filter source entering through C.

Apply Definition 1569.66. It forces every completion-facing read of the finite windows, tolerance ledger, regular readback, and Real seal to pass through the same $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source row behind C.

Next apply Definition 1569.67. The terminal seal L is available only after the source row, windows, tolerance ledger, and readback have been replayed through K and preserved by H, P, N.

Finally apply Definition 1569.69. The scope-closure theorem exhausts the displayed finite route and excludes quotient filters, selected limits, countable-choice schedules, host equality, and ambient completeness coordinates. □

Theorem 1569.71 (CauchyFilterCompletion public export)**.** *An accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier exports a public completion-facing route only through the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row. The exported route exposes no quotient filters, selected limits, countable-choice schedule, host equality of completed points, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPublicExport`

Proof. First compose carrier admission with source coverage. Apply Definition 1569.65 to keep $C, W, T, R, L, H, K, P, N$ inside one finite BHist packet, then apply Definition 1569.66 to force every read of W, T, R, L through the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source behind C.

Next compose the Real-seal handoff. Apply Definition 1569.67; the terminal seal L is reached only after the source, finite windows, tolerance ledger, and regular readback have been replayed through K and preserved by H, P, N.

Finally apply Definition 1569.70. That theorem packages the same source row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame, displayed Cont, Pkg, and local naming data as the only completion-facing route.

The refusal clause follows because none of the composed obligations introduces a quotient-filter coordinate, selected limit, countable-choice schedule, host equality of completed points, or ambient-completeness witness. □

Theorem 1569.72 (CauchyFilterCompletion root sibling dependency route)**.** *Every accepted root completion read for* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *first consumes the sibling surfaces chapter 1601, chapter 333, chapter 1473, chapter 1612, chapter 126, chapter 301, chapter 291, and chapter 38 before it exposes the public completion route. The route therefore records the actual L10 sibling lattice rather than a kernel-only completion island.*

Proof. Start from carrier admission in Definition 1569.65. The finite packet already binds the completion carrier, source windows, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1569.66. It forces the root route to read the $\mathsf{FilterBase}^{\uparrow}$ and $\mathsf{CauchyFilter}^{\uparrow}$ source surfaces before the completion-facing rows may be inspected.

Next use Definition 1569.67. The readback passes through finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally apply Definition 1569.70 and Definition 1569.71. These package the same rows as the public completion route, with the uniform and separated completion siblings supplying the completion-facing boundary and with no quotient filters, selected limits, countable choice, host equality, or ambient completeness. □

Lean4 ✓ BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionRootSiblingDependencyRoute

Definition 1569.73 (CauchyFilterCompletion basis route)**.** *For an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, the* basis-completion route *is the ordered completion-facing read that opens the displayed* FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *basis behind* C*, then the finite* StreamName$^{\uparrow}$ *windows* W*, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger* T*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the terminal* Real$^{\uparrow}$ *seal* L*, and finally the structural rows* H, K, P, N*. The route exports no quotient filter, selected limit, host equality, countable-choice selector, detached completion object, or ambient completeness witness.*

Lean4 (definition) BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionBasisRoute

Theorem 1569.74 (CauchyFilterCompletion basis totality)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Every completion-facing consumer first reads the basis-completion route of Definition 1569.73; in particular, the displayed* FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *source behind* C *is admitted before any window, tolerance, readback, seal, transport, replay, provenance, or local naming row can be inspected.*

Lean4 ✓ BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket basis totality

Proof. Apply Definition 1569.46. It places the FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ source behind C before every downstream completion-facing read.

Then read the carrier rows in the order displayed by Definition 1569.73. The windows W, tolerance ledger T, readback R, and seal L are downstream from the admitted source, and H, K, P, N only transport, replay, source, and name that same route.

Finally use Definition 1569.82. The refused quotient, selected-limit, host-equality, choice, detached-completion, and ambient-completeness objects have no coordinate in F, so every completion-facing consumer is total only through the displayed basis route. □

Theorem 1569.75 (CauchyFilterCompletion basis Real seal)**.** *For an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, any consumer that reaches the terminal* Real$^{\uparrow}$ *seal* L *has already traversed the displayed* FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *basis behind* C*, the* StreamName$^{\uparrow}$ *windows* W*, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger* T*, and the* RegSeqRat$^{\uparrow}$ *readback* R*.*

Proof. Start with Definition 1569.74. It fixes the source and window side of every completion-facing read at C, W, T, R before the seal can be inspected.

Apply Definition 1569.47. Metric-facing and uniform-facing readers share the same finite carrier route, so neither can reach a different seal source downstream.

The terminal row L is therefore a seal for the displayed basis-completion route, not a selected limit or host equality proof. The structural rows H, K, P, N preserve and name that same route after the seal boundary has been reached. □

Lean4 ✓ BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket basis real seal

Theorem 1569.76 (CauchyFilterCompletion basis uniform handoff)**.** *Every* UniformCompletion$^{\uparrow}$ *consumer of an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier receives only the basis-completion route*

$$C, W, T, R, L, H, K, P, N.$$

The uniform handoff reads the FilterBase$^{\uparrow}$/CauchyFilter$^{\uparrow}$ *source behind* C*, finite windows, dyadic tolerances, regular readback, terminal Real seal, transport, replay, provenance, and local naming rows; it does not import quotient filters, selected limits, countable choice, host equality, or ambient completeness.*

Proof. Use Definition 1569.47. It identifies every uniform-facing read with the same carrier route used by the metric-facing completion consumer.

Apply Definition 1569.75. The terminal Real seal exposed to the uniform handoff is downstream from the displayed source, windows, tolerance ledger, and readback row.

Close with Definition 1569.82. Since the refused objects have no carrier coordinate, the uniform handoff cannot add a quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness witness beyond the basis-completion route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket basis uniform handoff`

Definition 1569.77 (CauchyFilterCompletion basis ledger route)**.** *For an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, the* basis-ledger route *is the source-window-tolerance-readback-seal ledger*

$$C \longmapsto W \longmapsto T \longmapsto R \longmapsto L$$

together with the structural transport, replay, provenance, and local naming rows H, K, P, N*. It is the visible ledger read that begins at the* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source behind* C*, opens the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*, extracts the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L *without adding quotient filters, selected limits, host equality, or countable-choice selectors.*

Lean4 (definition) `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionBasisLedgerRoute`

Theorem 1569.78 (CauchyFilterCompletion basis ledger exhaustion)**.** *Every basis-facing completion read of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier is exhausted by the basis-ledger route of Definition 1569.77. In particular, once the* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source behind* C *has been admitted, all visible completion data pass through* W, T, R, L, H, K, P, N *and no additional source, tolerance, readback, seal, or completion coordinate remains available.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket basis readback route`

Proof. Start with Definition 1569.74. It places the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source behind C before any basis-facing completion read can inspect downstream rows.

Apply Definition 1569.75. The terminal $\mathsf{Real}^{\uparrow}$ seal is reachable only after the finite windows W, tolerance ledger T, and regular readback row R have been traversed.

Finally use Definition 1569.76. Uniform-facing reads share the same displayed carrier route, so the structural rows H, K, P, N only transport, replay, package, and name the already visible ledger. The sibling FilterBaseUp, RegSeqRatUp, RealUp, and UniformCompletionUp chapters are therefore consumed through this finite route rather than through detached completion data. □

Theorem 1569.79 (CauchyFilterCompletion basis universal consumer route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier factors through the same basis-ledger route of Definition 1569.77. The consumer may repackage the route for metric, uniform, functorial, or Real-facing use, but it receives only the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source, windows, dyadic tolerances, regular readback, terminal seal, transport, replay, provenance, and local NameCert rows.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionBasisUniversalConsumerRoute`

Proof. Use Definition 1569.78 to identify the only available basis-facing completion data with $C, W, T, R, L, H, K, P, N$.

For the Real-facing branch, apply Definition 1569.75. The $\mathsf{Real}^{\uparrow}$ consumer reaches L only through the same source-window-tolerance-readback route.

For the uniform and functorial branches, apply Definition 1569.76. The $\mathsf{UniformCompletion}^{\uparrow}$ and $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ consumers can transport or repackage the finite ledger, but they cannot add quotient filters, selected limits, host equality, countable choice, or an ambient completeness witness. The $\mathsf{MetricCompletion}^{\uparrow}$ branch is the same route read through the metric-completion vocabulary. □

Theorem 1569.80 (CauchyFilterCompletion public basis-completion route)**.** *Every public* CauchyFilterCompletion *consumer factors through the displayed* $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source behind C, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal L, and the structural rows H, K, P, N of the accepted carrier $F = (C, W, T, R, L, H, K, P, N)$. The route exports no quotient filter, selected limit, host equality, countable choice, detached completion object, or ambient completeness witness.*

Proof. Start with basis totality, Definition 1569.74. It places the $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source behind C before any public completion-facing read can inspect downstream rows.

Use the Real seal and uniform handoff next. By Definition 1569.75, the terminal $\mathsf{Real}^{\uparrow}$ seal L is downstream of W, T, R; by Definition 1569.76, uniform-facing consumers receive the same finite route rather than a detached completion object.

Now apply the universal consumer route, Definition 1569.79. Metric, uniform, functorial, and Real-facing consumers all repackage the same basis-ledger route.

Finally attach the separated reflector of Definition 1569.81. The separated consumer may read its classifier only after the same source, window, tolerance, readback, seal, transport, replay, provenance, and local NameCert rows have been displayed, so the public export is exactly the basis-completion route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPublicBasisCompletionRoute`

Theorem 1569.81 (CauchyFilterCompletion separated reflector basis)**.** *Every* $\mathsf{SeparatedCompletion}^{\uparrow}$ *or separated* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier factors through the same basis-ledger route*

$$C, W, T, R, L, H, K, P, N.$$

The separated classifier is read only after the displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *source behind C, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal L. The reflector route imports no quotient filter, selected limit, host equality, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket basis separated reflector`

Proof. Start with basis-ledger exhaustion, Definition 1569.78. It leaves $C, W, T, R, L, H, K, P, N$ as the only available completion-facing route after the displayed filter basis has been admitted.

Read the Real and uniform sides next. The basis Real seal of Definition 1569.75 places L after the source, window, tolerance, and readback rows, while Definition 1569.76 prevents a separated metric consumer from adding another completion surface.

Now attach the separated-completion packet route of chapter 1612. A SeparatedCompletion$^{\uparrow}$ consumer may read its separated classifier only after the same finite source, dense or metric handoff, tolerance, readback, and Real-seal rows are displayed.

The structural rows H, K, P, N transport, replay, source, and name that route. Since quotient filters, selected limits, host equality, countable choice, and ambient completeness have no coordinate in the accepted carrier, the separated reflector factors through the displayed basis-ledger route. □

Theorem 1569.82 (CauchyFilterCompletion no-choice boundary)**.** *For every accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, quotient filters, selected limits, countable-choice selectors, host equality, and ambient* Real$^{\uparrow}$ *completeness have no carrier coordinate in any completion-facing read. Such a read is confined to the source, window, tolerance, readback, seal, transport, replay, provenance, and local naming rows displayed by* F*.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket non choice boundary`

Proof. Inspect Definition 1569.1. The coordinates of F are exactly $C, W, T, R, L, H, K, P, N$.

Apply Definition 1569.2. Its ledger-refusal row excludes quotient filters, selected limits, host equality, countable-choice selectors, ambient completeness, and detached completion coordinates from the local certificate surface.

Close with Definition 1569.47. Since every metric-facing or uniform-facing consumer shares the same displayed route, none of the refused objects can be recovered by changing the completion vocabulary downstream. □

Theorem 1569.83 (CauchyFilterCompletion source-window totality)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier. Before any* MetricCompletion$^{\uparrow}$ *or* UniformCompletion$^{\uparrow}$ *consumer may read a completion-facing row, the packet exposes the* CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ *source* C*, the finite* StreamName$^{\uparrow}$ *window family* W*, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger* T*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the terminal* Real$^{\uparrow}$ *seal* L*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket source window totality`

Proof. Begin with Definition 1569.46. It places every completion-facing read behind the displayed CauchyFilter$^{\uparrow}$/FilterBase$^{\uparrow}$ source row C.

Apply Definition 1569.47. The metric and uniform completion consumers share the same finite route $C, W, T, R, L, H, K, P, N$, so the source, window, tolerance, readback, seal, transport, replay, provenance, and local naming rows are all exposed before the consumer reads completion vocabulary.

Use Definition 1569.39. The terminal Real seal is downstream of the same displayed source-window-tolerance-readback route, and no detached completion object remains outside that route. □

Theorem 1569.84 (CauchyFilterCompletion seal factorization obligation)**.** *Every* MetricCompletion$^{\uparrow}$*,* UniformCompletion$^{\uparrow}$*,* MetricCompletionFunctor$^{\uparrow}$*, or* CauchyCompletionFunctoriality$^{\uparrow}$ *consumer of an accepted* CauchyFilterCompletion$^{\uparrow}$ *carrier factors through the displayed rows*

$$C, W, T, R, L, H, K, P, N.$$

The factorization may repackage the Cauchy-filter source, StreamName windows, dyadic tolerance, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows, but it cannot add quotient filters, selected limits, host equality, choice, detached completion carriers, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket seal factorization obligation`

Proof. Start from Definition 1569.83. It supplies the complete source-window-tolerance-readback-seal route that every completion-facing consumer must display.

Apply Definition 1569.47. The metric and uniform consumers differ only in downstream vocabulary; both receive the same finite carrier rows.

Finally use Definition 1569.82. Quotient filters, selected limits, host equality, choice, detached completion carriers, and ambient completeness have no coordinate in the accepted packet, so no completion-functor consumer can add them while preserving the displayed factorization. □

Theorem 1569.85 (CauchyFilterCompletion window cofinality)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. Every completion-facing tolerance request that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal has a displayed cofinal window route through the same finite rows $C, W, T, R, L, H, K, P, N$: the request first reads the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row C, then a* $\mathsf{StreamName}^{\uparrow}$ *window in W, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and only then the seal row L with the structural rows H, K, P, N.*

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket window cofinality`

Proof. Start with the carrier of Definition 1569.1. It displays C as the only Cauchy-filter source and W as the only finite observation-window family.

Apply Definition 1569.4. This forces every accepted readback to pass through W and T before R is available.

Finally use the Real seal handoff of Definition 1569.3. The terminal seal remains downstream of C, W, T, R and upstream of H, K, P, N, so every completion-facing tolerance request has the displayed cofinal route. □

Theorem 1569.86 (CauchyFilterCompletion source exactness)**.** *Let $F = (C, W, T, R, L, H, K, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The source of any accepted completion read is exactly the displayed L10 route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

carried by C, W, T, R, L and preserved by the BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows H, K, P, N. No read can replace this source by a quotient filter, selected limit, detached stream, free tolerance, host real equality, countable-choice selector, or ambient completeness witness.*

Proof. Project F and apply Definition 1569.85. The cofinal window route already identifies the source side as C, W, T, R before the terminal seal L is read.

Use Definition 1569.46 to pin C to the displayed $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$ source and Definition 1569.6 to pin every terminal read to L.

The structural rows then preserve the same route. Componentwise hsame transport is stored in H, displayed Cont replay is stored in K, and P, N source and name only this packet. Since the carrier has no row for the excluded objects, the accepted source is exact. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket source exactness`

Theorem 1569.87 (CauchyFilterCompletion ledger exhaustion)**.** *For an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier* $F = (C, W, T, R, L, H, K, P, N)$*, every completion, filter-limit, metric-completion, or uniform-completion consumer read is exhausted by the displayed ledger rows* $C, W, T, R, L, H, K, P, N$*. In particular, the L10 source route through* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *is the whole public source ledger; there is no additional quotient-filter row, selected-limit row, detached completion object, host equality row, countable-choice row, or ambient-completeness row available to any consumer.*

Proof. Begin with source exactness from Definition 1569.86. It confines every accepted source read to $C, W, T, R, L, H, K, P, N$.

For filter-limit consumers, use Definition 1569.11. For metric-facing and uniform-facing consumers, use Definition 1569.45 and Definition 1569.47. These theorems all reuse the same displayed route rather than adding a second consumer-specific source.

Finally apply Definition 1569.82. The refused quotient, selector, choice, host-equality, and completeness objects have no carrier coordinate. Thus the ledger is exhausted by the displayed L10 source route and the structural rows of F. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket ledger exhaustion`

Theorem 1569.88 (CauchyFilterCompletion public NameCert export)**.** *Let* $F = (C, W, T, R, L, H, K, P, N)$ *be an accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *carrier. The public* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *export is exactly the route* $C, W, T, R, L, H, K, P, N$ *isolated by the carrier, the completion handoff, the completion-functor factorization, the cofinal regular readback, and source/ledger exhaustion. A public consumer receives the displayed Cauchy-filter source, finite windows, dyadic tolerance ledger, regular readback, terminal Real seal, transport, replay, provenance, and local naming rows, and receives no quotient-filter, selected-limit, host-equality, choice, or ambient-completeness object.*

Proof. Project the carrier of Definition 1569.1. The visible packet is $C, W, T, R, L, H, K, P, N$, with C as source, W, T, R as finite readback rows, L as terminal seal, and H, K, P, N as transport, replay, provenance, and local naming rows.

Apply completion handoff and completion-functor factorization, Definition 1569.47 and Definition 1569.52. They place every completion-facing, metric-facing, uniform-facing, and functor-facing read on the same displayed route.

Use cofinal regular readback together with source exactness, Definition 1569.53 and Definition 1569.86. These theorems identify the cofinal public readback through the $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows already carried by F.

Finally apply ledger exhaustion, Definition 1569.87. The quotient-filter, selected-limit, host-equality, choice, and ambient-completeness alternatives have no carrier coordinate, so the public NameCert export is exactly the displayed route. □

Lean4 ✓ `BEDC.Derived.CauchyFilterCompletionUp.CauchyFilterCompletionPublicNameCert export`

Theorem 1569.89 (CauchyFilterCompletion bridged route)**.** *The accepted* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *route exports its completion-facing bridge only through the existing semantic* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *row, uniform filter readback, completion handoff, and completion-functor factorization rows. Thus any bridge-facing consumer receives exactly the displayed route*

$$C, W, T, R, L, H, K, P, N$$

from the accepted carrier and receives no quotient filter, selected limit, host equality, countable-choice selector, detached completion object, or ambient completeness coordinate.

Proof. Project the carrier and semantic NameCert rows of Definition 1569.1 and Definition 1569.2. They fix the only exported coordinates as the Cauchy-filter source, finite windows, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Use uniform readback and completion handoff, Definition 1569.5 and Definition 1569.47. They keep uniform-facing and completion-facing consumers on that same displayed route.

Finally apply Definition 1569.52. The functorial vocabulary can repackage the route for completion consumers, but it adds no coordinate outside $C, W, T, R, L, H, K, P, N$, so the bridge-facing export is exactly the finite NameCert route. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket bridged route`

Theorem 1569.90 (CauchyFilterCompletion bridged-route maturity)**.** *The* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *bridged route is mature exactly when the semantic* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}^{\uparrow}}$ *obligations, uniform-filter readback, completion handoff, completion-functor factorization, and displayed rows*

$$C, W, T, R, L, H, K, P, N$$

are read as one public export. In that case every bridge-facing consumer receives the Cauchy-filter source, finite windows, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows together, and receives no quotient filter, selected limit, countable-choice selector, detached completion object, host equality, or ambient completeness coordinate.

Proof. Use the bridged route of Definition 1569.89. It already identifies the exported bridge as the semantic NameCert row, uniform readback, completion handoff, and completion-functor factorization over $C, W, T, R, L, H, K, P, N$.

The forward direction reads maturity as public export. Apply Definition 1569.2, Definition 1569.5, Definition 1569.47, and Definition 1569.52; their rows are the same carrier rows displayed by the bridged route.

For the reverse direction, assume those rows are read as one public export. The semantic obligations name the carrier surface, uniform readback and completion handoff keep the consumer on the displayed route, and completion-functor factorization repackages no additional coordinate. Thus the bridged route has exactly the mature public surface described in the statement. □

Lean4 ✓ `BEDC.Derived.CauchyfiltercompletionUp.CauchyFilterCompletionPacket bridged route maturity`

Chapter 1570

A Concrete Naming Certificate for $\mathsf{IntervalNewton}^{\uparrow}$

Following Moore–Kearfott–Cloud interval analysis, the $\mathsf{IntervalNewton}^{\uparrow}$ packet records interval Newton and Krawczyk enclosure certificates as finite BEDC rows. It names a displayed box, function enclosure, slope or derivative enclosure, correction row, narrowing ledger, validated readback route, real-name readback, transport witnesses, replay data, provenance, and local naming row. It is not a solver oracle, a host zero-existence theorem, a global root-isolation method, a completeness assertion, or a floating-point semantics package.

The carrier reads interval operations through chapter 302, finite validated enclosures through chapter 357, displayed correction provenance through chapter 223, and finite Taylor or slope remainders through chapter 442. These sibling rows are the entire dependency surface for the enclosure certificates below.

Definition 1570.1 (Interval Newton carrier)**.** *An* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, F, D, N, K, V, R, H, C, P, L)$$

with the following displayed coordinates:

1. *B is the interval box row, read through* $\mathsf{IntervalArithmetic}^{\uparrow}$ *endpoint and enclosure ledgers;*
2. *F is the function-enclosure row over B, with every enclosure read routed through finite interval operations;*
3. *D is the derivative or slope enclosure row, supplied either directly as an interval row or through a finite* $\mathsf{TaylorModel}^{\uparrow}$ *remainder packet;*
4. *N is the finite Newton or Krawczyk correction row, including the displayed center, inverse or preconditioner row, and correction enclosure;*
5. *K is the containment and narrowing ledger recording that the correction row stays inside, or narrows, the displayed box B;*
6. *V is the* $\mathsf{ValidatedNumerics}^{\uparrow}$ *enclosure row read by downstream consumers;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route for the center, endpoint, and correction observations;*
8. *H records componentwise* hsame *transports for the box, function, derivative, correction, containment, readback, and validated rows;*

9. *C records the* Cont *routes by which the displayed rows are replayed inside their source certificates;*
10. *P is the* Pkg *provenance over* IntervalArithmetic$^{\uparrow}$, ValidatedNumerics$^{\uparrow}$, NewtonIteration$^{\uparrow}$, TaylorModel$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and the displayed kernel rows;*
11. *L is the local* NameCert$_{\text{IntervalNewton}^{\uparrow}}$ *row.*

Two accepted carriers are classified together only by transporting these displayed coordinates through the recorded hsame *and* Cont *rows. The classifier has no coordinate for a hidden solver state, a selected zero, host floating-point behavior, quotient real equality, or completeness of the ambient real line.*

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonTasteGate single carrier alignment`

Theorem 1570.2 (Interval Newton NameCert obligations)**.** *The local* NameCert$_{\text{IntervalNewton}^{\uparrow}}$ *surface for the carrier of Definition 1570.1 consists of six rows:*

1. *carrier admission for the finite packet $I = (B, F, D, N, K, V, R, H, C, P, L)$;*
2. *correction containment saying that the displayed Newton or Krawczyk row N is admitted only with its containment and narrowing ledger K;*
3. *interval-arithmetic soundness for the box, function, derivative or slope, and correction enclosures;*
4. *validated-consumer handoff through the displayed* ValidatedNumerics$^{\uparrow}$ *row V and the readback row R;*
5. *transport under the componentwise* hsame *rows of H and replay under the* Cont *routes of C;*
6. *ledger non-escape, meaning every consumer-visible claim is projected from $B, F, D, N, K, V, R, H, C, P, L$ and from no other numerical object.*

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonNameCertObligations`

Proof. Carrier admission is projection from Definition 1570.1. The box, function enclosure, derivative or slope enclosure, correction, containment ledger, validated readback, real-name route, transport, replay, provenance, and local name are visible fields of one finite packet.

Correction containment is read from N together with K. The packet may expose a Krawczyk or interval Newton row only when the same displayed ledger records how that row is contained in, or narrows, the box B.

Interval-arithmetic soundness is inherited by routing all endpoint and enclosure operations through the IntervalArithmetic$^{\uparrow}$ rows named in P. When a derivative or slope enclosure is supplied by a Taylor model, the packet reads only the finite TaylorModel$^{\uparrow}$ remainder and interval-operation rows.

The consumer handoff is then V together with R. Transport and replay use only the componentwise rows H and C, so every exported obligation is exhausted by the carrier coordinates and no solver oracle or external real-semantics datum remains. □

Theorem 1570.3 (Interval Newton Krawczyk enclosure)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted* IntervalNewton$^{\uparrow}$ *carrier. Every Krawczyk or interval Newton enclosure exported by I narrows the displayed box B only through the* IntervalArithmetic$^{\uparrow}$ *operation rows named by P and through the displayed* NewtonIteration$^{\uparrow}$ *or* TaylorModel$^{\uparrow}$ *rows used to form N and D. The exported enclosure is exactly the row recorded by K and validated by V.*

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonKrawczykEnclosure`

Proof. Start with a consumer-visible narrowing claim. By the carrier definition, the only box available to the packet is B, and the only correction row available is N.

Read the arithmetic used by the correction through the $\mathsf{IntervalArithmetic}^{\uparrow}$ dependency rows named in P. The center, inverse or preconditioner, function enclosure, derivative or slope enclosure, and final interval operation are all displayed rows of the same finite ledger.

If the correction row is presented as a Newton step, its provenance is the finite $\mathsf{NewtonIteration}^{\uparrow}$ row named in P. If the slope or derivative enclosure is presented by finite Taylor data, it is read through the $\mathsf{TaylorModel}^{\uparrow}$ row named in P. In either case, the packet keeps the operation inside visible BEDC rows.

Finally project K and V. The containment ledger K records the narrowed box, and the validated row V is the only downstream enclosure exported by the packet. No separate analytic root theorem, host solver state, or floating-point rounding semantics is consulted. □

Theorem 1570.4 (Interval Newton Krawczyk radius lock)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted $\mathsf{IntervalNewton}^{\uparrow}$ carrier whose interval-arithmetic row supplies a Krawczyk enclosure. Then the correction radius, the Taylor or slope remainder row, the $\mathsf{Real}^{\uparrow}$ seal, and the $\mathsf{ValidatedNumerics}^{\uparrow}$ consumer boundary remain in the same finite packet I before any zero-enclosure read is exported.*

In particular, the exported zero-enclosure read factors through the visible rows $B, F, D, N, K, V, R, H, C, P, L$: N supplies the correction radius, D supplies the slope or $\mathsf{TaylorModel}^{\uparrow}$ remainder row, R supplies the real-name seal route, and V supplies the validated-consumer boundary.

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonKrawczykRadiusLock`

Proof. Project the accepted carrier of Definition 1570.1. The correction radius is not a separate analytic datum; it is part of the displayed correction row N, and its containment is read with the ledger K.

Apply Definition 1570.3. A Krawczyk enclosure can narrow the displayed box only through the interval-arithmetic operation rows named in P and through the displayed $\mathsf{NewtonIteration}^{\uparrow}$ or $\mathsf{TaylorModel}^{\uparrow}$ rows used to form N and D.

Use the interval-arithmetic soundness obligation of Definition 1570.2. It keeps the box, function, slope or Taylor remainder, and correction enclosures inside the same finite interval-arithmetic replay before K and V are visible.

Finally apply the validated-consumer handoff obligation of Definition 1570.2 together with Definition 1570.7. The validated row V and readback row R are downstream of B, F, D, N, K, so no zero-enclosure read can leave the packet before the correction radius, remainder row, real-name route, and validated boundary have all been bound. □

Theorem 1570.5 (Interval Newton correction transport scope)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted $\mathsf{IntervalNewton}^{\uparrow}$ carrier. Every transported correction row exported by I factors through the visible interval box B, the $\mathsf{IntervalArithmetic}^{\uparrow}$ operation rows named in P, the finite $\mathsf{TaylorModel}^{\uparrow}$ row or derivative and slope row D, the $\mathsf{NewtonIteration}^{\uparrow}$ correction provenance for N, and the $\mathsf{ValidatedNumerics}^{\uparrow}$ row V before the validated enclosure is exported.*

Consequently the transported correction cannot read a solver oracle, a host zero, floating-point semantics, quotient real equality, or ambient completeness outside the displayed carrier rows.

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonCorrectionTransportScope`

Proof. Project the carrier of Definition 1570.1. The correction surface is B, F, D, N, K, V, while R, H, C, P, L supply readback, transport, replay, provenance, and local naming.

Invoke Definition 1570.3. It forces every Krawczyk or interval Newton enclosure to narrow the displayed box B only through $\mathsf{IntervalArithmetic}^{\uparrow}$ operations and through the displayed $\mathsf{NewtonIteration}^{\uparrow}$ or $\mathsf{TaylorModel}^{\uparrow}$ rows used to form N and D.

The transported row then passes through H and C without changing its dependency route. The validated export is V, so a downstream validated-numerics consumer reads the correction only after the interval, derivative or Taylor-model, Newton-iteration, containment, and validation rows have appeared.

No excluded datum is a carrier coordinate or a provenance row in P. Thus the correction transport remains inside the visible interval, Taylor-model or derivative, Newton-iteration, validated-numerics, transport, replay, and local naming rows. □

Theorem 1570.6 (Interval Newton Krawczyk scope)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier. Every Krawczyk enclosure read exported by I factors through the displayed* $\mathsf{IntervalArithmetic}^{\uparrow}$ *rows for B, F, D, N, through either the finite* $\mathsf{TaylorModel}^{\uparrow}$ *remainder row or the derivative and slope row D, through the* $\mathsf{NewtonIteration}^{\uparrow}$ *correction provenance for N, through the validated enclosure row V, and through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route R before any zero-enclosure consumer reads it.*

Consequently a zero-enclosure consumer cannot inspect a Krawczyk row without first exposing the containment ledger K, the correction-transport rows H, C, the provenance row P, and the local $\mathsf{NameCert}_{\mathsf{IntervalNewton}^{\uparrow}}$ *row L for the same packet.*

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonKrawczykScope`

Proof. Start with the Krawczyk enclosure theorem Definition 1570.3. It keeps the displayed narrowing inside the interval-arithmetic operation rows and the Newton or Taylor-model rows that form N and D.

Apply the radius lock of Definition 1570.4. This places the correction radius, Taylor or slope remainder, real-name route, and validated-consumer boundary inside the same finite carrier before any zero-enclosure read is exported.

Use the correction transport scope of Definition 1570.5. Transport through H and replay through C preserve the visible interval, derivative or Taylor-model, Newton-iteration, and validated-numerics route rather than adding a solver oracle or host zero.

Finally apply the validated consumer boundary of Definition 1570.7. The consumer-facing read is V followed by R, with P and L recording provenance and local naming. Since the carrier has no coordinate outside $B, F, D, N, K, V, R, H, C, P, L$, the stated dependency route is forced for every Krawczyk read. □

Theorem 1570.7 (Interval Newton validated consumer boundary)**.** *Every* $\mathsf{ValidatedNumerics}^{\uparrow}$ *or root-isolation consumer of an accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *packet reads the correction only through the displayed carrier*

$$I = (B, F, D, N, K, V, R, H, C, P, L).$$

The consumer receives the interval box, function enclosure, derivative or slope enclosure, correction row, containment ledger, validated enclosure row, real-name readback route, transport rows, replay routes, provenance, and local naming row. It receives no solver oracle, no host zero, no floating-point semantics, no quotient real equality, and no completeness datum.

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonValidatedConsumerBoundary`

Proof. Project the accepted carrier. A validated or root-isolation consumer can inspect only the fields $B, F, D, N, K, V, R, H, C, P, L$.

Use Definition 1570.2 to identify the exported obligation rows. The consumer handoff is V and R, while transport and replay are restricted to H and C.

Use Definition 1570.3 for the correction read. The Krawczyk or interval Newton row is visible only through $\mathsf{IntervalArithmetic}^{\uparrow}$ operations and through the displayed $\mathsf{NewtonIteration}^{\uparrow}$ or $\mathsf{TaylorModel}^{\uparrow}$ provenance named in P.

Thus every consumer-facing row is a projection of the finite packet. Since no carrier coordinate names a solver oracle, selected zero, hardware arithmetic semantics, quotient-real equality witness, or completeness theorem, those data cannot be exported by the boundary. □

Theorem 1570.8 (Interval Newton containment obligation)**.** *For every accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier* $I = (B, F, D, N, K, V, R, H, C, P, L)$*, the containment obligation is exactly the visible pair* (N, K)*. The correction row* N *may be consumed only with the containment and narrowing ledger* K*, and every* hsame *transport or* Cont *replay of the correction must preserve the same box row* B*, the same correction row* N*, and the same containment ledger* K *before the local* $\mathsf{NameCert}_{\mathsf{IntervalNewton}^{\uparrow}}$ *row* L *is read.*

Proof. Project the carrier. The only correction coordinate is N, and the only containment coordinate attached to it is K.

Use Definition 1570.2. It requires correction containment as a named row of the local NameCert surface, so a consumer cannot detach N from the ledger K.

Transport and replay then use H and C. Since those rows are componentwise over the carrier coordinates, they preserve B, N, K before the local naming row L is exposed. □

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonContainmentObligation`

Theorem 1570.9 (Interval Newton interval-arithmetic soundness obligation)**.** *For every accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier* $I = (B, F, D, N, K, V, R, H, C, P, L)$*, interval-arithmetic soundness is the obligation that the box row* B*, the function-enclosure row* F*, the derivative or slope row* D*, and the correction row* N *are all replayed through the* $\mathsf{IntervalArithmetic}^{\uparrow}$ *rows named by* P*. When* D *is supplied by a finite* $\mathsf{TaylorModel}^{\uparrow}$ *remainder packet, the same obligation routes the Taylor remainder through interval endpoint operations before* K *and* V *are visible to consumers.*

Proof. Read the arithmetic provenance from P. It names the interval-arithmetic surface through which endpoint, enclosure, derivative or slope, and correction operations are replayed.

Apply Definition 1570.3. The narrowing claim is not a free analytic assertion; it is assembled from B, F, D, N through the displayed interval operations.

If the derivative or slope row is supplied by $\mathsf{TaylorModel}^{\uparrow}$, the finite Taylor remainder is still routed through the same interval endpoint operations before containment is recorded in K. The validated row V is therefore downstream of the interval-arithmetic replay, not a replacement for it. □

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonIntervalArithmeticSoundnessObligation`

Theorem 1570.10 (Interval Newton validated handoff obligation)**.** *For every accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier* $I = (B, F, D, N, K, V, R, H, C, P, L)$*, the validated handoff obligation is the route from the validated enclosure row* V *and readback row* R *through the transport row* H*, replay row* C*, provenance row* P*, and local naming row* L*. A downstream* $\mathsf{ValidatedNumerics}^{\uparrow}$ *consumer may read the correction only after* V, R, H, C, P, L *expose the same interval box, correction containment, and provenance rows already present in* B, F, D, N, K*.*

Proof. Start from the validated consumer boundary. It says the consumer receives the displayed carrier rows and no solver oracle, host zero, floating-point semantics, quotient real equality, or completeness datum.

The handoff itself is V together with R. These rows expose the validated enclosure and readback route, while H and C preserve them under transport and replay.

Finally P and L provide provenance and local naming. Since the route still points back to B, F, D, N, K, the validated consumer can read only the correction already certified by containment and interval-arithmetic soundness. □

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonValidatedHandoffObligation`

Theorem 1570.11 (Interval Newton Real readback scope)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing validated enclosure read first exposes the interval box B, function-enclosure row F, derivative or slope row D, correction row N, and containment ledger K. It then exposes the validated row V and only then the readback row R.*

Transport through H, replay through C, provenance through P, and local naming through L preserve that same route. They cannot add a solver oracle, selected zero, quotient real equality, floating-point semantics, or ambient completeness.

Proof. Project the carrier of Definition 1570.1. The only Real-facing or RegSeqRat-facing readback coordinate is R, and it is stored with $B, F, D, N, K, V, H, C, P, L$ in the same finite packet.

Apply Definition 1570.3. The Krawczyk or interval Newton enclosure is assembled from the displayed box, function, derivative or slope, correction, and containment rows before it can be named as an enclosure.

Use Definition 1570.9. This keeps B, F, D, N inside the interval-arithmetic replay named by P before the containment ledger K and validated row V become consumer-visible.

Finally apply Definition 1570.10. The handoff places V before R, and H, C, P, L only transport, replay, name, and package the same route. Since no excluded datum is a carrier coordinate, the Real or RegSeqRat readback cannot export one. □

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonRealReadbackScope`

Theorem 1570.12 (Interval Newton scoped consumer route)**.** *Let $I = (B, F, D, N, K, V, R, H, C, P, L)$ be an accepted* $\mathsf{IntervalNewton}^{\uparrow}$ *carrier. Every scoped consumer route for a zero-enclosure or correction read is exactly the displayed path through containment, interval-arithmetic soundness, validated handoff, and Real or RegSeqRat readback:*

$$B, F, D, N \longmapsto K \longmapsto V \longmapsto R \longmapsto H, C, P, L.$$

The route first binds the correction row N to the containment ledger K, then routes B, F, D, N through the $\mathsf{IntervalArithmetic}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, *and* $\mathsf{TaylorModel}^{\uparrow}$ *provenance named by P, then exposes the* $\mathsf{ValidatedNumerics}^{\uparrow}$ *handoff V, and only then permits the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. It exports no solver oracle, host zero, floating-point semantics, quotient real equality, selected representative, or ambient completeness.*

Proof. Begin with the containment obligation of Definition 1570.8. It identifies the scoped correction surface as the pair (N, K) over the displayed box B, so a consumer cannot detach a correction read from the containment and narrowing ledger.

Next apply the interval-arithmetic soundness obligation and the Krawczyk enclosure theorem, Definition 1570.9 and Definition 1570.3. These route the box, function enclosure, derivative or

slope row, and correction row through the interval-arithmetic operations and through the displayed Newton or Taylor-model provenance named by P.

Use the validated handoff obligation and the validated consumer boundary, Definition 1570.10 and Definition 1570.7. They place V after B, F, D, N, K and keep transport, replay, provenance, and local naming inside H, C, P, L.

Finally apply the Real readback scope of Definition 1570.11. The readback row R is downstream of the validated row, and the carrier has no coordinate for any excluded solver, host, quotient, selection, or completeness datum. Therefore the scoped consumer route is exactly the displayed path. □

Lean4 ✓ `BEDC.Derived.IntervalNewtonUp.IntervalNewtonScopedConsumerRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalNewton}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalNewton}\uparrow}, \mathsf{scopedClosed})$

Constructive story: An $\mathsf{IntervalNewton}^{\uparrow}$ packet is generated from a displayed interval box, function enclosure, derivative or slope enclosure, finite Newton or Krawczyk correction row, containment ledger, validated readback row, real-name route, transport witnesses, replay routes, provenance, and local NameCert row.

Scope closed: Containment, interval-arithmetic soundness, validated handoff, transport, and ledger non-escape are bound to the displayed BEDC primitive rows of the same interval Newton and Krawczyk packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalNewton}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close solver correctness, existence of a zero, uniqueness, floating-point hardware semantics, classical real completeness, quotient real equality, or bridge checking.

Upgrade path: Verification closure requires Lean coverage for the displayed containment, arithmetic, handoff, transport, and non-escape routes.

Chapter 1571

A Concrete Naming Certificate for $\mathsf{SequentialClosure}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{SequentialClosure}^{\uparrow}$ packet records the finite route by which a displayed sequence-limit witness may be consumed as closure evidence without importing host topological closure. It sits over the topology surface of chapter 88, the metric source of chapter 57, the finite windows of chapter 126, the regular rational handoff of chapter 301, the Real seal of chapter 38, the located-set boundary of chapter 1541, and the sequence-consumer interface of chapter 1466. The packet is a finite NameCert surface for certified sequence-limit closure; it is not an ambient closure operator, not a compactness theorem, not quotient stream equality, not arbitrary subsequence choice, and not completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1571.1 (SequentialClosure carrier)**.** *A* $\mathsf{SequentialClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row, including the named neighbourhood indices and the classifier transport available to topology-facing consumers.*
2. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row over the same visible carrier, including the distance classifier and metric comparison rows used when neighbourhood tests are read metrically.*
3. *S is the displayed subset or* $\mathsf{LocatedSet}^{\uparrow}$ *row whose admitted points form the source surface for the sequence.*
4. *Q is the sequence source row. It records a finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of admitted sequence entries over S together with the point-name rows inspected by the packet.*
5. *L is the candidate limit row, naming the target point over the common topology and metric source without asserting that it is host-closure equivalent to S.*
6. *U is the neighbourhood and metric test ledger. Each displayed request records either a topology neighbourhood row around L or a metric tolerance row around L, together with the sequence-entry test that answers it.*
7. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming the inspected sequence windows and the index budgets consumed by U.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row translating the displayed metric tolerance windows into regular rational readback data before the Real distance boundary is consulted.*
9. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row certifying the accepted distance comparison downstream of R and U.*
10. *H records componentwise* hsame *transport for the topology row, metric row, subset or located-set row, sequence source, candidate limit, test ledger, StreamName windows, RegSeqRat handoff, Real seal, continuation, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a closure-consumer request through $T, M, S, Q, L, U, W, R, A$.*
12. *P is the* Pkg *provenance over* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row.*

The carrier has no coordinate for host topological closure, arbitrary subsequence choice, quotient stream equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached* $\mathsf{SequentialContinuity}^{\uparrow}$ *theorem.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureTasteGate single carrier alignment`

Theorem 1571.2 (SequentialClosure NameCert obligations)**.** *For every accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *carrier $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the ambient topology, ambient metric, subset or located-set row, sequence source, candidate limit, neighbourhood and metric tests, finite StreamName windows, RegSeqRat handoff, Real seal, transport, continuation, provenance, and local naming row;*
2. *neighbourhood-test stability, requiring each topology or metric request around L to replay through the displayed test ledger U over the same T, M, S, Q, L rows;*
3. *sequence-window coverage, requiring every accepted closure read to expose the finite StreamName windows W that name the inspected sequence entries and index budgets;*
4. *limit-row handoff, requiring the RegSeqRat row R and Real seal A to be read downstream of the displayed metric test ledger before a distance conclusion is exported;*
5. *classifier transport, requiring all* hsame *comparison of closure packets to preserve the topology, metric, subset, sequence, limit, test, window, handoff, seal, continuation, provenance, and local NameCert rows componentwise;*
6. *non-escape from the host closure boundary, excluding host topological closure, arbitrary subsequence choice, quotient stream equality, open-cover compactness, and detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureCarrier namecert obligations`

Proof. Project the carrier of Definition 1571.1. The projection exposes exactly the topology row, metric row, subset or located-set row, sequence source, candidate limit, test ledger, finite StreamName windows, RegSeqRat handoff, Real seal, and structural rows H, C, P, N.

Neighbourhood-test stability is forced by the continuation row C. A closure-facing request reaches a neighbourhood or metric conclusion only by replaying the common T, M, S, Q, L source rows and then consulting the displayed ledger U.

Sequence-window coverage is the next step in the same replay. The ledger W is the only place where inspected sequence windows and index budgets are stored, so an accepted read cannot replace the displayed sequence by an arbitrary subsequence or by quotient stream equality.

The limit-row handoff is downstream of those windows. The RegSeqRat row R translates the metric tolerance read into regular rational data, and the Real seal A certifies the accepted distance comparison only after U and W have been consumed.

Finally, componentwise transport by H preserves every displayed coordinate, while P and N package only that finite route. Since host topological closure, arbitrary subsequence choice, quotient stream equality, open-cover compactness, and detached Real completeness have no carrier row, no continuation edge, and no provenance entry, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureNameCert obligation surface`

Theorem 1571.3 (SequentialClosure sequence-limit handoff)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. Every closure consumer of the displayed candidate limit factors through*

$$T, M, S, Q, L \longmapsto U, W \longmapsto R, A \longmapsto H, C, P, N.$$

Thus the consumer receives closure evidence only through the displayed sequence windows, the RegSeqRat handoff, the Real seal, the topology and metric tests, and the local NameCert rows; no host closure operator, arbitrary sequence selection, quotient stream equality, compactness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureSequenceLimitHandoff`

Proof. Start with a closure consumer of the candidate limit row L. Carrier admission gives access to L only together with the common topology row T, metric row M, subset or located-set row S, and sequence source row Q.

Replay the continuation row C. The consumer must pass through the neighbourhood and metric test ledger U and then through the finite StreamName window ledger W, so the inspected sequence entries and their index budgets remain displayed throughout the read.

The metric side of the request then factors through R and A. The RegSeqRat handoff records the regular rational readback for the tolerance window, and the Real seal records the accepted distance comparison after the topology and metric tests have already been displayed.

Transport, provenance, and local naming through H, P, N preserve the same dependency order. This proves the stated factorization and leaves no available row from which a consumer could extract host closure, arbitrary sequence selection, quotient stream equality, compactness, or detached completeness. □

Theorem 1571.4 (SequentialClosure RegSeqRat limit route)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. Any metric-side closure read of the candidate limit row L must expose the finite window ledger W, translate the requested tolerance through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, and seal the resulting distance comparison through the* $\mathsf{Real}^{\uparrow}$ *row A. Thus the packet exports a sequence-limit route only as displayed RegSeqRat/Real data downstream of T, M, S, Q, L, U, W.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureRegSeqRatLimitRoute`

Proof. Project the packet carrier. The rows T, M, S, Q, L name the ambient topology, ambient metric, source row, sequence source, and candidate limit, while U records the neighbourhood and metric requests that a closure consumer may ask.

The metric request cannot bypass the finite windows. The continuation row C first exposes the StreamName windows W, so the inspected sequence entries and index budgets remain visible before any distance comparison is read.

The handoff then passes through R and A. The row R records the regular rational readback for the displayed tolerance, and the row A seals the corresponding Real comparison. Transport by H and packaging by P, N preserve this order, so no detached Real completeness or host limit principle is exported. □

Theorem 1571.5 (SequentialClosure LocatedSet stability)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet whose source row S is read as a* $\mathsf{LocatedSet}^{\uparrow}$ *surface. If a second packet is componentwise* hsame *to K on $T, M, S, Q, L, U, W, R, A, C, P, N$, then admitted sequence entries, located-set membership reads, RegSeqRat handoffs, and Real seals are transported through the same S row. The stability claim is only this finite LocatedSet-preserving replay.*

Proof. Start from the componentwise hsame data recorded by H. It identifies the topology and metric rows, the located-set source row S, the displayed sequence row Q, the candidate limit row L, and the test and window ledgers U, W.

Membership stability is read before the limit handoff. Each accepted sequence entry is admitted through the same located-set source surface S, and the transported packet can only replay those displayed entries because no arbitrary subsequence or external closure row appears in the carrier.

Finally transport the metric side through R and A. The RegSeqRat and Real rows are downstream of the same located-set and sequence windows, so the transported closure read preserves located-set admission while adding no compactness, quotient stream equality, or detached completeness assertion. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureLocatedSetStability`

Theorem 1571.6 (SequentialClosure topology handoff)**.** *For an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$, every topology-facing closure consumer receives the candidate limit row through the finite handoff*

$$T, M, S, Q, L, U, W, R, A, H, C, P, N.$$

Neighbourhood requests are answered through U over the common topology row T, metric requests are answered through M and then R, A, and the exported closure evidence is repacked by the local $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row N without a host closure operator.*

Proof. Begin with a topology-facing request around the candidate limit L. The carrier admits L only beside the ambient topology row T, metric row M, source row S, and displayed sequence row Q.

The request ledger U determines how the consumer may proceed. A purely neighbourhood-facing read stays over T, S, Q, L, U, W, while a metric-facing read also consumes the distance comparison route through M, R, A.

The final packaging is local. Transport by H, replay by C, provenance by P, and naming by N repack the same finite rows as $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ evidence. Since the packet has no coordinate for host topological closure, compactness, arbitrary sequence selection, or $\mathsf{Real}^{\uparrow}$ completeness, the topology and metric handoff exports only the displayed closure route. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureTopologyHandoff`

Theorem 1571.7 (SequentialClosure root sequence carrier)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. A sequence-closure carrier read is available only after the packet displays the* $\mathsf{LocatedSet}^{\uparrow}$ *or subset source row S, the* $\mathsf{Met}^{\uparrow}$ *row M, the* $\mathsf{StreamName}^{\uparrow}$ *row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the* $\mathsf{Real}^{\uparrow}$ *seal A, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row N in the same finite* BHist *carrier.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureRootSequenceCarrier`

Proof. Project the carrier of Definition 1571.1. The sequence row Q is not a detached stream; it is read beside the source row S, metric row M, test ledger U, window ledger W, handoff row R, and Real seal A.

Use Definition 1571.2 to identify the local NameCert obligations and Definition 1571.3 to force every closure consumer through the displayed sequence-limit route. The RegSeqRat limit route of Definition 1571.4 supplies the rational readback boundary for metric requests.

The located-set stability theorem Definition 1571.5 keeps source membership and admitted sequence entries over the same S row, while Definition 1571.6 repacks the topology-facing read through H, C, P, N. Hence the carrier read is available only with the listed finite BHist rows displayed. □

Theorem 1571.8 (SequentialClosure root limit ledger)**.** *For an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$, the limit witness ledger is finite: all accepted reads of the candidate limit row L pass through U, W, R, A, H, C, P, N. The packet refuses selected subsequences, quotient stream equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as limit-witness sources.*

Proof. The finite ledger is visible in the carrier definition: requests are stored in U, inspected sequence windows in W, rational readback in R, Real comparison in A, and structural packaging in H, C, P, N.

Apply Definition 1571.3 for the dependency order from T, M, S, Q, L to U, W, R, A and then to H, C, P, N. Apply Definition 1571.4 for the metric side of the same ledger.

The refusal clauses are forced by absence of carrier coordinates. Neither selected subsequences nor quotient stream equality appear in Q or W, countable choice has no row in U or C, and ambient $\mathsf{Real}^{\uparrow}$ completeness is not part of the seal A. The NameCert obligations of Definition 1571.2 therefore close only the displayed finite ledger. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureRootLimitLedger`

Theorem 1571.9 (SequentialClosure root topology transport)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. Any topology-facing transport of the closure read preserves the same sequence-limit rows $T, M, S, Q, L, U, W, R, A$ under componentwise* hsame *and displayed* Cont *replay, and then repackages the transported read through P, N.*

Proof. Start with the componentwise hsame row H. By Definition 1571.5, transport preserves the source row S, admitted sequence entries, RegSeqRat handoffs, and Real seals along the same displayed coordinates.

Replay is controlled by C. The handoff theorem Definition 1571.3 keeps the sequence-limit route over $T, M, S, Q, L, U, W, R, A$, and the topology handoff theorem Definition 1571.6 states that neighbourhood-facing consumers receive no host closure operator.

Finally P and N repackage the transported rows as the local NameCert surface described in Definition 1571.2. Thus topology transport preserves the same finite sequence-limit ledger rather than creating a second closure witness. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureRootTopologyTransport`

Theorem 1571.10 (SequentialClosure Kuratowski idempotence)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. A second sequential-closure read whose source row is the closure output of K contracts to the same displayed limit ledger whenever its witnesses are expressed by* $\mathsf{StreamName}^{\uparrow}$ *windows over Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail data through R, and* $\mathsf{Real}^{\uparrow}$ *equality seals through A. The contraction is an idempotence obligation for the finite packet only: it does not assert an ambient Kuratowski closure operator on all subsets of the host space.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureKuratowskiIdempotence`

Proof. Read the first closure packet through Definition 1571.8. The candidate limit row is exported only after the finite test ledger U, StreamName windows W, RegSeqRat handoff R, and Real seal A have been displayed.

For the second read, inspect its source witness. If a sequence entry points to a prior closure output, replay that output by the same rows $T, M, S, Q, L, U, W, R, A$ rather than introducing a new host closure coordinate.

The contraction is then componentwise. Transport through H identifies the topology, located-source, sequence, handoff, and Real-seal rows, while C, P, N repack the same witness as a single $\mathsf{SequentialClosure}^{\uparrow}$ certificate. Since every step is a finite replay of displayed windows, idempotence holds only inside this BEDC carrier surface. □

Theorem 1571.11 (SequentialClosure closed-set fixpoint)**.** *Let $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet, and suppose the* $\mathsf{LocatedSet}^{\uparrow}$ *source row S carries a displayed sequential closedness witness: every* $\mathsf{StreamName}^{\uparrow}$ *sequence over S with* $\mathsf{RegSeqRat}^{\uparrow}$ *tail data and* $\mathsf{Real}^{\uparrow}$ *equality seal has its candidate limit admitted back through S. Then the closure output named by K is fixed by S under the same located-set transport. This is a NameCert fixpoint for the displayed closedness witness, not a choice-based closed-set theorem.*

Proof. Start with the located source row S. The closedness witness is read as finite data over S, not as a detached predicate on an ambient topology.

Apply the sequence-limit handoff of Definition 1571.3. The closure read presents exactly the sequence source, StreamName windows, RegSeqRat handoff, and Real seal required by the displayed closedness witness.

Now replay the witness back into S. LocatedSet transport preserves the admitted membership row, and componentwise `hsame` transport by H keeps the topology and metric rows fixed. Therefore the closure output is repacked as an S-admitted point by C, P, N, with no appeal to countable choice or host closedness. □

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureClosedSetFixpoint`

Theorem 1571.12 (SequentialClosure topology sequence-filter handoff)**.** *For an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$, every topology-facing neighbourhood request around L that is also read as a finite sequence-filter request factors through the same route*

$$T, S, Q, U, W, R, A, H, C, P, N.$$

The Topology$^{\uparrow}$ *request supplies the neighbourhood row,* StreamName$^{\uparrow}$ *supplies the inspected tail windows,* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *seal the metric comparison, and* LocatedSet$^{\uparrow}$ *transport keeps the source membership boundary visible.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureTopologySequenceFilterHandoff`

Proof. Begin with a neighbourhood request from the topology row T. The topology handoff of Definition 1571.6 forces the request through the displayed source, sequence, test, and window ledgers rather than through a host closure operator.

Read the same request as a sequence-filter witness by naming the finite StreamName windows in W. Each tail inspection remains tied to the source row S, so located-set membership is transported before the metric side is sealed.

Finally consume R and A. The RegSeqRat row records the rational tail budget and the Real row seals the comparison at the candidate limit. The structural rows H, C, P, N then package the topology and sequence-filter views as the same finite handoff. □

Theorem 1571.13 (SequentialClosure obligation closure surface)**.** *For every accepted* SequentialClosure$^{\uparrow}$ *carrier* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$*, the obligation surface is the finite list consisting of carrier admission, neighbourhood-test stability, sequence-window coverage, limit-row handoff, componentwise transport, continuation replay, package provenance, local naming, and nonescape from host closure, selected subsequences, quotient stream equality, open-cover compactness, and ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureObligationClosureSurface`

Proof. Project the carrier and apply Definition 1571.2. That theorem lists the local NameCert obligations over exactly the rows $T, M, S, Q, L, U, W, R, A, H, C, P, N$.

Use Definition 1571.7 to bind the carrier admission side to the displayed source, metric, sequence, RegSeqRat, Real, transport, replay, provenance, and local naming rows. Use Definition 1571.8 to bind the limit side to U, W, R, A, H, C, P, N.

The remaining exclusions are read from the same absence-of-coordinate argument used in Definition 1571.3. Since no host closure, selected subsequence, quotient stream equality, compactness, or ambient completeness row appears in the packet, the displayed finite list exhausts the obligation surface. □

Theorem 1571.14 (SequentialClosure neighbourhood-test stability)**.** *Let* $K = (T, M, S, Q, L, U, W, R, A, H, C, P,$ *be an accepted* SequentialClosure$^{\uparrow}$ *packet. Every neighbourhood request around the candidate limit row* L *is stable under componentwise* hsame *transport only when the transported packet preserves the same topology row* T*, metric row* M*, source row* S*, sequence row* Q*, test ledger* U*, and downstream window-handoff rows* W, R, A*.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureNeighbourhoodTestStability`

Proof. Start with a neighbourhood request around L. By Definition 1571.6, the request is answered through U over the common topology row T, with metric-facing reads continuing through M, R, A.

Transport is controlled by H. The located-set stability theorem Definition 1571.5 keeps source membership and admitted sequence entries over the same S row, and Definition 1571.9 preserves the same sequence-limit rows under componentwise hsame and displayed replay.

Thus a transported neighbourhood test remains stable exactly when the packet preserves T, M, S, Q, U, W, R, A and repackages them through H, C, P, N. No separate neighbourhood oracle or host closure coordinate is available. □

Theorem 1571.15 (SequentialClosure sequence-window coverage)**.** *For an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$*, every closure read of* L *exposes the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff or* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The coverage obligation is only this displayed finite window coverage over* Q *and* U*.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureSequenceWindowCoverage`

Proof. Read the closure consumer through Definition 1571.3. The consumer factors from T, M, S, Q, L to U, W before reaching R, A and the structural rows.

Apply Definition 1571.7. It makes the sequence source row Q available only with the source row S, metric row M, test ledger U, and finite window ledger W in the same carrier.

Finally use Definition 1571.12. The topology-facing sequence-filter read names the same finite windows and then passes through R, A, H, C, P, N. Hence every accepted closure read covers the inspected windows explicitly, without selected subsequences or quotient stream equality. □

Theorem 1571.16 (SequentialClosure limit-row handoff)**.** *Let* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$ *be an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *packet. The candidate limit row* L *may be exported to a closure consumer only through the route*

$$T, M, S, Q, L \longmapsto U, W \longmapsto R, A \longmapsto H, C, P, N.$$

In particular, the limit row is handed off through the displayed neighbourhood tests, finite sequence windows, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal, not through host topological closure or ambient completeness.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureLimitRowHandoff`

Proof. Begin with the candidate limit row. The sequence-limit handoff theorem Definition 1571.3 gives the displayed route from T, M, S, Q, L through U, W, R, A and then through H, C, P, N.

On the metric side, apply Definition 1571.4. It requires the finite window ledger W, the regular-rational handoff R, and the Real seal A before a distance conclusion is exported.

The root limit ledger theorem Definition 1571.8 excludes selected subsequences, quotient stream equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness as limit-witness sources. Therefore the only available handoff for L is the displayed finite route. □

Theorem 1571.17 (SequentialClosure kernel scope surface)**.** *For an accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *carrier* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$*, the scoped BEDC kernel surface is exactly the displayed packet over* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{LocatedSet}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *rows. Every topology or metric closure read must compose the existing sequence-limit handoff, neighbourhood-test stability, sequence-window coverage, and limit-row handoff rows before it can be presented to a downstream consumer.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureKernelScopeSurface`

Proof. Project the carrier. The rows $T, M, S, Q, L, U, W, R, A, H, C, P, N$ name the topology, metric, located source, displayed sequence, candidate limit, test ledger, finite windows, rational readback, Real seal, transport, replay, provenance, and local NameCert coordinates.

Compose the already displayed handoffs in dependency order. The sequence-limit handoff of Definition 1571.3 keeps every closure read on $T, M, S, Q, L, U, W, R, A, H, C, P, N$, while Definition 1571.14 fixes the topology and metric request rows.

The final scope is supplied by Definition 1571.15 and Definition 1571.16. Finite StreamName windows precede the RegSeqRat readback, and the Real seal follows that readback. Thus the kernel surface is scoped to the listed BEDC rows rather than to host closure or detached completeness. □

Theorem 1571.18 (SequentialClosure carrier admission scope)**.** *Carrier admission for* $\mathsf{SequentialClosure}^{\uparrow}$ *admits a closure packet only when the same finite* BHist *row displays the* $\mathsf{Topology}^{\uparrow}$ *source* T*,* $\mathsf{Met}^{\uparrow}$ *source* M*,* $\mathsf{LocatedSet}^{\uparrow}$ *or subset row* S*,* $\mathsf{StreamName}^{\uparrow}$ *sequence row* Q *and windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{Real}^{\uparrow}$ *seal* A*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row* N*. Admission does not create a second carrier for an ambient closure operator or for a detached limit theorem.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureCarrierAdmissionScope`

Proof. Start from Definition 1571.1. Its displayed tuple contains one topology row, one metric row, one source row, one sequence source, one candidate limit, one test ledger, one finite window ledger, one RegSeqRat handoff, one Real seal, and the structural rows.

Use Definition 1571.7 for the carrier side. It binds the sequence row to the LocatedSet or subset source, the metric row, StreamName windows, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming rows in the same packet.

Use Definition 1571.8 for the limit side. The candidate limit row is admitted only through U, W, R, A, H, C, P, N, so the carrier has no place to store host closure, arbitrary selection, quotient stream equality, or an independent completeness proof. □

Theorem 1571.19 (SequentialClosure nonescape scope)**.** *For every accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *carrier* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$*, a downstream* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{LocatedSet}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer can read closure evidence only through* $T, M, S, Q, L, U, W, R, A, H, C$ *and the local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row. The packet exports no host topological closure, selected subsequence, quotient stream equality, open-cover compactness, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or additional bridge row.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosureNonescapeScope`

Proof. Read the consumer route through Definition 1571.17. Topology and metric requests are scoped to T, M, U, located-source requests to S, Q, sequence windows to W, and metric limit reads to R, A.

Apply Definition 1571.18. Since all accepted carrier data lives in the same BHist tuple and is transported only by H and replayed only by C, a consumer cannot introduce a second closure source while preserving the local NameCert.

The exclusions follow from Definition 1571.2 and Definition 1571.3. The absent claims have no carrier coordinate, no continuation edge, no provenance entry, and no NameCert row, so they cannot escape through the scoped kernel packet. □

Theorem 1571.20 (SequentialClosure public export)**.** *For every accepted* $\mathsf{SequentialClosure}^{\uparrow}$ *carrier* $K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$*, any downstream topology or metric consumer receives closure evidence only through the displayed source row* S*, sequence windows* W*, RegSeqRat handoff* R*, Real seal* A*, componentwise transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$ *row* N*. The public export packages the existing scoped route; it does not add a host closure operator, selected subsequence, quotient stream equality, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a detached bridge row.*

Lean4 ✓ `BEDC.Derived.SequentialClosureUp.SequentialClosurePublicExport`

Proof. Begin with Definition 1571.2. It identifies the carrier rows and requires every closure-facing read to expose the source, sequence, test, handoff, Real seal, transport, replay, provenance, and local naming data.

Apply Definition 1571.3 and Definition 1571.4. These theorems put the sequence windows before the regular-rational readback and put the Real seal after that readback.

Now use the public topology surface already recorded by Definition 1571.6, Definition 1571.17, and Definition 1571.9. They keep topology and metric consumers on the same displayed rows $T, M, S, Q, L, U, W, R, A, H, C, P, N$.

Finally apply Definition 1571.18 and Definition 1571.19. The carrier admission theorem repacks the rows as one finite packet, and the nonescape theorem excludes every host closure or selection object absent from that packet. □

Theorem 1571.21 (SequentialClosure mature treatment)**.** *The complete paper surface for* $\mathsf{SequentialClosure}^{\uparrow}$ *is the finite carrier*

$$K = (T, M, S, Q, L, U, W, R, A, H, C, P, N)$$

together with the public carrier admission route, the local NameCert obligations, the sequence-limit handoff, the $\mathsf{RegSeqRat}^{\uparrow}$ *limit route,* $\mathsf{LocatedSet}^{\uparrow}$ *stability, the topology handoff, the root sequence and limit ledgers, root topology transport, Kuratowski idempotence, the closed-set fixpoint, kernel scope, carrier-admission scope, nonescape, and public export. A downstream closure consumer that cites* $\mathsf{SequentialClosure}^{\uparrow}$ *must stay on this displayed surface and receives no host topological closure, arbitrary sequence selection, general sequential compactness, quotient stream equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or detached bridge row.*

Proof. Start with the carrier of Definition 1571.1 and the NameCert obligations of Definition 1571.2. They expose the topology, metric, located-source, sequence, candidate-limit, test, window, RegSeqRat, Real, transport, replay, provenance, and naming rows as one finite packet.

The limit-facing route is already fixed. Apply Definition 1571.3, Definition 1571.4, Definition 1571.15, and Definition 1571.16 to force every closure read through finite StreamName windows before the RegSeqRat handoff and Real seal are consumed.

The source and topology routes are also fixed. Use Definition 1571.5, Definition 1571.6, Definition 1571.7, Definition 1571.8, and Definition 1571.9 to keep located-set membership, topology requests, and root ledgers on the same carrier rows.

Finally close the paper surface by Definition 1571.10, Definition 1571.11, Definition 1571.17, Definition 1571.18, Definition 1571.19, and Definition 1571.20. These theorems repack idempotence, displayed closedness, public consumer exposure, and nonescape as consequences of the same finite packet, so no excluded host closure or completeness object remains part of the paper claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1571.1, Definition 1571.2, Definition 1571.3, Definition 1571.13, Definition 1571.14, Definition 1571.15, Definition 1571.16, Definition 1571.17, Definition 1571.18, Definition 1571.19, Definition 1571.20, and Definition 1571.21 enumerate the finite obligation surface, public consumer nonescape route, and displayed sequence-limit, RegSeqRat, topology, root-ledger, Kuratowski, and closed-set fixpoint handoffs for metric closure consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topological closure, arbitrary sequence selection, general sequential compactness, quotient stream equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal closure requires checked carrier admission, classifier transport, nonescape, and bridge data for the displayed sequence-limit, RegSeqRat, and topology handoff.

Constructive story: A SequentialClosure$^{\uparrow}$ packet is generated from ambient TopologyUp and MetricUp rows, a subset or LocatedSet row, a sequence source, a candidate limit row, a neighbourhood and metric test ledger, finite StreamName windows, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1572

A Concrete Naming Certificate for $\mathsf{CofinalCauchyTail}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy convergence, the $\mathsf{CofinalCauchyTail}^{\uparrow}$ packet records the finite route by which a Cauchy source is read only through certified cofinal tail thresholds before it reaches a regular rational handoff and a terminal Real seal. It sits between the cofinal-subsequence discipline of chapter 405, the Cauchy criterion surface of chapter 392, the fast Cauchy route of chapter 323, the regular rational readback of chapter 301, and the Real naming boundary of chapter 38. The packet is a finite NameCert carrier for tail-normalized Cauchy access; it is not a quotient stream, not a selected limit, not host real equality, not countable choice, not trichotomy, and not a completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 1572.1 (Cofinal Cauchy tail carrier)**.** *A* $\mathsf{CofinalCauchyTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, \tau, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy row or* $\mathsf{StreamName}^{\uparrow}$ *row whose late observations are to be read through the tail packet.*
2. *τ is the cofinal tail-threshold ledger, recording the finite threshold cells that certify that later requests stay inside the accepted tail route.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that supplies the precision-to-threshold budget consumed by τ.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the requested dyadic radius against the tail observations named by S.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, τ, M, D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after the RegSeqRat handoff row has been replayed.*
7. *H records componentwise* hsame *transport for the source, threshold ledger, modulus, dyadic tolerance, RegSeqRat handoff, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through the cofinal threshold ledger, Cauchy modulus, dyadic tolerance ledger, RegSeqRat handoff, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchyTail}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, host real equality, countable-choice selectors, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1572.2 (Cofinal Cauchy tail NameCert obligations)**.** *For every accepted* $\mathsf{CofinalCauchyTail}^{\uparrow}$ *carrier $T = (S, \tau, M, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchyTail}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the source Cauchy or* $\mathsf{StreamName}^{\uparrow}$ *row, cofinal threshold ledger, Cauchy modulus, dyadic tolerance ledger, RegSeqRat handoff, Real seal, transport, continuation, provenance, and local naming rows;*
2. *cofinal-tail coverage, requiring each accepted precision request to read the threshold ledger τ together with the modulus row M before any late observation of S is consumed;*
3. *dyadic tolerance exactness, requiring the comparison row D to be the only tolerance row used for the accepted tail observations;*
4. *RegSeqRat handoff, requiring S, τ, M, D to repack as the regular rational readback row R before any Real-facing row is available;*
5. *Real seal refusal, excluding quotient streams, selected limits, host real equality, countable-choice selectors, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1572.1. The projection exposes the source row S, threshold ledger τ, modulus row M, dyadic tolerance row D, RegSeqRat handoff R, Real seal E, and structural rows H, C, P, N.

The continuation row C records the only replay route through the packet. Its first dependencies are the threshold ledger τ and the modulus row M; after those rows are consumed, the same route reads the late source observations in S and the tolerance comparisons in D.

The row R occurs downstream of S, τ, M, D, and E occurs downstream of R. Since the carrier contains no coordinates for quotient streams, selected limits, host real equality, countable-choice selectors, trichotomy, or completeness, the displayed five rows exhaust the local NameCert obligation surface. □

Theorem 1572.3 (Cofinal Cauchy tail RegSeqRat handoff)**.** *Let $T = (S, \tau, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CofinalCauchyTail}^{\uparrow}$ *carrier. Every accepted tail packet reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the rows S, τ, M, D, R: the source row S supplies the late observations, τ supplies the cofinal threshold ledger, M supplies the Cauchy modulus budget, D supplies the dyadic tolerance comparisons, and R is the resulting regular rational readback. No separate regular-sequence oracle is available.*

Proof. Begin with an accepted tail packet and project its carrier. The only rows before the RegSeqRat handoff are S, τ, M, D together with the structural transport and replay rows.

Replay C at the requested precision. The route first reads τ and M, then uses those rows to select the late observations of S and the dyadic comparisons in D.

The handoff row R is listed only after that route. Transport by H preserves the same row order, while P and N name the same finite route. Hence every accepted packet reaches $\mathsf{RegSeqRat}^{\uparrow}$ through S, τ, M, D, R and through no independent regular-sequence oracle. □

Theorem 1572.4 (Cofinal Cauchy tail Real seal boundary)**.** *Let $T = (S, \tau, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CofinalCauchyTail}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read passes through the RegSeqRat handoff row R before the seal row E is read. The exported surface contains no quotient stream, selected limit, host real equality, countable-choice selector, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Take a Real-facing consumer of the packet. Carrier admission exposes the seal row E, but only as a row downstream of the RegSeqRat handoff row.

Replay the continuation row C. The consumer must first pass through the source row S, threshold ledger τ, Cauchy modulus M, and dyadic tolerance row D; those rows then repack as R.

Only after R has been replayed can E be read. Because the carrier has no coordinate for quotient streams, selected limits, host real equality, countable-choice selectors, trichotomy, or completeness, the Real-facing surface exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalCauchyTail}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalCauchyTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1572.1, Definition 1572.2, Definition 1572.3, and Definition 1572.4 seed the finite route from cofinal Cauchy tail thresholds through CauchyModulus, DyadicRatCore, RegSeqRat, and the downstream Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalCauchyTail}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable-choice selectors, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-tail coverage, dyadic tolerance exactness, RegSeqRat handoff, Real seal boundary, and ledger refusal proofs for the same packet.

Constructive story: A $\mathsf{CofinalCauchyTail}^{\uparrow}$ packet is generated from a source Cauchy or StreamName row, a cofinal tail-threshold ledger, a CauchyModulus row, a DyadicRatCore tolerance row, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1573

A Concrete Naming Certificate for $\mathsf{TotallyBoundedCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ packet records the finite route by which a totally bounded metric carrier passes through constructive completion while retaining explicit net data. It reads the finite-net surface of chapter 127, the precompact bridge of chapter 1531, the basis generator of chapter 1501, the dense embedding row of chapter 1512, the constructive completion route of chapter 1556, and the uniformly continuous handoff of chapter 769. The packet is a finite completion-facing certificate for displayed total-bounded net ledgers; it is not an open-cover compactness theorem, a quotient completion, a selected limit-point operation, a countable-choice principle, or a full completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1573.1 (Totally bounded completion carrier)**.** *A* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, T, N, F, E, C, S, U, H, P, L)$$

with the following visible rows:

1. *X is the source metric carrier row, including the accepted point histories, distance-witness rows, and classifier transports read by the total-bounded and completion-facing coordinates.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger. For each displayed positive tolerance it records the closed* $\mathsf{ProbeBundle}$ *of centers,* $\mathsf{InBundle}$ *membership rows, center-carrier rows, distance witnesses, and rational bound ledgers.*
3. *N is the net-refinement row. It records how a finer tolerance request refines a previously displayed finite net without replacing the net by an open cover or by a host finite set.*
4. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row generated from the same metric and net data, including the finite basis packets and common-refinement reads consumed by the completion route.*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that sends source observations into the dense completion boundary while preserving the displayed metric and net ledgers.*
6. *C is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route through regular Cauchy names, dyadic tolerances, Cauchy-filter basis data, dense embedding, separated comparison, and uniformly continuous extension.*
7. *S is the separated completion equality row. It compares completion reads only through the displayed Cauchy-filter and zero-distance route.*

8. *U is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff row for consumers that extend uniformly continuous maps from the dense source through the completed packet.*

9. *H records componentwise* hsame *transport for the source metric, finite nets, net refinements, Cauchy-filter basis, completion embedding, constructive completion route, separated equality, extension handoff, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{PrecompactMetric}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *row naming the displayed packet and the permitted reads from it.*

The classifier on such packets is componentwise transport through H together with replay through the displayed route rows. No coordinate exports open-cover compactness, quotient representatives, selected limit points, countable choice, an ambient complete metric space, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TasteGate.TotallyBoundedCompletionTasteGate single carrier alignment`

Theorem 1573.2 (TotallyBoundedCompletion NameCert obligations)**.** *For every accepted* TotallyBoundedComplet *carrier $K = (X, T, N, F, E, C, S, U, H, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed source metric, total-bounded net ledger, net-refinement row, Cauchy-filter basis, dense completion embedding, constructive completion route, separated equality, uniformly continuous handoff, transport ledger, provenance, and local naming row;*

2. *finite-net persistence, requiring every completion-facing tolerance request to read the centers, membership constructors, distance witnesses, and rational bounds recorded in T and refined through N;*

3. *basis and embedding replay, requiring each completion read to consume F and E before it reaches the constructive completion route C;*

4. *separated and extension handoff, requiring equality of completion reads to pass through S and every uniformly continuous consumer to pass through U after F, E, C have been displayed;*

5. *ledger non-escape, excluding open-cover compactness, quotient completion, selected limit points, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, and ambient completeness.*

No NameCert obligation is stored outside these displayed rows.

Proof. Carrier admission is projection from Definition 1573.1. The packet lists the metric source, finite-net ledger, net-refinement row, Cauchy-filter basis, dense embedding, constructive completion route, separated equality, extension handoff, transport ledger, provenance, and local naming row.

Finite-net persistence is read from T and N. A tolerance request first inspects the closed $\mathsf{ProbeBundle}$, its $\mathsf{InBundle}$ constructors, the center-carrier rows, and the metric distance witnesses in T; refinement then follows the displayed row N and keeps the same ledger style at the finer tolerance.

Basis and embedding replay is forced by the route order. The Cauchy-filter basis row F consumes the finite net data before a completion-facing read is formed, and the embedding row E

places source observations inside the dense completion boundary before the constructive route C can be read.

The separated and extension obligations are then local to S and U. Equality of completion reads is compared through S, while uniformly continuous consumers can inspect the completed packet only through U after the basis, embedding, and constructive completion rows are already present.

Finally, the provenance row P and local naming row L name only the displayed coordinates. Since none of those coordinates contains open-cover compactness, quotient representatives, selected limit points, countable choice, detached Real completeness, or ambient completeness, no such datum can be exported by the NameCert surface. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier namecert obligations`

Theorem 1573.3 (TotallyBoundedCompletion finite-net Cauchy handoff)**.** *For every completion-facing read from an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, the consumer must expose the finite* ProbeBundle *centers and membership rows of* T*, the refinement ledger* N*, the* CauchyFilterBasis$^{\uparrow}$ *row* F*, the* CompletionEmbedding$^{\uparrow}$ *row* E*, and the* ConstructiveMetricCompletion$^{\uparrow}$ *route* C *before any separated comparison in* S *or uniformly continuous handoff in* U *is read. Componentwise* hsame *transport through* H *and displayed* Cont *replay preserve this order; they do not replace the finite-net-to-Cauchy-filter route.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionFiniteNetCauchyHandoff`

Proof. Start with the NameCert obligations of Definition 1573.2. Carrier admission displays the rows $X, T, N, F, E, C, S, U, H, P, L$ and finite-net persistence requires each tolerance request to read the center and membership data recorded in T.

The refinement row N is then the only permitted route from a displayed finite net to a finer tolerance read. It keeps the same ProbeBundle centers, membership constructors, distance witnesses, and rational bound ledgers visible before a Cauchy-filter basis is generated.

Apply the basis and embedding replay clause. The row F consumes the finite-net and refinement data, the row E embeds the resulting source observations, and the route C records the constructive completion read.

Finally use the separated and extension handoff clause. The rows S and U are downstream of F, E, C, while H, P, L only transport, source, and name the same packet. Thus no completion-facing consumer can bypass the finite-net-to-Cauchy-filter handoff. □

Theorem 1573.4 (TotallyBoundedCompletion scope dependency seal)**.** *Every accepted scoped consumer of* TotallyBoundedCompletion$^{\uparrow}$ *must expose the full route*

$$X, T, N, F, E, C, S, U, H, P, L$$

with TotallyBounded$^{\uparrow}$ *read first through the finite-net ledger* T*,* CauchyFilterBasis$^{\uparrow}$ *read next through* F*,* CompletionEmbedding$^{\uparrow}$ *read through* E*,* ConstructiveMetricCompletion$^{\uparrow}$ *read through* C*, and* UniformContinuousExtension$^{\uparrow}$ *read through* U*. The route is sealed only when the carrier definition, NameCert obligation surface, finite-net Cauchy handoff, and net-refinement stability all remain visible. No scoped read may replace this route by open-cover compactness, selected limits, quotient completion, countable choice, or detached Real completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier scope dependency seal`

Proof. Project the accepted carrier of Definition 1573.1. The rows $X, T, N, F, E, C, S, U, H, P, L$ are the complete packet inventory, so a scoped consumer cannot name a completion-facing read without exposing the finite-net, basis, embedding, constructive-completion, extension, transport, provenance, and local NameCert rows.

Apply the obligation surface of Definition 1573.2. It forces carrier admission, finite-net persistence, basis-and-embedding replay, separated and extension handoff, and ledger non-escape on the same tuple.

Use the finite-net Cauchy handoff of Definition 1573.3. That theorem places T, N, F, E, C before any separated comparison in S or uniformly continuous handoff in U can be read.

Finally apply net-refinement stability from Definition 1573.9. Refinement preserves the displayed finite-net route through T, N, F, E, C rather than replacing it by compactness, a selected limit, a quotient-completion representative, countable choice, or detached Real completeness. Thus the scoped dependency route is sealed exactly by the displayed L10 rows. □

Definition 1573.5 (TotallyBoundedCompletion carrier admission obligation)**.** *The carrier admission obligation for* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *is the requirement that every accepted* BHist *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$ *display all eleven rows before its local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *row is read. The source metric row* X *feeds the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger* T*; the refinement row* N *feeds the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row* F*; the dense* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* E *and* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route* C *precede the separated equality row* S *and the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff* U*; and* H, P, L *record componentwise* hsame *transport, package provenance, and local naming. The displayed* Cont *replay may follow only this row order.*

Theorem 1573.6 (TotallyBoundedCompletion refinement ledger obligation)**.** *For every accepted* BHist *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$ *satisfying Definition 1573.5, every refinement request admitted by* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *must consume the* $\mathsf{TotallyBounded}^{\uparrow}$ *ledger* T*, the net-refinement row* N*, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row* F*, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* E*, and the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route* C *before it is transported by* H *or replayed by* Cont*. The request cannot bypass* T, N, F, E, C *by reading only* S, U, H, P, L*.*

Proof. Project the refinement request from the displayed packet. Carrier admission supplies the rows $X, T, N, F, E, C, S, U, H, P, L$ and names the permitted dependency order through the local $\mathsf{NameCert}$ row.

The refinement request is indexed by a tolerance read, so it first inspects the finite centers, membership rows, distance witnesses, and rational bounds in the $\mathsf{TotallyBounded}^{\uparrow}$ ledger T. The row N is then the only permitted refinement coordinate, and the generated basis row F records the corresponding $\mathsf{CauchyFilterBasis}^{\uparrow}$ packet.

The completion-facing part of the request must pass through E and C before separated comparison or extension handoff is visible. Componentwise hsame transport through H and displayed Cont replay preserve this route; they do not create a shortcut around the finite-net, basis, embedding, and constructive-completion rows. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier refinement ledger obligation`

Theorem 1573.7 (TotallyBoundedCompletion separated extension obligation)**.** *For every accepted* BHist *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$ *admitted by* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$*, a separated equality read in* S *or a uniformly continuous extension read in* U *is valid only after the source row* X*, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger* T*, the refinement row* N*, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$

row F, the CompletionEmbedding$^{\uparrow}$ *row E, and the* ConstructiveMetricCompletion$^{\uparrow}$ *route C have been displayed. Componentwise* hsame *transport through H and displayed* Cont *replay may transport the separated or extension read, but they may not replace the dependency on T, N, F, E, C.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier separated extension obligation`

Proof. Read the separated equality coordinate S and the extension handoff coordinate U from the carrier. Both coordinates are downstream rows of the same BHist packet $K = (X, T, N, F, E, C, S, U, H, P, L)$, so their admission is governed by the local NameCert surface rather than by an external completion theorem.

The source, finite-net, refinement, basis, embedding, and constructive-completion rows are already displayed before S or U can be consumed. Thus a separated equality comparison still depends on the Cauchy-filter and completion route, and a uniformly continuous extension consumer still depends on the finite-net route that produced the completed packet.

Transport and replay preserve that dependency. The hsame row H moves each coordinate componentwise, while the displayed Cont replay follows the same row order; neither operation supplies a new separated quotient, a selected limit, or an extension principle outside TotallyBounded$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, ConstructiveMetricCompletion$^{\uparrow}$, and UniformContinuousExtension$^{\uparrow}$. □

Theorem 1573.8 (TotallyBoundedCompletion net handoff)**.** *Let $K = (X, T, N, F, E, C, S, U, H, P, L)$ be an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet. Every completion-facing consumer that requests finite total-bounded data factors through*

$$X, T, N \longmapsto F \longmapsto E \longmapsto C \longmapsto S, U \longmapsto H, P, L.$$

Thus the consumer receives the original finite net ledger and its refinement row as part of the completion route, rather than an open cover, a selected convergent subnet, a quotient completion class, or an ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier net handoff`

Proof. Start with the source metric row X and the finite-net ledger T. These two rows provide the point classifier, distance witnesses, center names, membership constructors, and rational bounds that any total-bounded read may inspect.

The refinement row N is the only refinement operation available to the consumer. It moves from one displayed tolerance request to a finer one while retaining the same finite ledger shape, so the consumer cannot replace the packet by an open cover or by a host-level finite set.

The completion route then consumes this refined net data through F, E, and C. The Cauchy-filter basis is generated from the displayed rows, the embedding row places source observations densely in the completion boundary, and the constructive completion route records the finite regular-Cauchy and dyadic reads.

The separated equality row S and the uniformly continuous handoff U are downstream of that route. Transport, provenance, and local naming through H, P, L preserve the same dependency order, which proves the stated factorization and excludes the unavailable compactness, subnet, quotient, and ambient-completeness reads. □

Theorem 1573.9 (TotallyBoundedCompletion net-refinement stability)**.** *For every accepted* TotallyBoundedCompl *packet $K = (X, T, N, F, E, C, S, U, H, P, L)$, any net-refinement read transported through T, N, F, E, C*

remains a read of the same displayed finite-net ledger before it reaches separated comparison, uniformly continuous extension, transport, provenance, or local naming. In particular, refinement stability cannot be witnessed by S, U, H, P, L alone and cannot replace the finite net row T or refinement row N by an open-cover compactness witness.

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier net refinement stability`

Proof. Project the packet using Definition 1573.1. The only finite-net and refinement coordinates are T and N, while F, E, C are the downstream Cauchy-filter, embedding, and constructive-completion rows generated from them.

Apply the NameCert obligations of Definition 1573.2. Their finite-net persistence and basis-and-embedding replay clauses require every refinement read to display T, N, F, E, C before it is transported or replayed.

Finally use the route of Definition 1573.8. Since the displayed route sends X, T, N through F, E, C before S, U, H, P, L are available, refinement stability is carried by the same finite-net ledger and not by an external compactness or open-cover row. □

Theorem 1573.10 (TotallyBoundedCompletion Cauchy-filter-basis handoff)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, each* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *handoff exposed by F must first expose the total-bounded ledger T and the refinement row N before the dense embedding row E or constructive completion route C is read. No Cauchy-filter-basis consumer can enter the dense completion boundary while bypassing T, N.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier cauchy filter basis handoff`

Proof. Open the carrier of Definition 1573.1. The row F is not an independent basis source; it is the Cauchy-filter-basis row generated from the same metric and net data displayed in X, T, N.

The NameCert obligations of Definition 1573.2 require basis and embedding replay. Thus the handoff through F is admitted only after the finite-net ledger and refinement rows have already been exposed.

The net handoff theorem, Definition 1573.8, fixes the order $X, T, N \longmapsto F \longmapsto E \longmapsto C$. Therefore dense embedding reads in E and constructive completion reads in C cannot replace or skip the total-bounded ledger that generated the basis. □

Theorem 1573.11 (TotallyBoundedCompletion extension nonescape)**.** *For every accepted* TotallyBoundedComplet *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, a uniformly continuous extension read through U remains inside the displayed route*

$$X, T, N, F, E, C, S, U, H, P, L.$$

It cannot bypass the source metric, total-bounded ledger, refinement row, Cauchy-filter basis, embedding, constructive completion route, separated comparison, transport, provenance, or local naming rows.

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier extension nonescape`

Proof. Start from the carrier definition. The extension handoff row U is one coordinate of the same finite packet, and its permitted context includes the source, net, refinement, basis, embedding, completion, separated equality, transport, provenance, and naming rows.

Apply Definition 1573.2. The separated and extension handoff clause places U downstream from F, E, C, while finite-net persistence keeps F, E, C tied to T, N.

Use Definition 1573.8 to read the complete route. Since the extension handoff occurs after X, T, N, F, E, C, S, and H, P, L only transport, source, and name the same packet, the extension read cannot bypass any displayed row in the listed ledger. □

Theorem 1573.12 (TotallyBoundedCompletion uniform-extension ledger)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, every* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff through* U *factors through the finite-net ledger* T, N*, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row* F*, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* E*, the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route* C*, and the separated equality row* S *before* U, H, P, L *are public. The handoff exports a finite uniform-extension ledger for the same packet and no quotient completion, selected limit, open-cover compactness, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or second completion route.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier uniform extension ledger`

Proof. Start with the net handoff of Definition 1573.8. It forces every completion-facing consumer to read the total-bounded finite-net ledger T, refinement row N, Cauchy-filter basis row F, embedding row E, and constructive completion route C before separated comparison or extension handoff is available.

Use the Cauchy-filter-basis handoff. The row F is generated from the same finite-net data T, N, so an extension consumer cannot enter the dense completion boundary while bypassing the net ledger.

Apply the separated extension obligation. It places separated equality S and uniformly continuous extension U downstream of X, T, N, F, E, C, with transport through H and replay by Cont preserving that dependency.

Finally invoke extension nonescape. Since a U-read remains inside $X, T, N, F, E, C, S, U, H, P, L$, the public rows U, H, P, L export only the displayed uniform-extension ledger and no quotient completion, selected limit, open-cover compactness, countable-choice schedule, detached Real completeness, or second completion route. □

Theorem 1573.13 (TotallyBoundedCompletion CompactMetric scope)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet*

$$K = (X, T, N, F, E, C, S, U, H, P, L)$$

must expose the finite-net ledger T, N*, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row* F*, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* E*, the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route* C*, separated equality* S*, the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff* U*, componentwise* hsame *transport* H*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* L*. The scope is finite-net completion data only; it is not open-cover compactness, selected subnet convergence, quotient completion, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the net handoff theorem. It requires a completion-facing consumer to read the finite total-bounded ledger T, N before the Cauchy-filter basis row F, embedding row E, and constructive completion route C are available.

Use the Cauchy-filter-basis handoff and uniform-extension ledger next. The row F remains tied to T, N, while E, C, S, U are downstream rows of the same finite route and not independent compactness data.

Apply ledger non-escape. It excludes open-cover compactness, quotient completion, selected limit points, countable choice, detached Real completeness, and ambient completeness from the packet.

Finally read the structural rows H, P, L. Transport preserves the displayed finite-net completion route, provenance records the same packet source, and local naming admits only that route for a $\mathsf{CompactMetric}^{\uparrow}$-facing consumer. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier compact metric scope`

Theorem 1573.14 (TotallyBoundedCompletion net-completion image)**.** *Every public completion-facing image of an accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$ *factors through* T, N, F, E, C, S, U *before the structural rows* H, P, L *can be read. Consequently the image exports only finite-net completion data: total-bounded net ledgers, refinement, Cauchy-filter-basis handoff, completion embedding, constructive completion route, separated comparison, and uniform-extension handoff. It does not export open-cover compactness, selected subnet convergence, quotient completion, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completeness.*

Proof. Start with the net handoff theorem, Definition 1573.8. It places every completion-facing read behind the finite-net ledger T, refinement row N, Cauchy-filter basis F, completion embedding E, and constructive completion route C.

Use the Cauchy-filter-basis handoff and uniform-extension ledger, Definition 1573.10 and Definition 1573.12. These keep F, E, C, S, U attached to the same finite-net data before a public completion consumer can receive an image.

Apply the CompactMetric scope theorem above. A $\mathsf{CompactMetric}^{\uparrow}$-facing read sees the finite-net completion scope only through $T, N, F, E, C, S, U, H, P, L$, so H, P, L are structural transport, provenance, and naming rows rather than image-forming data.

Finally invoke ledger non-escape, Definition 1573.20. Since the excluded open-cover, selected-subnet, quotient, choice, detached-Real, and ambient-completeness objects have no carrier row, the public image is exactly the finite-net completion data exported by T, N, F, E, C, S, U. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier net completion image`

Theorem 1573.15 (TotallyBoundedCompletion root finite-net ledger)**.** *For every accepted* TotallyBoundedComplet *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, the root finite-net ledger exposed to completion consumers is exactly the pair* T, N*. The row* T *records the* $\mathsf{TotallyBounded}^{\uparrow}$ *centers, membership constructors, distance witnesses, and rational bounds for each displayed positive tolerance, while* N *records permitted refinement between such displayed ledgers. No root consumer may replace* T, N *by an open cover, a host finite subset, a selected subnet, or a compactness theorem.*

Proof. Project the carrier through Definition 1573.1. The only rows typed as total-bounded finite-net data are T and N.

Use the route surface of Definition 1573.24. Its first completion-facing segment is X, T, N, so every later completion row must inherit the finite-net ledger from the same pair.

The non-escape theorem then excludes replacement data. Since open covers, host finite subsets, selected subnets, and compactness witnesses have no carrier coordinate, the root ledger remains exactly T, N. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier root net ledger certificate`

Theorem 1573.16 (TotallyBoundedCompletion root completion handoff)**.** *For every accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, every completion-facing handoff forced by the root ledger factors through* F, E, C, S *in that order after* T, N *have been displayed. The* CauchyFilterBasis$^{\uparrow}$ *row* F *consumes the finite-net rows, the* CompletionEmbedding$^{\uparrow}$ *row* E *inserts source observations, the* ConstructiveMetricCompletion$^{\uparrow}$ *route* C *records the constructive completion read, and the separated comparison row* S *is available only after that route.*

Proof. Start with the root finite-net ledger theorem above. It identifies T, N as the input that any completion consumer must read.

Apply Definition 1573.27. The only completion-facing rows are F, E, C, and the separated comparison row is downstream of those rows.

Finally use Definition 1573.25. It makes the route exhaustive, so the handoff from the finite-net ledger to separated completion comparison must pass through F, E, C, S in the displayed order. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier root completion handoff`

Definition 1573.17 (TotallyBoundedCompletion effective net completion selector)**.** *For an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, the effective net completion selector is the finite BEDC read that first opens the total-bounded ledger pair* T, N *and only then follows*

$$F, E, C, S, U.$$

It returns the completion-facing route selected from the displayed finite net and its refinement ledger: F *is the generated* CauchyFilterBasis$^{\uparrow}$ *row,* E *is the dense* CompletionEmbedding$^{\uparrow}$ *row,* C *is the* ConstructiveMetricCompletion$^{\uparrow}$ *route,* S *is the separated comparison row, and* U *is the uniformly continuous extension handoff. The selector has no coordinate for open-cover compactness, quotient completion, selected subnet limits, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier effective net completion selector`

Theorem 1573.18 (TotallyBoundedCompletion selector consumption)**.** *Every use of the effective selector of Definition 1573.17 is consumed by the root completion handoff and the root extension nonescape rows. In particular, any selected completion route reads* T, N *before* F, E, C, S *and reaches* U, H, P, L *only as downstream extension, transport, provenance, and naming data.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier effective net completion consumption`

Proof. Start with the selector definition. Its first action is to open T, N, so the selected route is already tied to the root finite-net ledger rather than to an open cover or host finite subset.

Apply Definition 1573.16. The selected completion segment must pass through F, E, C, S in order after the finite-net rows are displayed.

Finally use Definition 1573.19. The rows U, H, P, L can only consume that displayed route; they do not add quotient completion, selected limits, countable choice, open-cover compactness, ambient completeness, or a second completion route. □

Theorem 1573.19 (TotallyBoundedCompletion root extension nonescape)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, the downstream rows* U, H, P, L *export only the uniformly continuous extension handoff, componentwise transport, provenance, and local naming for the already displayed route. They export no quotient completion, selected limits, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or second completion route.*

Proof. Read U, H, P, L from the carrier. These rows occur after X, T, N, F, E, C, S in the displayed route and therefore have no independent source of completion data.

Use the extension consumer boundary Definition 1573.28. It requires uniformly continuous consumers to enter through T, N, F, E, C before they can read U.

The ledger non-escape theorem Definition 1573.20 supplies the final exclusion. Quotient completion, selected limits, countable choice, open-cover compactness, ambient Real completeness, and a second completion route have no coordinate in U, H, P, L and cannot be exported from them. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier root extension nonescape`

Theorem 1573.20 (TotallyBoundedCompletion ledger non-escape)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, every exported completion read remains inside the finite ledger*

$$X, T, N, F, E, C, S, U, H, P, L.$$

It cannot produce open-cover compactness, a quotient completion, a selected limit point, countable choice, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier no escape`

Proof. Project an exported completion read from the carrier. By Definition 1573.1, the read has access only to the eleven displayed coordinates and their componentwise transport rows.

Apply Definition 1573.2. Finite-net persistence keeps the read inside T, N; basis and embedding replay moves it through F, E, C; separated and extension handoff moves it through S, U; and the structural rows H, P, L record only the same route.

Every excluded principle is absent from this route. Open-cover compactness, quotient representatives, selected limit points, countable-choice schedules, and full $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate, no replay edge, and no provenance row in the packet, so the exported read cannot escape the displayed finite ledger. □

Theorem 1573.21 (TotallyBoundedCompletion finite-net completion obligations)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, a completion-facing read is admitted only after it displays the finite-net rows of* $\mathsf{TotallyBounded}^{\uparrow}$*, the generated* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row, the dense* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route, and the downstream* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff. The carrier has no completion obligation outside those rows.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier finite net completion obligations`

Proof. Project the read from Definition 1573.1. The finite-net rows are exactly T and their refinement requests are exactly N.

Next apply Definition 1573.8. The displayed route sends T, N through the Cauchy-filter basis F, the completion embedding E, and the constructive completion route C before separated comparison or extension reads are available.

Finally use Definition 1573.2. Its separated and extension handoff clause forces S and U to remain downstream of F, E, C, while H, P, L only transport, source, and name the same finite route. □

Theorem 1573.22 (TotallyBoundedCompletion refinement stability)**.** *Let $K = (X, T, N, F, E, C, S, U, H, P, L)$ and $K' = (X', T', N', F', E', C', S', U', H', P', L')$ be accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packets. If their displayed source metric rows, finite-net ledgers, Cauchy-filter basis rows, embedding rows, completion routes, extension rows, provenance rows, and local naming rows are related componentwise by* hsame*, and the displayed* Cont *replay sends each tolerance request in K to the corresponding request in K', then every refinement request in K' remains on the same finite-net and Cauchy-filter route as the corresponding request in K.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionRefinementStability`

Proof. Begin with the refinement coordinate. By carrier projection, a refinement request can inspect only the finite-net ledger T, the refinement row N, and their transported counterparts T', N'.

The componentwise hsame hypotheses identify the displayed source metric, centers, membership constructors, distance witnesses, and rational bounds. The Cont replay preserves the tolerance request, so the target request is not replaced by an open cover, a host finite set, or a selected subnet.

Apply Definition 1573.8 on both packets. The source refinement moves through F, E, C and the target refinement moves through F', E', C' in the same order, with S, U, H, P, L and S', U', H', P', L' only recording separated comparison, extension handoff, transport, provenance, and local naming. □

Theorem 1573.23 (TotallyBoundedCompletion extension handoff)**.** *Every* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *consumer of an accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet receives only the displayed route*

$$X, T, N, F, E, C, S, U, H, P, L.$$

In particular, the consumer cannot read a quotient completion, a selected limit, countable choice, an open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness in place of the finite completion route.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionExtensionHandoff`

Proof. The extension consumer first opens the carrier coordinate U. By Definition 1573.1, that row is downstream from the source metric, finite-net ledger, refinement row, Cauchy-filter basis, embedding, constructive completion route, and separated equality row.

Use Definition 1573.21. It requires the finite-net, Cauchy-filter, embedding, constructive completion, and extension rows to be displayed before the handoff can be read.

The non-escape conclusion follows from Definition 1573.20. The excluded objects have no carrier coordinate and no provenance row, so the uniformly continuous extension read is exactly the listed route. □

Definition 1573.24 (TotallyBoundedCompletion route surface)**.** *The* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *route surface of an accepted carrier* $K = (X, T, N, F, E, C, S, U, H, P, L)$ *is the displayed BEDC route*

$$X, T, N \longmapsto F \longmapsto E \longmapsto C \longmapsto S, U \longmapsto H, P, L.$$

It is admissible exactly when the source metric row X*, the total-bounded finite-net ledger* T*, and the net-refinement row* N *are consumed before the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row* F*;* F *is consumed before the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* E*;* E *is consumed before the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *row* C*;* C *is consumed before separated comparison* S *or uniformly continuous extension handoff* U*; and* H, P, L *only transport, source, and name that displayed route. No other row order is an admissible* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *route surface.*

Theorem 1573.25 (TotallyBoundedCompletion route coverage)**.** *Every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet displays exactly the route surface of Definition 1573.24. In particular, every accepted packet has the route*

$$X, T, N \longmapsto F \longmapsto E \longmapsto C \longmapsto S, U \longmapsto H, P, L$$

and has no second completion-facing route through open-cover compactness, quotient representatives, selected limit points, countable choice, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier route coverage`

Proof. Open the carrier of Definition 1573.1. Its visible coordinates are precisely $X, T, N, F, E, C, S, U, H, P, L$, and the classifier exports only componentwise transport through those coordinates.

The NameCert obligations of Definition 1573.2 make the same list exhaustive. Finite-net persistence reads T, N; basis and embedding replay reads F, E, C; separated and extension handoff reads S, U; and the remaining rows H, P, L transport, source, and name the same packet.

The route displayed in Definition 1573.8 is therefore not merely one possible consumer path. Together with the ledger non-escape statement of Definition 1573.20, it is the whole completion-facing surface, and the excluded completion principles have no carrier row from which a second route could be read. □

Theorem 1573.26 (TotallyBoundedCompletion total-bounded input admission)**.** *For every accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, the total-bounded finite-net rows* T, N *are consumed before any Cauchy-filter, embedding, constructive-completion, separated-equality, or uniformly continuous extension read is admitted. Thus no read of* F, E, C, S*, or* U *can supply the finite-net input that the route surface requires from* T, N*.*

Proof. Carrier admission gives the ordered coordinates of K by Definition 1573.1. The rows T and N are the only rows that record finite centers, membership constructors, distance witnesses, rational bounds, and tolerance refinement.

Apply the finite-net persistence clause of Definition 1573.2. It requires each completion-facing tolerance request to inspect the displayed $\mathsf{TotallyBounded}^{\uparrow}$ ledger and its refinement row before a completion read is formed.

The handoff theorem Definition 1573.8 then transports that input through F, E, C and only afterward reaches S or U. Since Definition 1573.20 excludes external compactness and selected-limit rows, none of F, E, C, S, or U can replace the total-bounded input supplied by T, N. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier total bounded input admission`

Theorem 1573.27 (TotallyBoundedCompletion completion route exactness)**.** *For every accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet, the only completion-facing route rows are the* CauchyFilterBasis$^{\uparrow}$ *row F, the* CompletionEmbedding$^{\uparrow}$ *row E, and the* ConstructiveMetricCompletion$^{\uparrow}$ *route C. All separated comparison, uniformly continuous extension, transport, provenance, and local naming reads are downstream of F, E, C and do not form another completion route.*

Proof. Project an accepted packet through Definition 1573.1. The rows named as completion-facing are exactly F, E, C: F forms the Cauchy-filter basis, E supplies the dense embedding boundary, and C records the constructive completion route.

The basis and embedding replay clause of Definition 1573.2 admits completion reads only by passing through those three rows. The displayed route of Definition 1573.8 places S, U, H, P, L strictly after them.

It remains to exclude hidden completion rows. The ledger non-escape theorem Definition 1573.20 says that exported completion reads stay inside the finite ledger $X, T, N, F, E, C, S, U, H, P, L$, and no coordinate outside F, E, C is typed as a Cauchy-filter, embedding, or constructive-completion route. Hence F, E, C are exact. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier completion route exactness`

Theorem 1573.28 (TotallyBoundedCompletion extension consumer boundary)**.** *Every* UniformContinuousExtensio *consumer of an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet must enter through the displayed finite-net and completion route surface of Definition 1573.24. Such a consumer cannot bypass T, N, F, E, C by reading only separated equality, transport, provenance, local naming, quotient completion, selected limits, countable choice, or open-cover compactness.*

Proof. Start from the extension coordinate. By Definition 1573.23, a uniformly continuous extension consumer receives the displayed route $X, T, N, F, E, C, S, U, H, P, L$.

The total-bounded input admission theorem above forces T, N to be read before the extension consumer reaches completion-facing rows. The completion route exactness theorem above then identifies F, E, C as the only completion-facing rows between those finite-net inputs and the downstream separated or extension reads.

Finally apply the ledger non-escape theorem Definition 1573.20. Since quotient completion, selected limits, countable choice, and open-cover compactness have no coordinate in the packet, and since S, H, P, L only compare, transport, source, and name the already displayed route, the extension consumer has no bypass around T, N, F, E, C. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier extension consumer boundary`

Theorem 1573.29 (TotallyBoundedCompletion root route exhaustion)**.** *Every accepted* TotallyBoundedCompletion *packet has all accepted packet routes exhausted by the finite BEDC rows*

$$X, T, N, F, E, C, S, U, H, P, L.$$

The rows X, T, N supply the root metric and total-bounded input, F, E, C supply the exact completion-facing route, S, U supply separated comparison and uniformly continuous extension handoff, and H, P, L supply transport, provenance, and local naming. No accepted route may enter through an open-cover compactness theorem, a quotient-completion carrier, a selected limit point, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Start with the route surface of Definition 1573.24. It lists the only admissible row order for an accepted carrier and places every consumer read inside the displayed finite route.

The coverage theorem Definition 1573.25 makes that displayed surface exhaustive for accepted packets. The exactness theorem Definition 1573.27 then identifies F, E, C as the only completion-facing segment of the route.

It remains to rule out an external root entry. The ledger non-escape theorem Definition 1573.20 excludes the open-cover, quotient, selected-limit, countable-choice, and ambient-real objects from the carrier. Thus every accepted route is exhausted by $X, T, N, F, E, C, S, U, H, P, L$. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier root route exhaustion`

Theorem 1573.30 (TotallyBoundedCompletion root extension ledger)**.** *Every uniformly continuous extension read through the U row of an accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet inherits the finite-net and completion rows T, N, F, E, C, S from the same* BHist *and* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *carrier. The read exports no open-cover compactness, quotient completion, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness beyond that ledger.*

Proof. The extension consumer boundary theorem Definition 1573.28 forces every U-read to enter through the displayed route surface before it may be treated as a uniformly continuous extension.

The route surface already carries the finite-net rows T, N, the completion rows F, E, C, and the separated comparison row S in the same accepted carrier. Since the read is through U, the transport and provenance rows H, P, L only preserve that finite ledger and do not supply another completion principle.

Finally apply ledger non-escape, Definition 1573.20. The excluded open-cover, quotient, selected-limit, countable-choice, and ambient-real principles have no row in the accepted BHist packet and no local $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ obligation from which an extension consumer could export them. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier root extension ledger`

Theorem 1573.31 (TotallyBoundedCompletion net-filter carrier admission)**.** *Every accepted* $\mathsf{TotallyBoundedComp}$ *packet admits its completion-facing carrier only after the source* $\mathsf{Met}^{\uparrow}$ *row X, finite epsilon-net ledger T, refinement ledger N,* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *handoff F, separated* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row E, constructive completion route C, separated comparison row S,* $\mathsf{Real}^{\uparrow}$*-facing completion seal implicit in the route, componentwise* hsame *transport H, displayed* Cont *replay,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}$ *row L have all been read from the same finite* BHist *packet. No downstream* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$*, or uniformly continuous extension consumer may replace those rows by open-cover compactness, a quotient completion, selected limits, countable choice, or ambient Real completeness.*

Proof. Project the accepted carrier through Definition 1573.1. The rows $X, T, N, F, E, C, S, U, H, P, L$ are exactly the metric source, finite-net ledger, refinement ledger, Cauchy-filter basis, dense embedding, constructive completion, separated comparison, extension handoff, transport, provenance, and local naming rows.

Use finite-net persistence and basis-and-embedding replay from Definition 1573.2. They force a completion-facing consumer to read T, N before F, and then to read F, E, C before separated comparison or extension handoff.

The root route exhaustion theorem Definition 1573.29 and the root extension ledger theorem above keep S, U, H, P, L downstream of the same route. Thus later complete-metric or compact-metric consumers inherit the finite net and Cauchy-filter rows as one carrier surface, not as an open-cover or selected-limit substitute. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier net filter carrier admission`

Theorem 1573.32 (TotallyBoundedCompletion Cauchy-filter stability)**.** *For every accepted* TotallyBoundedCompl*packet, any* CauchyFilterBasis$^{\uparrow}$ *read generated from finite epsilon-net data remains stable under refinement only through the same rows* $X, T, N, F, E, C, S, U, H, P, L$*. The refinement ledger, separated completion extension,* Met$^{\uparrow}$ *source,* Real$^{\uparrow}$*-facing completion seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row therefore stay attached to the displayed Cauchy-filter route before any downstream completion consumer reads the result.*

Proof. Begin with the Cauchy-filter-basis handoff of Definition 1573.10. It requires the total-bounded ledger T and refinement row N before the basis row F can enter the dense embedding or constructive completion route.

Apply net-refinement stability, Definition 1573.9. Refining a tolerance request preserves the same finite centers, membership rows, distance witnesses, rational bounds, and Cauchy-filter handoff rather than switching to an open cover or host compactness theorem.

Finally use completion route exactness and root extension non-escape. The rows E, C, S, U, H, P, L only embed, complete, compare, extend, transport, source, and name the already displayed Cauchy-filter route. Hence stability is a property of the finite net-filter carrier itself and exports no quotient completion, selected limit, countable choice, or ambient Real-completeness row. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier cauchy filter stability`

Theorem 1573.33 (TotallyBoundedCompletion finite-net completion route)**.** *Every accepted* TotallyBoundedComp*carrier that exports a completion-facing extension must first expose the* TotallyBounded$^{\uparrow}$ *finite-net row* T*, the* CauchyFilterBasis$^{\uparrow}$ *row* F*, the* CompactMetric$^{\uparrow}$ *and* CompleteMetric$^{\uparrow}$ *completion service rows read through the displayed completion route, the* CompletionEmbedding$^{\uparrow}$ *row* E*, the* Real$^{\uparrow}$*,* StreamName$^{\uparrow}$*, and* RegSeqRat$^{\uparrow}$ *readback rows implicit in the finite tolerance schedule, and the* UniformContinuousExtension$^{\uparrow}$ *consumer row* U*. The export is a finite-net completion route through the same packet* $K = (X, T, N, F, E, C, S, U, H, P, L)$*, not a quotient completion, selected representative, choice schedule, or ambient* Real$^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionFiniteNetCompletionRoute`

Proof. Project the carrier using Definition 1573.1. The source, finite-net ledger, refinement row, Cauchy-filter basis, embedding, constructive completion route, separated comparison, extension handoff, transport, provenance, and local naming rows are exactly $X, T, N, F, E, C, S, U, H, P, L$.

Use net-filter carrier admission and Cauchy-filter stability, Definition 1573.31 and Definition 1573.32. They force the finite-net rows T, N to remain attached to the Cauchy-filter row F before any downstream completion consumer can read the result.

Next apply completion route exactness and the extension consumer boundary, Definition 1573.27 and Definition 1573.28. The only completion-facing segment is F, E, C, and the extension row U is available only as a consumer of that segment.

Finally use the root extension ledger above. The Real, stream-name, and regular-rational readbacks remain schedule data for the finite tolerance route, while compact and complete metric service rows are read only through the displayed completion route. Hence no quotient completion, selected representative, choice schedule, or ambient Real completeness can be exported. □

Theorem 1573.34 (TotallyBoundedCompletion obligation ledger)**.** *Let $K = (X, T, N, F, E, C, S, U, H, P, L)$ be an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet. Its obligation ledger is exhausted by six rows of work: carrier admission; finite-net persistence;* CauchyFilterBasis$^{\uparrow}$ *generation; completion embedding; constructive completion route; and separated equality plus uniformly continuous extension handoff. The ledger exports no open-cover compactness, selected subnet, quotient completion, countable choice, ambient completeness, or detached* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier obligation ledger`

Proof. Carrier admission is the first row of work. It is supplied by the carrier definition and by Definition 1573.2, which display $X, T, N, F, E, C, S, U, H, P, L$ as the local NameCert surface.

Finite-net persistence is the second row. The net handoff theorem Definition 1573.8 keeps every completion-facing read on the finite centers, membership rows, distance witnesses, rational bounds, and refinement ledger carried by T, N.

The third and fourth rows are the Cauchy-filter-basis generation and completion embedding handoffs. Apply Definition 1573.10: the basis row F is generated only after T, N are exposed, and the dense embedding row E cannot be read while bypassing that finite-net source.

The fifth row is the constructive completion route. The completion route exactness theorem Definition 1573.27 identifies F, E, C as the only completion-facing segment, and the root route exhaustion theorem Definition 1573.29 keeps all accepted routes inside the same finite packet.

The sixth row is the separated and uniform-extension handoff. The extension nonescape theorem Definition 1573.11 and uniform-extension ledger Definition 1573.12 keep S, U, H, P, L downstream of the displayed completion route.

Finally apply ledger nonescape, Definition 1573.20. Since open-cover compactness, selected subnets, quotient completion, countable choice, ambient completeness, and detached Real completeness have no coordinate in the accepted packet, the six rows exhaust the obligation ledger. □

Theorem 1573.35 (TotallyBoundedCompletion obligation-closure route)**.** *Let $K = (X, T, N, F, E, C, S, U, H, P, L$ be an accepted* TotallyBoundedCompletion$^{\uparrow}$ *packet. The six rows of Definition 1573.34, together with carrier admission, finite-net persistence,* CauchyFilterBasis$^{\uparrow}$ *generation,* CompletionEmbedding$^{\uparrow}$, ConstructiveMetricCompletion$^{\uparrow}$, *separated equality, and* UniformContinuousExtension$^{\uparrow}$ *handoff, exhaust the obligation surface for K.*

The route is exactly the finite-net completion surface displayed by the same packet. It does not claim open-cover compactness, quotient completion, selected limit points, countable choice, detached Real$^{\uparrow}$ *completeness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier obligation closure route`

Proof. Start with carrier admission and the obligation ledger. The carrier definition and Definition 1573.2 display exactly the rows $X, T, N, F, E, C, S, U, H, P, L$, and Definition 1573.34 organizes the accepted work into the six listed obligation rows.

Next apply the finite-net handoff and persistence theorems. The net handoff Definition 1573.8, the Cauchy-filter-basis handoff Definition 1573.10, and the completion route exactness theorem

Definition 1573.27 force every completion-facing read through T, N, F, E, C before separated equality or extension data can be consumed.

Finally use the extension consumer boundary and ledger non-escape. The extension boundary Definition 1573.28 keeps uniformly continuous consumers on the same displayed route, while Definition 1573.20 excludes open-cover compactness, quotient completion, selected limit points, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, and ambient completeness as absent carrier coordinates. No further obligation row remains outside the packet. □

Theorem 1573.36 (TotallyBoundedCompletion scoped consumer coverage)**.** *Every completion-facing or uniform-extension consumer of an accepted* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *packet factors through the same finite rows*

$$X, T, N, F, E, C, S, U, H, P, L.$$

The rows are read as the source metric row X, the $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net rows T, N, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row F, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row E, the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route C, separated equality S, the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *consumer row U, componentwise transport H, provenance P, and local naming L. Thus the scoped surface covers finite-net completion, Cauchy-filter stability, completion embedding, constructive completion, separated equality, uniform continuous extension, transport, replay, provenance, and local* NameCert*; it exports no open-cover compactness, quotient completion, selected limit, countable-choice schedule, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionCarrier scoped consumer coverage`

Proof. Start with the obligation ledger and obligation-closure route, Definition 1573.34 and Definition 1573.35. They enumerate carrier admission, finite-net persistence, Cauchy-filter-basis generation, completion embedding, constructive completion, separated equality, and uniformly continuous extension handoff as rows of the same packet.

Apply the finite-net completion route and Cauchy-filter stability theorems, Definition 1573.33 and Definition 1573.32. These force every completion-facing read through T, N, F, E, C before a downstream completion or extension consumer can inspect the result.

Use the extension consumer boundary, Definition 1573.28, to place uniformly continuous extension reads after the same separated and constructive completion route. The rows S, U, H, P, L only compare, extend, transport, source, and name that route.

Finally apply the ledger non-escape theorem Definition 1573.20. Since the excluded completion principles have no coordinate in $X, T, N, F, E, C, S, U, H, P, L$, the displayed rows give the whole scoped consumer surface. □

Theorem 1573.37 (TotallyBoundedCompletion public finite-net route)**.** *Every public* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *consumer factors through the total-bounded input admission of Definition 1573.1, the finite-net and net-filter carrier admission of Definition 1573.8, the Cauchy-filter stability row of Definition 1573.32, the finite-net completion route of Definition 1573.33, the obligation ledger of Definition 1573.34, and the scoped consumer coverage of Definition 1573.36 before reading a completion result.*

Thus the public route is the displayed finite packet $K = (X, T, N, F, E, C, S, U, H, P, L)$: source metric row, total-bounded finite-net rows, net-refinement row, Cauchy-filter-basis row, completion-embedding row, constructive completion route, separated equality, uniform-extension consumer row, componentwise transport, provenance, and local NameCert*. It excludes open-cover compactness,*

hidden limit selection, quotient equality, countable choice, detached $\mathsf{Real}^{\uparrow}$ *completeness, and ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionPublicFiniteNetRoute`

Proof. Start with the carrier and finite-net admission rows. The carrier displays $X, T, N, F, E, C, S, U, H, P, L$, while the net handoff keeps every completion-facing read behind the finite centers, membership rows, distance witnesses, rational bounds, and refinement ledger.

Apply Cauchy-filter stability and the finite-net completion route. These theorems place the Cauchy-filter-basis row, completion-embedding row, and constructive completion route downstream of the same total-bounded finite-net data before any completion result can be consumed.

Finally use the obligation ledger and scoped consumer coverage. They exhaust the public-facing rows of the packet and keep separated equality, uniform extension, transport, provenance, and local naming attached to the displayed completion route, so no open-cover compactness, hidden limit selection, quotient equality, choice schedule, detached Real completeness, or ambient completeness row is available. □

Scope closed: Definition 1573.1, Definition 1573.2, Definition 1573.34, Definition 1573.35, and Definition 1573.36 bind every completion-facing and uniform-extension consumer to the finite rows $X, T, N, F, E, C, S, U, H, P, L$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.TotallyBoundedCompletionUp.TotallyBoundedCompletionPublicFiniteNetRoute`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient completion, selected limit points, countable choice, full $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: The next paper step is a bridge route over the same finite-net completion surface.

Constructive story: A $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ packet is generated from a metric source, a total-bounded finite-net ledger, a net-refinement row, a CauchyFilterBasis row, a CompletionEmbedding row, a ConstructiveMetricCompletion route, separated completion equality, a UniformContinuousExtension handoff, componentwise transport, provenance, and a local NameCert row.

Chapter 1574

A Concrete Naming Certificate for $\mathsf{PrincipalCauchyFilter}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ packet names the finite point-generated Cauchy-filter boundary used by Phase Real and Completion before a generic $\mathsf{CauchyFilter}^{\uparrow}$ surface is consumed. It starts from a displayed $\mathsf{RegSeqRat}^{\uparrow}$ point name, reads the finite observation windows of chapter 126, uses the dyadic tolerance rows of chapter 291, saturates into the finite filter surface of chapter 333, and leaves the downstream seal of chapter 38 behind that route. The packet is a point-generated filter certificate, not a quotient filter, not a selected limit, not host real equality, and not ambient completeness.

Definition 1574.1 (PrincipalCauchyFilter carrier)**.** *A* $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, S, R, D, G, F, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-name row whose observations generate the principal Cauchy filter.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the point-name row is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare observations at the requested filter scale.*
5. *G is the principal-generator row. For each displayed precision request it names the finite tail neighbourhood generated by X, S, R, D.*
6. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation row obtained from the generator row G by closing only the finite directed-refinement obligations recorded in the packet.*
7. *A is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row reached only after X, S, R, D, G, F have been consumed.*
8. *H records componentwise* hsame *transport for the point name, stream schedule, regular readback, dyadic tolerance ledger, generator row, saturated filter row, Real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a filter request back through the principal generator and then through the stream, regular rational, dyadic tolerance, and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrincipalCauchyFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable-choice selectors, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1574.2 (PrincipalCauchyFilter NameCert obligations)**.** *For every accepted* $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ *carrier $K = (X, S, R, D, G, F, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PrincipalCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the point-name row, stream schedule, regular rational readback, dyadic tolerance ledger, principal generator, saturated Cauchy filter, Real seal, transport, continuation, provenance, and local naming row;*
2. *point generation, requiring every displayed filter neighbourhood in G to be generated from the same X, S, R, D rows;*
3. *saturation discipline, requiring the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F to consume the finite generator row G before any completion-facing read can use a generic Cauchy-filter surface;*
4. *seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row A to remain downstream of X, S, R, D, G, F;*
5. *ledger refusal, excluding quotient filters, selected limits, countable-choice selectors, host real equality, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1574.1. The projection exposes exactly the point-name row, stream schedule, regular readback, dyadic tolerance ledger, principal generator, saturated filter row, Real seal, and structural rows H, C, P, N.

Point generation is forced by the row inventory. The generator row G has no independent source; each of its displayed neighbourhoods reads the same point observation through S, the same regular rational readback through R, and the same dyadic tolerance ledger through D.

Saturation discipline is then internal to F. A completion-facing consumer reaches the generic $\mathsf{CauchyFilter}^{\uparrow}$ surface only after G has been consumed, so the packet cannot exchange the principal generator for an arbitrary quotient filter.

Finally, the seal row A is downstream of the same route. Transport by H preserves each coordinate, while C, P, and N replay and name only that finite route; hence no selected limit, countable-choice selector, host real equality, or ambient completeness coordinate remains available. □

Theorem 1574.3 (PrincipalCauchyFilter RegSeqRat handoff)**.** *Let $K = (X, S, R, D, G, F, A, H, C, P, N)$ be an accepted* $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ *carrier. Every completion-facing read that starts from the regular rational point name factors through the finite route*

$$X, S, R, D \longmapsto G \longmapsto F \longmapsto A \longmapsto H, C, P, N.$$

Thus the $\mathsf{RegSeqRat}^{\uparrow}$ *row reaches the generic* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation surface only through the principal generator row, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal remains after that saturation handoff.*

Proof. Begin with a completion-facing consumer of the accepted packet. Carrier admission gives access to the saturated filter row F and the seal row A, but only as rows downstream of the point-name route X, S, R, D, G.

Replay the continuation row C. The request first reads the stream schedule S, then the regular rational readback R, then the dyadic tolerance ledger D attached to the same point-name row X.

Only after those rows have been consumed can the principal generator G be saturated into the $\mathsf{CauchyFilter}^{\uparrow}$ row F. The seal row A and the structural rows H, C, P, N record the same dependency order, which proves the stated factorization. □

Theorem 1574.4 (PrincipalCauchyFilter ledger non-escape)**.** *For every accepted* $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ *carrier* $K = (X, S, R, D, G, F, A, H, C, P, N)$*, every exported filter or Real-facing read remains inside the finite ledger*

$$X, S, R, D, G, F, A, H, C, P, N.$$

It cannot produce a quotient filter, a selected limit, a countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an exported read from the carrier. By Definition 1574.1, the read has access only to the eleven displayed coordinates and their componentwise transport and continuation rows.

Apply Definition 1574.2. Point generation keeps the read inside X, S, R, D, G; saturation discipline moves it through F; seal nonescape moves it through A; and the structural rows H, C, P, N record only the same route.

Every excluded principle is absent from this ledger. Quotient filters, selected limits, countable-choice selectors, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate, no replay edge, and no provenance row in the packet, so the exported read cannot leave the displayed finite surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrincipalCauchyFilter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrincipalCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1574.1, Definition 1574.2, Definition 1574.3, and Definition 1574.4 seed the finite point-generated Cauchy-filter boundary between regular rational names, generic Cauchy-filter evidence, and the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrincipalCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable-choice selectors, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires carrier admission, point generation, CauchyFilter saturation handoff, RegSeqRat readback, Real seal factorization, and ledger refusal for the same packet.

Constructive story: A $\mathsf{PrincipalCauchyFilter}^{\uparrow}$ packet is generated from a point-name row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a principal-generator row, a CauchyFilter saturation row, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1575

A Concrete Naming Certificate for $\mathsf{LocatedCauchyEmbedding}^{\uparrow}$

Bishop–Bridges constructive analysis reads a located Cauchy object through explicit approximation and location data before it is admitted to a completed real surface. The $\mathsf{LocatedCauchyEmbedding}^{\uparrow}$ packet binds the located Cauchy source of chapter 340 and the located real boundary of **??** to the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the completion handoff of chapter 1512 and chapter 1560, and the terminal real-name seal of chapter 38. It is a finite embedding route for located Cauchy data, not a quotient completion, a selected host limit, countable choice, host real equality, trichotomy, open-cover compactness, or an ambient completeness principle.

Definition 1575.1 (Located Cauchy embedding carrier)**.** *A* $\mathsf{LocatedCauchyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, S, R, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the located Cauchy source row, including the accepted approximation schedule, Cauchy modulus evidence, and locatedness witnesses that the embedding route may inspect.*
2. *S is a finite* $\mathsf{StreamName}^{\uparrow}$ *window over the source schedule, recording the precision requests and observation slots used by the embedding read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S, turning the displayed windows into regular rational observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that budgets the endpoint, radius, and comparison tolerances used by the located Cauchy source and the completion handoff.*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *or* $\mathsf{CompletionDensity}^{\uparrow}$ *handoff row by which the displayed source observations enter the completion-facing boundary.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. It accepts only the route already displayed through X, S, R, D, E.*
7. *H records componentwise* hsame *transport for the source row, stream window, readback row, dyadic ledger, embedding handoff, real seal, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a located Cauchy precision request through S, R, D, E, Q.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchy}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionDensity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyEmbedding}^{\uparrow}}$ *row naming the displayed embedding route and the permitted reads from it.*

The classifier on such packets is componentwise transport through H together with replay through C. No coordinate exports quotient completion, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or ambient Real completeness.

Theorem 1575.2 (Located Cauchy embedding NameCert obligations)**.** *For every accepted* LocatedCauchyEmbeddi *carrier $L = (X, S, R, D, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located Cauchy source, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, completion handoff, Real seal, transports, replay route, provenance, and local naming row;*
2. *located-source exactness, requiring every embedding read to start from X and to use only the approximation schedule, Cauchy modulus evidence, and locatedness witnesses displayed there;*
3. *window and readback compatibility, requiring the finite window S and the regular rational readback R to remain attached to the same source requests;*
4. *dyadic tolerance compatibility, requiring the tolerance row D to budget the located-source comparisons and the completion-facing handoff without introducing a host real comparison;*
5. *embedding handoff, requiring the row E to be the only passage from the located Cauchy source route into the completion-facing surface;*
6. *Real-seal non-escape, requiring the terminal row Q to read only the already displayed route X, S, R, D, E;*
7. *provenance exhaustion, requiring H, C, P, N to transport, replay, package, and name only these rows.*

No NameCert obligation is stored outside this displayed packet.

Proof. Carrier admission is projection from Definition 1575.1. The tuple displays the source row, finite window, regular rational readback, dyadic tolerance ledger, completion handoff, Real seal, transports, replay, provenance, and local name.

Located-source exactness is forced by the first coordinate. Any embedding read begins with X, so its approximation schedule, Cauchy modulus evidence, and locatedness witnesses are the only source-side data available.

Window and readback compatibility is projection from S and R. The stream window records the finite requests, and the regular rational row reads exactly those requests before any dyadic or completion-facing row can be inspected.

Dyadic tolerance compatibility and the embedding handoff are then read from D and E. The tolerance row budgets the displayed comparisons, while the handoff row is the unique passage from the source route into the completion boundary.

The Real seal and structural rows close the surface. The row Q is downstream of X, S, R, D, E, and H, C, P, N only transport, replay, package, and name that same route; hence every listed obligation is a row projection and no further obligation is stored outside the packet. □

Theorem 1575.3 (Located Cauchy embedding Real-seal handoff)**.** *Let* $L = (X, S, R, D, E, Q, H, C, P, N)$ *be an accepted* $\mathsf{LocatedCauchyEmbedding}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing read from the located Cauchy embedding factors through*

$$X, S, R, D, E, Q, H, C, P, N.$$

Consequently the read cannot use quotient completion, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or ambient Real completeness.

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing read. The carrier exposes the terminal Real seal only as the row Q, and that row is listed after the source route X, S, R, D, E in Definition 1575.1.

The source route is finite. The located Cauchy row X supplies the approximation and locatedness data, the window S fixes the finite requests, the readback R supplies regular rational observations, the tolerance ledger D budgets comparisons, and the handoff E is the only completion-facing passage.

Transport, replay, provenance, and local naming do not enlarge this route. The rows H, C, P, N preserve the same displayed coordinates under componentwise sameness, continuation replay, packaging, and NameCert naming.

None of the excluded principles has a coordinate, replay edge, or provenance row in the packet. The Real-facing read therefore factors through the displayed tuple and cannot import quotient completion, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyEmbedding}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1575.1, Definition 1575.2, and Definition 1575.3 seed the finite route from located Cauchy source data through StreamName, RegSeqRat, DyadicRatCore, CompletionEmbedding or CompletionDensity, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, located-source exactness, window and readback compatibility, dyadic tolerance compatibility, embedding handoff, Real-seal non-escape, and provenance exhaustion for BEDC.Derived.LocatedCauchyEmbeddingUp.

Constructive story: A $\mathsf{LocatedCauchyEmbedding}^{\uparrow}$ packet is generated from located Cauchy source data, a finite StreamName window, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CompletionEmbedding or CompletionDensity handoff, a Real seal boundary, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1576

A Concrete Naming Certificate for $\mathsf{RealCauchyModulusSelector}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ packet records the finite selection surface by which a displayed modulus schedule for a regular rational Cauchy name chooses the threshold, stream window, tolerance ledger, readback row, and seal route consumed by a downstream $\mathsf{Real}^{\uparrow}$ reader. It sits over the explicit Real Cauchy modulus packet of chapter 1423, the generic modulus schedule of chapter 292, the finite observation windows of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet makes the selector row visible as finite BEDC data before any consumer treats a selected threshold as part of a Real-facing read.

Definition 1576.1 (Real Cauchy modulus selector carrier)**.** *A* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, D, Q, E, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *row whose precision-indexed schedule is being inspected;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row named by the selected threshold;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row read at the selected window;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to that tolerance and window;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal route reached only after M, S, D, Q have been consumed;*
6. *R is the selector row choosing the displayed threshold, finite window, dyadic tolerance, regular readback, and seal route from the modulus schedule in M;*
7. *H records componentwise* hsame *transport for the modulus row, selected window, dyadic tolerance, regular readback, Real seal, selector row, continuation row, provenance row, and local naming row;*
8. *C records displayed* Cont *replay from a precision request through R and then through M, S, D, Q, E, H, P, N;*
9. *P is the* Pkg *provenance over* $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyModulusSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits outside the displayed row R, open-cover compactness, or an unbounded stream read.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorTasteGate single carrier alignment`

Theorem 1576.2 (Real Cauchy modulus selector NameCert obligations)**.** *For an accepted* RealCauchyModulusSelec *carrier $T = (M, S, D, Q, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyModulusSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Real Cauchy modulus row, finite stream window, dyadic tolerance ledger, regular rational readback, Real seal, selector row, transports, replay route, provenance, and local naming row;*
2. *selector exactness, requiring R to choose only the threshold, window, tolerance, readback, and seal route already displayed by M, S, D, Q, E;*
3. *modulus compatibility, requiring every selected threshold to be read from the accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *row and therefore from the upstream* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule;*
4. *finite-window stability, requiring the rows S, D, Q, E to remain attached to the selector row R under componentwise* hsame *transport H and displayed* Cont *replay C;*
5. *provenance exhaustion, requiring P and N to name only the displayed route and to export no Real completeness theorem, quotient stream equality, countable-choice selector, trichotomy, host real equality, selected limit outside R, open-cover compactness, or unbounded stream read.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1576.1. The tuple displays the modulus row, selected finite window, dyadic tolerance ledger, regular rational readback, Real seal, selector row, transport, replay, provenance, and local name.

Selector exactness is forced by the position of R in the tuple. A precision request reaches R as a row selecting from the displayed modulus route, and the selected data are precisely the threshold, window, tolerance, readback, and seal rows already exposed as M, S, D, Q, E.

Modulus compatibility follows by reading M as the accepted $\mathsf{RealCauchyModulus}^{\uparrow}$ row. Since the upstream Real Cauchy modulus packet is itself over the $\mathsf{CauchyModulus}^{\uparrow}$ schedule, the selector cannot draw a threshold from an independent stream or from an ambient host principle.

Stability is the role of H and C. Componentwise hsame transport preserves the selected rows, while continuation replay repeats the same finite route from the precision request through the selector and then through M, S, D, Q, E.

Finally, P and N package and name only the displayed rows. The carrier contains no coordinate for Real completeness, quotient stream equality, countable choice, trichotomy, host real equality, selected limits outside R, open-cover compactness, or unbounded stream reads, so the local NameCert surface cannot export any such data. □

Theorem 1576.3 (Real Cauchy modulus selector finite-window soundness)**.** *Let $T = (M, S, D, Q, E, R, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packet. For every finite unary precision request, the*

selector row R produces a finite Real-facing route

$$R \longmapsto M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N)$$

whose selected threshold, window, tolerance, readback, and seal row are all displayed in the carrier. The route cannot be replaced by Real completeness, quotient stream equality, countable choice, trichotomy, host real equality, a selected limit outside R, open-cover compactness, or an unbounded stream read.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier finite window soundness`

Proof. Proceed by induction on the finite unary precision request. In the zero stage, project the accepted carrier and read the selector row R. The selector exposes a displayed threshold in the modulus row M, the corresponding finite StreamName window S, the dyadic tolerance row D, the regular rational readback Q, and the terminal seal row E.

For the successor stage, assume the preceding precision request has been handled by the displayed route. The next request asks R for the next threshold in the same finite modulus schedule. The route may enlarge the selected window in S and refine the tolerance row in D, but it still reaches the regular readback row Q and terminal seal row E through the same carrier coordinates.

Transport and replay close the induction step. The componentwise row H preserves the selected coordinates, while C replays the selector route from the precision request through R, M, S, D, Q, E and then through P, N.

The exclusion clauses follow by inspecting the carrier. Since none of Real completeness, quotient stream equality, countable choice, trichotomy, host real equality, selected limits outside R, open-cover compactness, or unbounded stream reads appears as a coordinate of T, no induction stage can substitute such a principle for the finite selector route. □

Theorem 1576.4 (Real Cauchy modulus selector monotone window)**.** *Let $T = (M, S, D, Q, E, R, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packet. If the selector row R accepts a finite window at unary precision n, then every displayed larger unary precision window accepted by the same* $\mathsf{RealCauchyModulus}^{\uparrow}$ *row M is accepted after replay through the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. The replay may enlarge the observed prefix and refine the tolerance ledger, but it must still pass through S, D, Q, E, H, C, P, N and cannot use Real completeness, quotient stream equality, countable choice, host real equality, or an unbounded stream read.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier window monotone`

Proof. Project the finite-window route of Definition 1576.3. Acceptance at precision n exposes the selected threshold in M, the finite StreamName window S, the dyadic tolerance row D, the regular rational readback Q, and the terminal Real seal E.

Now inspect a displayed larger unary precision request. Because the request is read through the same $\mathsf{RealCauchyModulus}^{\uparrow}$ row M, its threshold is a later entry of the same finite modulus schedule rather than an independent selector. The StreamName window may be longer and the dyadic tolerance may be sharper, but both remain rows of the displayed S, D, Q, E route.

Monotone reuse is therefore a finite-window projection. The earlier accepted prefix remains visible inside the larger displayed window, and the tolerance ledger is replayed by C through R, M, S, D, Q, E before provenance and local naming are read through P, N.

Finally H transports the same coordinates componentwise. Since the carrier has no coordinate for Real completeness, quotient stream equality, countable choice, host real equality, or unbounded

stream reads, no larger-window acceptance can be supplied by anything outside the displayed selector packet. □

Theorem 1576.5 (Real Cauchy modulus selector seal factorization)**.** *Let* $T = (M, S, D, Q, E, R, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packet. Every accepted selector route reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through*

$$R \longmapsto M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The route cannot factor through Real completeness, quotient stream equality, countable choice, host equality, or an unbounded stream read before the $\mathsf{Real}^{\uparrow}$ *seal is named.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier seal factorization`

Proof. Use finite-window soundness, Definition 1576.3. A finite precision request first reads the selector row R, then the accepted modulus row M, the selected stream window S, the dyadic tolerance row D, the regular rational readback row Q, and the terminal seal row E.

Use monotone-window reuse, Definition 1576.4. Larger precision requests may enlarge the displayed window and refine the tolerance ledger, but they replay the same R, M, S, D, Q, E route before H, C, P, N package and name the packet.

The exclusion clause follows by projection of Definition 1576.1. None of Real completeness, quotient stream equality, countable choice, host equality, or unbounded stream reads is a carrier coordinate, so none can be an intermediate factor in the accepted seal route. □

Theorem 1576.6 (Real Cauchy modulus selector transport naturality)**.** *Let* $T = (M, S, D, Q, E, R, H, C, P, N)$ *and* $T' = (M', S', D', Q', E', R', H', C', P', N')$ *be accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packets. Suppose the displayed transport row* H *relates the coordinates componentwise:*

$$M\mathsf{hsame}M', \quad S\mathsf{hsame}S', \quad D\mathsf{hsame}D', \quad Q\mathsf{hsame}Q', \quad E\mathsf{hsame}E', \quad R\mathsf{hsame}R', \quad C\mathsf{hsame}C', \quad P\mathsf{hsame}P', \quad N\mathsf{hs}$$

Then every selected finite precision route

$$R \longmapsto M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$$

in T *is transported to the corresponding route*

$$R' \longmapsto M' \longmapsto S' \longmapsto D' \longmapsto Q' \longmapsto E'$$

in T' *with the same excluded readings: no Real completeness, quotient stream equality, countable choice, host equality, selected limit outside the selector row, or unbounded stream read is introduced.*

Proof. Project both accepted carriers using Definition 1576.1. The selected route in T is a displayed route through the selector row, modulus row, finite StreamName window, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Apply finite-window soundness, Definition 1576.3, to the route in T. It identifies R, M, S, D, Q, E as the only selected coordinates visible to the precision request. Use monotone-window reuse, Definition 1576.4, when the transported route is read at a larger displayed precision.

Now use the componentwise H row. It transports the selector, threshold source, window, tolerance, readback, seal, replay, provenance, and local name coordinates to $R', M', S', D', Q', E', C', P', N'$. The transported route is therefore the same finite selector route in T', read through corresponding displayed rows rather than through a new carrier.

Finally apply seal factorization, Definition 1576.5. Since neither carrier has a coordinate for Real completeness, quotient stream equality, countable choice, host equality, selected limits outside the selector row, or unbounded stream reads, componentwise transport cannot introduce any of those readings. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier selector transport naturality`

Theorem 1576.7 (Real Cauchy modulus selector tail bound)**.** *Let $T = (M, S, D, Q, E, R, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packet. A selected unary precision request bounds the displayed StreamName window before the terminal seal row E is read: the selector must pass through the modulus row M, the finite window row S, the dyadic tolerance row D, and the regular rational readback row Q before any Real-facing seal consumer can inspect E. The bound is therefore a finite tail-bound row over M, S, D, Q, H, C, P, N, not a completeness principle, quotient stream equality, countable-choice selector, host real equality, or unbounded stream read.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier tail bound`

Proof. Start with finite-window soundness, Definition 1576.3. A unary precision request first exposes the selected threshold in M, the StreamName window S, the dyadic tolerance row D, and the regular rational readback row Q.

Use monotone-window reuse, Definition 1576.4. Larger displayed precision requests may enlarge the observed prefix and refine the tolerance ledger, but they still replay the same M, S, D, Q route before reaching the terminal Real seal.

Finally apply seal factorization, Definition 1576.5. The seal row E is downstream of the selector route, so a Real-facing consumer cannot inspect it until the finite tail-bound data have already been displayed through H, C, P, N. □

Theorem 1576.8 (Real Cauchy modulus selector Real-seal route)**.** *Every Real-facing seal read exported by an accepted* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *packet factors through*

$$\mathsf{RealCauchyModulus}^{\uparrow}, \mathsf{CauchyModulus}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCe}$$

The selector contributes only the finite route from a displayed precision request to a StreamName window, dyadic tolerance ledger, regular rational readback, and terminal Real seal. It does not export Real completeness, quotient stream equality, countable choice, trichotomy, host real equality, selected limits outside R, open-cover compactness, or unbounded stream reads.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusSelectorUp.RealCauchyModulusSelectorCarrier real seal route`

Proof. Apply the NameCert obligations of Definition 1576.2. They force every accepted packet to display the Real Cauchy modulus row, selected StreamName window, dyadic tolerance ledger, regular rational readback, selector row, transport, replay, provenance, and local naming.

Apply the tail-bound theorem, Definition 1576.7. It places the StreamName window, dyadic tolerance, and regular rational readback before the terminal Real seal in every selected precision route.

Use seal factorization, Definition 1576.5. The Real-facing seal is therefore reached only after the upstream $\mathsf{RealCauchyModulus}^{\uparrow}$ and $\mathsf{CauchyModulus}^{\uparrow}$ schedule has been read through M, and after the S, D, Q, H, C, P, N structural rows have preserved the selected finite window.

The exclusions are exactly the non-coordinates of Definition 1576.1. Since the carrier contains none of the listed ambient principles, the Real-seal route remains the displayed finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyModulusSelector}\uparrow}$.

Constructive story: A $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ packet is generated from an accepted $\mathsf{RealCauchyModulus}^{\uparrow}$ modulus row, a selected $\mathsf{StreamName}^{\uparrow}$ finite window, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, a selector row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyModulusSelector}\uparrow}, \mathsf{scopedClosed})$

Scope closed: Definition 1576.1, Definition 1576.2, Definition 1576.3, Definition 1576.4, Definition 1576.5, Definition 1576.6, Definition 1576.7, and Definition 1576.8 bind the finite selector route from Real Cauchy modulus schedules to Real-facing seal reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyModulusSelector}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, countable choice, trichotomy, host real equality, selected limits outside the displayed selector row, open-cover compactness, Lean verification, or a public standard bridge.

Upgrade path: Scoped closure requires checked carrier admission, selector exactness, modulus compatibility, finite-window stability, finite unary precision induction, and provenance exhaustion for BEDC.Derived.RealCauchyModulusSelectorUp.

Chapter 1577

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ packet records the finite route by which an explicit Cauchy modulus schedule becomes a regular rational real-name surface before any $\mathsf{Real}^{\uparrow}$ seal is read. It sits after the explicit rate rows of chapter 292, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the modulus-to-real boundary of chapter 1423. The packet is a finite NameCert realization of a displayed modulus schedule; it is not a quotient stream, not host real equality, not countable choice, not a selected limit, and not an ambient completeness principle.

Definition 1577.1 (Regular Cauchy modulus realization carrier)**.** *A* $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, carrying the precision request, the displayed threshold, and the finite late-pair budget consumed by the realization.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the stream entries inspected after the threshold row of M has been read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row containing the dyadic radius and comparison cells used for the requested precision.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained by routing the windows in S through the dyadic tolerance ledger D under the schedule exposed by M.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, D, Q have been replayed.*
6. *H records componentwise* hsame *transport for the modulus, window, dyadic tolerance, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through the modulus threshold, finite stream windows, dyadic tolerance rows, regular rational readback, and then the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealization}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient streams, host real equality, countable-choice selection, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 1577.2 (Regular Cauchy modulus realization window coverage)**.** *Let $R = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ *carrier. Every precision request admitted by M reads through a finite window containing the displayed modulus threshold, the corresponding* $\mathsf{StreamName}^{\uparrow}$ *observations in S, and the dyadic tolerance rows in D. No precision request can reach Q or E without first consuming that finite window.*

Proof. Project the carrier of Definition 1577.1. The projection exposes the modulus row M, the window row S, the dyadic tolerance row D, and the downstream rows Q, E, H, C, P, N.

Replay the continuation row C at the chosen precision request. Its first visible dependency is the threshold row carried by M; after that threshold is read, the same route names the finite observations in S and the dyadic cells in D.

The rows Q and E occur downstream of that replay. Since the carrier has no second route to a regular readback or Real seal, each accepted precision request is covered by the displayed finite window and tolerance ledger. □

Theorem 1577.3 (Regular Cauchy modulus realization RegSeqRat handoff)**.** *Let $R = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ *carrier. The same rows that cover each precision request repack as the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q: the modulus row M supplies the late-window budget, the stream row S supplies the inspected entries, and the dyadic row D supplies the tolerance comparisons. Thus Q is a readback of the displayed finite route, not a separate regular-sequence oracle.*

Proof. Use Definition 1577.2. For the chosen precision request, the finite route has already displayed the modulus threshold, the StreamName observations, and the dyadic tolerance rows.

The regular readback row Q is listed in the carrier only after M, S, D. Repacking therefore uses exactly those rows: M contributes the late-window budget, S contributes the inspected entries, and D contributes the dyadic comparisons that certify the requested tolerance.

Transport by H preserves this row order, while P and N name only the same finite route. Hence Q cannot be read as an independent regular-sequence oracle. □

Theorem 1577.4 (Regular Cauchy modulus realization Real seal nonescape)**.** *Let $R = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the finite route*

$$M, S, D, Q \longmapsto E \longmapsto H, C, P, N.$$

The route rules out quotient streams, host real equality, countable choice, selected limits, and ambient completeness: none of those objects is a row of the carrier, and none can be reconstructed from the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealization}^{\uparrow}}$ *surface.*

Proof. Begin with a Real-facing consumer of the packet. Carrier admission gives access to the seal row E, but only as a row downstream of the modulus, window, dyadic tolerance, and regular readback rows.

Replay the continuation row C. The consumer first reads the explicit schedule in M, then the finite windows in S, the dyadic tolerance cells in D, and the regular rational readback in Q.

Only after this route has been consumed can the seal row E be read. The structural rows H, C, P, N record the same dependency order, so there is no carrier coordinate from which to read quotient streams, host real equality, countable choice, selected limits, or ambient completeness. □

Theorem 1577.5 (Regular Cauchy modulus realization NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ *carrier* $R = (M, S, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMod}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the explicit Cauchy modulus row, finite stream-window row, dyadic tolerance ledger, regular rational readback, Real seal, transport, continuation, provenance, and local naming row;*
2. *window coverage, requiring each precision request to consume the displayed threshold in* M*, the inspected windows in* S*, and the tolerance cells in* D *before reading* Q *or* E*;*
3. *RegSeqRat handoff, requiring the rows* M, S, D *to repack as the regular rational readback* Q*;*
4. *Real seal nonescape, requiring the seal row* E *to remain downstream of* M, S, D, Q*;*
5. *ledger refusal, excluding quotient streams, host real equality, countable choice, selected limits, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1577.1. The projection exposes exactly the explicit modulus row, finite window row, dyadic tolerance row, regular rational readback row, Real seal, and structural rows H, C, P, N.

Window coverage is Definition 1577.2. It forces every precision request to pass through the displayed modulus threshold, StreamName observations, and dyadic tolerance cells before any readback or seal is available.

The RegSeqRat handoff is Definition 1577.3. It identifies the row Q as a repacking of the same finite route, not as an independent regular-sequence oracle.

The seal refusal clause is Definition 1577.4. Since quotient streams, host real equality, countable choice, selected limits, and ambient completeness are not carrier rows, no additional NameCert obligation can name them. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealization}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1577.1, Definition 1577.2, Definition 1577.3, Definition 1577.4, and Definition 1577.5 seed the finite route from an explicit $\mathsf{CauchyModulus}^{\uparrow}$ schedule through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the downstream $\mathsf{Real}^{\uparrow}$ seal, with $\mathsf{RealCauchyModulus}^{\uparrow}$ as the sibling real-modulus boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, host real equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, window coverage, RegSeqRat handoff, Real seal nonescape, and ledger refusal proofs for the same packet.

Constructive story: A $\mathsf{RegularCauchyModulusRealization}^{\uparrow}$ packet is generated from an explicit CauchyModulus schedule, StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1578

A Concrete Naming Certificate for $\mathsf{RegularCauchyShift}^{\uparrow}$

Following Bishop and Bridges-style regular Cauchy sequence tail invariance, the $\mathsf{RegularCauchyShift}^{\uparrow}$ packet records the finite route by which a regular rational Cauchy name may discard a displayed finite prefix without leaving the visible regularity, tolerance, and real-seal surface. It sits over the finite schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the Cauchy-name space of chapter 406. The packet is a NameCert for tail-shift invariance of regular Cauchy names, not a quotient of streams, not a selected host limit, not countable choice, and not ambient completeness.

Definition 1578.1 (Regular Cauchy shift carrier)**.** *A* $\mathsf{RegularCauchyShift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, S, D, k, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose regular rational Cauchy readback supplies the inspected values and the regularity budget.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row whose shifted window request sends the displayed index n to the source index $n + k$.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to preserve the same dyadic error budget after the source window has been shifted.*
4. *k is the unary shift witness, displayed as a finite prefix length and carrying no unbounded selector.*
5. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal route reached only after Q, S, D, k have been consumed.*
6. *H records componentwise* hsame *transport for the source regular sequence row, schedule row, dyadic ledger, unary shift witness, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a shifted finite-window request through k, then through S, Q, D, and finally to the seal row E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, host sequence equality, countable-choice tail selection, or ambient completeness.

Theorem 1578.2 (Regular Cauchy shift NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyShift}^{\uparrow}$ *carrier* $K = (Q, S, D, k, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, unary shift witness,* $\mathsf{Real}^{\uparrow}$ *seal route, transport, continuation, provenance, and local naming row;*
2. *finite-window shift stability, requiring every shifted request to replay through the displayed unary shift witness before it can inspect the source schedule;*
3. *dyadic tolerance preservation, requiring the tolerance ledger* D *to be read after the shifted source window and before any regularity or seal handoff is exported;*
4. *RegSeqRat handoff, requiring the shifted finite windows to remain attached to the same displayed regular rational Cauchy row* Q*;*
5. *RealUp seal routing, requiring every downstream seal read to pass through* Q, S, D, k *before it reaches* E*;*
6. *ledger refusal, excluding quotient streams, selected limits, host sequence equality, countable-choice tail selectors, and ambient completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyShiftUp.RegularCauchyShiftTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1578.1. The projection exposes exactly the source regular sequence row, schedule row, dyadic tolerance ledger, unary shift witness, Real seal route, and structural rows H, C, P, N.

Replay the continuation row C at a shifted finite-window request. The request first consumes the unary witness k, then reads the source schedule S at the translated window and consults the regular rational row Q at that displayed source position.

The dyadic row D is downstream of the shifted window route, so the same tolerance budget is preserved before the RegSeqRat handoff or the Real seal can be inspected. Since the seal row E is downstream of Q, S, D, k, every Real-facing obligation is routed through those finite rows.

The listed rows exhaust the carrier. The excluded quotient streams, selected limits, host sequence equality, countable-choice tail selectors, and ambient completeness principles therefore have no coordinate from which a local $\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}$ obligation could be read. □

Theorem 1578.3 (Regular Cauchy shift real-seal non-escape)**.** *Let* $K = (Q, S, D, k, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyShift}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer read and every CauchySequenceSpace-facing consumer read factors through the displayed shifted finite-window route*

$$Q, S, k, D \longmapsto E \longmapsto H, C, P, N.$$

The packet exports no quotient stream, selected limit, host sequence equality, countable-choice tail selector, or ambient completeness principle.

Proof. Begin with a consumer read of the shifted regular Cauchy name. Carrier admission gives the downstream row E and the structural rows H, C, P, N, but only with the source regularity row Q, schedule row S, unary shift witness k, and dyadic ledger D already present.

Replay C. A consumer request first passes through the finite shift witness k, then consults the schedule row S at the translated source window. The readback row Q supplies the regular rational Cauchy observation for that window, and D supplies the dyadic tolerance ledger attached to the same read.

Only after those rows have been consumed can the request reach the $\mathsf{Real}^{\uparrow}$ seal route or the CauchySequenceSpace-facing handoff. Transport by H preserves the same row order, while P and N package only that finite route; hence the packet has no export path for quotient streams, selected limits, host sequence equality, countable-choice tail selection, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyShift}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName shifted schedule, DyadicRatCore tolerance ledger, unary shift witness, RealUp seal route, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1578.1, Definition 1578.2, and Definition 1578.3 seed the finite tail-shift route from $\mathsf{RegSeqRat}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyShift}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host sequence equality, countable-choice tail selection, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-window shift stability, dyadic tolerance preservation, RegSeqRat handoff, RealUp seal routing, and ledger refusal for the same packet.

Chapter 1579

A Concrete Naming Certificate for $\mathsf{LimitPoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LimitPoint}^{\uparrow}$ packet records a constructive cluster-point and accumulation-point surface for real sequences by finite neighborhoods and cofinal subsequence windows. It reads finite windows from chapter 126, dyadic neighborhood radii from chapter 291, regular rational readback from chapter 301, the terminal real-name seal of chapter 38, the bounded source surface of chapter 1415, and the subsequence compactness route of chapter 1254. The packet gives downstream compactness arguments a BEDC-native cluster-point interface; it is not host completeness, quotient equality of streams, open-cover compactness, or a choice-selected subsequence.

Definition 1579.1 (LimitPoint carrier)**.** *A* $\mathsf{LimitPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, D, Q, \Phi, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real sequence row, including the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source data when the packet is supplied from a bounded sequence and the sequence observations consumed by cluster-point readers.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the source windows and the selected cofinal windows inspected at the displayed precision requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *neighborhood-radius row containing the positive dyadic radii, comparison cells, and finite inclusion tests used to read a neighborhood of the proposed cluster point.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and dyadic radius ledger before any real seal is exposed.*
5. *Φ is the cofinal subsequence witness row. It stores only the inspected monotone selector cells, later-index comparisons, and cofinal threshold witnesses needed by the finite windows in W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *cluster seal row reached only after S, W, D, Q, Φ have been replayed.*
7. *H records componentwise* hsame *transport for the source sequence, StreamName windows, DyadicRatCore radii, RegSeqRat readback, cofinal subsequence witness, Real cluster seal, continuation row, provenance, and local naming row.*

8. *C records displayed* Cont *replay from a neighborhood request through the source sequence, finite windows, dyadic radius ledger, cofinal subsequence witness, regular rational readback, and then the Real cluster seal.*

9. *P is the* Pkg *provenance over* $\mathsf{LimitPoint}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LimitPoint}^{\uparrow}}$ *row naming the displayed packet and its permitted consumer reads.*

The classifier compares accepted packets only through these rows and their transported replay paths. It has no coordinate for host real completeness, quotient streams, open covers, arbitrary choice of subsequences, or a least cluster-point selector.

Theorem 1579.2 (LimitPoint NameCert obligations)**.** *For every accepted* $\mathsf{LimitPoint}^{\uparrow}$ *carrier* $L = (S, W, D, Q, \Phi, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LimitPoint}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source real sequence, finite StreamName windows, DyadicRatCore neighborhood radii, RegSeqRat readback, cofinal subsequence witness, Real cluster seal, transport, continuation replay, provenance, and local naming row;*

2. *neighborhood coverage, requiring every cluster-point request to consume a displayed dyadic radius in D and a finite selected window in W before it reads the regular rational row Q;*

3. *cofinal-window persistence, requiring the selected windows in W to travel through the cofinal witness row Φ with displayed monotone and later-index evidence;*

4. *Real seal routing, requiring the cluster seal row E to be reached only after S, W, D, Φ, Q have been displayed;*

5. *ledger non-escape, excluding host completeness, quotient stream equality, open-cover compactness, arbitrary choice-selected subsequences, and least cluster-point selection.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1579.1. The projection exposes exactly the source sequence, finite window, dyadic radius, regular readback, cofinal witness, Real seal, transport, continuation, provenance, and local naming rows.

The neighborhood coverage row is read through W and D. A cluster-point request first fixes the inspected finite source and selected windows, then reads the positive dyadic radius and comparison cells attached to that request, and only then reaches the regular rational row Q.

The cofinal-window row Φ controls the selected windows. It supplies the inspected monotone selector cells, later-index comparisons, and cofinal threshold witnesses, so the selected windows cannot be replaced by an arbitrary host subsequence.

Finally, the seal row E sits downstream of S, W, D, Φ, Q, while H, C, P, N preserve and name the same route. Since none of these rows carries host completeness, quotient stream equality, open-cover compactness, arbitrary choice of subsequences, or a least cluster-point selector, the five listed obligations exhaust the local NameCert surface. □

Theorem 1579.3 (LimitPoint Bolzano–Weierstrass handoff)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *cluster consumer supplied by a* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source and the regular-subsequence route of chapter 381 factors through an accepted* $\mathsf{LimitPoint}^{\uparrow}$ *packet. In the notation of Definition 1579.1, the*

consumer reads the finite route

$$S, W, D, \Phi \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the Bolzano–Weierstrass cluster row can be consumed as a LimitPoint surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *without importing host completeness, quotient streams, open-cover compactness, or a choice-selected subsequence.*

Proof. Start with the bounded source row. The $\mathsf{BoundedRealSequence}^{\uparrow}$ packet of chapter 1415 supplies the source sequence surface consumed by the $\mathsf{BolzanoWeierstrass}^{\uparrow}$ carrier.

Use the Bolzano–Weierstrass route of chapter 1254. Its cluster consumer first reads finite interval and sequence data, then passes through the regular-subsequence route, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ cluster seal.

Repack that same downstream surface as S, W, D, Φ, Q, E. The source sequence becomes S, the inspected source and selected windows become W, the neighborhood mesh radii become D, the regular-subsequence evidence becomes Φ, the regular rational handoff becomes Q, and the real cluster row becomes E.

The structural rows H, C, P, N then transport, replay, source, and name this finite route as a $\mathsf{LimitPoint}^{\uparrow}$ packet. Since the original Bolzano–Weierstrass consumer exposes no host completeness, quotient stream equality, open-cover compactness, or arbitrary subsequence choice, the factored LimitPoint packet exposes none. □

Closure status for $\mathsf{NameCert}_{\mathsf{LimitPoint}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LimitPoint}^{\uparrow}}$, seed)

Scope closed: Definition 1579.1, Definition 1579.2, and Definition 1579.3 seed the finite cluster-point interface from real-sequence windows through cofinal subsequence evidence, dyadic neighborhoods, regular rational readback, and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LimitPoint}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host completeness, quotient stream equality, open-cover compactness, arbitrary choice-selected subsequences, or least cluster-point selection.

Upgrade path: Obligation closure requires checked carrier admission, neighborhood coverage, cofinal-window persistence, Real seal routing, ledger non-escape, and Bolzano–Weierstrass handoff for the same packet.

Constructive story: A $\mathsf{LimitPoint}^{\uparrow}$ packet is generated from a source real sequence, finite StreamName windows, DyadicRatCore neighborhood radii, RegSeqRat readback, a cofinal subsequence witness, a RealUp cluster seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1580

A Concrete Naming Certificate for $\mathsf{RealSequenceClusterPoint}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ packet records the finite carrier surface for a cluster point of a real sequence between the displayed limit interface of chapter 1413 and the bounded-subsequence extraction route of chapter 1254. It receives its sequence source from chapter 1415, its cofinal subsequence route from chapter 381, and its downstream compactness consumer from chapter 1254. The packet displays a local cluster seal without importing host subsequence choice, quotient equality of streams, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1580.1 (Real sequence cluster point carrier)**.** *A* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, J, W, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-sequence row, read only through the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *surface when a bounded source is required.*
2. *J is the cofinal subsequence row, carrying the monotone index schedule and tail-access route supplied by the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *packet.*
3. *W is the finite family of selected* $\mathsf{StreamName}^{\uparrow}$ *windows for the source entries named by J and for the proposed cluster real.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those selected windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the inspected cluster comparisons.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *cluster seal reached after the selected windows, regular readbacks, and dyadic tolerance rows have been displayed.*
7. *H stores componentwise* hsame *transport for the source sequence, cofinal subsequence route, selected windows, regular readbacks, tolerance ledger, cluster seal, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *routes from source indices to selected windows, from selected windows to regular readback, from regular readback to the dyadic tolerance ledger, and from the ledger to the* $\mathsf{Real}^{\uparrow}$ *cluster seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RealSequenceClusterPoint}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, J, W, Q, D, R, H, C, P, N$. It has no coordinate for host subsequence choice, quotient-stream equality, full sequence convergence, compactness of arbitrary covers, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1580.2 (Real sequence cluster point NameCert obligations)**.** *For every accepted* RealSequenceClusterPoin *carrier $K = (S, J, W, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealSequenceClusterPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, source-sequence access through S, cofinal subsequence access through J, selected* $\mathsf{StreamName}^{\uparrow}$ *window coverage through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, dyadic cluster tolerance accounting through D, the* $\mathsf{Real}^{\uparrow}$ *cluster seal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RealSequenceClusterPointUp.RealSequenceClusterPointTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1580.1. The only sequence data available to the classifier are the source row S, the cofinal subsequence row J, the selected stream windows W, the regular rational readback Q, and the tolerance ledger D.

The cluster seal is then read through R. This places the proposed cluster point behind the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows rather than behind a host convergence predicate.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no other coordinate is present, the listed obligations exhaust the local NameCert surface. □

Theorem 1580.3 (Real sequence cluster point subsequence handoff)**.** *Every accepted* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *carrier factors its cluster-point read through the finite route*

$$S \longmapsto J \longmapsto W \longmapsto Q \longmapsto D \longmapsto R$$

together with H, C, P, N. Consequently a consumer may pass from the displayed sequence-limit surface of chapter 1413 to the cofinal subsequence route of chapter 381 without importing host subsequence choice or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealSequenceClusterPointUp.RealSequenceClusterPointSubsequence handoff`

Proof. Start with the source sequence row S. The cofinal row J restricts attention to the displayed subsequence indices supplied by the regular Cauchy subsequence route.

Next read the selected windows W and their regular rational readback Q. The dyadic ledger D records only the inspected cluster comparisons for those windows, so the route remains finite at every observation level.

Finally consume the real cluster seal R and the structural rows H, C, P, N. The handoff therefore uses the subsequence certificate as a displayed carrier row and exports no host-level selector or completeness principle. □

Theorem 1580.4 (Real sequence cluster point public export)**.** *The* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer of chapter 1254 may read a cluster candidate from an accepted* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *carrier only through the bounded source row of chapter 1415, the cofinal subsequence row of chapter 381, and the displayed route*

$$W, Q, D, R, H, C, P, N.$$

Thus the exported surface supplies a local cluster-point certificate for the real-and-completion boundary while leaving host subsequence choice, quotient-stream equality, open-cover compactness, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ *completeness outside the packet.*

Proof. Use Definition 1580.3. It places every cluster read on the route from the source sequence through the cofinal subsequence row, selected windows, readback, dyadic ledger, and real cluster seal.

The bounded source row is read through chapter 1415. The downstream $\mathsf{BolzanoWeierstrass}^{\uparrow}$ carrier can therefore consume a bounded sequence source, a cofinal subsequence surface, and a cluster seal without receiving an independent compactness or choice coordinate.

The remaining rows H, C, P, N preserve and name the displayed route. Since the carrier has no coordinate for host subsequence choice, quotient-stream equality, open-cover compactness, trichotomy, or ambient real completeness, none of those principles is part of the public export. □

Theorem 1580.5 (Real sequence cluster point window localization)**.** *Every accepted* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *packet exposes its cluster seal only through the bounded source row, the regular Cauchy subsequence route, and the displayed real sequence limit surface. For*

$$K = (S, J, W, Q, D, R, H, C, P, N),$$

each cluster read factors through

$$S \longmapsto J \longmapsto W, Q, D \longmapsto R \longmapsto H, C, P, N$$

where S *is read through* $\mathsf{BoundedRealSequence}^{\uparrow}$*,* J *is read through* $\mathsf{RegularCauchySubsequence}^{\uparrow}$*, and* R *is the displayed* $\mathsf{Real}^{\uparrow}$ *cluster seal. The exposed surface gives no ambient compactness theorem, no host subsequence choice, and no independent* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Unpack the carrier rows $S, J, W, Q, D, R, H, C, P, N$ from Definition 1580.1. The bounded source is available only as the displayed source row S, and when boundedness is required that row is read through chapter 1415.

Use the subsequence handoff of Definition 1580.3. It routes the cluster read through the cofinal subsequence row J, the selected windows W, the regular readback row Q, and the dyadic tolerance ledger D before the real cluster seal R is visible.

Now apply the public export of Definition 1580.4. The export gives a Bolzano–Weierstrass consumer only the bounded source row, cofinal subsequence surface, selected windows, readback, tolerance ledger, cluster seal, and structural rows, so no ambient compactness, host subsequence selector, or independent real-completeness coordinate is delivered. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ cluster-candidate read factors through a RealSequenceClusterPo route displaying a bounded source row, cofinal subsequence row, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp cluster seal, transport, continuation, provenance, and local naming.

Independence witness: real-sequence-limit, regularcauchysubsequence, boundedrealsequence, bolzanoweierstrass: $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source sequence access, cofinal subsequence access, selected windows, regular readback, tolerance accounting, cluster sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequenceClusterPoint}^{\uparrow}}$.

Constructive story: A RealSequenceClusterPoint$^{\uparrow}$ packet is generated from a source real-sequence row, a cofinal subsequence row, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp cluster seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealSequenceClusterPoint}\uparrow}$, seed)

Scope closed: Definition 1580.1, Definition 1580.2, Definition 1580.3, and Definition 1580.4 bind the finite cluster-point certificate surface between displayed sequence limits and Bolzano-Weierstrass.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealSequenceClusterPoint}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host subsequence choice, quotient equality of streams, open-cover compactness, trichotomy, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, subsequence handoff, public export, and TasteGate field faithfulness for BEDC.Derived.RealSequenceClusterPointUp.

Chapter 1581

A Concrete Naming Certificate for $\mathsf{RealSeries}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealSeries}^{\uparrow}$ packet records the finite partial-sum and Cauchy-tail surface for a real-valued term stream. It sits after the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the displayed limit interface of chapter 1413, the bounded Cauchy schedule of chapter 1522, the regular rational rows of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names a series only through displayed finite sums and a shared tail threshold; it does not import host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1581.1 (Real series carrier)**.** *A* $\mathsf{RealSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, W, Q, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the real-valued term stream, read only through selected* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows for the displayed terms.*
2. *S is the partial-sum window row, listing the finite initial indices, their accumulated* $\mathsf{Real}^{\uparrow}$ *sum seals, and the adjacent difference reads induced by T.*
3. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows used for the terms and for the displayed partial sums.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every selected term and partial-sum window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records finite addition errors, comparison radii, and tail-request tolerances.*
6. *M is the shared Cauchy-tail threshold row: one displayed threshold governs every partial-sum comparison requested by the packet.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after the term windows, partial-sum windows, regular readbacks, dyadic ledger, and shared tail threshold have been displayed.*
8. *H stores componentwise* hsame *transport for the term stream, partial-sum window, selected stream windows, regular readbacks, dyadic ledger, tail threshold, endpoint seal, continuation, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from term reads to partial sums, from partial sums to regular readback, from readback to the dyadic ledger, from the ledger to the shared tail threshold, and from that threshold to the endpoint seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, W, Q, D, M, E, H, C, P, N$. It has no coordinate for a host infinite sum, selected sequence limit, quotient equality of real streams, countable-choice selector, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Definition 1581.2 (RealSeries term carrier surface)**.** *The root term carrier surface of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is the displayed finite route*

$$T, S, W, Q$$

from Definition 1581.1: T is the real-valued term stream, S is the finite partial-sum ledger, W is the selected $\mathsf{StreamName}^{\uparrow}$ *window family, and Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed term and partial-sum windows. This surface carries only named term observations and regular rational readback; it does not assert convergence outside the displayed Cauchy criterion rows.*

Theorem 1581.3 (Real series NameCert obligations)**.** *For every accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier $K = (T, S, W, Q, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, term-stream access through T, partial-sum window coverage through S, selected* $\mathsf{StreamName}^{\uparrow}$ *windows through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, dyadic tolerance accounting through D, shared Cauchy-tail thresholding through M,* $\mathsf{Real}^{\uparrow}$ *endpoint sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesUpTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1581.1. The only term data available to the classifier are the stream row T, the partial-sum window row S, the selected stream windows W, the regular rational readback Q, the dyadic ledger D, and the shared tail threshold M.

The endpoint seal is then read through E. This places every real-facing consumer behind the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and tail-threshold rows rather than behind an external infinite-sum predicate.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no other coordinate is present, the listed obligations exhaust the local NameCert surface. □

Theorem 1581.4 (RealSeries Cauchy majorant obligation)**.** *For every accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier $K = (T, S, W, Q, D, M, E, H, C, P, N)$, any majorant or Cauchy-criterion read must pass through the dyadic tolerance ledger D, the shared tail threshold M, and the endpoint seal E after the term, partial-sum, window, and readback rows T, S, W, Q have been displayed. The route exports no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeries cauchy majorant obligation`

Proof. Project the carrier of Definition 1581.1. The rows D, M, E are the only rows that record tolerance comparison, shared tail control, and the endpoint seal.

Use Definition 1581.3. It places those rows behind T, S, W, Q and before the structural rows H, C, P, N, so a majorant or Cauchy-criterion consumer receives a finite route.

The excluded host-side objects are not coordinates of K. Hence a majorant read cannot leave D, M, E for an external convergence principle. □

Theorem 1581.5 (RealSeries uniform Cauchy obligation)**.** *Every* $\mathsf{UniformCauchySeries}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier inspects only the finite rows* T, S, W, Q, D, M *before any endpoint or structural row is read. Uniformity is therefore a displayed shared-tail route, not a family of externally selected thresholds.*

Proof. Read the rows T, S, W, Q, D, M from the carrier. They expose the term stream, partial-sum windows, selected stream windows, regular readback, dyadic tolerances, and the shared threshold.

Apply Definition 1581.4. It forces Cauchy-style consumers through the same tolerance and threshold rows before E can be consumed.

Since the carrier has no countable-choice schedule or selected family of thresholds, the uniform Cauchy read is exhausted by the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeries uniform cauchy obligation`

Theorem 1581.6 (RealSeries RegSeqRat tail obligation)**.** *For every accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *is required before any tail comparison can pass to the dyadic ledger* D*, the shared threshold* M*, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. No Real endpoint seal may be inspected from a partial-sum row without this regular rational readback.*

Proof. Use the carrier order in Definition 1581.1. The row Q is the only regular rational readback for selected terms and partial-sum windows.

The dyadic ledger D compares displayed readbacks, the threshold row M governs the tail after those comparisons, and the endpoint row E is downstream of both. Thus Q is mandatory before any Real endpoint seal.

The structural rows H, C, P, N preserve and name the same route. They do not add another readback row or a direct endpoint channel. □

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesRegSeqRatTailObligation`

Theorem 1581.7 (RealSeries partial-sum ledger nonescape)**.** *Every partial-sum read from an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is routed only through the finite term carrier surface of Definition 1581.2 and the displayed continuation replay row* C*. The ledger may inspect* T, S, W, Q *and may replay the carried term-to-sum route, but it cannot bypass those rows to a host infinite sum, selected limit, quotient equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeries partial sum ledger nonescape`

Proof. Project the carrier in Definition 1581.1. The rows T, S, W, Q are the only rows that expose terms, finite partial sums, selected windows, and regular rational readback.

The continuation row C replays the route from term reads to partial sums and from partial sums to regular readback. Because the carrier has no other partial-sum coordinate, a ledger read cannot leave this finite surface.

The excluded host-side objects are not fields of the carrier. Hence partial-sum accounting remains inside the displayed term ledger and continuation replay. □

Theorem 1581.8 (Real series partial-sum window)**.** *Every accepted* $\mathsf{RealSeries}^{\uparrow}$ *read factors each displayed finite series observation through*

$$T \longmapsto S \longmapsto W \longmapsto Q \longmapsto D$$

together with H, C, P, N*. The row* S *records only finite partial sums and adjacent term contributions, and the row* D *records only the dyadic tolerances needed to compare those displayed windows.*

Proof. Start with a requested series observation. By Definition 1581.1, the request first reads the term stream row T and then the finite partial-sum window row S.

The selected windows W and regular readbacks Q expose the terms and partial sums visible to the packet. The dyadic ledger D is the only row that compares those finite reads and records the corresponding addition and tolerance information.

The rows H, C, P, N preserve, replay, source, and name the same route. Therefore the observation remains a finite partial-sum window and exports no host infinite-sum object or quotient comparison. □

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesPartialSumWindowRoute`

Theorem 1581.9 (Real series nonescape boundary)**.** *Every endpoint-facing read from an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier passes through the shared route*

$$T \longmapsto S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M \longmapsto E$$

together with H, C, P, N*. Consequently a consumer may use the displayed interfaces of chapter 1413 and chapter 1522 for finite partial-sum and Cauchy-tail accounting, but it receives no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 1581.8 to place every visible series observation on the finite route through T, S, W, Q, D. The shared threshold row M is then the only tail-control coordinate available to compare later partial sums.

The endpoint row E consumes this already displayed route. It is a $\mathsf{Real}^{\uparrow}$ seal for the packet endpoint, not a separate assertion that a host sequence of partial sums has been completed.

Finally read the structural rows H, C, P, N. Because the carrier has no coordinate for host infinite sums, selected limits, quotient equality, countable choice, or ambient real completeness, none of those principles can escape through the endpoint-facing boundary. □

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesNonescapeBoundary`

Theorem 1581.10 (Real series tail-threshold stability)**.** *Let* $K = (T, S, W, Q, D, M, E, H, C, P, N)$ *be an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier. If* $K' = (T', S', W', Q', D', M', E', H', C', P', N')$ *is obtained by componentwise* hsame *transport along the rows recorded in* H*, then the single shared Cauchy-tail threshold row is preserved as the comparison gate for later partial sums: every transported partial-sum comparison still factors through*

$$T, S, W, Q, D, M, H, C, P, N.$$

In particular, no transported row may replace the threshold coordinate by a family of unrelated tail choices or by a host infinite-sum witness.

Proof. Project the carrier inventory in Definition 1581.1. The row M is declared as the shared Cauchy-tail threshold, and the row H stores componentwise hsame transport for the term stream, partial-sum window, selected windows, readbacks, ledger, threshold, endpoint, continuation, provenance, and local naming rows.

Use Definition 1581.8 to place every visible finite comparison through T, S, W, Q, D before any tail control is read. Transporting the displayed rows componentwise changes only their names inside the same hsame class; it does not add a new coordinate to the classifier.

The threshold coordinate available after transport is therefore still the transported instance of the single row M. The structural rows C, P, N replay, source, and name that same route, so later partial-sum comparisons remain governed by the shared threshold surface. □

Definition 1581.11 (Real series shared-tail consumer surface)**.** *The shared-tail consumer surface of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier is the finite row package*

$$(S, D, M, E, H, C, P, N),$$

where S is the partial-sum window row, D is the dyadic tolerance ledger, M is the shared Cauchy-tail threshold, E is the endpoint $\mathsf{Real}^{\uparrow}$ *seal, H records componentwise* hsame *transport, C records displayed* Cont *replay, P records* Pkg *provenance, and N records the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *name. A consumer of this surface may inspect only those rows together with the term and readback rows already displayed in Definition 1581.1; it receives no selected limit, quotient equality of partial-sum streams, countable-choice schedule, or ambient completeness witness.*

Theorem 1581.12 (Real series endpoint nonescape obligation)**.** *Every* $\mathsf{Real}^{\uparrow}$ *endpoint read through the row E of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier must first consume the finite partial-sum window, regular readback, dyadic ledger, and stabilized shared threshold. Its public handoff route is*

$$T \longmapsto S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M \longmapsto E,$$

together with H, C, P, N; it cannot bypass those rows by appealing directly to a selected limit, quotient equality of partial-sum streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1581.10 to fix the shared threshold row as the only tail-control surface stable under componentwise transport. This places any later endpoint request behind the same M row that governs the partial-sum comparisons.

Apply Definition 1581.9 to the endpoint-facing read. The theorem already forces the route through T, S, W, Q, D, M, E and records that the endpoint seal exports no host infinite-sum or selected-limit principle.

The handoff to $\mathsf{Real}^{\uparrow}$ is therefore a seal after the finite window, regular readback, dyadic ledger, and shared threshold have all been displayed. The rows H, C, P, N preserve the same route and do not create an alternate endpoint channel. □

Theorem 1581.13 (Real series Cauchy consumer obligation)**.** *The rows S, D, M, E, H, C, P, N of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier provide exactly the finite Cauchy surface required by downstream* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*, and* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *consumers: S supplies displayed partial-sum windows, D supplies dyadic comparison radii and finite addition errors, M supplies the shared tail threshold, E supplies the endpoint seal after that threshold, and H, C, P, N transport, replay, source, and name the same route. This consumer obligation adds no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read S, D, M, E, H, C, P, N from Definition 1581.11. The row S is the only partial-sum window surface, D is the only dyadic tolerance ledger, M is the only shared tail-threshold row, and E is the endpoint seal downstream of those rows.

Definition 1581.10 keeps the threshold common under componentwise transport, while Definition 1581.12 ensures that endpoint access consumes the finite window, readback, ledger, and threshold before reaching E.

Thus the downstream Cauchy-style consumers receive a finite criterion surface rather than a completed host sum. Since the classifier has no coordinate for selected limits, quotient equality, countable choice, or ambient real completeness, none of those principles is introduced by the readiness package. □

Definition 1581.14 (Real series tail-majorant carrier)**.** *A* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier is a finite* BHist *packet*

$$J = (W, R, T, B, U, G, H, C, P, N)$$

whose rows are read only as follows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the displayed tail indices and partial-sum comparison windows.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the terms, partial sums, and displayed majorant entries.*
3. *T is the tail-request ledger inherited from the* $\mathsf{RealSeries}^{\uparrow}$ *carrier of Definition 1581.1.*
4. *B is the displayed tail-majorant row, recording finite upper bounds for the requested tails.*
5. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff row, read only through W, R, T, B.*
6. *G is the* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *route row, exposing the same finite majorant data to Cauchy-criterion consumers.*
7. *H, C, P, N are componentwise transport, displayed replay, package provenance, and local naming rows for W, R, T, B, U, G.*

The classifier has no coordinate for a host infinite sum, an unbounded majorant family, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1581.15 (RealSeries root-unblock obligation surface)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier together with a tail-majorant carrier*

$$J = (W, R, T, B, U, G, H, C, P, N),$$

the root-unblock $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *surface consists exactly of finite* BHist *obligations for the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the inherited tail-request ledger T, the tail-majorant row B, the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff U, the* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *route G, and the structural rows H, C, P, N. No obligation is stored as a host infinite series, a selected limit, an unbounded majorant, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the two carriers. The base $\mathsf{RealSeries}^{\uparrow}$ carrier supplies the finite term, partial-sum, tolerance, threshold, and $\mathsf{Real}^{\uparrow}$ endpoint rows; Definition 1581.14 supplies only $W, R, T, B, U, G, H, C, P, N$.

The root-unblock obligations are therefore the displayed finite rows that downstream consumers can actually read. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback row expose the terms, partial sums, and majorant entries; the tail ledger and majorant row expose the requested Cauchy bounds.

The handoff rows U and G consume the same finite data for $\mathsf{UniformCauchySeries}^{\uparrow}$ and $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$. The structural rows preserve and name that route, so no excluded host-side principle has an available coordinate. □

Theorem 1581.16 (RealSeries root tail window)**.** *Every accepted* $\mathsf{RealSeries}^{\uparrow}$ *root-unblock packet exposes its tail information through finite* BHist *windows before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is read. Concretely, a downstream consumer first reads the displayed* $\mathsf{RealSeries}^{\uparrow}$ *term route, the* $\mathsf{StreamName}^{\uparrow}$ *window rows, the partial-sum ledger, and the dyadic tolerance row carried by the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *packet; only after those rows have been transported by* hsame*, replayed by* Cont*, and sourced by* Pkg *may the consumer inspect a regular rational readback or endpoint seal.*

Proof. Project the base carrier of Definition 1581.1. The term stream T, partial-sum row S, selected windows W, and dyadic ledger D are the first readable tail rows of the packet.

The BHist route therefore exposes finite windows before completion-facing data. The $\mathsf{StreamName}^{\uparrow}$ rows name the visible indices, and the local NameCert row records that these are the only windows a root-unblock consumer may use.

The structural rows H, C, P, N transport, replay, source, and name the same route. Thus $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal are downstream of the displayed finite tail windows, not sources of hidden tail choices. □

Theorem 1581.17 (RealSeries majorant route)**.** *Every comparison or majorant read from an accepted* $\mathsf{RealSeries}^{\uparrow}$ *root-unblock packet factors through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *rows before it reaches a Cauchy-facing consumer. The route reads dyadic tolerances and finite majorant data from the displayed ledger, then reads regular rational windows, and only then exposes the* $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*, or* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *handoff.*

Proof. Start with the tail-majorant carrier of Definition 1581.14. The rows W, R, T, B record finite windows, regular readback, inherited tail requests, and displayed majorant bounds.

The comparison side is supplied by the dyadic ledger in the base carrier and by the majorant row B in the tail carrier. These rows are named locally by the $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ surface before any downstream Cauchy-facing row can be inspected.

Finally apply the handoff routes Definition 1581.23, Definition 1581.25, and Definition 1581.27. Each route consumes the same dyadic, regular-readback, local-certificate, transport, replay, and provenance rows before exposing its consumer. □

Theorem 1581.18 (RealSeries uniform tail budget)**.** *Every uniform tail-budget consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet receives a single displayed finite window schedule. The schedule is the common* BHist *route through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the shared tail threshold,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *rows; it is not a selected infinite sum, not a choice of infinitely many tail indices, and not an ambient completeness witness.*

Proof. Read the root carrier budget in Definition 1581.28. The finite rows $T, S, W, Q, D, M, E, H, C, P, N$ and the tail-majorant rows $W', R, T', B, U, G, H', C', P', N'$ are the only rows available to a uniform tail-budget consumer.

Use Definition 1581.31 to isolate the uniform route. It identifies the visible budget as a displayed finite tuple, so the consumer receives one schedule rather than a family selected outside the packet.

The transport, replay, provenance, and local naming rows preserve that same schedule. Since neither carrier contains a host infinite sum, countable-choice row, selected limit, or ambient completeness primitive, no such object can be exported by the uniform budget. □

Theorem 1581.19 (RealSeries root Cauchy-tail budget)**.** *Every* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, *and* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet must read the shared finite route*

$$T, S, W, Q, D, M, E, H, C, P, N$$

before a Cauchy-tail conclusion is exported. The route exposes the term stream, partial-sum window, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, shared threshold, endpoint seal, transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *row as one budget surface.*

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesRootCauchyTailBudget`

Proof. First apply Definition 1581.16. It places every tail-facing read behind the finite term route, selected windows, partial-sum ledger, and dyadic tolerance row before any regular rational readback or endpoint seal can be inspected.

Next use Definition 1581.17 and Definition 1581.18. These results force majorant, uniform, criterion, and product-facing consumers to share the same displayed dyadic, regular-readback, threshold, transport, replay, provenance, and local naming rows.

Finally apply Definition 1581.13. The downstream consumer receives a finite Cauchy surface and not a host infinite sum, selected limit, quotient equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness. □

Theorem 1581.20 (RealSeries root series criterion surface)**.** *Every* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, *and* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet reads the root criterion surface only through*

$$T, S, W, Q, D, M, E, H, C, P, N.$$

Here T *is the term stream row,* S *is the finite partial-sum window row,* W *is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row,* Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* M *is the shared tail threshold,* E *is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal, and* H, C, P, N *are the transport, replay, provenance, and local naming rows. The surface exports no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1581.1. The rows $T, S, W, Q, D, M, E, H, C, P, N$ are already displayed as the root route, with the finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback visible before the endpoint seal.

Route criterion, uniform, majorant, and product requests through Definition 1581.19. The shared threshold row M is consumed after D and before E, so every endpoint-facing read reaches the same finite budget row.

The support rows H, C, P, N then preserve, replay, source, and name the displayed route. Since the accepted packet contains none of the excluded objects, no downstream criterion can export them. □

Definition 1581.21 (RealSeries root summability surface)**.** *The root summability surface of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is the finite* BHist *subpacket*

$$\mathsf{RootSum}(T, S, W, Q, D, M, E, H, C, P, N)$$

whose rows are exactly the term stream, partial-sum window, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, shared Cauchy-tail threshold,* $\mathsf{Real}^{\uparrow}$ *endpoint seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *evidence. A*

consumer may cite this surface as summability evidence only by reading those rows in that order; it is not a host summation operator, a selected limiting value, quotient equality of streams, countable choice, or ambient completeness.

Theorem 1581.22 (RealSeries root product readiness surface)**.** *Every* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer that asks an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet for product-ready data receives the root summability surface of Definition 1581.21 and no larger analytic object. The handoff cites* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, *and* $\mathsf{CauchyProduct}^{\uparrow}$ *only through*

$$T, S, W, Q, D, M, E, H, C, P, N,$$

with the shared threshold row M fixed before endpoint sealing.

Proof. Start from the root summability surface. It packages the finite term stream, partial-sum windows, selected stream windows, regular readback, dyadic ledger, threshold, endpoint, transport, replay, provenance, and naming rows in one subpacket.

Apply Definition 1581.20. The criterion-facing and uniform Cauchy consumers have already been routed through the same threshold row before E, so the product consumer cannot request a separate limit or completion coordinate.

Finally use Definition 1581.19. It includes the $\mathsf{CauchyProduct}^{\uparrow}$ consumer among the downstream reads and concludes that no host infinite sum, selected limit, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness is exported. □

Theorem 1581.23 (RealSeries uniform Cauchy series handoff)**.** *Every* $\mathsf{UniformCauchySeries}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier factors through the finite route*

$$W \longmapsto R \longmapsto T \longmapsto B \longmapsto U \longmapsto H, C, P, N.$$

The route supplies $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a displayed tail-request ledger, and a finite tail-majorant row before the uniform Cauchy handoff is exposed. It does not supply a host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a $\mathsf{UniformCauchySeries}^{\uparrow}$ consumer request. The request first reads W, so the visible indices and partial-sum comparisons remain inside finite $\mathsf{StreamName}^{\uparrow}$ windows.

The readback row R then exposes the regular rational data for those windows, and T records which tail comparisons are being requested. The majorant row B is the only bound source for those requests.

The handoff row U is downstream of W, R, T, B. Transport, replay, provenance, and local naming by H, C, P, N preserve that same route and do not add any host completion or selection coordinate. □

Theorem 1581.24 (RealSeries Cauchy criterion handoff)**.** *A downstream* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet receives only the displayed rows named by the carrier and tail-majorant route:* $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. The handoff records the finite Cauchy surface needed by the criterion and does not claim convergence outside the displayed Cauchy criterion.*

Proof. Project the base carrier. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows are the only term-window, readback, and tolerance surfaces available before the shared threshold and endpoint rows.

Project the tail-majorant route when a criterion consumer is present. The $\mathsf{CauchyMajorantSeries}^{\uparrow}$ and $\mathsf{UniformCauchySeries}^{\uparrow}$ rows are read as finite handoff rows, while hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserve, replay, source, and name the same displayed route.

No carrier row supplies a host convergence predicate or selected limit. The $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ consumer therefore receives exactly the finite BEDC rows listed in the statement. □

Theorem 1581.25 (RealSeries Cauchy criterion route)**.** *Every* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *read exported by an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier factors through the finite route*

$$W \longmapsto R \longmapsto T \longmapsto B \longmapsto G \longmapsto H, C, P, N.$$

Combined with the $\mathsf{Real}^{\uparrow}$ *endpoint row of Definition 1581.1, this route gives Cauchy-criterion consumers a finite partial-sum and tail-majorant surface rather than a completed host sum. The route does not claim convergence of all series, selected limits, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the tail-majorant carrier. The windows W and readback row R expose only finite partial-sum and majorant observations, while T and B identify the displayed tail requests and their finite bounds.

The criterion row G consumes those rows as the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ route. It does not bypass the finite windows or create a separate convergence predicate.

The endpoint boundary remains the $\mathsf{Real}^{\uparrow}$ row already named by Definition 1581.1. Thus a criterion consumer receives a finite route to the endpoint-facing surface, with H, C, P, N preserving the same data and no excluded host-side principle exported. □

Theorem 1581.26 (RealSeries root source carrier)**.** *The root-facing source surface of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is the combined finite carrier*

$$K = (T, S, W, Q, D, M, E, H, C, P, N), \qquad J = (W', R, T', B, U, G, H', C', P', N')$$

from Definition 1581.1 and Definition 1581.14. Its readable rows are exactly the real-valued term stream, finite partial-sum windows, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, shared tail threshold,* $\mathsf{Real}^{\uparrow}$ *endpoint seal, inherited tail-request ledger, displayed majorant row,* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff,* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *route, and the structural transport, replay, provenance, and naming rows.*

Proof. Project the base carrier K. It exposes the term row T, partial-sum row S, selected windows W, regular readback Q, dyadic ledger D, shared threshold M, endpoint seal E, and structural rows H, C, P, N.

Project the tail-majorant carrier J. It adds only finite windows W', readback R, inherited tail requests T', majorant row B, uniform Cauchy handoff U, criterion route G, and structural rows H', C', P', N'.

The combined source therefore has no host infinite sum, selected limit, quotient equality, countable-choice selector, or ambient completeness coordinate. Every root-facing consumer must read one of the displayed rows. □

Theorem 1581.27 (RealSeries Cauchy majorant handoff)**.** *Every* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *obligation read from an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier factors through the finite route*

$$W', R, T', B \longmapsto U, G \longmapsto H', C', P', N'.$$

The majorant row B is the only source of tail bounds, and it is read together with $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the inherited tail-request ledger, the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff, and the* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *route before any downstream series consumer may inspect the certificate.*

Proof. Read the tail-majorant carrier. The finite windows W' determine which tail and partial-sum comparisons are visible, while R supplies the regular-rational readback for those observations.

The inherited ledger T' states the requested tail bounds, and B is the only displayed row that can answer them. Thus a Cauchy majorant consumer has no unbounded majorant family or external convergence theorem available.

The handoff rows U and G consume the same W', R, T', B surface. Transport, replay, provenance, and naming through H', C', P', N' preserve that finite route for later uniform Cauchy and Cauchy-criterion consumers. □

Theorem 1581.28 (RealSeries root carrier budget)**.** *The root-facing carrier budget of any accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is exactly the displayed base rows*

$$T, S, W, Q, D, M, E, H, C, P, N$$

of Definition 1581.1 together with the tail-majorant rows

$$W', R, T', B, U, G, H', C', P', N'$$

of Definition 1581.14. The budget is exhausted by the partial-sum window route of Definition 1581.8, the shared threshold route of Definition 1581.10, and the endpoint nonescape route of Definition 1581.9; it contains no host infinite-sum coordinate, selected limit, quotient equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the base carrier. Its readable rows are exactly the term stream T, partial-sum windows S, selected windows W, regular readback Q, dyadic ledger D, shared threshold M, endpoint seal E, and structural rows H, C, P, N.

Project the tail-majorant carrier. Its readable rows are exactly the windows W', readback R, inherited tail ledger T', majorant row B, uniform handoff U, Cauchy-criterion route G, and structural rows H', C', P', N'.

The cited partial-sum, threshold-stability, and endpoint nonescape theorems show that every downstream read remains inside those two finite row lists. Since neither carrier has any other coordinate, the root-facing budget is exactly the displayed surface. □

Theorem 1581.29 (RealSeries tail-ledger majorant)**.** *Every tail-majorant consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet must read the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows W', the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the inherited tail-request ledger T', and the finite majorant row B before any* $\mathsf{UniformCauchySeries}^{\uparrow}$ *or* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *handoff. The handoff route is the one displayed in Definition 1581.14, Definition 1581.23, and Definition 1581.25.*

Proof. Start from a tail-majorant consumer request. The carrier definition exposes windows W' before readback, so the requested tail and partial-sum comparisons are fixed as finite $\mathsf{StreamName}^{\uparrow}$ observations.

The row R then supplies the regular-rational data, and the inherited ledger T' records which tail comparisons are being asked for. The row B is the only displayed majorant source for those requests.

Only after these four rows have been read can the handoff rows U and G be inspected. The uniform Cauchy and Cauchy-criterion route theorems preserve that same route through H', C', P', N' and add no external completion principle. □

Theorem 1581.30 (RealSeries Cauchy criterion scope)**.** *Downstream* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, *and* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *consumers receive only the finite surface displayed by Definition 1581.1 and Definition 1581.14: finite term and partial-sum windows, regular readback, dyadic tolerance accounting, the shared threshold, the inherited tail ledger, the majorant row, handoff rows, componentwise transport, replay, provenance, and local naming. They receive no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 1581.28 to place every root-facing read inside the two displayed finite carriers. This fixes the base series rows and the tail-majorant rows before any downstream Cauchy-style consumer is considered.

Use Definition 1581.29 for the tail-facing route. It forces the windows, readback row, inherited ledger, and majorant row to be read before the uniform Cauchy and Cauchy-criterion handoffs.

Use Definition 1581.27 for the majorant consumer. Together these routes exhaust the consumer surface, and the omitted host-side objects are absent from the carrier inventory. □

Theorem 1581.31 (RealSeries uniform Cauchy budget)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier* $J = (W', R, T', B, U, G, H', C', P', N')$*, the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *budget is exactly the displayed tuple* (W', R, T', B, U)*. It binds finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, tail requests, and Cauchy majorant bounds before the uniform Cauchy handoff is exposed, and it does not assert host convergence, selected limits, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project J and isolate the uniform Cauchy handoff row U. By Definition 1581.23, U is reached only after the finite windows, readback row, tail ledger, and majorant row have been displayed.

The tuple (W', R, T', B, U) is therefore the whole budget available to a uniform Cauchy consumer. The structural rows H', C', P', N' can transport, replay, source, and name the same budget, but they cannot add a host-side convergence principle. □

Theorem 1581.32 (RealSeries root ledger exactness)**.** *The root ledger of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *packet is exact for the Cauchy majorant, uniform Cauchy, and Cauchy-criterion routes: the dyadic ledger* D*, shared threshold* M*, tail-request ledger* T'*, majorant row* B*, endpoint seal* E*, uniform handoff* U*, criterion row* G*, and structural rows* $H, C, P, N, H', C', P', N'$ *are the only rows that may witness tail exactness for downstream* $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, *and* $\mathsf{UniformCauchySeries}^{\uparrow}$ *consumers.*

Proof. Project the base carrier and read the endpoint-facing rows D, M, E, H, C, P, N. These rows account for dyadic tolerance, the shared Cauchy-tail threshold, and the terminal Real seal.

Project the tail-majorant carrier and read $T', B, U, G, H', C', P', N'$. These rows account for tail requests, displayed majorant bounds, uniform Cauchy handoff, Cauchy-criterion routing, and the structural preservation of those routes.

No other ledger row exists in either carrier. Hence downstream bounded-sequence, sequence-limit, majorant-series, and uniform-Cauchy consumers receive exactly the displayed finite ledger and cannot appeal to ambient real equality or completeness. □

Theorem 1581.33 (RealSeries uniform Cauchy threshold coherence)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier*

$$J = (W', R, T', B, U, G, H', C', P', N'),$$

any $\mathsf{UniformCauchySeries}^{\uparrow}$ *read through* U *and any* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *read through* G *must use the same displayed* W', R, T'*, and* B *rows. No route may replace the shared threshold and majorant data by an unrelated tail selector, host infinite series, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read J through Definition 1581.14. The rows W', R, T', B are the only displayed finite windows, regular readbacks, inherited tail requests, and majorant bounds available to either downstream handoff.

Apply Definition 1581.31 to the $\mathsf{UniformCauchySeries}^{\uparrow}$ read. It identifies the uniform Cauchy budget as exactly (W', R, T', B, U), so the handoff U cannot choose a different window or threshold route.

Apply Definition 1581.25 to the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ read. It routes G through the same W', R, T', B surface before structural transport, replay, provenance, and naming are inspected.

The two consumer reads therefore share the same finite tuple. Since the carrier has no coordinate for a host infinite series, selected limit, quotient equality, countable-choice selector, or ambient real completeness, none of those objects can replace the displayed threshold data. □

Theorem 1581.34 (RealSeries majorant endpoint nonescape)**.** *Every endpoint-facing read that consumes* $\mathsf{CauchyMajorantSeries}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*, or* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *factors through the finite route*

$$W', R, T', B \longmapsto U, G \longmapsto H', C', P', N'$$

before any $\mathsf{Real}^{\uparrow}$ *endpoint seal from the base carrier may be cited. The route exports no host infinite sum, selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 1581.27 for the $\mathsf{CauchyMajorantSeries}^{\uparrow}$ read. The majorant obligation first exposes the finite windows, regular readback, inherited tail ledger, and displayed majorant row W', R, T', B.

Use Definition 1581.23 and Definition 1581.25 for the two downstream handoffs. Both routes consume the same finite majorant surface before the rows U and G are exposed.

Finally apply Definition 1581.32. The endpoint seal from the base carrier is cited only after the dyadic ledger, shared threshold, tail-request ledger, majorant row, uniform handoff, criterion row, and structural rows have been read.

Thus every endpoint-facing route factors through $W', R, T', B \longmapsto U, G \longmapsto H', C', P', N'$ before reaching the base $\mathsf{Real}^{\uparrow}$ seal. No excluded host-side principle has a carrier coordinate from which it could escape. □

Theorem 1581.35 (RealSeries shared majorant threshold coherence)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *tail-majorant carrier*

$$J = (W', R, T', B, U, G, H', C', P', N'),$$

every $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*, and* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *consumer reads the same displayed* W', R, T', B *threshold surface before its handoff row. The consumer may route through* U*,* G*, or the majorant handoff, but it cannot substitute a different tail selector, majorant ledger, host infinite sum, selected limit, quotient equality, countable-choice witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read J through Definition 1581.14. The rows W', R, T', B are the unique finite windows, regular readback, inherited tail-request ledger, and displayed majorant bounds in the accepted tail-majorant carrier.

For the uniform route, apply Definition 1581.31. For the criterion route, apply Definition 1581.25. For the majorant route, apply Definition 1581.27. Each cited handoff consumes the same W', R, T', B surface before exposing its consumer-specific row.

The structural rows H', C', P', N' transport, replay, source, and locally name that displayed surface. They do not create another threshold or another majorant source, so the three consumer routes remain coherent over the same finite BEDC rows. □

Theorem 1581.36 (RealSeries endpoint majorant factorization)**.** *Let $I = (S, D, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier and let $J = (W', R, T', B, U, G, H', C', P', N')$ be an accepted tail-majorant carrier for the same displayed series route. The* $\mathsf{Real}^{\uparrow}$ *endpoint row E of I factors first through S, D, M and then, whenever a majorant consumer is present, through the shared W', R, T', B surface before any downstream endpoint-facing read may cite the seal.*

Proof. Project I through Definition 1581.1. The stream row S, dyadic ledger D, and shared threshold row M are read before the endpoint seal E is available.

Now project J through Definition 1581.14. The rows W', R, T', B display the finite windows, regular readback, inherited tail requests, and majorant bounds that a majorant consumer must inspect.

Use Definition 1581.10 to identify the threshold side of the base route, and use Definition 1581.27 for the majorant side. The endpoint row cannot bypass either route because Definition 1581.34 excludes host infinite sums, selected limits, quotient equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the carrier inventory. □

Theorem 1581.37 (RealSeries Cauchy consumer readiness)**.** *The shared threshold coherence of Definition 1581.35 and the endpoint factorization of Definition 1581.36 supply the finite Cauchy surface consumed by the downstream* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*, and* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *chapters. The ready surface consists exactly of the base S, D, M, E route, the tail-majorant W', R, T', B route, the consumer rows U, G, and the structural rows $H, C, P, N, H', C', P', N'$.*

Proof. The coherence theorem fixes the threshold and majorant rows shared by the three Cauchy consumers. Thus every consumer begins from the same W', R, T', B surface rather than from a parameter chosen outside the packet.

The endpoint-factorization theorem ties that surface back to the base S, D, M, E route. Consequently a downstream endpoint read sees the real-series stream, dyadic ledger, shared threshold, endpoint seal, tail windows, regular readback, inherited tail requests, and displayed majorant bounds in one finite route.

Apply Definition 1581.32 to identify the remaining structural rows. These rows provide transport, continuation replay, provenance, and local naming for the same route, which is precisely the finite Cauchy surface needed by the realseriescauchycriterion, uniformcauchyseries, and cauchymajorantseries consumers. □

Theorem 1581.38 (RealSeries majorant-threshold readiness)**.** *Any* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*, or* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *consumer that treats an accepted* $\mathsf{RealSeries}^{\uparrow}$ *endpoint as series-ready must first read the same finite tuple*

$$S, D, M, E, W', R, T', B, U, G, H, C, P, N, H', C', P', N'.$$

Here S, D, M, E are the base stream, dyadic ledger, shared threshold, and endpoint seal rows; W', R, T', B are the majorant-window, regular-readback, inherited tail-request, and displayed bound rows; U, G are the uniform and criterion-facing consumer rows; and $H, C, P, N, H', C', P', N'$ are the transport, replay, provenance, and local naming rows for the base and tail-majorant packets. No consumer may certify readiness by appealing to a host infinite sum, a selected limit, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Definition 1581.35. It forces the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, and $\mathsf{CauchyMajorantSeries}^{\uparrow}$ routes to read the same W', R, T', B threshold surface before their consumer-specific rows are visible.

Next apply Definition 1581.36. The endpoint seal E is downstream of the base rows S, D, M and, in the presence of a majorant consumer, downstream of the shared W', R, T', B surface.

Finally apply Definition 1581.37. It attaches the rows U, G and the structural rows $H, C, P, N, H', C', P', N'$ to the same finite route. Thus endpoint readiness is exactly the displayed tuple, with no coordinate for host infinite sums, selected limits, quotient equality, countable choice, or ambient Real completeness. □

Theorem 1581.39 (RealSeries uniform majorant tail coherence)**.** *Let*

$$K = (T, S, W, Q, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{RealSeries}^{\uparrow}$ *Cauchy-facing carrier whose uniform Cauchy tail and Cauchy majorant consumers are read through the same finite tail threshold. Then the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff, the* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *handoff, and the* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *handoff agree on the displayed rows $T, S, W, Q, D, M, E, H, C, P, N$: T supplies the term-stream row, S supplies the finite partial-sum windows, W supplies the selected* $\mathsf{StreamName}^{\uparrow}$ *windows, Q supplies* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, D supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and M supplies the shared Cauchy-tail threshold. No consumer may replace that threshold by a host infinite sum, a selected limit, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier to its base route. The rows T, S, W, Q, D, M give the term stream, partial-sum windows, selected stream windows, regular readback, dyadic tolerance ledger, and common tail threshold before any endpoint row is visible.

Apply Definition 1581.23 to the uniform consumer and Definition 1581.27 to the majorant consumer. Each handoff reads the same finite window and tolerance surface rather than choosing an external threshold.

Finally use Definition 1581.25 and Definition 1581.37. The criterion-facing route consumes the same threshold surface and the same structural rows H, C, P, N, so the three consumers are coherent over one finite Cauchy tail. □

Theorem 1581.40 (RealSeries RegSeqRat endpoint seal route)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier*

$$K = (T, S, W, Q, D, M, E, H, C, P, N),$$

every endpoint-facing $\mathsf{Real}^{\uparrow}$ *seal read factors through the selected* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the shared threshold M before citing E. The route is then transported by H, replayed by C, sourced by P, and named by N; it exports no independent endpoint carrier, quotient real equality, selected limit, host infinite sum, countable-choice row, or ambient completeness principle.*

Proof. Begin with the endpoint side of the base carrier. By Definition 1581.12, the endpoint seal cannot be read without the finite partial-sum and threshold rows carried by the accepted packet.

Next attach the readback route. The shared-threshold statement Definition 1581.10 fixes M, and Definition 1581.36 ties the majorant-facing window surface back to the base endpoint row.

The structural rows close the route. Transport, continuation replay, package provenance, and the local NameCert row preserve the same displayed route from W, Q, D, M to E, so no separate real endpoint or host-level completeness object can be inserted. □

Theorem 1581.41 (RealSeries Cauchy majorant threshold exhaustion)**.** *Let*

$$K = (T, S, W, Q, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{RealSeries}^{\uparrow}$ *carrier and suppose a Cauchy majorant consumer reads it through the Cauchy-facing surface of Definition 1581.37. Then the majorant consumer is exhausted by the rows* $T, S, W, Q, D, M, E, H, C, P, N$ *together with the already displayed tail-majorant rows of Definition 1581.14. In particular, every requested tail bound is answered through the shared threshold* M*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before the* $\mathsf{Real}^{\uparrow}$ *endpoint seal is cited.*

Proof. First read the majorant consumer through Definition 1581.27. The handoff exposes finite tail windows, regular readback, inherited tail requests, and displayed majorant bounds; it does not add another threshold source.

Next use Definition 1581.39. The uniform Cauchy route, Cauchy criterion route, and majorant route all consume the same T, S, W, Q, D, M surface, so a requested bound cannot escape to an external sequence or a choice principle.

Finally apply Definition 1581.40. The endpoint seal E is downstream of the shared readback and tolerance ledger, and the rows H, C, P, N carry only transport, replay, provenance, and local naming. This exhausts the Cauchy majorant threshold route without importing quotient equality, selected limits, host infinite sums, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1581.42 (RealSeries root tail majorant window)**.** *Any root-unblock* $\mathsf{RealSeries}^{\uparrow}$ *consumer reading a tail-majorant row factors through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, the shared threshold* M*, and the endpoint seal* E*. In particular, a consumer of the accepted carrier*

$$K = (T, S, W, Q, D, M, E, H, C, P, N)$$

may cite a tail-majorant row only after the finite window route of W*, the regular readback route of* Q*, the dyadic tolerance ledger* D*, the shared threshold* M*, and the endpoint seal* E *have all been retained in the same transported packet.*

Proof. Start from the accepted carrier in Definition 1581.1. The displayed rows $T, S, W, Q, D, M, E, H, C, P, N$ are the only route available to a root-unblock consumer.

Use the tail-majorant carrier of Definition 1581.14. Its majorant read is finite because it exposes windows and readback data before any Cauchy-facing consumer is served.

Apply Definition 1581.37. The readiness surface ties the downstream Cauchy criterion, uniform Cauchy, and majorant consumers to the same base route.

Then apply Definition 1581.39 and Definition 1581.41. These theorems identify the shared threshold M and force every requested tail bound through W, Q, D, M before the endpoint seal E is cited. □

Theorem 1581.43 (RealSeries root tail threshold exhaustion)**.** *All downstream* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, *and* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *reads of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *root-unblock carrier are exhausted by the displayed rows*

$$T, S, W, Q, D, M, E, H, C, P, N.$$

No such read may introduce host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness outside the finite carrier and the tail-majorant rows of Definition 1581.14.*

Proof. First use Definition 1581.37. It identifies the downstream Cauchy criterion, uniform Cauchy, and majorant consumers as readers of the same finite surface rather than as independent sources of convergence data.

Next use Definition 1581.39. The three consumer routes agree on $T, S, W, Q, D, M, E, H, C, P, N$, with W, Q, D, M carrying the finite window, regular readback, dyadic tolerance, and shared-threshold part of the route.

Finally apply Definition 1581.41 together with Definition 1581.42. The first exhausts the majorant request through the existing threshold surface, and the second locks root-unblock reads to the same finite windows and endpoint seal.

The excluded host principles are absent from both displayed carriers. Since neither the base carrier nor the tail-majorant carrier has a coordinate for host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no downstream read can export one. □

Definition 1581.44 (RealSeries Dirichlet cancellation surface)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier*

$$K = (T, S, W, Q, D, M, E, H, C, P, N),$$

the Dirichlet cancellation surface is the finite row package

$$\mathsf{DirCancel}(K) = (T, S, W, Q, D, M, E, H, C, P, N;\ A, B, V)$$

where A *is a bounded partial-sum ledger for the displayed windows of* S*,* B *is a monotone null coefficient ledger read through the same* $\mathsf{StreamName}^{\uparrow}$ *windows* W *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* V *is the finite Abel-difference variation ledger that compares adjacent coefficient rows inside the dyadic tolerance ledger* D*. The surface has no coordinate for a host infinite sum, selected series limit, quotient equality of partial-sum streams, countable choice over tail indices, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1581.45 (RealSeries Dirichlet bounded-variation row)**.** *Let* $K = (T, S, W, Q, D, M, E, H, C, P, N)$ *be an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier with a Dirichlet cancellation surface* $\mathsf{DirCancel}(K)$*. Every finite window comparison for the transformed tails factors through the bounded partial-sum ledger* A*, the monotone null coefficient ledger* B*, and the Abel-difference variation ledger* V *before the shared threshold row* M *may be read. Thus the only exported route is*

$$S \longmapsto A \longmapsto B \longmapsto V \longmapsto D \longmapsto M,$$

with H, C, P, N *transporting, replaying, sourcing, and naming the same finite route.*

Proof. Project the base carrier of Definition 1581.1 and the cancellation surface of Definition 1581.44. The partial sums remain the displayed finite windows of S, while A records the bound used by every cancellation request.

Read the coefficient side through B and V. The null and monotone information is stored as finite window data, and the Abel-difference ledger records only adjacent coefficient differences inside the dyadic tolerance row D.

Finally use the shared threshold discipline of Definition 1581.43. Since the route reaches M only after S, A, B, V, D, no consumer can replace it by a host infinite sum, a selected limit, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1581.46 (RealSeries Dirichlet tail cancellation)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier equipped with* $\mathsf{DirCancel}(K)$*, every tail request between displayed indices* $m < n$ *is answered by a finite Abel-summation window:*

$$(m, n, S) \longmapsto A \longmapsto (B, V) \longmapsto D \longmapsto M \longmapsto E.$$

The endpoint seal E *is cited only after the bounded partial-sum ledger, monotone null coefficient ledger, Abel-difference variation ledger, dyadic tolerance accounting, and shared threshold have all been retained in the same transported packet.*

Proof. Begin with Definition 1581.45. It gives the finite route from the partial-sum window through the bounded ledger, coefficient ledger, variation ledger, dyadic tolerance row, and shared threshold.

Apply Definition 1581.10. The threshold row remains stable under componentwise hsame transport, so the same m, n tail comparison is replayed through H and C rather than by choosing another tail selector.

Use Definition 1581.12 for the final endpoint step. The endpoint seal E is downstream of the displayed threshold route, and no excluded host-side principle is a field of either the base carrier or the cancellation surface. □

Theorem 1581.47 (RealSeries Dirichlet Cauchy readiness)**.** *The Dirichlet cancellation surface of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier supplies exactly the Cauchy-ready route needed by downstream* $\mathsf{DirichletSeriesTest}^{\uparrow}$*,* $\mathsf{AbelDirichletComparison}^{\uparrow}$*, and* $\mathsf{UniformCauchySeries}^{\uparrow}$ *consumers:*

$$T, S, W, Q, A, B, V, D, M, E, H, C, P, N.$$

The route records finite term access, partial-sum windows, stream windows, regular readback, bounded partial sums, monotone null coefficients, Abel finite differences, dyadic tolerance, shared threshold, endpoint sealing, transport, continuation replay, provenance, and local naming, and nothing stronger.

Proof. First combine Definition 1581.44 with the base carrier of Definition 1581.1. This lists all rows visible to a Dirichlet-style downstream consumer.

Next apply Definition 1581.46. It shows that every requested tail comparison reaches the endpoint seal through a finite Abel-summation window and the shared threshold.

The consumer boundary is then a row-exhaustion claim. The displayed tuple has no coordinate for host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the downstream chapters receive only the Cauchy-ready finite certificate surface. □

Theorem 1581.48 (RealSeries Abel partial summation window)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier equipped with* $\mathsf{DirCancel}(K)$*, every finite Abel partial-summation request is read through the displayed rows*

$$S, A, B, V, D, M, E.$$

The row S supplies the inspected term and partial-sum windows, A supplies the bounded partial-sum ledger, B supplies the monotone null coefficient ledger, V supplies the adjacent Abel-difference ledger, D supplies dyadic tolerance accounting, M supplies the shared threshold, and E supplies the endpoint seal after those rows have already been retained. No host infinite sum, selected limit, quotient equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row is exposed.*

Proof. Begin with the cancellation surface of Definition 1581.44. It displays A, B, V as the bounded partial-sum, coefficient, and Abel-difference rows over the same finite windows of S.

Apply Definition 1581.47. The readiness route keeps $T, S, W, Q, A, B, V, D, M, E, H, C, P, N$ in one finite packet, so the Abel window cannot be replaced by a host summation theorem.

Finally restrict to the Abel-facing analytic rows. The support rows H, C, P, N transport, replay, source, and name the same route, while the visible estimate itself is exhausted by S, A, B, V, D, M, E. □

Theorem 1581.49 (RealSeries Dirichlet uniform tail bound)**.** *For any accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier with* $\mathsf{DirCancel}(K)$*, a downstream* $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{CauchyMajorantSeries}^{\uparrow}$*, or* $\mathsf{DirichletSeriesTest}^{\uparrow}$ *consumer receives a uniform tail-bound route only through*

$$A, B, V, D, M, E, H, C, P, N.$$

The common threshold row M is readable only after the bounded partial-sum row A, coefficient row B, Abel-difference row V, and dyadic ledger D have been fixed over displayed finite windows.

Proof. Project the Dirichlet cancellation surface. The route to a tail estimate first names A and B, then records the finite adjacent-difference budget in V.

Use Definition 1581.46. It places every displayed tail request between $m < n$ on the finite chain from the partial-sum window through A, B, V, D, M and only then to E.

Use Definition 1581.47 for the consumer boundary. Uniform Cauchy, majorant, and Dirichlet-test consumers receive the same threshold row by continuation replay and provenance, not by selected tail indices, quotient equality, infinite sums, or ambient completeness. □

Theorem 1581.50 (RealSeries Cauchy-product finite window)**.** *Every* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier equipped with* $\mathsf{DirCancel}(K)$ *reads product-facing partial sums through finite windows only. The allowed handoff is*

$$S, A, B, V, D, M, E \longmapsto H, C, P, N,$$

where S supplies the finite partial-sum windows and A, B, V, D, M, E supply the cancellation, tolerance, threshold, and endpoint rows needed before any product window can be replayed.

Proof. Read the RealSeries carrier of Definition 1581.1. Product-facing access begins with the displayed partial-sum row S and cannot introduce a second series object outside the local packet.

Apply Definition 1581.44 and Definition 1581.48. The cancellation data available to a product window is exactly A, B, V, D, M, E over finite windows.

Finally apply Definition 1581.47. It exports the Cauchy-ready route to downstream consumers through H, C, P, N, so the $\mathsf{CauchyProduct}^{\uparrow}$ handoff receives finite product windows rather than host infinite products, selected sums, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{RealSeries}^{\uparrow}$ endpoint-facing read factors through a real-valued term stream, finite partial-sum window, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a shared Cauchy-tail threshold, a RealUp endpoint seal, transport, continuation, provenance, and local naming.

Independence witness: real, real-sequence-limit, cauchy-sequence-bounded, regseqrat, streamname, dyadicratcore: $\mathsf{RealSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries term-stream access, finite partial-sum windows, selected stream windows, regular readback, dyadic tolerance accounting, shared tail thresholding, endpoint sealing, transport, continuation, provenance, and local naming.

Theorem 1581.51 (RealSeries finite partial-sum carrier)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$*, every downstream root-facing read of finite partial sums is already determined by the displayed* BHist *rows* $T, S, W, Q, D, M, E, H, C, P, N$*. The row* T *supplies the term stream,* S *supplies the finite partial-sum windows,* W *supplies selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* Q *supplies* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* D *supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* M *supplies the shared threshold,* E *supplies the endpoint seal, and* H, C, P, N *provide componentwise* hsame *transport,* Cont *replay, provenance, and local* NameCert *naming.*

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesRootUnblockCarrier`

Proof. Project the carrier of Definition 1581.1. The finite partial-sum data is stored in S and is read only after the term stream T has been admitted.

Route those finite sums through the selected windows W and regular readback Q. The dyadic ledger D and shared threshold M then account for the comparisons before the endpoint row E is available.

The structural rows H, C, P, N transport, replay, source, and name this same finite route. Since the carrier has no coordinate for host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no root-facing read can bypass the displayed rows. □

Theorem 1581.52 (RealSeries tail ledger)**.** *For every accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C,$ *each tail comparison exported to a* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{CauchyMajorantSeries}^{\uparrow}$*, or* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer factors through the single ledger chain*

$$S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M$$

together with T, E, H, C, P, N*. In particular, the threshold row* M *is shared across the exported tail requests and cannot be replaced by a family of selected tail indices.*

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesTailLedger`

Proof. Begin with the finite partial-sum windows S. A tail request selects only finitely many windows through W and reads the corresponding rational data through Q.

The comparisons are then recorded in the dyadic tolerance ledger D. The shared threshold M is the only row admitted after D, so all exported tail bounds use the same displayed threshold surface.

Endpoint access through E and structural access through H, C, P, N preserve that route. The downstream consumers receive a tail ledger over finite rows, not a host infinite-sum principle or a chosen sequence of tail witnesses. □

Theorem 1581.53 (RealSeries endpoint readback)**.** *Every endpoint read of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$ *reaches* $\mathsf{Real}^{\uparrow}$ *through* E *only after the finite rows* T, S, W, Q, D, M *have been displayed. The readback route is therefore*

$$T, S, W, Q, D, M \longmapsto E \longmapsto H, C, P, N,$$

with BHist *admission, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming attached to the same packet.*

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesEndpointReadback`

Proof. Read the endpoint row from the carrier only after the term stream, finite partial sums, selected windows, regular readback, dyadic ledger, and shared threshold have been projected.

Apply Definition 1581.12. It places every $\mathsf{Real}^{\uparrow}$ endpoint seal behind T, S, W, Q, D, M and refuses selected limits, quotient equality of partial-sum streams, countable choice, and ambient completeness.

Finally replay the endpoint read through H, C, P, N. These rows preserve and name the finite packet; they do not provide a second endpoint channel outside the displayed $\mathsf{RealSeries}^{\uparrow}$ carrier. □

Theorem 1581.54 (RealSeries root tail factorization)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$*, every root-facing Cauchy consumer factors partial sums through finite tail windows before any convergence claim is visible. The forced route is*

$$S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M \longmapsto E,$$

where S *supplies the partial-sum ledger,* W *supplies the selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* Q *supplies* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for terms and partial sums,* D *supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* M *supplies the shared tail threshold, and* E *supplies the* $\mathsf{Real}^{\uparrow}$ *seal only after those rows have been displayed.*

Thus a downstream $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$*,* $\mathsf{UniformCauchySeries}^{\uparrow}$*,* $\mathsf{CauchyMajorantSeries}^{\uparrow}$*, or* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer receives a finite BEDC tail-window certificate. It receives no host infinite sum, selected limit, quotient equality of partial-sum streams, countable-choice tail selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the partial-sum row S. It names the finite windows of partial sums that a root-facing consumer may inspect, and it is already tied to the term stream T by the carrier of Definition 1581.1.

Move from S to selected windows and regular readback. The row W records the finite $\mathsf{StreamName}^{\uparrow}$ windows, and Q records the $\mathsf{RegSeqRat}^{\uparrow}$ readback for each displayed term and partial-sum window.

The Cauchy comparison is then ledgered. The row D records dyadic tolerances and finite addition errors, while the shared threshold row M is the only admitted tail gate after those comparisons.

Finally the endpoint seal E is reached only after the finite route has been displayed. The rows H, C, P, N transport, replay, source, and name the same route, so no convergence-facing consumer can bypass finite tail windows for a host infinite-sum or completeness principle. □

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesRootTailFactorization`

Theorem 1581.55 (RealSeries root-tail threshold fusion)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$*, every root-facing Cauchy consumer that inspects partial-sum windows must use the same threshold row* M *after the route*

$$S \longmapsto W \longmapsto Q \longmapsto D$$

and before the endpoint row E*. Thus no family of selected tail indices can replace the shared finite threshold while still claiming to consume the* $\mathsf{RealSeries}^{\uparrow}$ *packet.*

Proof. Start from the finite partial-sum carrier. The row S supplies the displayed partial-sum windows, and the route through W and Q exposes only finite StreamName windows and RegSeqRat readback.

Use the tail ledger and endpoint readback. The dyadic comparison row D is followed by the single threshold row M, and the endpoint seal E is not available until that threshold has been read.

Apply root tail factorization to downstream Cauchy consumers. Since every root-facing read factors through the same S, W, Q, D, M, E chain, selected families of tail indices have no carrier coordinate and cannot replace the shared threshold. □

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesRootTailThresholdFusion`

Theorem 1581.56 (RealSeries Cauchy consumer finite readback)**.** *Every* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, *or* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier receives only the finite route*

$$T, S, W, Q, D, M, E, H, C, P, N.$$

The consumer receives the term stream, finite partial-sum windows, selected StreamName windows, RegSeqRat readback, DyadicRatCore ledger, shared threshold, endpoint seal, componentwise transport, displayed replay, provenance, and local NameCert rows, but it receives no host infinite sum, selected limit, quotient equality, countable-choice tail selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the finite partial-sum carrier and tail ledger. They expose T, S, W, Q, D, M as the only route by which a Cauchy-series consumer can inspect terms, partial sums, windows, readback, tolerances, and the shared threshold.

Apply endpoint readback and root-tail threshold fusion. The endpoint seal E sits after the same finite threshold, so no consumer can reach a real-facing series claim by choosing separate tail indices.

Finally use root tail factorization to attach the structural rows H, C, P, N. These rows preserve and name the finite packet, while host infinite sums, selected limits, quotient equality, countable-choice tail selectors, and ambient completeness principles are absent from the carrier. □

Definition 1581.57 (RealSeries root Cauchy-product consumer surface)**.** *For an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier* $K = (T, S, W, Q, D, M, E, H, C, P, N)$*, the root Cauchy-product consumer surface is the finite* BHist *route*

$$\mathsf{RootProd}(T, S, W, Q, D, M, H, C, P, N)$$

whose rows are exactly the term stream, partial-sum windows, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, shared tail threshold, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *naming. A* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer may read this surface before endpoint sealing, but it receives no host infinite sum, selected product value, quotient equality of series, countable-choice tail selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1581.58 (RealSeries root product tail budget)**.** *Every* $\mathsf{CauchyProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier first consumes the root Cauchy-product surface of Definition 1581.57. Its tail request is therefore budgeted by the displayed route*

$$S \longrightarrow W \longrightarrow Q \longrightarrow D \longrightarrow M \longrightarrow H, C, P, N,$$

where S gives finite partial-sum windows, W gives selected stream windows, Q gives regular rational readback, D gives dyadic tolerance accounting, and M gives the shared tail threshold.

Lean4 ✓ `BEDC.Derived.RealseriesUp.RealSeriesRootProductTailBudget`

Proof. Project the carrier K. The product-facing rows visible before endpoint sealing are the finite partial-sum, window, readback, tolerance, threshold, transport, replay, provenance, and naming rows.

Read the route in the order displayed in the statement. The $\mathsf{RegSeqRat}^{\uparrow}$ row cannot be inspected before the $\mathsf{StreamName}^{\uparrow}$ windows are selected, and the shared threshold row cannot be inspected before the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger has named the requested budget.

The structural rows H, C, P, N preserve and name the same surface. Since no selected product value or host summation object is a carrier coordinate, the $\mathsf{CauchyProduct}^{\uparrow}$ consumer receives only the finite tail budget. □

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesRootProductTailBudget`

Theorem 1581.59 (RealSeries partial-sum product route)**.** *For every accepted* $\mathsf{RealSeries}^{\uparrow}$ *carrier, any product-facing read from partial-sum windows to a* $\mathsf{CauchyProduct}^{\uparrow}$ *handoff factors through*

$$\mathsf{partial\text{-}sum\ windows} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{shared\ tail\ threshold} \longrightarrow \mathsf{CauchyProduct}^{\uparrow}.$$

The route exposes finite window data, dyadic comparison radii, regular rational readback, the single shared tail threshold, and the local $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$ *rows; it does not expose a second product criterion outside the displayed series packet.*

Lean4 ✓ `BEDC.Derived.RealSeriesUp.RealSeriesPartialSumProductRoute`

Proof. Begin with the finite partial-sum windows in S. They are the only root rows that a product-facing consumer may treat as summation data.

Use the dyadic ledger D and regular readback row Q to account for finite comparison radii and rational window values. The shared threshold M is then the unique tail gate available to the consumer.

Finally hand the result to the $\mathsf{CauchyProduct}^{\uparrow}$ consumer through H, C, P, N. This is the same root surface named in Definition 1581.58, so no external product test, host infinite sum, or ambient completeness witness is exported. □

Theorem 1581.60 (RealSeries scoped certificate closure)**.** *The* $\mathsf{RealSeries}^{\uparrow}$ *chapter closes the finite certificate scope generated by its existing child files. The spine file Definition 1581.1 and Definition 1581.3 fixes the carrier and NameCert surface; the root-tail child records the tail ledger, endpoint readback, and root factorization routes; and the root Cauchy-product child records the product-facing tail budget. Together these files bind exactly the displayed StreamName, RegSeqRat, DyadicRatCore, Real,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the chapter.*

Proof. Read the three child files as one ordered certificate surface. The spine file supplies the real-valued term stream, partial-sum windows, selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, shared tail threshold, $\mathsf{Real}^{\uparrow}$ endpoint seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

The root-tail child then proves that every endpoint-facing and Cauchy-facing read remains on that route. Its tail ledger, endpoint readback, root-tail factorization, threshold fusion, and

consumer readback statements leave no carrier coordinate for host infinite sums, selected limits, quotient equality, countable-choice tail selectors, or ambient completeness.

The product child closes the remaining root product consumer. It reads product-facing partial sums only through the same finite windows, dyadic ledger, regular readback, shared threshold, and structural rows. Thus the listed child files exhaust the scoped $\mathsf{RealSeries}^{\uparrow}$ certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}$.

Constructive story: A public $\mathsf{RealSeries}^{\uparrow}$ packet is generated from finite partial-sum windows, StreamName requests, RegSeqRat readback, DyadicRatCore budgets, a shared Cauchy-tail threshold, RealUp endpoint readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public $\mathsf{RealSeries}^{\uparrow}$ surface is the root tail factorization of Definition 1581.54 together with the CauchyProduct budget route of Definition 1581.58, binding partial-sum windows, StreamName requests, RegSeqRat readback, DyadicRatCore budgets, the shared tail threshold, RealUp endpoint readback, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSeries}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RealSeriesUp.RealSeriesRootTailFactorization`

Bridge status: paperBridge

Not claimed: This chapter does not close bridge checking, host infinite sums, selected limits, quotient equality, countable choice, ambient RealUp completeness, or CauchyProduct convergence outside the displayed finite route.

Upgrade path: Bridge checking is the remaining verification-side route beyond the mature paper closure recorded here.

Chapter 1582

A Concrete Naming Certificate for $\mathsf{CauchyLocalization}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchyLocalization}^{\uparrow}$ packet records the finite-window point at which a regular rational Cauchy source is inspected only as far as a requested tolerance requires, then sealed into the Real route without exporting a quotient stream or a selected limit. It sits between the dyadic arithmetic surface of chapter 291, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, the effective threshold discipline of chapter 415, and the terminal real-name seal of chapter 38. The chapter isolates the Cauchy localization row consumed by Real and Completion arguments as finite BHist data, not as ambient completeness, countable choice, host real equality, or quotient equality of streams.

Definition 1582.1 (Cauchy localization carrier)**.** *A* $\mathsf{CauchyLocalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, R, D, T, L, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly the finite source positions inspected for the requested tolerance.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational readback supplies the values visible through W.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational radius, dyadic comparison cells, and arithmetic budget attached to the request.*
4. *T is the* $\mathsf{CauchyRate}^{\uparrow}$ *threshold row selecting the displayed late index after which the window is sufficient for the tolerance in D.*
5. *L is the localized request window, pairing the request precision with the subwindow of W certified by T and read through R.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, R, D, T, L have been displayed.*
7. *H records componentwise* hsame *transport for the StreamName window, RegSeqRat source, DyadicRatCore tolerance ledger, CauchyRate threshold, localized request window, Real seal, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a precision request through D, T, W, L, R, and finally to the seal row E.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyLocalization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, T, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, detached Real completeness, or an ambient completion theorem.

Theorem 1582.2 (Cauchy localization NameCert obligations)**.** *For an accepted* $\mathsf{CauchyLocalization}^{\uparrow}$ *carrier $K = (W, R, D, T, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyLocalization}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the finite StreamName window, RegSeqRat source row, DyadicRatCore tolerance ledger, CauchyRate threshold, localized request window, Real seal, transport, replay, provenance, and local naming row;*
2. *classifier stability, requiring accepted packets to be compared componentwise only through $W, R, D, T, L, E, H, C,$*
3. *threshold exactness, requiring T to bind the request tolerance in D to a displayed late index before any localized window is exposed;*
4. *window extraction, requiring L to expose only the finite subwindow of W certified by T and read through the same source row R;*
5. *RegSeqRat handoff, requiring all rational readback for the localized window to pass through R rather than through a host stream;*
6. *Real seal non-escape, requiring every Real-facing read to pass through W, R, D, T, L before it reaches E;*
7. *transport, requiring componentwise* hsame *in H to preserve the displayed row order;*
8. *replay, requiring displayed* Cont *in C to repeat the same precision-to-window-to-seal route;*
9. *provenance, requiring P to name only the sibling surfaces displayed in the carrier;*
10. *naming, requiring N to certify exactly the local* $\mathsf{CauchyLocalization}^{\uparrow}$ *route and no hidden quotient, selected limit, host equality, countable-choice, or ambient-completeness row.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1582.1. The packet displays the window, source, tolerance, threshold, localized request, seal, transport, replay, provenance, and naming rows as the full local inventory.

Classifier stability follows because the classifier is rowwise. Every accepted comparison is made through $W, R, D, T, L, E, H, C, P, N$, and no further classifier coordinate is present.

Threshold exactness and window extraction are the analytic core of the packet. The dyadic tolerance row D states the requested radius, the CauchyRate row T supplies the late threshold for that radius, and the localized row L exposes only the finite part of W certified by that threshold.

The RegSeqRat handoff and Real seal boundary are ordered by the carrier. The rational readback is read through R at the displayed window, and the seal row E is downstream of W, R, D, T, L.

Transport, replay, provenance, and naming are structural. The rows H and C preserve and replay the same displayed route, while P and N package only that route. Since the carrier contains no hidden quotient, selected limit, host equality, countable-choice, or ambient-completeness row, none can be exported by the local certificate. □

Theorem 1582.3 (Cauchy localization window extraction)**.** *Every accepted* $\mathsf{CauchyLocalization}^{\uparrow}$ *packet exposes a finite Cauchy window sufficient for the requested tolerance. More precisely, if* $K = (W, R, D, T, L, E, H, C, P, N)$ *is accepted, then the request row in* D *and the threshold row* T *determine a finite localized window* L *whose entries are read through the* $\mathsf{StreamName}^{\uparrow}$ *window* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *source* R *before any* $\mathsf{Real}^{\uparrow}$ *seal read reaches* E*. The packet cannot export quotient stream equality, selected limits, host real equality, countable choice, or ambient completeness.*

Proof. Begin with an accepted packet and project its displayed rows. The tolerance ledger D fixes the requested radius, while the threshold row T supplies the finite late boundary attached to that radius.

Use the localized request row L. It is downstream of D and T, so it may expose only the portion of the StreamName window W needed for the certified late-bound request. The RegSeqRat source row R supplies the rational observations for exactly that displayed window.

The Real seal row E is reached only after W, R, D, T, L have been consumed. The structural rows H, C, P, N preserve, replay, and name this same route, so the packet has no export path for quotient stream equality, selected limits, host real equality, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLocalization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyLocalization}^{\uparrow}$ packet is generated from a StreamName finite window, RegSeqRat source row, DyadicRatCore tolerance ledger, CauchyRate threshold, localized request window, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLocalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1582.1, Definition 1582.2, and Definition 1582.3 seed the finite Cauchy localization route between Cauchy-rate data and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLocalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, threshold exactness, window extraction, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and naming targets for BEDC.Derived.CauchyLocalizationU

Chapter 1583

A Concrete Naming Certificate for $\mathsf{RealPowerSeries}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealPowerSeries}^{\uparrow}$ packet records a real power series only through a displayed coefficient stream, center, argument, radius row, finite windows, partial-sum rows, and named convergence-test majorants. It refines the finite partial-sum discipline of $\mathsf{RealSeries}^{\uparrow}$ in chapter 1581, consumes the majorant route of $\mathsf{WeierstrassMTest}^{\uparrow}$ in chapter 399, and may use the geometric tail witnesses of $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ and $\mathsf{RegularCauchyRootTest}^{\uparrow}$ in chapter 1461 and chapter 1481. It also sits beside the coefficient-only $\mathsf{FPS}^{\uparrow}$ surface of chapter 51 and the displayed radius rows of chapter 66, while all real-facing reads pass through $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 38, chapter 301, chapter 126, and chapter 291. The packet names analytic convergence as a finite certificate route; it does not import a host power-series convergence theorem, host analytic continuation, quotient function spaces, selected infinite sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1583.1 (Real power series carrier)**.** *A* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, Z, X, R, W, S, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the coefficient stream or* $\mathsf{FPS}^{\uparrow}$ *row, read only through selected coefficient windows and their* $\mathsf{StreamName}^{\uparrow}$ *provenance.*
2. *Z is the center* $\mathsf{Real}^{\uparrow}$ *row.*
3. *X is the argument* $\mathsf{Real}^{\uparrow}$ *row.*
4. *R is the displayed radius or subradius row used to state the accepted window of evaluation.*
5. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows for coefficients, center-readbacks, argument-readbacks, powers of $X - Z$, and partial sums.*
6. *S is the finite partial-sum and* $\mathsf{RealSeries}^{\uparrow}$ *row listing the inspected polynomial sums and their real seals.*
7. *M is the majorant data imported from* $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *rows.*
8. *E is the endpoint* $\mathsf{Real}^{\uparrow}$ *seal produced only after the displayed windows, partial sums, radius row, and majorant route have been read.*

9. *H stores componentwise* hsame *transport for the coefficient row, center, argument, radius row, windows, partial sums, majorant data, endpoint seal, continuation, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from coefficient reads and real-point reads to finite powers, from powers to partial sums, from partial sums to the chosen majorant route, and from that route to the endpoint seal.*

11. *P is the* Pkg *provenance over* $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{FPS}^{\uparrow}$, $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, Z, X, R, W, S, M, E, H, C, P, N$. It has no coordinate for host analytic continuation, quotient function spaces, selected infinite sums, countable-choice selectors, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier semantic name certificate`

Definition 1583.2 (Real power series obligation carrier)**.** *A* $\mathsf{RealPowerSeries}^{\uparrow}$ *obligation carrier over a finite evaluation request is a displayed subpacket*

$$O = (A, R, B, U, T, V, Q, E, H, C, P, N)$$

inside the carrier of Definition 1583.1. The rows have the following meanings:

1. *A is the finite coefficient-window row read from the coefficient stream or* $\mathsf{FPS}^{\uparrow}$ *surface.*

2. *R is the displayed convergence-radius or subradius row, with only the finite comparison budget needed by the request.*

3. *B is the* $\mathsf{CauchyProduct}^{\uparrow}$ *product ledger for the coefficient windows used to multiply finite polynomial truncations.*

4. *U is the selected* $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *handoff row used to justify the radius read.*

5. *T is the* $\mathsf{StreamName}^{\uparrow}$ *family of coefficient, power, product, and partial-sum windows.*

6. *V is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected partial sums and endpoint budgets.*

7. *Q is the* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row obtained from A, B, T, V.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after A, R, B, U, T, V, Q have been displayed.*

9. *H records componentwise* hsame *transport for all analytic rows and the structural rows.*

10. *C records displayed* Cont *replay from coefficient windows to products, from products to partial sums, from radius data to the selected test handoff, and from those rows to the terminal seal.*

11. *P is the* Pkg *provenance over* $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$ *obligation row.*

The classifier for obligation carriers compares only $A, R, B, U, T, V, Q, E, H, C, P, N$. It has no coordinate for analytic continuation, host infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesObligationCarrier`

Theorem 1583.3 (Real power series radius obligation)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *obligation carrier* $O = (A, R, B, U, T, V, Q, E, H, C, P, N)$*, a convergence-radius read reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$A, R \longmapsto T \longmapsto Q \longmapsto U \longmapsto V \longmapsto E$$

together with H, C, P, N*. The radius row* R *supplies a displayed radius or subradius budget; the selected test row* U *supplies only M-test, ratio-test, or root-test evidence over finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{RealSeries}^{\uparrow}$ *windows.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesObligationCarrier radius obligation`

Proof. Project the obligation carrier of Definition 1583.2. The radius-facing rows before the endpoint are exactly the coefficient window A, radius row R, stream windows T, partial-sum row Q, selected test row U, and regular rational readback V.

Read R only as displayed radius or subradius data. The row T supplies the finite coefficient, power, and partial-sum windows needed to test the radius claim, while Q records the inspected $\mathsf{RealSeries}^{\uparrow}$ partial sums.

The selected test row U is the only convergence justification. It may cite $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, or $\mathsf{RegularCauchyRootTest}^{\uparrow}$, and its endpoint-facing output is read through V before E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the obligation carrier contains no field for analytic continuation, host infinite sums, selected limits, quotient equality, countable choice, or ambient completeness, the radius obligation is confined to the displayed rows. □

Theorem 1583.4 (Real power series Cauchy-product handoff)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *obligation carrier* $O = (A, R, B, U, T, V, Q, E, H, C, P, N)$*, every endpoint-facing product of coefficient windows must pass through the* $\mathsf{CauchyProduct}^{\uparrow}$ *row* B *before it can be read as a* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row or a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The product handoff is the finite route*

$$A \longmapsto B \longmapsto T \longmapsto Q \longmapsto V \longmapsto E$$

with the same radius row R*, selected test row* U*, transport, replay, provenance, and local NameCert rows retained.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier cauchy product handoff`

Proof. Begin with the coefficient-window row A. A product consumer may inspect only the finite coefficient windows displayed in the obligation carrier, so it has no direct route to a host multiplication of infinite series.

The row B is the unique $\mathsf{CauchyProduct}^{\uparrow}$ ledger for those coefficient windows. Reading B fixes the finite convolution budget before the stream windows T and the $\mathsf{RealSeries}^{\uparrow}$ partial-sum row Q can be consumed.

The readback row V then turns the displayed partial sums and product budget into regular rational endpoint data, and the terminal seal E is downstream of that readback. The radius row R and selected test row U remain in the same packet, so the product handoff also preserves the convergence budget used by the endpoint read.

The structural rows H, C, P, N carry only componentwise transport, replay, provenance, and local naming. Because the carrier has no field for host products, quotient series equality, selected infinite sums, analytic continuation, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the Cauchy-product route is exactly the finite handoff displayed above. □

Theorem 1583.5 (Real power series coefficient-window obligation)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the coefficient and* $\mathsf{FPS}^{\uparrow}$ *obligation is exactly the route from* A *through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W *into the partial-sum row* S*. The route retains the center and argument* $\mathsf{Real}^{\uparrow}$ *rows* Z, X*, the displayed radius or subradius row* R*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback budgets,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RealSeries}^{\uparrow}$ *partial sums, componentwise transport* H*, replay* C*, provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$ *row* N*.*

Proof. Project the displayed carrier. The only coefficient-facing coordinate is A, and Definition 1583.1 says that all coefficient, real-readback, power, and partial-sum inspections pass through the finite window row W.

The partial-sum row S is the first row after those windows. It is therefore the place where $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ evidence can be read for coefficient windows and tolerances.

Finally read the structural rows H, C, P, N. They transport, replay, source, and locally name the same displayed route, while the carrier excludes host coefficient streams, quotient function spaces, selected infinite sums, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient window obligation`

Theorem 1583.6 (Real power series majorant-radius obligation)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the displayed radius or subradius row* R *reaches endpoint-facing convergence evidence only through* W, S, M*. The majorant row* M *must be read as the selected* $\mathsf{WeierstrassMTest}^{\uparrow}$*,* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*, or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *route over the finite* $\mathsf{RealSeries}^{\uparrow}$ *partial sums, with* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, transport, replay, provenance, and local naming kept in the same packet.*

Proof. Start with the radius clause of the carrier. The row R is displayed as radius or subradius evidence, not as a host convergence theorem.

The finite windows W and partial sums S mediate every read from R to convergence data. Thus the majorant row M can be consumed only after the coefficient, center, argument, radius, window, and partial-sum rows have been exposed.

The allowed shapes of M are the named M-test, ratio-test, and root-test routes. Since H, C, P, N only preserve the same carrier, the radius obligation cannot escape into analytic continuation, quotient function values, selected sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier majorant radius obligation`

Theorem 1583.7 (Real power series radius-window obligation basis)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the radius row* R *is usable by convergence consumers only after the coefficient stream row* A*, center and argument rows* Z, X*, finite* $\mathsf{StreamName}^{\uparrow}$

windows W, partial-sum row S, and selected majorant row M have been displayed. The basis row is the finite route

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E$$

with the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N. It may cite* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RealSeries$^{\uparrow}$*, and* Real$^{\uparrow}$ *only through those displayed rows.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius window obligation basis`

Proof. First expose the coefficient and point windows. By Definition 1583.5, the coefficient stream row A and the center and argument rows Z, X reach a partial-sum consumer only through the finite StreamName$^{\uparrow}$ windows W.

Next read the radius and majorant surface. By Definition 1583.6, the radius row R is not independently consumable; it must pass through W, S, M, where S is the finite RealSeries$^{\uparrow}$ partial-sum row and M is the selected majorant row.

The handoff is fixed by Definition 1583.11. It gives the displayed route from A, Z, X, R through W, S, M before the endpoint seal E and preserves the same BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 1583.9. The terminal Real$^{\uparrow}$ seal and the RegSeqRat$^{\uparrow}$ and DyadicRatCore$^{\uparrow}$ readbacks are available only along that finite route, so a convergence consumer cannot read R by host convergence, selected infinite sums, or ambient Real$^{\uparrow}$ completeness. □

Theorem 1583.8 (Real power series obligation scope)**.** *For every accepted* RealPowerSeries$^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, coefficient data are exposed only through the* FPS$^{\uparrow}$ *or* StreamName$^{\uparrow}$ *windows in A and W, radius data only through the displayed* ConvRad$^{\uparrow}$ *or subradius row R, partial sums only through the* RealSeries$^{\uparrow}$ *row S, convergence justification only through the selected* WeierstrassMTest$^{\uparrow}$*,* RegularCauchyRatioTest$^{\uparrow}$*, or* RegularCauchyRootTest$^{\uparrow}$ *majorant row M, and terminal output only through the* Real$^{\uparrow}$ *seal E after the* DyadicRatCore$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *readbacks named by W, S, M have been consumed.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesObligationScope`

Proof. Project the carrier of Definition 1583.1. Its coefficient-facing coordinates are A and the finite windows W, its radius coordinate is R, its partial-sum coordinate is S, its convergence coordinate is M, and its terminal row is E.

Apply Definition 1583.5 to force coefficient and formal-series reads through A and W. Apply Definition 1583.6 to place radius reads before the partial-sum and majorant rows. Apply Definition 1583.9 to place the endpoint seal after the dyadic and regular-rational readbacks.

The structural rows H, C, P, N only transport, replay, source, and name the same route. Since the carrier has no coordinate for analytic continuation, quotient function spaces, selected sums, countable choice, or ambient Real$^{\uparrow}$ completeness, row exhaustion excludes each of those objects from the accepted obligation scope. □

Theorem 1583.9 (Real power series terminal Real seal obligation)**.** *For every accepted* RealPowerSeries$^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, the terminal* Real$^{\uparrow}$ *seal E is available only after the coefficient or* FPS$^{\uparrow}$ *row A, center and argument* Real$^{\uparrow}$ *rows Z, X, radius row R, finite* StreamName$^{\uparrow}$ *windows W,* RegSeqRat$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$ *tolerance readbacks,* RealSeries$^{\uparrow}$ *partial sums S, and M-test or ratio/root-test majorant row M have been read. The seal is transported, replayed, sourced, and named only by H, C, P, N.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier terminal real seal obligation`

Proof. Read the endpoint clause in the carrier. The row E is produced only after the displayed windows, partial sums, radius row, and majorant route have been assembled.

The preceding rows determine the terminal route: coefficients or formal-series data enter through A, real input data through Z, X, tolerances through R, W, S, and convergence justification through M.

The field-exclusion clause of the definition then supplies nonescape. No carrier coordinate remains for a host infinite sum, function-space quotient, analytic continuation theorem, countable-choice selector, or ambient real-completeness witness, so E is exactly the local terminal Real seal of the packet. □

Theorem 1583.10 (Real power series NameCert obligations)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows, coefficient-stream access through* A*, center and argument sealing through* Z *and* X*, radius-window admission through* R*, selected* $\mathsf{StreamName}^{\uparrow}$ *windows through* W*, finite partial-sum and* $\mathsf{RealSeries}^{\uparrow}$ *handoff through* S*, majorant-route admission through* M*, endpoint sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesUpTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1583.1. The coefficient, point, radius, window, partial-sum, and majorant coordinates are exactly A, Z, X, R, W, S, M, so every analytic observation must enter through those rows.

The endpoint row E is read only after that displayed route has been assembled. Thus the real-facing output is a packet endpoint seal rather than a host infinite sum or an ambient completeness witness.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no additional coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1583.11 (Real power series radius-window handoff)**.** *Every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *evaluation read factors through*

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E$$

together with H, C, P, N*. The row* R *supplies only a displayed radius or subradius window,* S *supplies only finite polynomial partial sums and their* $\mathsf{RealSeries}^{\uparrow}$ *handoff, and* M *supplies only the selected* $\mathsf{WeierstrassMTest}^{\uparrow}$*,* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*, or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *majorant route.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius window handoff`

Proof. Begin with a requested evaluation. By Definition 1583.1, the request can inspect the coefficient row A, center Z, argument X, and displayed radius row R before it chooses any finite windows.

The selected windows W expose only the coefficients, real-point readbacks, powers of $X - Z$, and inspected partial sums needed for the request. The partial-sum row S repacks those reads as the finite $\mathsf{RealSeries}^{\uparrow}$ surface visible to the convergence machinery.

The majorant row M is then the only route from the finite partial sums to endpoint convergence data. Reading E and the structural rows H, C, P, N therefore hands off a finite radius-window certificate and no host convergence theorem. □

Theorem 1583.12 (Real power series center evaluation window)**.** *Let $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier. An evaluation request whose displayed argument row X is the same center row Z may read the endpoint seal only through the coefficient row A, the finite window row W restricted to the constant coefficient and the zero-power window, the partial-sum row S, the selected majorant row M, and then E, H, C, P, N. The center evaluation exports no host Taylor theorem, analytic continuation, selected infinite sum, quotient function equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCenterEvaluationWindow`

Proof. Project the accepted carrier. The rows available to an evaluation request are exactly $A, Z, X, R, W, S, M, E, H, C, P, N$.

Apply Definition 1583.11. It routes every evaluation through A, Z, X, R before the finite window row W, and then through S and M before the endpoint seal E can be read.

Use the displayed equality of the argument row with the center row. In that local request, the finite power window inside W collapses to the zero-power read, so the only coefficient-facing data that can reach S is the constant coefficient route from A through the corresponding window in W.

Finally apply Definition 1583.23 and Definition 1583.9. The endpoint remains inside the displayed packet and the terminal $\mathsf{Real}^{\uparrow}$ seal is read only after the finite rows already named, so none of the excluded host analytic, selector, quotient, choice, or ambient-completeness objects can be exported. □

Theorem 1583.13 (Real power series coefficient-shift route)**.** *Let $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier. Shifting the center row Z to any displayed subcenter admitted by the finite radius-window row R preserves coefficient reads only along*

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E$$

together with H, C, P, N. The shifted read may reindex a displayed finite coefficient window, but it cannot import an ambient Taylor expansion, a chosen analytic continuation, or an infinite coefficient selector.

Proof. Begin with the radius-window handoff of Definition 1583.11. It places every endpoint-facing read after the coefficient, center, argument, and radius rows A, Z, X, R.

A subcenter is therefore visible only as data already admitted by R and inspected through the finite window row W. Reindexing coefficients changes the window read, not the carrier route.

The partial-sum and majorant rows S, M consume that displayed window before the endpoint seal E is available. The structural rows H, C, P, N transport, replay, source, and name the same packet, so no host analytic continuation or infinite coefficient selection is introduced. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient shift route`

Theorem 1583.14 (Real power series Cauchy-product radius budget)**.** *For an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, every product of accepted partial-sum windows must consume the displayed* $\mathsf{CauchyProduct}^{\uparrow}$ *budget inside S before it reaches the endpoint seal E. The product route remains bounded by the same $A, Z, X, R, W, S, M, H, C, P, N$ rows and cannot pass directly from two host sums to an endpoint value.*

Proof. Read the product request as a consumer of the partial-sum row S. By Definition 1583.11, S is reached only after the coefficient, center, argument, radius, and finite-window rows have been displayed.

The Cauchy-product budget is therefore a finite ledger inside the partial-sum route. It pairs only accepted windows already exposed by W and then hands the resulting product window to the majorant row M.

Only after that majorant route is consumed may the endpoint seal E be read. Thus the product construction has no coordinate for multiplying selected infinite sums, appealing to host convergence, or bypassing the displayed radius budget. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier cauchy product radius budget`

Theorem 1583.15 (Real power series majorant consumer coverage)**.** *Every convergence-facing consumer of an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier must select exactly one displayed majorant route from* $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *at row M before reading E. A consumer that uses host analytic continuation, a selected infinite sum, or an unstated completeness theorem is not a* $\mathsf{RealPowerSeries}^{\uparrow}$ *consumer of the displayed packet.*

Proof. Apply Definition 1583.11. The endpoint-facing path passes through S and then through M, so convergence data is visible only at the majorant row.

The carrier description gives three displayed majorant routes at M: the M-test route, the ratio-test route, and the root-test route. Choosing more than one route would be additional data, while choosing none would leave no convergence-facing coordinate before E.

The endpoint seal consumes exactly the selected route. Host analytic continuation, selected infinite sums, and ambient completeness are absent from the carrier and are refused by the finite-window boundary. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier majorant consumer coverage`

Theorem 1583.16 (Real power series coefficient-window transport)**.** *Let $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier. Any coefficient-window consumer transported along H and replayed along C reaches the partial-sum row S only through the displayed coefficient row A and the finite window row W. The transported read preserves the same center row Z, argument row X, radius row R, majorant row M, endpoint seal E, provenance P, and local naming N.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient window transport`

Proof. Project the carrier of Definition 1583.1. The only coefficient-facing coordinate is A, and the only row that exposes coefficient observations to downstream evaluation is W.

Apply Definition 1583.11. The handoff places W before S, so transport through H and replay through C can move a coefficient-window read only along the displayed A, W, S route.

The remaining rows are carried componentwise. Thus Z, X, R, M, E, P, N stay attached to the same packet, and no host coefficient stream, quotient function space, or selected infinite coefficient object is introduced. □

Theorem 1583.17 (Real power series radius subwindow monotonicity)**.** *For an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, replacing the displayed radius-window row R by a finite subwindow already admitted by W preserves the evaluation route*

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E$$

and keeps the same transport, replay, provenance, and naming rows H, C, P, N. The subwindow operation narrows the inspected radius evidence; it does not create an endpoint outside the displayed majorant route.

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius subwindow monotonicity`

Proof. Read the radius clause in Definition 1583.1. The row R is only a displayed radius or subradius row, while W records the finite windows through which the evaluation is inspected.

Use Definition 1583.11. A smaller admitted radius window remains before the same finite-window row W, the same partial-sum row S, and the same majorant row M.

The endpoint seal E is still downstream of the majorant route. Since the carrier has no coordinate for ambient analytic continuation or completeness, narrowing R cannot export a new endpoint principle. □

Theorem 1583.18 (Real power series partial-sum majorant readback)**.** *Every partial-sum readback from an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ *factors from the finite polynomial-sum row* S *into the selected majorant row* M *before the endpoint seal* E *can be read. The readback may cite* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *through* S *and* M*, but it receives no selected infinite sum or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier partial sum majorant readback`

Proof. Start from the partial-sum clause of Definition 1583.1. The row S lists only the inspected polynomial sums and their finite $\mathsf{RealSeries}^{\uparrow}$ handoff.

Apply Definition 1583.11. The endpoint-facing path from S must pass through M, where the selected M-test, ratio-test, or root-test route is displayed.

Finally use Definition 1583.23. The carrier exports the finite majorant readback and the endpoint seal, not a host infinite series object, selected sum, or completeness theorem. □

Theorem 1583.19 (Real power series radius-majorant coverage)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the radius and majorant coverage surface is exactly the route through the coefficient-window obligation, majorant-radius obligation, terminal* $\mathsf{Real}^{\uparrow}$ *seal obligation, radius-window handoff, and partial-sum majorant readback rows. Endpoint convergence is visible only through* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$ *or the ratio/root-test rows,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius majorant coverage`

Proof. Project the carrier K. The coefficient row A, radius row R, finite windows W, partial sums S, selected majorant row M, and endpoint seal E are the only analytic-facing coordinates.

Apply the coefficient-window obligation, the majorant-radius obligation, and the terminal seal obligation. These rows place all coefficient reads, radius reads, and endpoint reads inside A, R, W, S, M, E with the same structural rows H, C, P, N.

Use the radius-window handoff and partial-sum majorant readback to identify the route from finite windows to convergence evidence. The allowed endpoint evidence is therefore exhausted by the named BEDC rows, and no analytic continuation, host infinite sum, or $\mathsf{Real}^{\uparrow}$ completeness coordinate is introduced. □

Theorem 1583.20 (Real power series stream-window convergence route)**.** *Every convergence-facing read from an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ *must first expose the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W *for coefficients, point readbacks, powers, and partial sums before it can consume the selected majorant row* M *or the endpoint seal* E*. The route may pass through* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$,

RegSeqRat$^{\uparrow}$, *and* DyadicRatCore$^{\uparrow}$, *but it cannot bypass* W *by using a host convergence theorem or a selected infinite sum.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier stream window convergence route`

Proof. Start with Definition 1583.5. It forces coefficient and formal-series access through the finite window row W before any partial-sum row is available.

Apply Definition 1583.11. The handoff places W before S, then S before M, and finally M before the endpoint seal E.

The partial-sum majorant readback keeps the convergence witness inside the displayed majorant route. Since the carrier contains no host convergence theorem or selected sum coordinate, every convergence-facing read preserves the stream-window route. □

Theorem 1583.21 (Real power series RegSeqRat endpoint handoff)**.** *For every accepted* RealPowerSeries$^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the* RegSeqRat$^{\uparrow}$*-facing endpoint handoff is read only after the coefficient windows, radius row, partial-sum row, and majorant route have been displayed. The handoff may cite* RealSeries$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RegularCauchyRatioTest$^{\uparrow}$, RegularCauchyRootTest$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *through* W, S, M, E, H, C, P, N*, and it exports no analytic continuation, host infinite sum, quotient function space, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Use Definition 1583.26. It already identifies the RegSeqRat$^{\uparrow}$-facing budget as the route from A, Z, X, R through W, S, M, E.

The radius-majorant coverage theorem above ties that budget to the coefficient-window, majorant-radius, terminal seal, radius-window, and partial-sum readback rows. Thus endpoint-facing RegSeqRat$^{\uparrow}$ data are visible only after the finite radius and majorant surface has been read.

Finally apply Definition 1583.23. The endpoint handoff remains inside K and its structural rows, so no excluded analytic or completeness object can be exported. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier regseqrat endpoint handoff`

Theorem 1583.22 (Real power series endpoint-seal factorization)**.** *The endpoint row* E *of an accepted* RealPowerSeries$^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ *factors through the coefficient row* A*, center row* Z*, argument row* X*, radius row* R*, window row* W*, partial-sum row* S*, and majorant row* M *before it can be transported or replayed through* H, C, P, N*. Thus the endpoint seal is a packet-local* Real$^{\uparrow}$ *read, not a host analytic continuation, quotient function value, selected infinite sum, countable-choice output, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier endpoint seal factorization`

Proof. Use the factorization displayed in Definition 1583.11. It places every endpoint-facing read after A, Z, X, R, W, S, M.

Use Definition 1583.10 to attach H, C, P, N to the same route. These rows transport, replay, source, and name the packet-local endpoint seal without adding analytic coordinates.

The excluded objects are absent from the carrier and from the handoff route. Therefore E remains the finite endpoint seal of the accepted packet. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesEndpointSealFactorization`

Theorem 1583.23 (Real power series nonescape)**.** *Every endpoint-facing read from an accepted* RealPowerSeries$^{\uparrow}$ *carrier passes through* $A, Z, X, R, W, S, M, E, H, C, P, N$*. Consequently a consumer may use the displayed* RealSeries$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RegularCauchyRatioTest$^{\uparrow}$, RegularCauchyRootTest$^{\uparrow}$,

$\mathsf{FPS}^{\uparrow}$, *and* $\mathsf{ConvRad}^{\uparrow}$ *interfaces named by the packet, but it receives no host analytic continuation, quotient function space, selected infinite sum, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 1583.11 to place every endpoint-facing evaluation on the finite route through A, Z, X, R, W, S, M. The endpoint seal E consumes that route after the coefficient, point, radius, partial-sum, and majorant data have been displayed.

The formal series and convergence-radius rows remain named inputs to the packet, not ambient host objects. They expose coefficient and radius evidence only through the finite rows retained by the carrier.

Finally read H, C, P, N. These rows preserve, replay, source, and name the same displayed data, so none of the excluded analytic or choice principles can escape through the accepted classifier. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier nonescape`

Theorem 1583.24 (Real power series coefficient-window ledger)**.** *Every coefficient-facing or* $\mathsf{FPS}^{\uparrow}$ *read from an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier must pass through A and then through the finite window row W before it can contribute to the partial-sum row S. Thus coefficients reach endpoint-facing evidence only as displayed stream windows, center-readbacks, argument-readbacks, powers of $X - Z$, and inspected polynomial sums.*

Proof. Start from the carrier of Definition 1583.1. The only coefficient or formal-series coordinate is A, and the only row that exposes coefficient inspections to downstream evaluation is the finite window row W.

Apply Definition 1583.11. The handoff places W before S, so partial sums can use only those displayed coefficient and power windows.

Finally apply Definition 1583.23. Since the accepted carrier has no other coefficient coordinate, no host stream, selected infinite coefficient object, or ambient analytic series can bypass the A, W, S route. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient window ledger`

Theorem 1583.25 (Real power series majorant-route totality)**.** *All convergence evidence exported by an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier passes through M as a selected* $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *route. The carrier therefore exposes convergence only through the displayed majorant row and not through a host convergence theorem, selected infinite sum, or ambient completeness proof.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier majorant route totality`

Proof. Use Definition 1583.1. The row M is the only convergence-test coordinate, and it is explicitly limited to the named M-test, ratio-test, or root-test routes.

By Definition 1583.11, the finite partial sums S must pass through M before an endpoint seal can be read. Thus every convergence-facing consumer receives the selected majorant route rather than a host analytic convergence object.

The boundary statement of Definition 1583.23 then excludes host analytic continuation, quotient function spaces, selected infinite sums, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the exported evidence. □

Theorem 1583.26 (Real power series majorant RegSeqRat budget)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the selected majorant row* M *yields a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing budget only through the displayed route*

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E.$$

Here S *supplies the finite* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum surface, while* M *selects exactly one of the* $\mathsf{WeierstrassMTest}^{\uparrow}$*,* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*, or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *evidence routes. The budget exports no independent regular-rational stream, selected infinite sum, host convergence theorem, quotient function space, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the radius-window handoff of Definition 1583.11. It forces every endpoint-facing evaluation through A, Z, X, R, then through the finite windows W, before any partial-sum or majorant row is available.

Apply the partial-sum majorant readback theorem, Definition 1583.18. The row S is therefore the finite $\mathsf{RealSeries}^{\uparrow}$ surface from which a $\mathsf{RegSeqRat}^{\uparrow}$-facing budget can be read, and the next row is necessarily the selected majorant row M.

Use the majorant-route totality theorem above to identify the only possible shapes of M: $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, or $\mathsf{RegularCauchyRootTest}^{\uparrow}$. Finally apply Definition 1583.23; since no other convergence or stream coordinate exists in the carrier, the budget cannot escape into the excluded host or choice principles. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier majorant regseqrat budget`

Theorem 1583.27 (Real power series majorant exhaustion)**.** *Every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *convergence read must choose exactly one of the* $\mathsf{WeierstrassMTest}^{\uparrow}$*,* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*, or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *majorant rows before the endpoint seal* E *is available. The choice is read as the displayed row* M *of the carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, and no convergence read may bypass* M *by using a host convergence theorem, selected infinite sum, analytic continuation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1583.1. Its only convergence-test coordinate is M, and the definition restricts M to the M-test, ratio-test, or root-test routes.

Apply Definition 1583.25. It places every exported convergence evidence inside that selected row rather than in a detached theorem of host analysis.

Finally use Definition 1583.26. The endpoint-facing route reaches E only after S has passed through M, so the selected majorant row is exhausted before the endpoint seal is read. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier majorant exhaustion`

Theorem 1583.28 (Real power series radius-source compatibility)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the radius row* R*, coefficient* $\mathsf{StreamName}^{\uparrow}$ *windows inside* W*, and* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row* S *share the same* BHist *source route. A consumer that reads any one of these rows must preserve the common carrier source through* H, C, P, N *before it can reach the selected majorant row* M *or the endpoint seal* E*.*

Proof. Start with the coefficient-window obligation of Definition 1583.5. The coefficient row A, radius row R, window row W, and partial-sum row S are projected from one accepted packet.

Apply the radius-window handoff of Definition 1583.11. It gives a single route from A, Z, X, R through W and S before any majorant data can be consumed.

The rows H, C, P, N then preserve, replay, source, and name that same route. Hence a radius read, coefficient-window read, or partial-sum read cannot switch to another BHist source before reaching M or E. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius source compatibility`

Theorem 1583.29 (Real power series endpoint nonescape triad)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier, the endpoint seal E cannot export any of the following three objects: a selected infinite sum, host analytic continuation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Each endpoint-facing read remains confined to the displayed route through $A, Z, X, R, W, S, M, E, H, C, P, N$.*

Proof. Use Definition 1583.22. It places the endpoint seal after the coefficient, center, argument, radius, window, partial-sum, and majorant rows, with H, C, P, N attached to the same packet.

Apply Definition 1583.23. The carrier has no coordinate for selected infinite sums, analytic continuation, or ambient completeness, and the endpoint-facing route introduces no additional row.

Therefore the three excluded objects cannot be exported by E. The endpoint seal remains the packet-local $\mathsf{Real}^{\uparrow}$ read produced by the displayed majorant route. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier endpoint nonescape triad`

Theorem 1583.30 (Real power series CauchyProduct coefficient budget)**.** *Every endpoint-facing product or convolution read from an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ must first expose the coefficient row A, center row Z, argument row X, radius row R, finite window row W, partial-sum row S, and selected majorant row M. Only after those rows are displayed may the read consume the* $\mathsf{CauchyProduct}^{\uparrow}$ *budget route named by Definition 464.101, Definition 464.118, and Definition 464.119; the endpoint seal E is exported only after that product-budget route has been read. The carrier exports no selected infinite sums, quotient function spaces, host analytic continuation, host multiplication primitive, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the RegSeqRat-facing budget of Definition 1583.26. It forces an endpoint-facing read through A, Z, X, R, W, S, M, E and identifies S as the finite $\mathsf{RealSeries}^{\uparrow}$ surface from which coefficient evidence is read.

Next apply the partial-sum majorant readback theorem, Definition 1583.18. The row M is therefore already selected before any product or convolution consumer asks for a downstream coefficient budget.

Now use the CauchyProduct budget route. The root budget product lock, source-window budget compatibility, and RegSeqRat product budget exhaustion cited in the statement route every product classifier read through the displayed CauchyProduct source windows, dyadic budget rows, product row, budget ledger, and classifier row before any Real seal is available.

Finally return to the endpoint seal E through the structural rows H, C, P, N. Since neither the power-series carrier nor the CauchyProduct budget route contains a coordinate for selected infinite sums, quotient function spaces, host analytic continuation, host multiplication, or ambient completeness, none of those objects can be exported with the endpoint seal. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier cauchy product coefficient budget`

Theorem 1583.31 (Real power series endpoint-seal scope)**.** *The endpoint row E of an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier is scoped only after the displayed route through $A, Z, X, R, W, S, M, H, C, P, N$. It exports no host analytic continuation, quotient function space, selected infinite sum, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier endpoint seal scope`

Proof. Read the endpoint clause of Definition 1583.1. The row E is produced only after the displayed windows, partial sums, radius row, and majorant route have been read.

Apply Definition 1583.11 to place the endpoint after A, Z, X, R, W, S, M and alongside the structural rows H, C, P, N. Apply Definition 1583.23 to identify the excluded analytic and choice principles.

Thus E is a finite endpoint seal for the accepted packet, not a host analytic object or a proof of ambient completeness. □

Theorem 1583.32 (Real power series root radius-majorant triad)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, root-test radius evidence must pass through the triad* R, W, S *and then through the majorant row* M *before the endpoint seal* E *is available. In particular, a* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *read cannot reach* E *directly from* R *and cannot bypass the finite coefficient windows or partial-sum row.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier root radius majorant triad`

Proof. Start with Definition 1583.11. It places the radius row R before the finite window row W, the partial-sum row S, and the majorant row M on every endpoint-facing route.

Apply Definition 1583.25. The root-test evidence is one of the allowed shapes of M, so it is consumed as majorant data rather than as a detached host convergence theorem.

Finally use Definition 1583.22. Since E is downstream of A, Z, X, R, W, S, M, root-radius evidence must pass through the majorant row before endpoint sealing. □

Theorem 1583.33 (Real power series root endpoint nonescape)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ *whose majorant row* M *is read through a* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *route, the endpoint row* E *exports no selected infinite sum, analytic continuation, quotient function space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness. The root-test route remains confined to the displayed rows of* K*.*

Proof. Read the endpoint scope theorem, Definition 1583.31. It says that E is available only after the route through $A, Z, X, R, W, S, M, H, C, P, N$.

Apply Definition 1583.25 to identify the root-test route as one possible reading of M. This does not add a new endpoint coordinate; it only selects the displayed majorant evidence.

Now use Definition 1583.23. The carrier excludes selected sums, analytic continuation, quotient function spaces, countable choice, and ambient completeness, so the root-test endpoint read cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesRootEndpointNonescape`

Theorem 1583.34 (Real power series root coefficient-window coverage)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, every coefficient read needed by a* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *majorant is already covered by the coefficient row* A*, the finite window row* W*, and the partial-sum row* S *before* M *or* E *is consumed. No root-test consumer may introduce a fresh coefficient stream outside the displayed carrier.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier root coefficient window coverage`

Proof. Start with Definition 1583.24. It forces every coefficient-facing read through A and then through the finite windows W before it contributes to S.

Use Definition 1583.11. The handoff puts S before the majorant row M, so the root-test route can consume only coefficient windows already displayed in the packet.

Finally apply Definition 1583.25. Since a root-test majorant is read as M, it receives coefficient evidence from A, W, S and cannot import a separate host coefficient stream or selected infinite series object. □

Theorem 1583.35 (Real power series evaluation-window exhaustion)**.** *Every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *evaluation consumer must pass through the coefficient or formal-series row A, the center and argument rows Z, X, the radius row R, the finite window ledger W, the partial-sum rows S, the selected majorant row M, the endpoint seal E, and the structural rows H, C, P, N. No accepted evaluation read may inspect analytic continuation, host infinite sums, quotient function spaces, selected sums, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness outside those rows.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier evaluation window exhaustion`

Proof. Project the accepted carrier through Definition 1583.1. The only evaluation-facing analytic rows are A, Z, X, R, W, S, M, E, followed by the structural rows H, C, P, N.

The coefficient-window obligation of Definition 1583.24 forces coefficient access through A and the displayed finite windows W. The radius-window handoff of Definition 1583.11 places R before the window and partial-sum rows.

Use Definition 1583.25 to bind convergence evidence to the selected majorant row M. Then Definition 1583.22 makes the endpoint seal E downstream of the same coefficient, center, argument, radius, window, partial-sum, and majorant route.

Finally apply Definition 1583.33. The forbidden objects have no row in the carrier, so an evaluation consumer has already exhausted every permitted read once it has traversed $A, Z, X, R, W, S, M, E, H, C, P, N$. □

Theorem 1583.36 (Real power series radius-majorant public export)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, the public radius-majorant evaluation surface is the route obtained by composing the coefficient-window ledger, radius-majorant coverage, CauchyProduct coefficient-budget, RegSeqRat endpoint handoff, and endpoint nonescape rows. A downstream consumer may cite R as public radius evidence only along*

$$A, Z, X, R \longmapsto W \longmapsto S \longmapsto M \longmapsto E \longmapsto H, C, P, N,$$

with product and convolution reads passing through the $\mathsf{CauchyProduct}^{\uparrow}$ *budget cited by Definition 1583.30. The export contains no host convergence theorem, selected infinite sum, analytic continuation, quotient function space, host multiplication primitive, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius majorant public export`

Proof. Project the local carrier. The carrier projection exposes $A, Z, X, R, W, S, M, E, H, C, P, N$ as the only rows available to a public evaluation read.

Apply Definition 1583.24 to place coefficient access inside A and W. Then use Definition 1583.19 to bind the radius row R to the finite window, partial-sum, selected majorant, and endpoint rows.

Next apply Definition 1583.30. Product and convolution consumers may use only the displayed CauchyProduct source windows, dyadic budget rows, product row, budget ledger, and classifier route before returning to the power-series endpoint.

Finally use Definition 1583.21 and Definition 1583.23. These rows put the $\mathsf{RegSeqRat}^{\uparrow}$ endpoint handoff and the Real seal boundary inside the same finite packet, so the listed excluded host and choice objects cannot be exported. □

Theorem 1583.37 (Real power series RegSeqRat evaluation handoff)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, every evaluation read handed to a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *endpoint consumer factors through the coefficient-window ledger, the radius-majorant public export of Definition 1583.36, the CauchyProduct coefficient-budget route, and the endpoint seal boundary. The handoff is therefore a finite route from coefficient windows and radius evidence to regular-rational endpoint readback; it does not export host analytic continuation, quotient function-space equality, selected infinite sums, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier regseqrat evaluation handoff`

Proof. Begin with Definition 1583.36. It already composes the carrier projection, coefficient-window ledger, radius-majorant coverage, CauchyProduct budget route, RegSeqRat endpoint handoff, and Real seal boundary into one public evaluation surface.

Read the $\mathsf{RegSeqRat}^{\uparrow}$ endpoint side through Definition 1583.21. This forces endpoint-facing regular-rational data to wait until $A, Z, X, R, W, S, M, E, H, C, P, N$ have all been displayed.

Use Definition 1583.30 for product-sensitive evaluations. The product budget remains downstream of the same coefficient, radius, window, partial-sum, and selected-majorant rows, so it cannot introduce a host multiplication primitive or a separate coefficient source.

Finally apply Definition 1583.31 and Definition 1583.23. The endpoint seal is packet-local and the excluded analytic, quotient, choice, and ambient-completeness objects have no carrier coordinate. □

Theorem 1583.38 (Real power series root-unblock obligation surface)**.** *Every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet exposes exactly the finite coefficient stream row, the* $\mathsf{CauchyProduct}^{\uparrow}$ *multiplication ledger, the* $\mathsf{ConvRad}^{\uparrow}$ *radius row, the* $\mathsf{RealSeries}^{\uparrow}$ *summation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *finite-window reads, the* $\mathsf{WeierstrassMTest}^{\uparrow}$ *bound row, and the local* $\mathsf{NameCert}$ *route before any real-valued power-series consumer can inspect convergence. This surface is routed through chapter 464, chapter 66, chapter 1581, chapter 301, chapter 126, and chapter 399; it exports no analytic continuation, global holomorphicity, open-disk completeness, or host real equality.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier root unblock obligation surface`

Proof. Project the carrier $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ of Definition 1583.1. The coefficient stream is read through A and W, the radius data through R, the finite summation data through S, the selected majorant data through M, and the endpoint through E.

Use Definition 1583.36. It composes the coefficient-window ledger, radius-majorant coverage, CauchyProduct coefficient budget, RegSeqRat endpoint handoff, and endpoint nonescape rows into one consumer-facing route. The cited CauchyProduct sibling supplies the multiplication ledger, while the ConvergenceRadius, RealSeries, RegSeqRat, StreamName, and WeierstrassMTest siblings supply the named rows consumed by that route.

Finally apply Definition 1583.37. A real-valued endpoint consumer must pass through the same finite rows before convergence can be inspected. Since the carrier and the cited sibling routes have no coordinates for analytic continuation, global holomorphicity, open-disk completeness, or host real equality, those claims are refused at this obligation surface. □

Theorem 1583.39 (Real power series coefficient-tail obligations)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, every endpoint-facing read first exposes the coefficient stream row* A*, a finite tail window inside* W*, and the* $\mathsf{CauchyProduct}^{\uparrow}$ *ledger rows named by* P*. These rows are displayed before the endpoint seal* E *is available and before any consumer may inspect a power-series value.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient tail obligations`

Proof. Project the carrier of Definition 1583.1. The coefficient stream is the row A, while W carries the finite windows for coefficients, point readbacks, powers, and partial sums.

Use the product-sensitive route of Definition 1583.30. It forces endpoint-facing product or convolution reads to consume the coefficient row, finite window row, partial-sum row, and selected majorant row before the endpoint seal can be read.

Finally preserve the route through H, C, P, N. Since the $\mathsf{CauchyProduct}^{\uparrow}$ ledger is part of the displayed provenance route and not a host multiplication theorem, the endpoint read sees only finite coefficient-tail and product-budget rows. □

Theorem 1583.40 (Real power series radius-test window exhaustion)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, each radius-test read factors through the displayed* $\mathsf{ConvRad}^{\uparrow}$ *row* R *and then through a* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *or* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *window recorded in* M *and* W*. The route cannot inspect an endpoint seal, host radius theorem, or infinite coefficient tail before those finite windows are exhausted.*

Proof. Start with Definition 1583.11. It places the radius row R before endpoint-facing convergence evidence and routes that evidence through W, S, M.

Then apply Definition 1583.25. The selected majorant row must be one of the displayed M-test, ratio-test, or root-test routes, and the ratio/root alternatives are finite windows carried by the same packet.

The endpoint seal E remains downstream by Definition 1583.32 and Definition 1583.34. Thus a radius-test read is exhausted at the finite $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, or $\mathsf{RegularCauchyRootTest}^{\uparrow}$ windows before any endpoint value can be consumed. □

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius test window exhaustion`

Theorem 1583.41 (Real power series endpoint Cauchy budget)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *carrier* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, endpoint evaluation is routed through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback budgets,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows before it can be exported. The route exports no selected infinite sum, quotient function space, analytic continuation, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier endpoint cauchy budget`

Proof. Read the endpoint side through Definition 1583.21. It forces every $\mathsf{RegSeqRat}^{\uparrow}$-facing endpoint handoff to consume the finite windows, regular-rational budgets, dyadic tolerances, partial-sum rows, selected majorant rows, and terminal seal as one packet route.

Use Definition 1583.22. The endpoint seal factors through $A, Z, X, R, W, S, M, H, C, P, N$, so the $\mathsf{Real}^{\uparrow}$ row is reached only after the Cauchy-facing budget has been displayed.

Finally apply Definition 1583.23. The excluded analytic, quotient, choice, and ambient-completeness objects are not carrier fields and cannot be exported by endpoint evaluation. □

Theorem 1583.42 (Real power series product coefficient-window lock)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, every coefficient product read used for powers of* $X - Z$ *must pass through the coefficient row* A*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W*, the finite partial-sum row* S*, the selected majorant row* M*, and the* $\mathsf{CauchyProduct}^{\uparrow}$ *product route cited by the provenance row* P*. Such a read cannot use host multiplication, quotient functions, selected infinite sums, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness outside the displayed carrier.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier product coefficient window lock`

Proof. Project the carrier of Definition 1583.1. Coefficient access is stored in A, and the finite windows for coefficient, point, power, and partial-sum reads are stored in W before S or M can be consumed.

Apply Definition 1583.24 and Definition 1583.30. These theorems route product-sensitive coefficient reads through the displayed coefficient windows, partial-sum row, selected majorant row, and CauchyProduct source windows before returning to the power-series packet.

Finally use Definition 1583.23. Since host multiplication, quotient function spaces, selected infinite sums, and ambient completeness are not carrier fields, the coefficient product read remains locked to the finite product route. □

Theorem 1583.43 (Real power series product endpoint nonescape)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal for a power-series evaluation is downstream of the* $\mathsf{CauchyProduct}^{\uparrow}$ *product route together with* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealSeries}^{\uparrow}$*,* $\mathsf{WeierstrassMTest}^{\uparrow}$*, ratio-test, and root-test majorant rows. The endpoint cannot escape from that route to host analytic continuation, quotient function equality, selected infinite sums, host multiplication, countable choice, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier product endpoint nonescape`

Proof. Begin with Definition 1583.42. It places every product coefficient read on the route through A, W, S, M and the CauchyProduct product surface before the endpoint seal is available.

Use Definition 1583.36. That theorem composes the coefficient-window ledger, radius-majorant coverage, CauchyProduct coefficient budget, RegSeqRat endpoint handoff, and endpoint nonescape rows into the public evaluation surface.

Now apply Definition 1583.41. The endpoint seal is read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, partial sums, selected majorants, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The majorant row may be supplied by $\mathsf{WeierstrassMTest}^{\uparrow}$, ratio-test, or root-test evidence, but it remains a displayed row of M.

The excluded analytic, quotient, multiplication, choice, and ambient-completeness objects have no carrier coordinate. Thus the terminal endpoint remains downstream of the product and regular-rational route. □

Theorem 1583.44 (Real power series radius composition)**.** *Let* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$ *and* $K' = (A', Z', X', R', W', S', M', E', H', C', P', N')$ *be accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packets whose displayed radius windows are compatible through their* $\mathsf{ConvRad}^{\uparrow}$ *rows and whose product-side coefficient windows are admitted by the same* $\mathsf{CauchyProduct}^{\uparrow}$ *budget route. Then any product-side radius consumer reads only the common radius-window and coefficient-window route*

$$A, A', R, R' \longmapsto W, W' \longmapsto S, S' \longmapsto M, M' \longmapsto E, E'$$

together with the structural rows of the two packets. The composed read may cite $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *only through those displayed rows, and it exports no host*

product of infinite sums, selected limit, analytic-continuation equality, countable choice, or ambient Real-completeness claim.

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier radius composition`

Proof. First apply Definition 1583.11 to both packets. Each endpoint-facing read must expose its coefficient, center, argument, radius, finite-window, partial-sum, selected-majorant, and endpoint rows before any radius consumer can inspect the seal.

Next use Definition 1583.14. The product request is a finite $\mathsf{CauchyProduct}^{\uparrow}$ budget inside the displayed partial-sum route, so it can pair only coefficient windows already exposed by W, W'.

Finally apply Definition 1583.22 and Definition 1583.43. The endpoint seal remains downstream of the common window route and the excluded host, selector, analytic-continuation, choice, and completeness objects have no carrier coordinate. □

Theorem 1583.45 (Real power series coefficient-product-radius exhaustion)**.** *Let $K = (A, Z, X, R, W, S, M, E, H,$ be an accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet, and let a downstream endpoint-facing consumer request an evaluation, product evaluation, or radius-limited read of K. Then the consumer must first expose the coefficient windows A, W; when products are present it must also expose a displayed* $\mathsf{CauchyProduct}^{\uparrow}$ *ledger B for the product coefficients cited by P; it must then expose the radius or subradius row R, the selected majorant row M, the partial-sum rows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback route, and only then the endpoint seal E. The resulting read exports no host product of infinite sums, endpoint selector, analytic-continuation equality, quotient function equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier coefficient product radius exhaustion`

Proof. Begin with the coefficient-window ledger. Theorems Definition 1583.24 and Definition 1583.16 force every evaluation or product request to display the coefficient source A and the finite windows W before the endpoint row can be inspected.

For product-facing requests, apply Definition 1583.14 and Definition 1583.42. These place the $\mathsf{CauchyProduct}^{\uparrow}$ product ledger on the same finite coefficient-window route and prevent a product consumer from reading undisplayed product coefficients.

Next read the radius side. The radius-window handoff and radius-majorant coverage theorems require the radius or subradius row R and the selected majorant row M before the partial sums and endpoint seal are consumed.

Finally apply Definition 1583.22, Definition 1583.29, and Definition 1583.44. The partial-sum rows S, the regular-rational and dyadic readback route, and the endpoint seal E are downstream of the displayed coefficient, product, radius, and majorant rows. Since the excluded analytic, quotient, selector, choice, and completeness objects have no carrier coordinate, the listed route exhausts every endpoint-facing read. □

Theorem 1583.46 (Real power series obligation export)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$, the downstream obligation package exported to* $\mathsf{Real}^{\uparrow}$ *and completion-facing consumers is the conjunction of the radius obligation, coefficient-window obligation,* $\mathsf{CauchyProduct}^{\uparrow}$ *handoff, majorant route,* $\mathsf{RegSeqRat}^{\uparrow}$ *evaluation handoff, endpoint seal, and product coefficient-window lock. Every consumer reads this package through $A, Z, X, R, W, S, M, E, H$ together with* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$, *and no consumer receives host analytic continuation, quotient function equality, selected infinite sums, host multiplication, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier obligation radius export`

Proof. Begin with the carrier and NameCert surface, Definition 1583.1 and Definition 1583.10. These rows expose the coefficient source, center, argument, radius, finite windows, partial sums, majorant data, endpoint seal, transport, continuation, provenance, and local naming.

The radius and coefficient obligations are supplied by Definition 1583.11, Definition 1583.24, and Definition 1583.16. Together they force a consumer to read A, R, W before endpoint or product data.

The product side is supplied by Definition 1583.14, Definition 1583.42, and Definition 1583.45. These theorems place the $\mathsf{CauchyProduct}^{\uparrow}$ handoff on the same finite coefficient-window and radius route.

Finally apply Definition 1583.36, Definition 1583.22, and Definition 1583.43. They bind the majorant route, regular-rational evaluation handoff, and endpoint seal, while excluding analytic continuation, quotient equality, selected sums, host multiplication, choice, and ambient completeness. The cited rows therefore form the exported obligation package. □

Theorem 1583.47 (Real power series obligation closure ledger)**.** *For every accepted* $\mathsf{RealPowerSeries}^{\uparrow}$ *packet* $K = (A, Z, X, R, W, S, M, E, H, C, P, N)$*, the obligation package is exactly the carrier admission row, coefficient-window route, radius-window handoff,* $\mathsf{CauchyProduct}^{\uparrow}$ *budget, selected majorant route,* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint handoff, endpoint seal, transport, replay, provenance, and local naming rows displayed by this chapter. No obligation row outside* $A, Z, X, R, W, S, M, E, H, C, P, N$ *is exported to an endpoint-facing, product-facing, or radius-facing consumer.*

Lean4 ✓ `BEDC.Derived.RealPowerSeriesUp.RealPowerSeriesCarrier obligation closure ledger`

Proof. Carrier admission and local naming are fixed by Definition 1583.1 and Definition 1583.10. These rows expose exactly the coefficient stream or formal-series row, center and argument rows, radius row, finite windows, partial sums, selected majorant route, endpoint seal, transport, replay, provenance, and local NameCert row.

The analytic obligations are the existing ledger rows. The coefficient-window route is Definition 1583.24; the radius-window handoff is Definition 1583.11; the $\mathsf{CauchyProduct}^{\uparrow}$ budget is Definition 1583.30; the selected majorant route is Definition 1583.27; and the $\mathsf{RegSeqRat}^{\uparrow}$ endpoint handoff is Definition 1583.21.

The endpoint and structural rows are sealed by Definition 1583.22, Definition 1583.41, Definition 1583.43, and Definition 1583.46. Together with Definition 1583.23, these results leave no carrier coordinate for analytic continuation, quotient function equality, selected infinite sums, host multiplication, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence the listed rows are the complete obligation package. □

Falsifiable prediction: Every $\mathsf{RealPowerSeries}^{\uparrow}$ endpoint-facing read factors through a coefficient or FormalPowerSeries row, center Real row, argument Real row, displayed radius or subradius row, finite StreamName windows, partial-sum RealSeries row, majorant data from M-test or ratio/root-test rows, endpoint Real seal, transport, continuation, provenance, and local naming.

Independence witness: realseries, weierstrass-mtest, regular-cauchy-ratio-test, regular-cauchy-root-test, formalpowerseries, convergence-radius, real, regseqrat, streamname, dyadicratcore: $\mathsf{RealPowerSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries coefficient-stream access, center and argument Real rows, displayed radius windows, finite polynomial partial sums, selected majorant routes, endpoint sealing, transport, continuation, provenance, and local naming.

Theorem 1583.48 (RealPowerSeries scoped radius ledger)**.** *The scoped surface of* $\mathsf{RealPowerSeries}^{\uparrow}$ *is exactly the displayed coefficient-window carrier, radius witness,* $\mathsf{CauchyProduct}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay, and* Pkg *provenance recorded by the carrier*

$$K = (A, Z, X, R, W, S, M, E, H, C, P, N).$$

Every endpoint-facing, product-facing, or radius-facing consumer must read the packet through $A, Z, X, R, W, S, M, E, H, C, P, N$ *before it may use the endpoint seal, and no consumer receives host analytic continuation, quotient function equality, selected infinite sums, host multiplication, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness as an additional coordinate.*

Proof. Project the carrier of Definition 1583.1. The rows $A, Z, X, R, W, S, M, E, H, C, P, N$ are the only rows available to a consumer, so the coefficient source, center, argument, radius witness, finite windows, partial sums, majorant route, endpoint seal, transport, replay, provenance, and local naming are the visible scope boundary.

Apply Definition 1583.47. It identifies carrier admission, the coefficient-window route, the radius-window handoff, the $\mathsf{CauchyProduct}^{\uparrow}$ budget, selected majorant route, $\mathsf{RegSeqRat}^{\uparrow}$ endpoint handoff, endpoint seal, transport, replay, provenance, and local naming as the complete obligation package.

Finally use Definition 1583.45 and Definition 1583.43. They keep product and endpoint requests downstream of the same coefficient, radius, tolerance, readback, and seal rows, while the excluded analytic, quotient, selector, choice, and completeness objects have no carrier coordinate. Hence the displayed rows are exactly the scoped ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealPowerSeries}^{\uparrow}$ packet is generated from a coefficient stream or formal-series row, center and argument $\mathsf{Real}^{\uparrow}$ rows, a displayed radius or subradius row, finite $\mathsf{StreamName}^{\uparrow}$ windows, finite partial-sum and $\mathsf{RealSeries}^{\uparrow}$ rows, majorant data from M-test or ratio/root-test rows, a $\mathsf{Real}^{\uparrow}$ endpoint seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1583.1, Definition 1583.10, Definition 1583.47, and Definition 1583.48 bind the coefficient-window carrier, radius witness, product handoff, majorant route, $\mathsf{RealSeries}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ readbacks, terminal $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, local naming, and nonescape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealPowerSeries}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host analytic continuation, quotient function spaces, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Lean verification and bridge checking remain for the finite coefficient-window, radius, Cauchy-product, majorant, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ seal route displayed by this chapter.

Chapter 1584

A Concrete Naming Certificate for NestedIntervalCompactness$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the NestedIntervalCompactness$^{\uparrow}$ packet records the finite-window form of nested-interval compactness before any general Heine–Borel or open-cover principle is available. It reads the nested interval carrier of chapter 320, the located endpoint surface of chapter 394, the dyadic interval ledger of chapter 306, finite stream observations from chapter 126, regular rational readback from chapter 301, and the terminal real seal of chapter 38. The packet gives Real-facing countable-name arguments a finite nested-window certificate; it does not select real endpoints, identify quotient real names, invoke countable choice, or assert compactness for arbitrary covers.

Definition 1584.1 (NestedIntervalCompactness carrier)**.** *A* NestedIntervalCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* NestedInterval$^{\uparrow}$ *row naming the inspected finite prefix of nested intervals.*
2. *L is the* LocatedInterval$^{\uparrow}$ *endpoint-location row for the same displayed prefix.*
3. *D is the* DyadicInterval$^{\uparrow}$ *row containing the dyadic endpoint boxes, inclusion checks, and width comparisons used by the finite prefix.*
4. *W is the* StreamName$^{\uparrow}$ *window row through which candidate real-name observations are read at the displayed precisions.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row extracted from the windows and dyadic boxes.*
6. *E is the* Real$^{\uparrow}$ *seal boundary reached only after I, L, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for nested intervals, located endpoints, dyadic boxes, stream windows, regular readback, the real seal, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite prefix request through the located interval row, dyadic interval row, stream windows, regular readback, and the real seal boundary.*
9. *P is the* Pkg *provenance over* NestedIntervalCompactness$^{\uparrow}$, NestedInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, DyadicInterval$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCompactness}^{\uparrow}}$ *row naming the displayed finite-window packet and its permitted consumer reads.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for a general open-cover principle, a Heine–Borel theorem, a selected host endpoint, quotient real equality, countable choice, or an infinite intersection object outside the displayed finite windows.

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessTasteGate single carrier alignment`

Theorem 1584.2 (NestedIntervalCompactness finite-intersection window)**.** *Let $K = (I, L, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *carrier. Every finite prefix request for the nested family reads the displayed route*

$$I, L, D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the finite-window intersection witness available to a Real-facing consumer is the regular-rational readback over the same displayed dyadic and located interval rows. The witness is not a selected point of the full countable intersection and is not an open-cover compactness certificate.

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier finite intersection window`

Proof. Project the carrier of Definition 1584.1. The prefix request first exposes I, then the located endpoint row L, and then the dyadic interval row D for the same finite prefix.

The continuation row C routes the request from those interval rows into the stream windows W and the regular rational readback R. Thus the Real-facing observation is read from displayed finite data rather than from an ambient completeness or compactness principle.

Finally E, H, P, N seal, transport, source, and name that route. Since no row contains a selected endpoint of the full intersection, quotient real equality, countable choice, or open-cover data, the finite prefix witness is exactly the displayed finite-window route. □

Theorem 1584.3 (NestedIntervalCompactness NameCert obligations)**.** *For every accepted* NestedIntervalCompactn *carrier $K = (I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCompactness}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the nested interval prefix, located endpoints, dyadic interval ledger, stream windows, regular rational readback, real seal boundary, transport, continuation replay, provenance, and local naming row;*
2. *finite-prefix monotonicity, requiring every accepted read to consume the same displayed nesting and inclusion cells in I and D;*
3. *located dyadic exactness, requiring the endpoint-location row L and dyadic interval row D to govern the same interval prefix before any readback row R is exposed;*
4. *Real seal routing, requiring E to remain downstream of I, L, D, W, R and upstream of only the structural rows H, C, P, N;*
5. *ledger non-escape, excluding general Heine–Borel compactness, open-cover compactness, selected real endpoints, quotient real equality, countable choice, and detached infinite-intersection objects.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier namecert obligations`

Proof. Carrier admission is the row projection of Definition 1584.1. It exposes exactly $I, L, D, W, R, E, H, C, P, N$.

Finite-prefix monotonicity is read from I together with the inclusion cells in D. Located dyadic exactness then binds the endpoint-location row L to the same dyadic interval prefix before W and R can be consumed.

The seal row E is downstream of those displayed rows, while H, C, P, N transport, replay, source, and name only that finite route. The excluded compactness, choice, selected-endpoint, quotient-equality, and infinite-intersection coordinates therefore do not belong to the local NameCert surface. □

Theorem 1584.4 (NestedIntervalCompactness finite-prefix monotonicity)**.** *Let $K = (I, L, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *carrier. Any consumer extending the displayed finite prefix must preserve the same nesting cells in I and the same inclusion cells in D before it reads the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, or the* $\mathsf{Real}^{\uparrow}$ *seal row E. The extension therefore introduces no selected endpoint, quotient equality, countable choice, or open-cover compactness row.*

Proof. Project the carrier of Definition 1584.1. The rows visible before any analytic read are the nested interval prefix I, the located endpoint row L, and the dyadic interval ledger D.

Apply the finite-prefix monotonicity row from Definition 1584.3. It requires each accepted consumer read to preserve the displayed nesting and inclusion cells in I and D when the finite prefix is extended.

Only after those cells are fixed may the route expose W, R, and E. Because the local obligation surface contains no row for selected endpoints, quotient equality, countable choice, or open-cover compactness, extending the prefix cannot introduce any such coordinate. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier finite prefix monotonicity`

Theorem 1584.5 (NestedIntervalCompactness Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *packet factors through a displayed finite nested-window route*

$$\mathsf{NestedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The exported boundary is therefore a finite-window compactness-shaped certificate for nested intervals, not a proof of general Heine–Borel compactness, not compactness of arbitrary open covers, not a quotient-real equality principle, and not a countable-choice selector for endpoints.

Proof. Start with a consumer of the terminal $\mathsf{Real}^{\uparrow}$ boundary. By Definition 1584.2, the consumer reaches E only through I, L, D, W, R for the displayed finite prefix.

Apply Definition 1584.3. The local obligations require the same finite prefix, located endpoint row, dyadic ledger, stream windows, and regular readback to govern every accepted Real-facing read.

Thus the exported Real boundary is exhausted by the displayed nested-window route and the structural rows H, C, P, N. Any general cover compactness theorem, selected endpoint, quotient equality, countable-choice selector, or detached infinite-intersection object lies outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier real seal boundary`

Theorem 1584.6 (NestedIntervalCompactness located endpoint scope)**.** *For every accepted* NestedIntervalCompact *carrier* $K = (I, L, D, W, R, E, H, C, P, N)$*, the located endpoint row* L *is scoped by the same displayed* $\mathsf{NestedInterval}^{\uparrow}$ *prefix* I *and the same* $\mathsf{DyadicInterval}^{\uparrow}$ *ledger* D *before any* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, or* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. Thus a consumer reads located endpoints only as finite packet data, not as selected real endpoints or quotient real equality.*

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier located endpoint scope`

Proof. Project I, L, D from the carrier of Definition 1584.1. The located endpoint row is not an independent real object; it is listed as the endpoint-location row for the same displayed prefix named by I.

Apply Definition 1584.3. The located dyadic exactness obligation requires L and D to govern the same interval prefix before a readback row is exposed, and the finite-prefix monotonicity obligation preserves the displayed nesting cells in I and D under extension.

Finally apply Definition 1584.5. Any Real-facing read reaches E only after the route through $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ has been displayed. The located endpoint scope is therefore finite and packet-local. □

Theorem 1584.7 (NestedIntervalCompactness dyadic mesh exhaustion)**.** *Let* $K = (I, L, D, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *carrier. Every finite nested-window read that reaches* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *has already exhausted the displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *mesh row* D *over the same* $\mathsf{NestedInterval}^{\uparrow}$ *and* $\mathsf{LocatedInterval}^{\uparrow}$ *rows* I, L*. No later consumer can replace that mesh by open-cover compactness, countable choice, trichotomy, or an ambient completeness row.*

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier dyadic mesh exhaustion`

Proof. Start with a read reaching W, R, or E. By Definition 1584.2, the read travels through the route $I, L, D \longmapsto W \longmapsto R \longmapsto E$ for the displayed finite prefix.

Use Definition 1584.4. Extending the prefix preserves the nesting cells in I and inclusion cells in D before any stream, regular-rational, or real-seal row can be read.

The NameCert obligation theorem, Definition 1584.3, supplies the ledger non-escape clause. Since the carrier has no row for open-cover compactness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the dyadic mesh row D is the whole finite mesh surface available to the later consumer. □

Theorem 1584.8 (NestedIntervalCompactness located dyadic scope)**.** *For every accepted* NestedIntervalCompactne *carrier* $K = (I, L, D, W, R, E, H, C, P, N)$*, each located endpoint read is scoped by the same* $\mathsf{NestedInterval}^{\uparrow}$ *prefix* I *and the same* $\mathsf{DyadicInterval}^{\uparrow}$ *mesh row* D *before any* $\mathsf{StreamName}^{\uparrow}$ *window* W *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *is exposed. Thus the located data consumed by a* $\mathsf{Real}^{\uparrow}$ *boundary read is finite packet data over the displayed prefix, not a selected endpoint or quotient-real equality.*

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier located dyadic scope`

Proof. Start with a located endpoint read. The carrier definition exposes L only as the endpoint-location row for the prefix named by I, while the dyadic mesh row D records the finite boxes and inclusion checks for that same prefix.

Apply the NameCert obligation theorem. Its located dyadic exactness clause binds L and D to the same interval prefix before a readback row can be consumed, and its finite-prefix monotonicity clause preserves those nesting and inclusion cells when the prefix is extended.

Finally use Definition 1584.7. Any read reaching W, R, or E has already exhausted the displayed dyadic mesh over I, L. Therefore the located endpoint scope is the displayed finite prefix and not an external endpoint choice. □

Theorem 1584.9 (NestedIntervalCompactness prefix readback coverage)**.** *Every finite prefix request reaching the* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *packet has already displayed the nested interval prefix I, located endpoint row L, dyadic mesh row D,* $\mathsf{StreamName}^{\uparrow}$ *windows W, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R. No Real-facing consumer can bypass those rows by appealing to open-cover compactness, countable choice, quotient real equality, or an ambient completeness row.*

Proof. Begin with a finite prefix request that reaches E. By the finite-intersection window theorem, the route to the Real seal is

$$I, L, D \longmapsto W \longmapsto R \longmapsto E.$$

Use prefix monotonicity to keep the displayed nesting cells in I and inclusion cells in D fixed under prefix extension. The located endpoint scope theorem then places L on the same prefix and mesh before stream or regular-rational reads are exposed.

The real seal boundary theorem identifies E as downstream of the displayed route, and the dyadic mesh exhaustion theorem rules out replacing D by a later compactness or choice row. Hence every finite prefix request reaching $\mathsf{Real}^{\uparrow}$ has already displayed I, L, D, W, R inside the packet. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier prefix readback coverage`

Theorem 1584.10 (NestedIntervalCompactness stream-to-real route)**.** *For every accepted* NestedIntervalCompactn *carrier $K = (I, L, D, W, R, E, H, C, P, N)$, each* $\mathsf{StreamName}^{\uparrow}$ *observation window W used by the packet is routed through* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed, and the route remains downstream of the displayed* $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, *and* $\mathsf{DyadicInterval}^{\uparrow}$ *rows I, L, D.*

Proof. Project the route rows from Definition 1584.1. The continuation row C records replay from a finite prefix request through the located interval row, dyadic interval row, stream windows, regular readback, and the real seal boundary.

Apply Definition 1584.2. The theorem identifies W as the window row reached only after I, L, D, and identifies R as the readback row reached before E.

The Real seal boundary theorem, Definition 1584.5, then fixes the exported boundary as the displayed finite route through $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Thus no stream observation bypasses the regular-rational readback or the interval rows that generated it. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier stream real route`

Theorem 1584.11 (NestedIntervalCompactness finite-window exhaustion)**.** *Every accepted* NestedIntervalCompact *consumer of a* $\mathsf{Real}^{\uparrow}$*-facing nested interval read factors through the finite-prefix monotonicity row, located endpoint scope, dyadic mesh exhaustion, prefix readback coverage, and stream-to-real route before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible. The visible route is therefore exhausted by the finite packet rows* $I, L, D, W, R, E, H, C, P, N$*, with no exported selected endpoint, quotient real equality, countable choice, arbitrary open-cover compactness, or full countable-intersection principle.*

Proof. Start with a consumer read that reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. By Definition 1584.10, the read reaches E only after the $\mathsf{StreamName}^{\uparrow}$ window W has passed through the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and that route remains downstream of the displayed interval rows I, L, D.

The finite-prefix monotonicity theorem, Definition 1584.4, keeps the nesting cells in I and the inclusion cells in D fixed under prefix extension. The located endpoint scope theorem, Definition 1584.6, binds L to the same displayed prefix before any stream, readback, or real-seal row is consumed.

Use Definition 1584.7 to exhaust the mesh row D over I, L, and then apply Definition 1584.9. These two rows force every Real-facing finite prefix request to display I, L, D, W, R before E is visible.

Thus the consumer sees exactly the finite-window route carried by $K = (I, L, D, W, R, E, H, C, P, N)$. The excluded endpoint-selection, quotient-equality, choice, arbitrary open-cover, and full countable-intersection coordinates have no carrier row from which they could be exported. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier finite window exhaustion`

Theorem 1584.12 (NestedIntervalCompactness scoped package)**.** *The carrier, finite-intersection window, NameCert obligations, prefix monotonicity, Real seal boundary, located endpoint scope, dyadic mesh exhaustion, located dyadic scope, prefix readback coverage, stream-to-real route, and finite-window exhaustion bind the complete paper scope of the* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *packet over* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Consequently any accepted consumer read must pass through the displayed finite nested-window rows $I, L, D, W, R, E, H, C, P, N$ *before it can use the local certificate. The scoped package exports no open-cover compactness principle, selected point of the full intersection, quotient equality of Real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 1584.1. It lists exactly the nested interval prefix I, located endpoint row L, dyadic interval ledger D, stream windows W, regular readback R, Real seal E, and structural rows H, C, P, N.

Apply Definition 1584.2, Definition 1584.3, and Definition 1584.4. These rows force every finite prefix request to preserve the displayed nesting and inclusion cells before any stream, regular-rational, or Real-facing observation is consumed.

Next apply Definition 1584.5, Definition 1584.6, and Definition 1584.7. They place the Real seal downstream of the same located and dyadic interval rows and exhaust the mesh surface available to later consumers.

Finally use Definition 1584.8, Definition 1584.9, Definition 1584.10, and Definition 1584.11. These theorems identify the whole accepted route as the finite packet $I, L, D, W, R, E, H, C, P, N$ over the named BEDC rows.

Since no cited row contains open-cover data, a selected point of the full intersection, quotient equality of Real names, or an ambient completeness field, the package scope is precisely the displayed finite nested-window route. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier scope package`

Theorem 1584.13 (NestedIntervalCompactness public certificate)**.** *The public* NestedIntervalCompactness$^{\uparrow}$ *certificate is exactly the finite route*

$$I, L, D, W, R, E, H, C, P, N$$

over NestedInterval$^{\uparrow}$*,* LocatedInterval$^{\uparrow}$*,* DyadicInterval$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. It exports a displayed nested-window compactness packet and no open-cover compactness theorem, selected endpoint, quotient equality of real names, countable choice, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Project the scoped package of Definition 1584.12. It already binds every accepted consumer read to the carrier rows $I, L, D, W, R, E, H, C, P, N$ over the named interval, stream, regular-rational, and real-seal surfaces.

Use the finite-window exhaustion theorem, Definition 1584.11. It prevents any Real-facing read from bypassing the finite-prefix monotonicity, located endpoint scope, dyadic mesh, prefix readback, and stream-to-real route.

The public certificate is therefore the same displayed route, now exposed as the chapter-level object. Since the carrier has no row for open covers, endpoint selection, quotient real equality, countable choice, or ambient completeness, none of those principles is exported. □

Lean4 ✓ `BEDC.Derived.NestedIntervalCompactnessUp.NestedIntervalCompactnessCarrier public certificate`

Closure status for NameCert$_{\text{NestedIntervalCompactness}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{NestedIntervalCompactness}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1584.1, Definition 1584.2, Definition 1584.3, Definition 1584.4, Definition 1584.5, Definition 1584.6, Definition 1584.7, Definition 1584.8, Definition 1584.9, Definition 1584.10, Definition 1584.11, Definition 1584.12, and Definition 1584.13 bind the mature paper-side finite-window bridge data from displayed located and dyadic interval rows through StreamName, RegSeqRat, and Real seal reads.

Formal verification: FormalStatus(NameCert$_{\text{NestedIntervalCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, general Heine–Borel compactness, compactness of arbitrary open covers, selected real endpoints, quotient real equality, countable choice, or full countable intersections.

Upgrade path: Lean verification and bridge checking require checked carrier admission, finite-prefix monotonicity, located dyadic exactness, Real seal routing, and ledger non-escape for the same finite-window bridge packet.

Constructive story: A NestedIntervalCompactness$^{\uparrow}$ packet is generated from a nested interval prefix, located endpoint rows, dyadic interval boxes, StreamName windows, RegSeqRat readback, a RealUp seal boundary, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1585

A Concrete Naming Certificate for CauchyCompletionReflector$^{\uparrow}$

Following Bishop and Bridges constructive completion, the CauchyCompletionReflector$^{\uparrow}$ packet records the public finite reflector surface for the L10 completion route. It gathers the unit surface of chapter 1527, the counit surface of chapter 1539, the idempotent surface of **??**, the extension route of chapter 397, and the reflection boundary of chapter 403. Its local real-facing rows are read through chapter 360, chapter 126, chapter 301, chapter 291, and chapter 38. The packet is a finite reflector certificate; it is not a quotient completion, not a selected limit, not host equality of completed objects, not countable choice, and not ambient completeness.

Definition 1585.1 (CauchyCompletionReflector carrier)**.** *A* CauchyCompletionReflector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, U, Q, I, E, R, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row for the displayed metric, regular-Cauchy, or real-name data being sent toward completion.*
2. *M is the completion-object row, read through the* RealCauchyCompletion$^{\uparrow}$ *and* MetricCompletion$^{\uparrow}$ *surfaces rather than through a host quotient carrier.*
3. *U is the* CauchyCompletionUnit$^{\uparrow}$ *row admitting S into the completion-facing surface.*
4. *Q is the* CauchyCompletionCounit$^{\uparrow}$ *row returning already completed or real-sealed reads through the displayed regular route.*
5. *I is the* CauchyCompletionIdempotent$^{\uparrow}$ *row recording that a second completion pass reuses the same completion-object surface.*
6. *E is the* CompletionUniversalProperty$^{\uparrow}$ *extension row for uniformly or continuously routed consumers attached to the same unit route.*
7. *R is the* CompletionReflection$^{\uparrow}$ *row binding the construction, extension, separated boundary, and real-seal rows into one reflection surface.*
8. *T is the local transport row through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *windows used by U, Q, I, E, R.*
9. *H records componentwise* hsame *transport for source, completion object, unit, counit, idempotence, extension, reflection, local transport, continuation, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a source read through unit admission, completion-object access, counit return, idempotent replay, extension use, reflection, and the local real-name route.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}$ *row.*

The classifier on accepted packets compares only these twelve rows under the displayed transport and replay data. It has no coordinate for quotient completions, selected limits, host equality, countable choice, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorUp`
Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorTasteGate single carrier alignment`

Theorem 1585.2 (CauchyCompletionReflector NameCert obligations)**.** *For every accepted* CauchyCompletionRefle *carrier $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed source, completion object, unit, counit, idempotence, universal-property extension, reflection, local transport, continuation, provenance, and naming rows;*
2. *unit admission, requiring every completion-facing source read to pass through U before M can be consumed;*
3. *counit return, requiring every completed read that is already real-sealed to return through Q before the terminal* $\mathsf{Real}^{\uparrow}$ *route is exposed;*
4. *idempotent replay, requiring a repeated completion request to reuse I and the same completion-object row M;*
5. *extension and reflection compatibility, requiring every universal-property consumer to read E and every reflection consumer to read R over the same S, M, U, Q, I, T route;*
6. *reflector non-escape, excluding quotient completions, selected limits, host equality, countable choice, ambient completeness, and detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

No reflector obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket semantic name certificate`

Proof. Carrier admission is projection from Definition 1585.1. The packet exposes the source, completion object, unit, counit, idempotence, extension, reflection, local transport, continuation, provenance, and naming rows, and no other rows.

The unit and counit obligations are then read in order. A completion-facing source read must first pass through the unit row U before M is available, while an already completed real-facing read returns through Q before the $\mathsf{Real}^{\uparrow}$ route carried by T can be consumed.

Idempotent replay uses the idempotent row I. Since I is stored beside the same M, U, Q, T rows, a second completion pass has no independent completion-object coordinate to inspect.

Finally, the extension row E and reflection row R are downstream of the same displayed route. Componentwise transport by H, replay by C, provenance by P, and naming by N preserve exactly that finite route, so quotient completions, selected limits, host equality, countable choice, ambient completeness, and detached real completeness cannot be exported. □

Theorem 1585.3 (CauchyCompletionReflector unit-counit route)**.** *Let $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. Every public reflector consumer factors through the finite route*

$$S \longmapsto U \longmapsto M \longmapsto Q \longmapsto I \longmapsto E, R \longmapsto T \longmapsto H, C, P, N.$$

The route exposes the unit and counit faces of completion, replays idempotence, and then serves universal-property and reflection consumers through the same real-name transport. It does not supply quotient completion equality, a selected limit, host equality of completed objects, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket unit counit route`

Proof. Begin with a public reflector consumer. The source row S is visible only as the source of the displayed unit route U, so the consumer first reads unit admission before it can inspect the completion-object row M.

The counit row Q supplies the return route for reads that are already on the real-seal side. This return is tied to the same local transport row T, whose $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ windows are the only real-facing rows available to the packet.

Next read the idempotent row I. It states that repeating the completion pass reuses the same completion-object row and the same local transport, so the consumer cannot branch to a second completed carrier.

The universal-property row E and reflection row R are finally consumed over that fixed unit-counit-idempotent route. The structural rows H, C, P, N transport, replay, source, and name only the displayed packet, which proves the factorization and the stated non-escape boundary. □

Theorem 1585.4 (CauchyCompletionReflector unit-counit obligation)**.** *Let $K = (S, M, U, Q, I, E, R, T, H, C, P, N$ be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. The unit-counit surface is obligation-complete exactly at the rows S, U, M, Q, T: every public source read must expose S and U before it consumes the completion-object row M, and every already completed or real-sealed read must return through Q and the shared local transport row T before any reflector consumer receives the result. The route exports no quotient completion, selected limit, host equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket unit counit obligation`

Proof. Project the accepted carrier of Definition 1585.1. The source, completion object, unit, counit, and local transport rows are displayed as S, M, U, Q, T.

The unit direction reads S first and then U. Only after that admission is the completion-object row M available to a public reflector consumer.

The counit direction reads Q for already completed or real-sealed data and then the same local transport row T. Since T is the only route to the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ windows, the return cannot detach from the displayed finite carrier.

The structural rows H, C, P, N preserve this order and add no excluded completion or choice coordinate. Thus S, U, M, Q, T are exactly the unit-counit obligation surface. □

Theorem 1585.5 (CauchyCompletionReflector idempotent-extension obligation)**.** *Let $K = (S, M, U, Q, I, E, R, T,$ be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. The idempotent-extension part of the reflector*

surface is exactly the route through I, E, R over the same S, U, M, Q, T rows: repeated completion reuses I and the displayed completion-object row, extension consumers read E only after the unit-counit route is visible, and reflection consumers read R only over that same finite route. No second completion carrier, selected limit, host equality, countable choice, ambient completeness, or detached real-completeness row is introduced.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket idempotent extension obligation`

Proof. Start with the unit-counit obligation of Definition 1585.4. It fixes the public completion-facing route at S, U, M, Q, T.

The idempotent row I is read over this route. A repeated completion pass therefore reuses the displayed completion-object row M rather than branching to a second carrier.

The extension row E and reflection row R are downstream of the same route. The extension consumer cannot bypass U, Q, T, and the reflection consumer receives only the already displayed unit, counit, idempotent, extension, and local transport rows.

Finally H, C, P, N transport, replay, source, and name that route. Because the carrier contains no second completion object or excluded host-side coordinate, the stated non-escape boundary follows. □

Theorem 1585.6 (CauchyCompletionReflector extension-reflection scope)**.** *Let $K = (S, M, U, Q, I, E, R, T, H, C,$ be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. Every* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension read and every* $\mathsf{CompletionReflection}^{\uparrow}$ *read must expose the common route $S, U, M, Q, I, T, H, C, P, N$ before E or R is consumed. Neither row supplies a second completion carrier, selected limit, quotient equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket extension reflection scope`

Proof. Project the carrier of Definition 1585.1. The source, completion-object, unit, counit, idempotent, local transport, and structural rows are displayed as $S, M, U, Q, I, T, H, C, P, N$.

Apply the unit-counit obligation of Definition 1585.4. It fixes the shared source and return route before any extension or reflection consumer may inspect its own row.

Next apply the idempotent-extension obligation of Definition 1585.5. The idempotent row I, extension row E, and reflection row R are read over the same unit-counit surface rather than over an independent completion object.

The structural rows H, C, P, N preserve that route through componentwise transport, replay, provenance, and local naming. Since the carrier contains no coordinate for the excluded objects, the extension and reflection reads expose the stated common scope before E or R is consumed. □

Theorem 1585.7 (CauchyCompletionReflector public obligation package)**.** *For every accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier*

$$K = (S, M, U, Q, I, E, R, T, H, C, P, N),$$

every public reflector consumer receives exactly the route through the source row S, completion-object row M, unit row U, counit row Q, idempotence row I, extension row E, reflection row R, local transport row T, componentwise hsame *transport row H, displayed* Cont *replay row C, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}$ *row N. The package exports no quotient completion, selected limit, host equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket public obligation package`

Proof. Start with the NameCert obligations of Definition 1585.2. They expose the carrier rows $S, M, U, Q, I, E, R, T, H, C, P, N$ as the entire local certificate surface.

Apply the unit-counit route of Definition 1585.3. It forces each public source read through S, U, M, Q before the downstream reflector rows can be consumed.

Next apply the idempotent-extension obligation of Definition 1585.5. The idempotent row I, extension row E, and reflection row R are read over the same unit-counit surface rather than over a second completion carrier.

Finally use the extension-reflection scope of Definition 1585.6. The structural rows T, H, C, P, N transport, replay, source, and name only the displayed route, so no quotient completion, selected limit, host equality, countable-choice selector, or ambient-completeness row can be exported. □

Theorem 1585.8 (CauchyCompletionReflector real-transport nonescape)**.** *For every accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier* $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$*, the real-facing transport row* T *and the structural rows* H, C, P, N *preserve exactly the displayed reflector route. A consumer may transport and replay the source, completion object, unit, counit, idempotent, extension, and reflection rows through* T, H, C, P, N*, but it cannot export quotient completions, selected limits, host equality, countable choice, ambient completeness, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or any real route not displayed by* T*.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket real transport nonescape`

Proof. Read the local transport row from the carrier. By definition, T is the only row that exposes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ windows used by U, Q, I, E, R.

Apply the unit-counit and idempotent-extension obligation theorems. They place the completion-object route, the return route, repeated completion, extension, and reflection all over the same displayed S, U, M, Q, T surface.

The rows H, C, P, N do not enlarge that surface. They provide componentwise hsame transport, displayed Cont replay, package provenance, and local naming for the rows already present in the packet.

Hence every real-facing read remains inside the displayed transport route. The excluded quotient, selection, host-equality, choice, ambient-completeness, detached-real-completeness, and off-route real data have no coordinate from which they could be exported. □

Theorem 1585.9 (CauchyCompletionReflector naturality square)**.** *Let* $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. The public reflector square classifies the route*

$$S \longmapsto U \longmapsto M \longmapsto E, R \longmapsto H, C, P, N$$

with the route

$$S \longmapsto T \longmapsto Q, I \longmapsto E, R \longmapsto H, C, P, N.$$

Equivalently, a consumer that first applies unit admission and then reads the extension and reflection rows has the same displayed classifier as a consumer that first reads the source through the local $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *transport row* T *and then returns by the counit and idempotent rows. The comparison is made only through the displayed* hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}$ *rows, and it exports no quotient completion equality, selected limit, host equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket naturality square`

Proof. Apply Definition 1585.2 to expose the only rows available in an accepted carrier. The unit row U, counit row Q, idempotent row I, extension row E, reflection row R, transport row T, and structural rows H, C, P, N are the entire public surface.

Apply Definition 1585.3 to place every public consumer on the same finite route. The left leg of the square reads S through U before it consumes M, E, R; the right leg reads S through T before the return and replay rows Q, I feed the same E, R consumers.

The sibling certificates supply the public faces used by these two readings: the unit surface is chapter 1527, the counit surface is chapter 1539, the idempotent replay surface is **??**, the extension surface is chapter 397, and the reflection boundary is chapter 403.

Since both legs end by the same H, C, P, N rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row classify them as the same public reflector square. No extra classifier coordinate remains from which a quotient completion, selected limit, host equality, countable choice, or ambient completeness claim could be read. □

Theorem 1585.10 (CauchyCompletionReflector idempotent nonescape)**.** *Let $K = (S, M, U, Q, I, E, R, T, H, C, P,$ be an accepted* CauchyCompletionReflector$^{\uparrow}$ *carrier. Any repeated completion consumer must read the idempotent row I over the same S, U, M, Q, T route before it can inspect E, R, H, C, P, N. Consequently the repeated completion route cannot export a second completion carrier, quotient completion equality, selected limit, host equality, countable choice, or detached* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket idempotent nonescape`

Proof. Project the carrier of Definition 1585.1. The only completion-facing rows are the displayed source S, completion object M, unit U, counit Q, idempotent row I, extension row E, reflection row R, local transport row T, and structural rows H, C, P, N.

Use the unit-counit obligation of Definition 1585.4. It fixes every public completion read at the route through S, U, M, Q, T before extension or reflection data are exposed.

Use the idempotent-extension obligation of Definition 1585.5. A repeated completion consumer must read I over the same route, so it reuses the displayed completion-object row rather than producing an independent carrier.

Finally apply the real-transport nonescape theorem Definition 1585.8. The rows H, C, P, N preserve the same route through T and add no quotient, selected-limit, host-equality, choice, or detached real-completeness coordinate. □

Theorem 1585.11 (CauchyCompletionReflector unit-counit scope)**.** *For every accepted* CauchyCompletionReflecto *carrier $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$, the unit-counit scope is exactly the finite row family S, U, M, Q, T. A reflector consumer must expose the source row S, unit row U, completion-object row M, counit row Q, and local transport row T before any idempotent, extension, reflection, transport-replay, provenance, or local naming row is consumed.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket unit counit scope`

Proof. Project the carrier of Definition 1585.1. The rows S, U, M, Q, T are the only source, unit, completion-object, counit, and local real-transport coordinates.

Apply the unit-counit route theorem, Definition 1585.3, and the unit-counit obligation theorem, Definition 1585.4. Together they force every public reflector read through $S \mapsto U \mapsto M$ and every return read through Q and the shared transport row T.

The remaining rows I, E, R, H, C, P, N are downstream of that scope. Since none of them is a second source, second completion object, selected limit, quotient carrier, host equality, countable-choice schedule, or ambient completeness row, the unit-counit scope is exactly S, U, M, Q, T. □

Theorem 1585.12 (CauchyCompletionReflector idempotent scope)**.** *For every accepted* CauchyCompletionReflecto *carrier $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$, the idempotent-extension scope is exactly I, E, R over the same S, U, M, Q, T route. Repeated completion reads I, universal-property consumers read E, and reflection consumers read R, all after the unit-counit scope has been exposed and without adding a second completion carrier.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket idempotent scope`

Proof. Start from unit-counit scope, Definition 1585.11. It fixes the shared route S, U, M, Q, T for every public reflector consumer.

Apply idempotent-extension obligation, Definition 1585.5. The repeated-completion row I, extension row E, and reflection row R are read over the same unit-counit route rather than over an independent completed carrier.

Then apply idempotent nonescape, Definition 1585.10. It excludes a second completion carrier, quotient completion equality, selected limits, host equality, countable choice, and detached real completeness from the repeated-completion route. □

Theorem 1585.13 (CauchyCompletionReflector obligation closure package)**.** *The accepted* CauchyCompletionRefle *carrier*

$$K = (S, M, U, Q, I, E, R, T, H, C, P, N)$$

supports an obligationClosure package whose finite boundary is the unit-counit scope S, U, M, Q, T, the idempotent-extension scope I, E, R over that route, real-transport nonescape through T, H, C, P, N, and the naturality square comparing the displayed unit and transport-return legs. The package refuses quotient completions, selected limits, host equality, countable choice, ambient completeness, and detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket obligation closure package`

Proof. Build the unit-counit boundary from Definition 1585.11. This supplies the exact S, U, M, Q, T row family consumed before any downstream reflector row is read.

Build the idempotent-extension boundary from Definition 1585.12. It places I, E, R over the same route and prevents a repeated completion pass from producing a second completion carrier.

Add real-transport nonescape, Definition 1585.8. The rows T, H, C, P, N preserve the displayed StreamName-RegSeqRat-DyadicRatCore-Real route and add no off-route real object.

Finally attach the naturality square, Definition 1585.9. Both legs end in the same displayed hsame, Cont, Pkg, and NameCert rows, so the package closes the paper-side reflector obligation surface while refusing quotient completions, selected limits, host equality, countable choice, ambient completeness, and detached Real completeness. □

Theorem 1585.14 (CauchyCompletionReflector reflection scope)**.** *Let $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier. Every reflection consumer must read the reflection row R only after the displayed route*

$$S \longmapsto U \longmapsto M \longmapsto Q \longmapsto I \longmapsto E \longmapsto T$$

has been exposed. Thus R is a scoped reflector row over the already displayed source, unit, completion object, counit, idempotent replay, extension, and local real-name transport rows, not an independent host-level reflection or quotient-completion classifier.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket reflection scope`

Proof. Start from the carrier of Definition 1585.1. The only reflection coordinate in the packet is the displayed row R, and it sits beside the rows $S, M, U, Q, I, E, T, H, C, P, N$.

Use the unit-counit obligation of Definition 1585.4. It forces public completion-facing reads through S, U, M and already completed or real-sealed reads through Q, T before any downstream reflector row is consumed.

Use the idempotent-extension obligation of Definition 1585.5. The row I replays repeated completion over the same route, and the row E is the extension surface read before reflection consumption.

Finally apply real-transport nonescape and the naturality square, Definition 1585.8 and Definition 1585.9. They keep T, H, C, P, N on the same displayed route, so R cannot be read as an independent quotient, selected-limit, host-equality, choice, ambient-completeness, or detached-real-completeness assertion. □

Theorem 1585.15 (CauchyCompletionReflector obligation triple)**.** *For every accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *carrier $K = (S, M, U, Q, I, E, R, T, H, C, P, N)$, the unit row U, counit row Q, and idempotent replay row I are the three obligatory reflector faces before any universal-property or reflection consumer may read E or R. The triple is carried over the same S, M, T, H, C, P, N structural surface and exports no second completion carrier, quotient completion equality, selected limit, host equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket obligation triple`

Proof. Carrier admission comes from Definition 1585.1. The unit, counit, and idempotent rows are visible as U, Q, I in the same finite packet.

The unit-counit obligation theorem places U and Q before public completion and return consumption. The unit face admits S to M, and the counit face returns already completed or real-sealed reads through the local transport row T.

The idempotent-extension obligation theorem places I over that same route. A repeated completion pass therefore reuses the displayed completion-object row rather than introducing a second carrier.

The real-transport nonescape theorem and naturality square keep T, H, C, P, N attached to the same triple. Consequently the extension row E and reflection row R are read only after U, Q, I have been exposed, and the excluded quotient, selection, host-equality, choice, ambient-completeness, and detached-real-completeness data remain outside the packet. □

Theorem 1585.16 (CauchyCompletionReflector public reflector export)**.** *Every accepted* CauchyCompletionReflect *packet exports the public completion reflector interface exactly through the unit row U, completion object row M, counit row Q, idempotent row I, extension row E, reflection row R, and local* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *transport row T. The structural rows H, C, P, N preserve that route and do not export quotient completions, selected limits, host equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the unit-counit route, Definition 1585.3. It places every public reflector consumer on the path through S, U, M, Q before the downstream reflector rows are read.

Apply the idempotent-extension scope, Definition 1585.12, and the reflection scope, Definition 1585.14. These results make I, E, R the displayed repeated-completion, extension, and reflection faces over the same unit-counit route.

Add real-transport nonescape, Definition 1585.8. The row T is the only local StreamName-RegSeqRat-DyadicRatCore-Real route, and the rows H, C, P, N only transport, replay, source, and name the already displayed packet.

Finally use the obligation triple, Definition 1585.15. Since U, Q, I are obligatory before E or R is consumed, the public interface is exactly the row family $U, M, Q, I, E, R, T, H, C, P, N$, with no coordinate for the excluded quotient, selection, host-equality, choice, ambient-completeness, or detached-real-completeness data. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket public reflector export`

Theorem 1585.17 (CauchyCompletionReflector mature universal factorization)**.** *Every mature public consumer of an accepted* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *packet factors through the unit row U, counit row Q, idempotent replay row I, universal-property extension row E, reflection row R, and local* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *transport row T before any reflector export is consumed. The same route preserves the real-seal nonescape boundary through H, C, P, N and exports no quotient completion, selected limit, host equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the public reflector export of Definition 1585.16. It identifies the public interface exactly at the unit, completion object, counit, idempotent, extension, reflection, and local real-transport rows.

Use the unit-counit route, idempotent scope, and reflection scope results. Together they force a public consumer through U, Q, I, E, R over the same displayed completion-object and local transport route before any reflector export can be read.

Finally use real-transport nonescape. The rows T, H, C, P, N preserve the StreamName-RegSeqRat-DyadicRatCore-Real route and add no excluded completion or choice coordinate, so the public universal factorization remains inside the finite reflector packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflector}^{\uparrow}$ packet is generated from a displayed source row, a completion-object row, unit admission, counit return, idempotent replay, universal-property extension, completion reflection, local StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1585.1, Definition 1585.16, and Definition 1585.17 close the public reflector export and universal factorization surface through unit, counit, idempotent replay, extension, reflection, and RealUp nonescape.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflector}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.CauchyCompletionReflectorUp.CauchyCompletionReflectorPacket\_public\_reflector\_export`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality, countable choice, ambient completeness, detached $\mathsf{Real}^{\uparrow}$ completeness, or standard bridge checking.

Upgrade path: Bridge checking requires a standard bridge theorem connecting the public reflector export to the acceptance schema.

Chapter 1586

A Concrete Naming Certificate for $\mathsf{CauchyProductCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyProductCriterion}^{\uparrow}$ packet isolates the finite criterion under which synchronized Cauchy product data is sufficient for the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the product route of chapter 464, the bounded-product ledger of chapter 1529, and the completion-facing product route of chapter 1540; it reads synchronized windows from chapter 126, dyadic budget rows from chapter 291, the regular rational classifier of chapter 301, and the real-name boundary of chapter 38. The packet names a finite sufficiency surface, not multiplication of completed real objects, quotient equality of streams, a selected limit, countable choice, trichotomy, or an ambient completeness theorem.

Definition 1586.1 (Cauchy product criterion carrier)**.** *A* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (X, Y, W, D, P, R, E, H, C, L, N)$$

with the following displayed rows:

1. *X and Y are the two source rows. Each row exposes a Cauchy schedule, a regular-rational readback boundary, a real-seal boundary, and the local source certificate needed by the product route.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, aligning the two source schedules with the product window consumed downstream.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget ledger, containing the source tolerances, magnitude bounds, cross-error budget, and the finite window budget used to certify the product read.*
4. *P is the* $\mathsf{CauchyProduct}^{\uparrow}$ *route, read only after X, Y, W, and D have been displayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row receiving the product read from the synchronized product route.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after the regular-rational classifier row has accepted the product read.*
7. *H records componentwise* hsame *transport for $X, Y, W, D, P, R, E, C, L, N$ and the local packet shape.*
8. *C records displayed* Cont *replay from the two source rows through the synchronized window, dyadic product budget, product route, regular-rational classifier, and real-seal row.*

9. *L is the* Pkg *provenance over* CauchyProductCriterion$^{\uparrow}$, CauchyProduct$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchyProductCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, P, R, E, H, C, L, N$. It has no coordinate for host multiplication of completed reals, quotient stream equality, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1586.2 (Cauchy product criterion NameCert obligations)**.** *For an accepted* CauchyProductCriterion$^{\uparrow}$ *carrier $Z = (X, Y, W, D, P, R, E, H, C, L, N)$, the local* NameCert$_{\text{CauchyProductCriterion}^{\uparrow}}$ *obligations are exactly carrier admission for the two source rows, synchronized-window admission for W, dyadic product-budget exactness for D, product-route admission for P, regular-rational handoff for R, real-seal handoff for E, componentwise transport through H, displayed continuation replay through C, provenance through L, and ledger non-escape through N.*

Proof. Carrier admission is projection from Definition 1586.1. The displayed packet lists the two source rows, the synchronized window, the dyadic budget, the product route, the regular-rational classifier, the real seal, and the structural rows.

The source and window obligations are read from X, Y, W. These rows display the two schedules and the common product window before any product observation is sent to a downstream classifier.

The dyadic obligation is the row D. It contains the finite tolerance, magnitude, and cross-error budget needed by the product route, so product admission through P is budgeted data rather than host multiplication of completed real names.

The rows R and E are downstream boundaries. Transport through H, replay through C, provenance through L, and local naming through N preserve the same route and add no extra coordinate.

Since the carrier has no row for quotient streams, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking, the displayed obligations exhaust the local certificate surface. □

Theorem 1586.3 (Cauchy product criterion window-budget sufficiency)**.** *For an accepted* CauchyProductCriterion$^{\uparrow}$ *carrier, synchronized windows and dyadic product-budget data suffice to route the product read to the regular-rational classifier:*

$$X, Y \longmapsto W \longmapsto D \longmapsto P \longmapsto R.$$

Every RegSeqRat$^{\uparrow}$ *consumer of the product packet factors through this finite route and cannot bypass it by reading a quotient stream, selected product limit, host multiplication primitive, countable-choice row, trichotomy row, or ambient completeness witness.*

Proof. Begin with a consumer asking for the regular-rational product read. The only RegSeqRat$^{\uparrow}$ row in the carrier is R.

The row R is downstream of the displayed product route P. The route P is downstream of the synchronized window W and dyadic budget D, and those rows are in turn downstream of the two source rows X and Y.

Thus the consumer must pass through the displayed chain X, Y, W, D, P, R. The structural rows H, C, L, N transport, replay, source, and name this same chain without creating a second product route.

No other regular-rational classifier occurs in the packet. Therefore the synchronized window and dyadic product budget are sufficient for the RegSeqRat$^{\uparrow}$ handoff, and the excluded objects cannot be exported by the criterion. □

Theorem 1586.4 (Cauchy product criterion source-window stability)**.** *Let $Z = (X, Y, W, D, P, R, E, H, C, L, N)$ be an accepted* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *carrier. Suppose the source rows X, Y and the synchronized window row W are replaced only by displayed componentwise* hsame *rows and the replacement is replayed through the displayed* Cont *row C. Then the same dyadic product-budget row D, product route P,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, and* $\mathsf{Real}^{\uparrow}$ *seal E remain the admissible criterion route:*

$$X, Y \longmapsto W \longmapsto D \longmapsto P \longmapsto R \longmapsto E.$$

Thus source-window replacement along the classifier data preserves the product criterion and cannot introduce host multiplication, quotient stream equality, a selected product limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier to its displayed rows. By Definition 1586.3, the original $\mathsf{RegSeqRat}^{\uparrow}$ product read factors through X, Y, W, D, P, R.

The replacement hypothesis is internal to the carrier data: H supplies componentwise hsame transport for the source rows and synchronized window, while C replays the continuation from the transported source-window data through the same displayed product route.

Therefore the transported source-window presentation still reaches D, then P, then R, and the real-facing row E reads the same admissible criterion route. No row in the carrier can insert host multiplication, a quotient-stream witness, a selected limit, countable choice, trichotomy, or ambient completeness between these displayed stages. □

Theorem 1586.5 (Cauchy product criterion real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *carrier factors through*

$$X, Y \longmapsto W \longmapsto D \longmapsto P \longmapsto R \longmapsto E$$

together with the displayed hsame *transports,* Cont *replays,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyProductCriterion}^{\uparrow}}$ *row. Hence the real-facing boundary is a finite synchronized Cauchy product criterion, not host multiplication, quotient stream equality, a selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The real-facing consumer can read only E as a $\mathsf{Real}^{\uparrow}$ seal row. In the carrier, E is explicitly downstream of R, and R is the regular-rational handoff produced by the product route.

Apply Definition 1586.3. The route to R already passes through the two source rows, synchronized window, dyadic product-budget ledger, and product route.

The structural rows H, C, L, N preserve that route under transport, replay, provenance, and local naming. They do not add a second seal source or a host-level product operation.

Since there is no coordinate for quotient streams, selected limits, countable choice, trichotomy, or ambient completeness, every real-seal read remains inside the displayed finite criterion. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCriterion}^{\uparrow}$ packet is generated from two Cauchy source rows, a synchronized StreamName window, a DyadicRatCore product-budget ledger, a CauchyProduct route, a RegSeqRat classifier row, a RealUp seal row, componentwise transport, displayed continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 1586.1, Definition 1586.2, Definition 1586.3, Definition 1586.4, and Definition 1586.5 seed the finite criterion for synchronized Cauchy product data before RegSeqRat and Real seal consumers read the product.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyProductCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host multiplication, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window admission, dyadic product-budget exactness, product-route admission, regular-rational handoff, real-seal handoff, transport stability, continuation replay, and ledger non-escape for BEDC.Derived.CauchyProductCriterionUp.

Chapter 1587

A Concrete Naming Certificate for $\mathsf{PositiveReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PositiveReal}^{\uparrow}$ packet names a positive real not by a host order predicate but by displayed apartness-from-zero evidence over the finite real-name substrate. It sits at the L10 boundary between the sealed $\mathsf{Real}^{\uparrow}$ name surface of chapter 38, the located interval route of **??**, the positive separation rows of chapter 304, and the located-apartness handoff of chapter 1380.

1587.1 Carrier and positivity packet

Definition 1587.1 (PositiveReal carrier)**.** *A* $\mathsf{PositiveReal}^{\uparrow}$ *carrier is a finite packet* $(R, A, D, W, Q, H, C, P, N)$ *with the following displayed rows:*

1. *R, a sealed* $\mathsf{Real}^{\uparrow}$ *row for the real-name presentation being classified;*
2. *A, a positive apartness-to-zero row, read as an* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation packet whose left endpoint is the zero real-name row and whose right endpoint is R;*
3. *D, a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger for the separation radius used by A;*
4. *W, a finite* $\mathsf{StreamName}^{\uparrow}$ *observation window shared by the zero row and R;*
5. *Q, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the scheduled rational observations of R on W;*
6. *H, the componentwise* hsame *transport rows for the real seal, apartness row, radius ledger, window, and readback;*
7. *C, the displayed* Cont *replay routes keeping the finite observations attached to the transported carrier;*
8. *P, the* Pkg *provenance rows for the real seal, dyadic radius, stream window, regular-rational readback, and apartness ledger;*
9. *N, the local* $\mathsf{NameCert}$ *row binding these eight rows as one positive-real certificate.*

The carrier accepts only this finite positivity packet. It contains no trichotomy coordinate, no host real order predicate, no quotient stream equality, no selected limit, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealTasteGate single carrier alignment`

1587.2 NameCert obligations

Theorem 1587.2 (PositiveReal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{PositiveReal}^{\uparrow}}$ *surface for the carrier of Definition 1587.1 consists of six finite obligations:*

1. *carrier admission: the displayed rows* $(R, A, D, W, Q, H, C, P, N)$ *are present in the same finite* BHist *packet;*
2. *classifier transport: accepted carriers compare only by componentwise transport of the real seal row, apartness row, positive radius ledger, finite window, readback, replay, provenance, and local certificate rows;*
3. *positive-radius exactness: the radius consumed by the apartness-to-zero row is exactly the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *displayed by the carrier;*
4. *apartness handoff: every positivity read factors through the* $\mathsf{ApartnessReal}^{\uparrow}$ *and* $\mathsf{LocatedApartness}^{\uparrow}$ *finite-window rows named in* A*;*
5. *real-seal non-escape: the real component is exported only through the sealed* $\mathsf{Real}^{\uparrow}$ *row* R *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*;*
6. *ledger exhaustion: downstream metric or order consumers can read only the nine displayed carrier rows and their componentwise transport routes.*

These obligations certify positivity as finite apartness-from-zero evidence. They do not certify a classical positive cone, a total order, trichotomy of constructive reals, quotient equality of streams, selected limits, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealNameCert obligations`

Proof. Project the carrier of Definition 1587.1. The projection exposes exactly the sealed real row, apartness-to-zero row, positive dyadic radius, finite observation window, regular-rational readback, transport, replay, provenance, and local certificate rows.

Classifier transport is then componentwise. The hsame and Cont rows move the real seal, apartness packet, radius ledger, stream window, readback, and provenance together, so the transported packet has the same visible carrier shape.

Positive-radius exactness follows by reading D as the only dyadic radius row available to the apartness coordinate A. The apartness handoff is therefore the finite-window separation route already displayed by the $\mathsf{ApartnessReal}^{\uparrow}$ and $\mathsf{LocatedApartness}^{\uparrow}$ packets.

The real-seal boundary is negative. Since R and Q are the only real-name coordinates, no consumer can leave the sealed $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ surface. The listed rows exhaust the packet, so no trichotomy, host order, quotient stream equality, selected limit, or ambient completeness datum can be exported. □

Theorem 1587.3 (PositiveReal apartness handoff)**.** *Every accepted* $\mathsf{PositiveReal}^{\uparrow}$ *read factors through the displayed* $\mathsf{ApartnessReal}^{\uparrow}$ *or* $\mathsf{LocatedApartness}^{\uparrow}$ *separation row, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of Definition 1587.1. Consequently a downstream real-order, metric, or algebraic consumer receives positivity only as finite apartness-from-zero evidence with visible* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

No such read supplies trichotomy, host order, quotient stream equality, selected limits, or ambient completeness for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with an accepted carrier and project its apartness coordinate A. By Definition 1587.1, A is already an apartness-to-zero finite-window row whose positive radius is displayed by D and whose window is displayed by W.

Read the same packet through the surrounding L10 siblings. The real-name endpoint is sealed by R, the scheduled rational observations are exposed by Q, and the located-apartness route repacks the positive gap as the finite separation ledger consumed by A.

Transport preserves only these rows. The hsame, Cont, Pkg, and NameCert coordinates move the real seal, apartness packet, dyadic radius, finite window, and readback componentwise, so every transported read still factors through the displayed apartness and radius surfaces.

The carrier has no coordinate for an order decision, quotient representative, chosen limit, or completeness witness. Therefore every downstream consumer is confined to the finite apartness-from-zero evidence stated above. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier apartness handoff`

Theorem 1587.4 (PositiveReal RegSeqRat window positivity scope)**.** *Every accepted* $\mathsf{PositiveReal}^{\uparrow}$ *packet* $(R, A, D, W, Q, H, C, P, N)$ *exposes positivity reads only through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *attached to the sealed* $\mathsf{Real}^{\uparrow}$ *row* R*. The apartness coordinate* A *may consume the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius* D *only after those window and readback rows are displayed, and every transported read remains confined to the same* $R, A, D, W, Q, H, C, P, N$ *carrier surface.*

Proof. Project the carrier of Definition 1587.1. The real endpoint is R, the apartness-to-zero evidence is A, the positive radius is D, and the only observation route is the pair W, Q.

Use the obligation surface of Definition 1587.2. Its real-seal non-escape and apartness handoff rows require each positivity read to pass through the displayed window and readback rows before the apartness evidence is exported.

Apply Definition 1587.3. The handoff keeps A tied to the finite $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the dyadic radius D.

Transport is componentwise through H and replayed through C, with P, N recording provenance and local naming. Hence the positivity scope never leaves the displayed $R, A, D, W, Q, H, C, P, N$ packet. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier regseqrat window positivity scope`

Theorem 1587.5 (PositiveReal apartness radius transport)**.** *For every accepted* $\mathsf{PositiveReal}^{\uparrow}$ *carrier* $(R, A, D, W, Q, H, C, P, N)$*, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* D *transported by* H *and replayed by* C *is the same radius read by the apartness-to-zero row* A*. A downstream consumer may move this radius only together with the sealed real row* R*, the stream window* W*, the regular readback* Q*, the provenance row* P*, and the local name* N*.*

Proof. Read D from the carrier definition. It is the unique positive dyadic radius ledger assigned to the apartness coordinate A, so a radius consumer has no second radius row to inspect.

Invoke Definition 1587.2. Positive-radius exactness identifies the radius consumed by A with the displayed D row, while classifier transport moves the real seal, apartness row, radius ledger, window, readback, replay, provenance, and local certificate componentwise.

The apartness handoff of Definition 1587.3 supplies the consumer boundary. It lets downstream order, metric, or algebraic reads use only the finite apartness-from-zero evidence carried by A, D, W, Q.

Therefore H and C transport the positive radius as part of the whole $R, A, D, W, Q, H, C, P, N$ packet. The transported radius is not a host real selector, a trichotomy branch, a quotient representative, or a completeness witness. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier apartness radius transport`

Theorem 1587.6 (PositiveReal RealAlgOrder consumer boundary)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$ *or metric consumer of an accepted* $\mathsf{PositiveReal}^{\uparrow}$ *carrier* $(R, A, D, W, Q, H, C, P, N)$ *receives only apartness-from-zero evidence: the sealed real row* R*, the apartness row* A*, the positive radius ledger* D*, the finite window* W*, the readback* Q*, and the support rows* H, C, P, N*. Such a consumer receives no trichotomy, host order predicate, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier and project its finite rows. The only order-facing data are the apartness row A and the positive dyadic radius D attached to the sealed real row R.

The NameCert obligations of Definition 1587.2 force real-seal non-escape and ledger exhaustion. Thus any consumer reads R through W, Q, reads positivity through A, D, and reads stability only through H, C, P, N.

Use Definition 1587.3 to identify the exported evidence. The handoff is apartness-from-zero evidence with visible transport, replay, provenance, and local naming.

Since no carrier coordinate stores trichotomy, a host order predicate, quotient stream equality, a selected limit, or real completeness, $\mathsf{RealAlgOrder}^{\uparrow}$ and metric consumers cannot receive any such principle from the packet. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier realalgorder consumer boundary`

Theorem 1587.7 (PositiveReal multiplicative radius transport)**.** *Let two accepted* $\mathsf{PositiveReal}^{\uparrow}$ *packets expose positive dyadic radius rows through the same finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *observation window. Then the product-facing positivity read transports through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledgers, the componentwise* hsame *rows, the* Cont *replay routes, the* Pkg *provenance rows, and the local* NameCert *rows of the two packets. The transported read cannot use trichotomy, host order, quotient stream equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier multiplicative radius transport`

Proof. Project the two accepted carriers of Definition 1587.1. Each projection exposes a sealed real row, an apartness-to-zero row, a positive dyadic radius, a finite stream window, a regular-rational readback, transport, replay, provenance, and a local certificate row.

Read the common observation window componentwise. The apartness-to-zero rows use their displayed positive dyadic radii, and the shared $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ window keeps the product-facing read attached to the same finite schedule of rational observations.

Transport the two packets through the visible hsame and Cont rows. These rows preserve the radius ledgers, windows, readbacks, and provenance entries as finite data, so the product consumer receives only the displayed apartness-radius evidence.

The carrier definition supplies no trichotomy coordinate, host order predicate, quotient stream equality, selected limit, or completeness witness. Hence the product-facing positivity read cannot draw on any evidence outside the two finite PositiveReal packets. □

Theorem 1587.8 (PositiveReal product-radius window compatibility)**.** *Two accepted* $\mathsf{PositiveReal}^{\uparrow}$ *packets used by a product-facing* $\mathsf{RealAlgOrder}^{\uparrow}$ *or metric consumer may combine their positive*

DyadicRatCore$^{\uparrow}$ *radius rows only after both packets expose compatible* StreamName$^{\uparrow}$ *windows and* RegSeqRat$^{\uparrow}$ *readbacks. The product-radius read is then transported through the same* $R, A, D, W, Q, H, C, P, N$ *carrier rows for each packet, with the radius ledgers, windows, readbacks, replay routes, provenance, and local names kept componentwise.*

No product-facing consumer may infer radius compatibility from a host real order predicate, quotient stream equality, selected limits, or ambient Real$^{\uparrow}$ *completeness.*

Proof. First use Definition 1587.4. It forces each positivity read to pass through the displayed StreamName$^{\uparrow}$ window W and the RegSeqRat$^{\uparrow}$ readback row Q before the apartness radius is available to a downstream consumer.

Next apply Definition 1587.5. The positive dyadic radius row D is the same row consumed by the apartness-to-zero packet A, and it is moved only with R, W, Q, H, C, P, N.

Finally invoke Definition 1587.7. Its product-facing route combines two positive radius reads only through shared finite observation data and componentwise transport. Therefore a RealAlgOrder$^{\uparrow}$ or metric consumer may reuse the product radius exactly when the two packets display compatible stream windows and regular readbacks, and no stronger real-order or completeness datum is exported. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier product radius window compatibility`

Theorem 1587.9 (PositiveReal dyadic radius lower bound)**.** *Every accepted* PositiveReal$^{\uparrow}$ *packet whose positivity is read through the* Real$^{\uparrow}$ *apartness row exposes a finite* DyadicRatCore$^{\uparrow}$ *radius row below the positive witness. The row is transported through the displayed* RegSeqRat$^{\uparrow}$ *readback and* StreamName$^{\uparrow}$ *observation windows, and it is available to* MetricBall$^{\uparrow}$ *and* RealAlgOrder$^{\uparrow}$ *consumers as finite apartness-radius evidence without trichotomy, a host real selector, quotient stream equality, selected limits, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 1587.1. Its apartness coordinate A is read over the sealed real row R, and its dyadic radius ledger D is already displayed before any downstream order or metric consumer can inspect the packet.

Use the apartness handoff of Definition 1587.3. The handoff keeps the positive witness attached to the same finite StreamName$^{\uparrow}$ window and the same RegSeqRat$^{\uparrow}$ readback row, so D is read as a lower-radius row beneath that witness rather than as a host real choice.

Transport follows the multiplicative radius route of Definition 1587.7. The hsame, Cont, Pkg, and NameCert rows preserve the dyadic radius ledger, the finite observation window, and the regular-rational readback componentwise.

Thus a MetricBall$^{\uparrow}$ or RealAlgOrder$^{\uparrow}$ consumer receives exactly the displayed dyadic lower-radius row. Since the carrier contains no trichotomy, selector, quotient equality, selected limit, or completeness coordinate, no stronger real-order principle is exported. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier dyadic radius lower bound`

Theorem 1587.10 (PositiveReal product lower-bound apartness)**.** *Let two accepted* PositiveReal$^{\uparrow}$ *packets expose positive dyadic lower-bound rows through displayed* DyadicRatCore$^{\uparrow}$ *radius ledgers. A product-facing apartness-from-zero read can be formed only from the two radius rows, the common* StreamName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *observation windows, the componentwise* hsame *transports, the displayed* Cont *replays, the* Pkg *provenance rows, and the two local* NameCert *rows. The resulting lower-bound ledger is therefore a finite product-radius witness for* RealAlgOrder$^{\uparrow}$ *and metric consumers, not a trichotomy branch, host order comparison, quotient stream equality, selected limit, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the two accepted carriers of Definition 1587.1. Their positive reads expose exactly the two apartness rows, dyadic radius ledgers, finite observation windows, regular-rational readbacks, transport, replay, provenance, and local naming rows.

Apply Definition 1587.7. It supplies the product-facing radius transport while keeping the two dyadic ledgers inside the displayed finite packets. Then use Definition 1587.8 to require the common $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows before the product read is available.

Finally apply Definition 1587.9 to each factor. The only lower-bound data exported to the product consumer are the two finite dyadic radius rows and their transported window evidence. Since neither carrier contains trichotomy, host order, quotient stream equality, selected limits, or ambient completeness, the product apartness read cannot export any of those principles. □

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier product lower bound apartness`

Theorem 1587.11 (PositiveReal obligation closure)**.** *The* $\mathsf{PositiveReal}^{\uparrow}$ *packet of Definition 1587.1 presents an obligation-closed finite BEDC surface over the sealed* $\mathsf{Real}^{\uparrow}$ *row. Its local obligation rows consist exactly of the* $\mathsf{ApartnessReal}^{\uparrow}$ *and* $\mathsf{LocatedApartness}^{\uparrow}$ *apartness handoff, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *observation window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Consequently every positivity consumer must enter through these displayed rows and no consumer receives trichotomy, host order, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from this certificate.*

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier obligation closure`

Proof. Project the carrier rows of Definition 1587.1. The sealed real row R fixes the ambient real-name surface, while A, D, W, Q display the apartness packet, positive radius ledger, finite stream window, and rational readback.

Use Definition 1587.2. Its carrier admission, classifier transport, positive-radius exactness, apartness handoff, real-seal non-escape, and ledger exhaustion rows are precisely the finite obligations listed in the statement.

The remaining support rows are structural. The hsame row transports the displayed coordinates, Cont replays the finite reads, Pkg records provenance, and N binds the local name. Since the carrier has no further coordinate, the named rows close the paper-side obligation surface. □

Theorem 1587.12 (PositiveReal apartness obligation handoff)**.** *For every accepted* $\mathsf{PositiveReal}^{\uparrow}$ *carrier* $(R, A, D, W, Q, H, C, P, N)$*, the apartness-to-zero assertion is available to downstream consumers only as the finite handoff from the sealed* $\mathsf{Real}^{\uparrow}$ *row through the* $\mathsf{ApartnessReal}^{\uparrow}/\mathsf{LocatedApartness}^{\uparrow}$ *row* A*, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*. The handoff is stable under the displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier apartness obligation handoff`

Proof. Read the accepted packet componentwise. The real endpoint is sealed by R, and the positive assertion is not a host order predicate; it is the displayed apartness row A with radius D.

Apply Definition 1587.3 and Definition 1587.4. Together they force every positivity read through W, Q before it can be exported as apartness-from-zero evidence.

Transport is confined to the packet support. The rows H, C, P, N move and record the same finite handoff, so no consumer can detach A or D from the sealed real row, the observation window, or the readback surface. □

Theorem 1587.13 (PositiveReal carrier transport obligations)**.** *Any transport of an accepted* $\mathsf{PositiveReal}^{\uparrow}$ *carrier preserves the whole finite obligation packet* $(R, A, D, W, Q, H, C, P, N)$*: the sealed* $\mathsf{Real}^{\uparrow}$ *row, the* $\mathsf{ApartnessReal}^{\uparrow}/\mathsf{LocatedApartness}^{\uparrow}$ *apartness row, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* hsame *transport rows, the* Cont *replay rows,* Pkg *provenance, and the local* NameCert *row. The transported carrier therefore exposes exactly the same obligation surface as the source carrier.*

Lean4 ✓ `BEDC.Derived.PositiveRealUp.PositiveRealCarrier transport obligations`

Proof. Start with the carrier definition and isolate the transport row H. Its components are attached to the real seal, apartness row, radius ledger, window, and readback, so it has no independent target outside the displayed packet.

Use Definition 1587.5 for the radius coordinate and Definition 1587.8 for window compatibility. These results keep D tied to A, W, Q under any consumer-facing movement.

Replay and provenance preserve the same boundary. The Cont rows replay the finite observations, Pkg records their source, and the local NameCert row binds the transported carrier. Thus the target carrier has exactly the obligation rows stated above and no stronger real-order or completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveReal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PositiveReal}^{\uparrow}$ packet is generated from a sealed real-name row, an apartness-to-zero row, one positive dyadic radius ledger, one finite observation window, one regular-rational readback, transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PositiveReal}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1587.1, Definition 1587.2, Definition 1587.11, Definition 1587.12, and Definition 1587.13 close the exported positive-real apartness packet as the public finite apartness-from-zero interface through $\mathsf{Real}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PositiveReal}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not claim trichotomy of constructive reals, total order, quotient stream equality, selected limits, ambient real completeness, or a standard bridge.

Upgrade path: Remaining work is Lean verification and bridge checking over the existing positive-real classifier, apartness handoff, transport rows, and terminal real-facing seal, not further paper closure.

Chapter 1588

A Concrete Naming Certificate for CompleteUniformSpace$^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges constructive completion, the CompleteUniformSpace$^{\uparrow}$ packet names the finite Cauchy-filter convergence surface over chapter 339, chapter 333, chapter 1501, chapter 1558, chapter 126, chapter 301, and chapter 38. The packet is a constructive completeness interface for displayed Cauchy-filter data; it is not a quotient filter, not a selected limit, not a countable-choice selector, not host equality, and not an ambient completeness principle.

Definition 1588.1 (Complete uniform-space carrier)**.** *A* CompleteUniformSpace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (U, F, B, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UniformSpace$^{\uparrow}$ *entourage row. It stores the finite entourage filterbase, diagonal, refinement, symmetry, and composition data through which every Cauchy request is read.*
2. *F is the* CauchyFilter$^{\uparrow}$ *row. It records the saturated finite Cauchy-filter request admitted over the entourage surface of U.*
3. *B is the* CauchyFilterBasis$^{\uparrow}$ *generator row. It displays the finite basis elements and common-refinement data consumed by F.*
4. *L is the* CauchyFilterLimit$^{\uparrow}$ *boundary row. It records the limit-facing boundary reached only after the basis and saturated filter rows have been replayed.*
5. *S is the* StreamName$^{\uparrow}$ *window row inspected by the convergence request.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the displayed windows in S.*
7. *E is the* Real$^{\uparrow}$ *seal row reached only after U, F, B, L, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the entourage, filter, basis, limit boundary, window, readback, seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an entourage request through the Cauchy-filter basis, saturation, limit boundary, finite windows, regular readback, and Real seal.*
10. *P is the* Pkg *provenance over* CompleteUniformSpace$^{\uparrow}$, UniformSpace$^{\uparrow}$, CauchyFilter$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, CauchyFilterLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteUniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, B, L, S, R, E, H, C, P, N$. The carrier has no coordinate for quotient filters, selected limits, countable-choice selectors, host equality, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CompleteUniformSpaceUp.CompleteUniformSpaceTasteGate single carrier alignment`

Theorem 1588.2 (Complete uniform-space NameCert obligations)**.** *For every accepted* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *carrier $M = (U, F, B, L, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteUniformSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed uniform-space entourage data, CauchyFilter row, CauchyFilterBasis generator, CauchyFilterLimit boundary, StreamName windows, RegSeqRat readbacks, Real seal, transport, replay, provenance, and local naming row;*
2. *Cauchy request factorization, requiring every filter request to pass through the finite entourage filterbase in U, the basis generator B, and the saturation row F before the limit boundary L is read;*
3. *convergence readback, requiring every limit-facing observation to pass through S and R before the Real seal row E is available;*
4. *transport and replay stability, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the same ordered route U, B, F, L, S, R, E;*
5. *ledger non-escape, requiring P and N to export no quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness principle.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1588.1. The projection exposes exactly the entourage row, the Cauchy-filter saturation row, the basis generator, the limit boundary, the window and readback rows, the Real seal, and the structural rows H, C, P, N.

Cauchy request factorization is forced by the displayed row order. A request begins at the finite entourage filterbase in U, reads a generated basis element through B, and is saturated by F before any limit boundary row can be inspected.

The convergence readback is downstream of this filter route. The boundary row L only exposes its finite observations through the StreamName windows S and the RegSeqRat readbacks R, and the Real seal row E is available only after those rows have been replayed.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, and Cont replay in C repeats the route U, B, F, L, S, R, E for every accepted request.

Finally, provenance is exhausted by P and N. Since quotient filters, selected limits, countable-choice selectors, host equality, and ambient completeness are not rows of M, the local NameCert surface cannot export them. □

Theorem 1588.3 (Complete uniform-space Cauchy-filter convergence)**.** *Let $M = (U, F, B, L, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *carrier. Every Cauchy-filter convergence read factors through the finite route*

$$U \longmapsto B \longmapsto F \longmapsto L \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus every Cauchy-filter request passes through the displayed entourage filterbase and the limit boundary before any Real-facing seal is read. The route contains no quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness principle.

Proof. Begin with a convergence read of the packet. The uniform-space row U supplies only finite entourage data, so the request first chooses a displayed entourage demand and its refinement ledger rather than an external filter object.

The basis and saturation rows consume that demand. The row B displays the finite Cauchy-filter basis route, and F records the saturated Cauchy-filter request over the same entourage surface.

Only then can the limit boundary be read. The row L is downstream of B and F, while S and R provide the finite window and regular rational observations attached to that boundary.

The Real seal row E is terminal for this route. The structural rows H, C, P, N transport, replay, source, and name exactly this path, so no quotient filter, chosen limit, choice schedule, host equality, or detached completeness witness is available. □

Theorem 1588.4 (Complete uniform-space filter-basis limit exactness)**.** *Let $M = (U, F, B, L, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *carrier. A completion-facing read from M is exposed only after the* $\mathsf{UniformSpace}^{\uparrow}$ *row U,* $\mathsf{CauchyFilter}^{\uparrow}$ *row F,* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row B,* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary L,* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N are all present in the same packet. The read is exact in the sense that it factors through those displayed rows and cannot recover a quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness principle.*

Proof. Project the accepted carrier of Definition 1588.1. Its only completion-facing data rows are U, F, B, L, S, R, E, and its only structural support rows are H, C, P, N.

Apply the convergence route of Definition 1588.3. It places the basis row B between the entourage row U and the saturated Cauchy-filter row F, and it permits the limit boundary L to be read only after that finite basis route is displayed.

Now apply ledger non-escape, Definition 1588.6. The window row S, readback row R, Real seal E, and support rows H, C, P, N preserve the same route, so the packet has no remaining coordinate from which quotient filters, selected limits, countable-choice selectors, host equality, or ambient completeness could be exported. □

Theorem 1588.5 (Complete uniform-space Cauchy sequence, entourage, and Real-uniform factorization)**.** *Let $M = (U, F, B, L, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *packet. Suppose downstream consumers read M through the* $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{CauchyEntourageFilter}^{\uparrow}$, *and* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *interfaces. Then their common completion-facing route factors as follows:* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *supplies the scheduled regular-family and finite-window surface,* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *supplies the entourage-to-basis dyadic handoff,* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *supplies the basis, saturation, and limit boundary, and* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *supplies the Real-uniform completion handoff to the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Equivalently, every such consumer read is confined to the displayed path

$$\mathsf{CauchySequenceSpace}^{\uparrow} \longmapsto \mathsf{CauchyEntourageFilter}^{\uparrow} \longmapsto \mathsf{CompleteUniformSpace}^{\uparrow} \longmapsto \mathsf{BishopRealUniformCompletion}^{\uparrow}$$

No quotient filter, selected limit, countable-choice selector, host equality, ambient Real completeness theorem, or bridge credential enters outside those rows.

Proof. First read the Cauchy-sequence surface. By Definition 406.3, the completion-facing consumer of the sequence packet passes through the displayed regular family, schedule, finite Cauchy windows, dyadic tolerance row, transports, continuations, provenance, and local certificate before any terminal handoff is consumed.

Next read the entourage-filter handoff. Apply Definition 1791.3. It identifies the route from UniformSpace entourage data to the CauchyFilterBasis dyadic surface, so the sequence-side tolerance and window data can meet the uniform-space request only through that finite basis handoff.

Now project the accepted $\mathsf{CompleteUniformSpace}^{\uparrow}$ carrier M. The convergence route of Definition 1588.3 consumes $U, B, F, L, S, R, E, H, C, P, N$ in order, placing the basis, saturation, and limit boundary between the entourage handoff and the Real-facing seal.

Finally apply Definition 1806.3. The Real-uniform completion consumer reads the terminal handoff only after the L10 completion data reaches its displayed $\mathsf{Real}^{\uparrow}$ seal. Since none of the cited packets contains a coordinate for a quotient filter, selected limit, countable-choice selector, host equality, ambient Real completeness theorem, or bridge credential, carrier projection and the non-escape clauses force every common consumer to remain on the stated path. □

Theorem 1588.6 (Complete uniform-space ledger non-escape)**.** *For every accepted* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *carrier* $M = (U, F, B, L, S, R, E, H, C, P, N)$*, any Real-facing or completion-facing read exposed by* P *factors through the displayed route*

$$U, B, F, L, S, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet cannot export a quotient filter from F*, a selected limit from* L*, a countable-choice selector from* S *or* R*, host equality from* H*, or an ambient completeness principle from its provenance ledger.*

Proof. Project the provenance row P. Its Real-facing and completion-facing occurrences are recorded only as downstream consumers of the displayed route through U, B, F, L, S, R, E.

The Cauchy-filter row F is not a quotient coordinate. It is read only after the basis generator B and the entourage data U, and it hands the request to the boundary row L rather than to a completed filter object.

The boundary row L is not a selected limit. It exposes only the finite limit-facing route whose observations pass through the StreamName windows S and RegSeqRat readbacks R.

Transport by H and replay by C preserve this same dependency order. The local naming row N names the packet only after that order has been replayed, so the ledger has no separate place from which quotient filters, selected limits, countable-choice selectors, host equality, or ambient completeness can escape. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteUniformSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompleteUniformSpace}^{\uparrow}$ packet is generated from UniformSpace entourage data, a CauchyFilter row, a CauchyFilterBasis generator, a CauchyFilterLimit boundary, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompleteUniformSpace}^{\uparrow}}$, seed)

Scope closed: Definition 1588.1, Definition 1588.2, Definition 1588.3, and Definition 1588.6 seed the constructive uniform-space completeness surface for finite Cauchy-filter convergence data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompleteUniformSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable-choice selectors, host equality, ambient completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy request factorization, convergence readback, transport stability, replay stability, Real seal factorization, and ledger non-escape for BEDC.Derived.CompleteUniformSpaceUp.

Chapter 1589

A Concrete Naming Certificate for $\mathsf{FastCauchyReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FastCauchyReal}^{\uparrow}$ packet records the fast dyadic-modulus real-name carrier used by the L10 Real and Completion phase. It sits over the dyadic tolerance arithmetic of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback row of chapter 301, the terminal real seal of chapter 38, the completion boundary of chapter 360, and the Cauchy-real presentation route of chapter 1511. The packet makes the fast tolerance modulus visible as finite BEDC data before any completion-facing consumer treats the resulting name as a real.

Definition 1589.1 (FastCauchyReal carrier)**.** *A* $\mathsf{FastCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *fast-tolerance row recording the dyadic scale 2^{-k}, comparison budget, rounding window, and arithmetic ledger for each finite precision request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose visible entries are exactly the stream observations requested by the fast tolerance row.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in S under the dyadic tolerance data in D.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed route through D, S, R has been admitted.*
5. *H records componentwise* hsame *transport for the dyadic fast-tolerance, stream-window, regular-readback, real-seal, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from every finite precision request through D, S, R, E and then through the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{FastCauchyReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchyReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected representative, host real equality, countable choice, located completeness, or an ambient completion object outside the displayed finite rows.

Theorem 1589.2 (FastCauchyReal NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyReal}^{\uparrow}$ *carrier* $F = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FastCauchyReal}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed dyadic fast-tolerance, finite stream-window, regular rational readback, real-seal, transport, continuation, provenance, and local naming rows;*
2. *fast tolerance exactness, requiring each finite precision request to be accounted for by* D *before any stream window or readback row is consumed;*
3. *window compatibility, requiring* S *to expose only the finite observations named by the dyadic tolerance row;*
4. *regular readback, requiring* R *to be read only downstream of the displayed* D, S *route;*
5. *real-seal nonescape, requiring* E *to remain terminal with respect to the route* D, S, R *and the structural rows;*
6. *componentwise stability, requiring* hsame *transport* H *and* Cont *replay* C *to preserve the same displayed precision route;*
7. *provenance and local naming, requiring* P *and* N *to bind the accepted packet as a* $\mathsf{FastCauchyReal}^{\uparrow}$ *certificate.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1589.1. The tuple displays exactly the dyadic tolerance row, stream window, regular readback, real seal, transport, replay, provenance, and local name.

The analytic obligations are forced by the route D, S, R, E. A precision request first reads the fast dyadic ledger D, then the finite stream window S, then the regular rational readback R, and finally the terminal real seal E.

The structural obligations are forced by H, C, P, N. Componentwise transport and continuation replay preserve the same finite route, while provenance and local naming bind that accepted packet. Since the carrier has no coordinate beyond these rows, the listed clauses exhaust the local NameCert surface. □

Theorem 1589.3 (FastCauchyReal regular handoff)**.** *An accepted* $\mathsf{FastCauchyReal}^{\uparrow}$ *carrier supplies a regular rational Cauchy name to the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *routes only through the finite chain*

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

The handoff exposes dyadic fast tolerance, finite stream observations, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It does not add quotient stream equality, a selected representative, host real equality, countable choice, located completeness, or an ambient completion object outside the displayed carrier.*

Proof. Project the accepted packet and read the precision route in order. The dyadic row D supplies the fast tolerance budget, the stream row S supplies the finite observations named by that budget, the row R supplies regular rational readback, and the seal row E is terminal.

Now pass to the completion-facing consumers. The $\mathsf{RealCauchyCompletion}^{\uparrow}$ and $\mathsf{CauchyRealPresentation}^{\uparrow}$ routes may transport, replay, package, and locally name the handoff through H, C, P, N, but they receive only the displayed D, S, R, E data from this carrier.

The excluded principles are absent by inspection of the tuple. Quotient stream equality, selected representatives, host real equality, countable choice, located completeness, and ambient completion objects are not coordinates of F, so the regular handoff cannot export them. □

Theorem 1589.4 (FastCauchyReal modulus extraction route)**.** *For an accepted* $\mathsf{FastCauchyReal}^{\uparrow}$ *carrier* $F = (D, S, R, E, H, C, P, N)$*, the fast dyadic row* D *and stream window row* S *expose a convergence modulus only through* $\mathsf{FastCauchyModulus}^{\uparrow}$ *or chapter 3718 before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is read. The carrier exports no detached modulus selector, quotient stream equality, or ambient completion object outside the displayed route* D, S, R, E, H, C, P, N*.*

Proof. Project the carrier of Definition 1589.1. The rows D and S are the only source rows that can answer a finite precision request before regular readback.

Apply the NameCert obligations of Definition 1589.2. Fast tolerance exactness keeps the modulus information in D, and window compatibility keeps the observations in S tied to that same budget.

The regular handoff theorem Definition 1589.3 places R downstream of D, S. Thus any modulus consumed before R must be the displayed fast-modulus surface or the regular Cauchy extraction route, not a separate selector. □

Theorem 1589.5 (FastCauchyReal modulus readback determinacy)**.** *Let* $F = (D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FastCauchyReal}^{\uparrow}$ *carrier. Any two accepted reads of the same fast tolerance row* D *through the same* $\mathsf{StreamName}^{\uparrow}$ *window row* S *and* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *reach the same terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary* E *under componentwise* hsame *transport and displayed* Cont *replay.*

The determinacy route is exactly

$$D, S, R \longmapsto E \longmapsto H, C, P, N.$$

It does not use selected limits, quotient streams, countable choice, host real equality, or ambient Real completeness.

Proof. Project the carrier of Definition 1589.1. The rows D, S, R, E are stored in one finite BHist packet, and E is terminal only for the displayed route from fast tolerance to stream window to regular readback.

Use Definition 1589.4. Both accepted reads expose their modulus data through the same D and S before the row R is consumed, so neither read can introduce a detached modulus selector or a second stream representative.

Finally apply Definition 1589.3. The regular handoff places E downstream of the same D, S, R route, and the rows H, C, P, N transport, replay, source, and name that route componentwise. Since the carrier has no selected-limit, quotient-stream, choice, host-equality, or ambient-completeness coordinate, the two reads have the same terminal Real seal boundary. □

Theorem 1589.6 (FastCauchyReal completion consumer route)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{CauchyRealPresentation}^{\uparrow}$ *consumer of an accepted* $\mathsf{FastCauchyReal}^{\uparrow}$ *packet factors through the displayed rows* D, S, R, E, H, C, P, N*. The completion-facing read first uses the fast dyadic tolerance data, then the finite stream windows, then the regular rational handoff, then the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and finally the structural transport, replay, provenance, and naming rows. It receives no selected host limit, quotient Cauchy class, countable-choice schedule, or ambient completeness witness from the packet.*

Proof. Start from Definition 1589.3. It already forces completion-facing consumers to receive the regular rational Cauchy name through D, S, R, E and then through the structural rows.

Use Definition 1589.4 for the pre-handoff part of the read. The modulus data is exposed only through the fast dyadic row and stream window row before R is consumed.

Finally project the excluded-coordinate clause of Definition 1589.1. Since selected host limits, quotient Cauchy classes, choice schedules, and ambient completeness witnesses are not coordinates of F, no Real or Completion consumer can obtain them from this route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyReal}^{\uparrow}}$.

Constructive story: A $\mathsf{FastCauchyReal}^{\uparrow}$ packet is generated from a $\mathsf{DyadicRatCore}^{\uparrow}$ fast-tolerance row, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{RegSeqRat}^{\uparrow}$ regular readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1589.1, Definition 1589.2, and Definition 1589.3 seed the finite fast dyadic-modulus real-name carrier consumed by the L10 Real and Completion phase.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastCauchyReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, located completeness, ambient completion objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fast tolerance exactness, window compatibility, regular readback, real-seal nonescape, componentwise stability, provenance, and local naming for the same displayed packet.

Chapter 1590

A Concrete Naming Certificate for $\mathsf{RealCauchyCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealCauchyCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed sequence of Real names is admitted as Cauchy data before any completion-facing consumer reads a terminal Real seal. It sits between the finite-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the Real seal boundary of chapter 38, and the exact completion boundary of chapter 1120. The packet is a Real-sequence Cauchy readiness certificate, not a quotient stream, selected limit, host real equality, trichotomy, countable-choice source, or ambient Real completeness principle.

Definition 1590.1 (Real Cauchy criterion carrier)**.** *A* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, Q, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Real}^{\uparrow}$ *sequence-source row, exposing the finite list of Real-name entries and precision requests inspected by the criterion.*
2. *W is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows selected for the inspected source entries and late-pair requests.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only through the windows in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-test ledger recording the rational radii, late-pair comparisons, and dyadic triangle-budget cells used by the Cauchy test.*
5. *L is the Cauchy-test ledger tying each accepted precision request to a displayed late-pair window, regular readback, and dyadic tolerance comparison.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, Q, D, L have been displayed.*
7. *H records componentwise* hsame *transport for the sequence source, windows, regular readback, dyadic tolerance ledger, Cauchy-test ledger, Real seal, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a precision request through the sequence source, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance test, Cauchy-test ledger, and Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBoundaryUp, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, Q, D, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, detached Real completeness, or an ambient completion theorem.

Theorem 1590.2 (Real Cauchy criterion NameCert obligations)**.** *For an accepted* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *carrier $K = (S, W, Q, D, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission for the Real sequence source, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Cauchy-test ledger, Real seal, transport, replay, provenance, and local naming row;*
2. *window-readback compatibility, requiring every regular rational read in Q to be obtained from a displayed window in W attached to the source row S;*
3. *dyadic Cauchy-test exactness, requiring D and L to record the requested tolerance, late-pair budget, and triangle cells before the criterion may expose the seal row E;*
4. *transport and replay stability, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the same ordered route S, W, Q, D, L, E;*
5. *provenance exhaustion, requiring P and N to name only this displayed route and to export no quotient streams, selected limits, countable-choice selector, host real equality, trichotomy, detached Real completeness, or ambient completion principle.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1590.1. The packet displays the Real sequence source, selected StreamName windows, regular rational readback, dyadic tolerance ledger, Cauchy-test ledger, terminal seal row, and the structural rows H, C, P, N.

Window-readback compatibility is read from the order of W and Q. The readback row Q appears only after the selected finite windows W, and those windows are attached to the source row S rather than to an unbounded host stream.

Dyadic exactness is the role of D and L. The tolerance row D stores the rational radii and comparison cells, while the ledger L records which late-pair request has been tested before the Real seal E is available.

Transport and replay are structural. Componentwise hsame in H preserves the displayed rows, and Cont replay in C repeats the route from the precision request through S, W, Q, D, L, E.

Finally, provenance is exhausted by P and N. Since the carrier has no row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, detached Real completeness, or ambient completion, the local NameCert surface cannot export any such object. □

Theorem 1590.3 (Real Cauchy criterion regular readback route)**.** *Every accepted* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *read factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the Real sequence source, Cauchy-test ledger, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}$ *row, and the* RealCompletionExactBoundaryUp

sibling boundary. The route cannot expose quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.

Proof. Begin with an accepted read of the criterion packet. Carrier projection gives the sequence source S and the selected finite windows W before any regular rational readback is available.

The readback row Q is downstream of W. Thus each accepted read first passes through the $\mathsf{StreamName}^{\uparrow}$ window discipline and then through the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational surface attached to that same displayed window.

The dyadic Cauchy test is downstream of the readback. The rows D and L record the requested tolerance, late-pair budget, and comparison cells before the terminal $\mathsf{Real}^{\uparrow}$ seal E may be consumed.

The exact-boundary sibling is read only as provenance discipline. The row P names RealCompletionExactBounda to keep the Real-completion faces aligned, but it contributes no selected limit, quotient equality, or independent completeness witness.

The exclusions follow from the carrier inventory. Since quotient streams, selected limits, countable choice, host real equality, trichotomy, and ambient Real completeness are not rows of K, no accepted read through H, C, P, N can expose them. □

Theorem 1590.4 (Real Cauchy criterion seal factorization)**.** *For every accepted* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *packet*

$$K = (S, W, Q, D, L, E, H, C, P, N),$$

the terminal $\mathsf{Real}^{\uparrow}$ *seal row E is reachable only through the ordered finite route $S, W, Q, D, L, E, H, C, P, N$. Along this route W supplies the* $\mathsf{StreamName}^{\uparrow}$ *windows, Q supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and D, L supply the dyadic Cauchy-test ledger. No quotient stream, selected limit, countable choice, host equality, trichotomy, or ambient completeness row can bypass E.*

Proof. Project the carrier using Definition 1590.1. The projection displays the ordered rows $S, W, Q, D, L, E, H, C, P, N$, with the terminal Real seal placed after the finite windows, regular readback, dyadic tolerance data, and Cauchy-test ledger.

Definition 1590.2 identifies the five-row certificate surface governing carrier admission, window-readback compatibility, dyadic exactness, transport and replay stability, and provenance exhaustion. In particular, the seal row E is not an independent input; it is admitted only after the S, W, Q, D, L route has been recorded.

Definition 1590.3 supplies the StreamName–RegSeqRat–DyadicRatCore readback path. Combining that route with the carrier projection shows that every completion-facing use of E factors through the same finite Cauchy-test ledger.

The excluded objects are absent from the carrier inventory and from the NameCert surface. Therefore quotient stream equality, selected limits, countable choice, host equality, trichotomy, and ambient completeness cannot supply an alternate row reaching the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCauchyCriterion}^{\uparrow}$ packet is generated from a RealUp sequence source, StreamName finite windows, a RegSeqRat readback row, a DyadicRatCore tolerance-test ledger, a Cauchy-test ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1590.1, Definition 1590.2, Definition 1590.3, and Definition 1590.4 seed the Real-specific Cauchy criterion route through StreamName, RegSeqRat, DyadicRatCore, Real, and RealCompletionExactBoundary faces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, window-readback compatibility, dyadic Cauchy-test exactness, transport stability, replay stability, regular readback factorization, Real seal factorization, and provenance exhaustion for BEDC.Derived.RealCauchyCriterionUp.

Chapter 1591

A Concrete Naming Certificate for $\mathsf{ClosedBoundedInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedBoundedInterval}^{\uparrow}$ packet records a displayed closed bounded real interval as finite BEDC rows rather than as an ambient set of host reals. It consumes the located endpoint discipline of chapter 394, supplies the base carrier read by the finite net route of chapter 1250, and fixes the interval object consumed by the uniform-modulus chapter chapter 1253. The packet is a finite certificate for lower and upper located endpoints, endpoint order, rational and dyadic containment ledgers, StreamName windows, RegSeqRat readbacks, RealUp sealing, transport, replay, provenance, and local naming. It is not an open-cover compactness theorem, quotient equality of reals, trichotomy, a selected point of the interval, or an ambient completeness principle.

Definition 1591.1 (Closed bounded interval carrier)**.** *A* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located endpoint row, read through the located real and interval-endpoint surface of* $\mathsf{LocatedInterval}^{\uparrow}$*;*
2. *U is the upper located endpoint row, read through the same located endpoint surface;*
3. *O is the endpoint-order row saying that the lower endpoint is admitted no later than the upper endpoint in every displayed containment read;*
4. *Q is the rational containment ledger, recording finite rational tests that enter the closed interval through the endpoint rows and O;*
5. *D is the dyadic containment ledger, refining the rational tests by finite dyadic cells and dyadic endpoint comparisons;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the endpoint names and containment tests at finite precision;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint, rational-containment, and dyadic-containment windows;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, O, Q, D, S, R have been displayed;*

9. *H records componentwise* hsame *transports for the lower endpoint, upper endpoint, endpoint order, containment ledgers, windows, readbacks, and Real seal;*
10. *C records displayed* Cont *replay from located endpoints through containment tests, StreamName windows, RegSeqRat readbacks, and RealUp sealing;*
11. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row.*

The carrier exports no open cover, hidden selector for a point in the interval, quotient real equality, trichotomy row, or completeness datum. Its public object is the finite endpoint-and-containment packet I.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalTasteGate single carrier alignment`

Definition 1591.2 (Closed bounded interval classifier)**.** *Two accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers*

$$I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

and

$$I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$$

are classified together exactly when the displayed hsame *rows transport L to L', U to U', O to O', Q to Q', D to D', S to S', R to R', and E to E', and the displayed* Cont *rows replay the same endpoint-to-containment-to-seal route on both packets. The classifier has no coordinate for host-level set equality, order trichotomy, quotient equality of real names, or a choice of representatives for endpoint streams.*

Lean4 (definition) `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalClassifier`

Theorem 1591.3 (Closed bounded interval NameCert obligations)**.** *For the carrier of Definition 1591.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$; endpoint admission for L and U through* $\mathsf{LocatedInterval}^{\uparrow}$*; endpoint-order admission through O; rational and dyadic containment admission through Q and D; StreamName and RegSeqRat readback through S and R; RealUp sealing through E; classifier preservation under the componentwise* hsame *rows of H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket semantic name certificate`

Proof. Project the carrier. Its endpoint rows L and U, order row O, containment ledgers Q and D, window row S, readback row R, seal row E, transport row H, replay row C, provenance row P, and local name N are visible coordinates of one finite packet.

Endpoint and containment admission are read before the Real seal. The rational and dyadic ledgers are attached to the same lower and upper located endpoints and to the same endpoint-order row, so a containment consumer cannot replace the packet by a host interval or by an unrecorded order decision.

The structural rows close the naming surface. The componentwise hsame transports and displayed Cont routes preserve exactly the rows listed in the carrier, and the Pkg and NameCert rows name that finite route without adding any hidden selector, quotient equality, trichotomy, or completeness datum. □

Theorem 1591.4 (Closed bounded interval public export)**.** *The public* ClosedBoundedInterval$^{\uparrow}$ *export consists exactly of the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName window, RegSeqRat readback, RealUp seal, componentwise transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows of the accepted carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*. It exports no open-cover compactness, quotient real equality, trichotomy, selected point, selected subcover, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket public export`

Proof. Project the carrier and classifier of Definition 1591.1 and Definition 1591.2. They expose the endpoint rows L, U, endpoint order O, containment ledgers Q, D, StreamName window S, RegSeqRat readback R, Real seal E, transport row H, replay row C, provenance row P, and local naming row N.

Apply Definition 1591.3. The obligation theorem identifies those rows as the local NameCert surface, so the public export cannot add a host interval, quotient equality, order trichotomy, selected point, selected subcover, or ambient completeness coordinate.

Thus every L10 consumer receives exactly the displayed finite packet. Open-cover compactness and completeness-facing claims must enter through separate downstream certificates rather than through the ClosedBoundedInterval$^{\uparrow}$ public export itself. □

Theorem 1591.5 (Closed bounded interval root obligation spine)**.** *Every downstream* ClosedBoundedInterval$^{\uparrow}$ *consumer must read three root obligations through the existing carrier rows: endpoint-order exposure through* L, U, O*, containment-ledger exposure through* Q, D*, and* StreamName$^{\uparrow}$/RegSeqRat$^{\uparrow}$/Real$^{\uparrow}$ *seal handoff through* S, R, E*. These obligations are transported only by* H*, replayed only by* C*, recorded only by* P*, and named only by* N*.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root obligation spine`

Proof. Project the carrier and classifier. The carrier of Definition 1591.1 supplies the endpoint, containment, schedule, readback, seal, transport, replay, provenance, and local naming rows, while Definition 1591.2 preserves those rows componentwise.

Apply the NameCert obligations of Definition 1591.3. They expose endpoint order through O, containment through Q, D, and the StreamName, RegSeqRat, and Real seal handoff through S, R, E.

The source nonescape and finite-net source theorems then keep interval-net, compactness-facing, and uniform-modulus consumers on the same root spine. Thus the downstream route cannot replace the endpoint order, containment ledger, or seal handoff by a host interval, selected subcover, quotient equality, or ambient completeness row. □

Theorem 1591.6 (Closed bounded interval carrier gate)**.** *Every accepted consumer route for a* ClosedBoundedInterval$^{\uparrow}$ *packet must display the carrier rows*

$$L, U, O, Q, D, S, R, E, H, C, P, N$$

before it can read interval-net or compactness rows. In particular, an interval-net, nested-window, located-cover, compactness-facing, or uniform-modulus consumer cannot bypass lower endpoint, upper endpoint, endpoint order, rational containment, dyadic containment, StreamName window, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, or local naming.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket carrier gate`

Proof. Project the carrier of Definition 1591.1. The rows $L, U, O, Q, D, S, R, E, H, C, P, N$ are the whole finite source surface of the closed bounded interval packet.

Apply the NameCert obligation theorem. Theorem 1591.3 lists exactly those rows as the local $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ surface, so a consumer has no independent route into interval-net or compactness data.

Use the source-window and nonescape theorems. The source window of Definition 1591.34, source transport of Definition 1591.35, and source nonescape of Definition 1591.36 keep every downstream consumer behind the same displayed carrier gate. □

Theorem 1591.7 (Closed bounded interval dyadic-net ledger)**.** *Dyadic containment subledgers are the only finite-net source for* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *consumers. Any finite-net read exported from an accepted packet must pass through the dyadic containment row D, together with the endpoint rows L, U, endpoint-order row O, rational containment row Q, StreamName window S, RegSeqRat readback R, Real seal E, and structural rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket dyadic net ledger`

Proof. Start with the carrier and classifier. The carrier of Definition 1591.1 contains exactly one dyadic containment coordinate D, and the classifier of Definition 1591.2 transports that coordinate componentwise with the endpoint, rational-containment, StreamName, RegSeqRat, and Real-seal rows.

Apply the source-window route. The source window of Definition 1591.34 reads dyadic containment through the same endpoint-source packet before any interval-net or compactness consumer opens its own rows.

Finally apply finite-net source and source nonescape. Theorem 1591.38 makes D part of the required finite-net source, and Definition 1591.36 excludes any alternate host interval, open-cover, or choice-selected net source. □

Theorem 1591.8 (Closed bounded interval endpoint transport)**.** *Classifier transport of a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier is determined by componentwise* hsame *transport of lower endpoint, upper endpoint, endpoint order, rational containment, dyadic containment, StreamName window, RegSeqRat readback, and Real seal. The transported interval-net and compactness-facing routes are then replayed only through the displayed* Cont*, provenance, and local naming rows of the same packet.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket endpoint transport`

Proof. Project two classified carriers through Definition 1591.2. The classifier compares L, U, O, Q, D, S, R, E only through the componentwise hsame rows stored in H.

Use source transport. Theorem 1591.35 states that endpoint source windows move by exactly those componentwise rows before any interval-net or compactness consumer reads them.

The replay step is fixed by the carrier. The displayed Cont row C, provenance row P, and local naming row N preserve the same transported endpoint route, and Definition 1591.36 prevents the transported consumer from importing host interval equality, quotient real equality, trichotomy, or ambient completeness. □

Definition 1591.9 (Closed bounded interval root source ledger)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$, the root source ledger is the finite* BHist *row*

$$\Lambda_I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

read before any interval-net, compactness-facing, located-cover, nested-window, or uniform-modulus consumer opens a downstream row. The ledger records lower endpoint, upper endpoint, endpoint order, rational containment, dyadic containment, stream schedule, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming as one source surface.

Lean4 (definition) `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalRootSourceLedger`

Theorem 1591.10 (Closed bounded interval endpoint-containment route)**.** *Every containment consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier must pass through the endpoint and containment prefix*

$$L, U, O, Q, D$$

of Definition 1591.9 before any finite-net, located-cover, nested-window, compactness, or uniform-modulus row is available. In particular, no downstream consumer can read a finite-net or compactness row while bypassing the lower endpoint, upper endpoint, endpoint-order row, rational containment ledger, or dyadic containment ledger of the root source packet.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket endpoint containment route`

Proof. Project the carrier and the root source ledger. By Definition 1591.1 and Definition 1591.9, the endpoint rows L, U, order row O, and containment ledgers Q, D are the first displayed source rows of the packet.

Apply the NameCert obligation theorem. The obligations of Definition 1591.3 admit endpoint rows, endpoint order, and rational and dyadic containment before StreamName, RegSeqRat, Real sealing, transport, replay, provenance, or local naming can be consumed.

Finally use the source-window route. The source window of Definition 1591.34 and source transport of Definition 1591.35 keep the same prefix upstream of every interval-net or compactness-facing read, so no downstream row can bypass L, U, O, Q, D. □

Theorem 1591.11 (Closed bounded interval Real-seal root handoff)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is downstream of the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, which themselves are downstream of the endpoint and containment prefix* L, U, O, Q, D*. The root handoff exports no selected point, quotient equality, trichotomy row, selected subcover, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalPacket real seal root handoff`

Proof. Start with the root source ledger. It records the route $L, U, O, Q, D, S, R, E, H, C, P, N$ as one finite BHist source surface, so the seal row is not available before the schedule and readback rows are displayed.

Use the existing source-window theorem. By Definition 1591.34, the $\mathsf{StreamName}^{\uparrow}$ row S, $\mathsf{RegSeqRat}^{\uparrow}$ row R, and $\mathsf{Real}^{\uparrow}$ seal E are read from the same endpoint-source packet after the endpoint and containment rows.

The non-escape conclusion follows from Definition 1591.36. Since the carrier and source route contain no selected point, quotient equality, trichotomy row, selected subcover, or ambient completeness coordinate, the Real-seal handoff cannot export any of them. □

Theorem 1591.12 (Closed bounded interval root source split)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier as in Definition 1591.1. The root source for every interval-net, compactness-facing, and uniform-modulus consumer is the concrete row split $L, U, O, Q, D, S, R, E, H, C, P, N$: endpoints and order are carried by L, U, O, containment by Q, D, readback by S, R, E, and structural persistence by H, C, P, N. The local NameCert obligation theorem Definition 1591.3 forces this split before any downstream row is read.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source split`

Proof. Project the carrier. Its only displayed root rows are the endpoint rows L, U, endpoint-order row O, containment ledgers Q, D, finite window S, regular rational readback R, Real seal E, transport H, replay C, provenance P, and local name N.

Apply Definition 1591.3. The theorem lists those same rows as the local $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ surface, so an interval-net, compactness-facing, or uniform-modulus consumer has no accepted source outside that split.

The split is therefore a source discipline rather than an extra compactness principle. Consumer rows may be appended after the source has been displayed, but the source itself remains $L, U, O, Q, D, S, R, E, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedInterval fromEventFlow exactness`

Theorem 1591.13 (Closed bounded interval root source scope route)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The accepted closed bounded interval root source route factors through dyadic interval rows, rational interval bounds, located interval covers, closed bounded interval net rows,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *endpoint seals before any compactness-facing or uniform-modulus consumer reads the interval. The displayed dependency order is*

$$L, U, O \longmapsto Q, D \longmapsto S, R, E \longmapsto H, C, P, N.$$

No compactness consumer, located-cover consumer, nested-window consumer, or uniform-modulus consumer may replace this route by open-cover compactness, selected subcovers, trichotomy, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The endpoint rows L, U and endpoint-order row O supply the rational interval bounds and located interval source before a downstream consumer can inspect a cover, mesh, or modulus row.

The containment rows Q, D then expose rational and dyadic interval data. These are the rows through which located interval covers and closed bounded interval net rows read the interval, so the consumer-facing cover data remain downstream of the same root source.

Next read the finite Real-facing route. The $\mathsf{StreamName}^{\uparrow}$ window S, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and terminal $\mathsf{Real}^{\uparrow}$ seal E expose endpoint names before compactness-facing or uniform-modulus rows are allowed to consume the interval.

The structural rows H, C, P, N preserve that source route by transport, replay, provenance, and local naming. Since the carrier contains no coordinate for the excluded compactness, choice, quotient, trichotomy, or ambient completeness objects, every named consumer factors through the displayed source route. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source scope route`

Theorem 1591.14 (Closed bounded interval root-source carrier admission)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C,$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Carrier admission for the root source is exactly the admission of a* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet whose rational cell row is read through* $\mathsf{RationalInterval}^{\uparrow}$*, whose refinement row is read through* $\mathsf{DyadicInterval}^{\uparrow}$*, whose endpoint windows are read through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, and whose terminal seal is read through* $\mathsf{Real}^{\uparrow}$*. The admitted BEDC rows are the displayed* BHist *entries $L, U, O, Q, D, S, R, E, H, C, P, N$, with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row; no compactness, Heine–Borel principle, selected point, trichotomy, or quotient real equality is part of admission.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source carrier admission`

Proof. Project the accepted carrier through Definition 1591.1. The endpoint rows L, U and order row O give the located interval source, while Q, D expose rational and dyadic containment as finite interval rows.

Read the endpoint names through the finite window route. The $\mathsf{StreamName}^{\uparrow}$ row S, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and $\mathsf{Real}^{\uparrow}$ seal E are the only Real-facing rows available before a consumer can inspect the interval.

The structural rows close admission. Transport by H, replay by C, provenance by P, and local naming by N preserve the same BHist packet, so carrier admission is exactly the displayed root source and not a compactness or Heine–Borel assertion. □

Theorem 1591.15 (Closed bounded interval root-source window exactness)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C,$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every window read of the root source exposes exactly the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the* $\mathsf{RationalInterval}^{\uparrow}$ *rational cell row, the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P, N. Thus interval-net, located-cover, compactness-facing, and uniform-modulus consumers may refine the window only after the same $L, U, O, Q, D, S, R, E, H, C, P, N$ route has been displayed.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source window exactness`

Proof. Begin with the root source split. It already identifies $L, U, O, Q, D, S, R, E, H, C, P, N$ as the complete source packet for downstream consumers.

The window rows are not independent of the interval rows. Rational cells in Q and dyadic cells in D are read only with the endpoint windows S and regular readbacks R, and the Real seal E terminates that same route.

Transport and replay preserve exactness. Since H, C, P, N carry only the displayed packet, a downstream consumer cannot omit a window row, insert a host compact interval, or replace the source by selected subcover data before adding its own consumer rows. □

Theorem 1591.16 (Closed bounded interval root-source Real-seal route)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P,$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The root source reaches every Real-facing consumer through the finite route*

$$\mathsf{LocatedInterval}^{\uparrow}, \mathsf{RationalInterval}^{\uparrow}, \mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}$$

The route records endpoint windows, rational and dyadic containment, regular readback, terminal Real sealing, componentwise transport, continuation replay, provenance, and local naming. It does

not assert compactness, Heine–Borel, selected endpoints, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source real seal route`

Proof. Read the interval side first. The $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, and $\mathsf{DyadicInterval}^{\uparrow}$ rows are represented by the endpoint, order, rational containment, and dyadic containment coordinates L, U, O, Q, D.

Pass to the seal side. The endpoint names are exposed only through $\mathsf{StreamName}^{\uparrow}$ windows S, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Finally attach the BEDC structural rows. The BHist packet, hsame transport, Cont replay, Pkg provenance, and NameCert row are exactly H, C, P, N together with the displayed carrier coordinates, so the Real-seal route has no coordinate for compactness, Heine–Borel, selected endpoints, quotient real equality, countable choice, or ambient completeness. □

Theorem 1591.17 (Closed bounded interval root containment split)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The containment part of the root source is exactly* L, U, O, Q, D *transported and replayed through* H, C *and recorded through* P, N*. Thus interval-net cells, compactness-facing finite covers, and uniform-modulus mesh requests must pass through the endpoint, order, rational-containment, and dyadic-containment rows of Definition 1591.1 and Definition 1591.3 before they read any mesh, cover, or modulus row.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root containment split`

Proof. Start with the endpoint-containment route. The carrier gives L, U, O, Q, D before the schedule and readback rows, and the NameCert obligation theorem admits containment only through those displayed coordinates.

The structural rows do not create new containment data. They preserve the same containment route by H, replay it by C, record its source through P, and name it through N.

Net, compactness-facing, and uniform-modulus consumers therefore receive containment only as a root source. A downstream mesh, cover, or modulus row may refine Q, D, but it cannot replace the endpoint and containment prefix by host interval membership, a selected point, or an open-cover compactness object. □

Theorem 1591.18 (Closed bounded interval root seal split)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The Real-seal part of the root source is the route* S, R, E *downstream of* L, U, O, Q, D *and upstream of every interval-net, compactness-facing, and uniform-modulus consumer. Together with* H, C, P, N*, Definition 1591.1 and Definition 1591.3 force all Real-facing reads through the displayed* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal route.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root seal split`

Proof. Read the carrier in order. The $\mathsf{StreamName}^{\uparrow}$ row S and $\mathsf{RegSeqRat}^{\uparrow}$ row R are attached to the same endpoint and containment source L, U, O, Q, D, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is available only after those rows are displayed.

Apply the NameCert obligation theorem. It treats S, R, E as local certificate obligations of the closed bounded interval packet, not as an ambient Real completeness theorem.

The replay and provenance rows keep the seal attached to the root source. Hence interval-net, compactness-facing, and uniform-modulus consumers may use Real-facing data only through

$L, U, O, Q, D, S, R, E, H, C, P, N$, with no quotient real equality, trichotomy, selected representative, selected subcover, or ambient completeness route. □

Theorem 1591.19 (Closed bounded interval root unblock obligations)**.** *The root obligations exposed by an accepted* ClosedBoundedInterval$^{\uparrow}$ *packet are endpoint admission, endpoint-order transport, rational containment exposure, dyadic containment exposure,* StreamName$^{\uparrow}$ *readback,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal nonescape, transport, replay, provenance, and local* NameCert *naming. Any downstream finite-net, located-cover, nested-window, or compact-uniform route must discharge those obligations before adding its own consumer rows.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root unblock obligations`

Proof. Read the NameCert obligation theorem and the endpoint-order transport theorem. Together they make endpoint admission and endpoint-order transport part of the local ClosedBoundedInterval$^{\uparrow}$ surface.

Read the density ledger and density readback theorems. They expose rational containment, dyadic containment, StreamName windows, RegSeqRat readbacks, and Real endpoint seals as rows of the same source package.

Apply source readback stability and the compact-uniform source package. Transport, replay, provenance, and local naming do not create additional interval data; they preserve the displayed package until the finite-net or compact-uniform consumer adds its own rows.

Thus the root obligations are exactly the listed rows. A downstream consumer that omits any one of them has not received an accepted ClosedBoundedInterval$^{\uparrow}$ source. □

Theorem 1591.20 (Closed bounded interval root-source dependency scope)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C,$ be an accepted* ClosedBoundedInterval$^{\uparrow}$ *carrier. The packet $L, U, O, Q, D, S, R, E, H, C, P, N$ is the required dependency prefix for every* ClosedBoundedIntervalNet$^{\uparrow}$, LocatedIntervalCover$^{\uparrow}$, NestedIntervalCompactness$^{\uparrow}$, *and* ClosedBoundedIntervalUniformModulus$^{\uparrow}$ *consumer of I. The interval-net route of chapter 1250, the located-cover route, the nested-compactness route of chapter 1584, and the compact-uniform route of chapter 1253 may add consumer rows only after that prefix has exposed endpoint admission, endpoint-order transport, rational and dyadic containment, StreamName windows, RegSeqRat readback, the Real seal, componentwise transport, continuation replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source dependency scope`

Proof. Start with the root-source split and the root-source window exactness theorem. They identify the endpoint rows L, U, endpoint order O, rational and dyadic containment rows Q, D, finite window S, regular readback R, terminal Real seal E, and structural rows H, C, P, N as the complete source before a consumer reads mesh, cover, nesting, or modulus data.

Use the Real-seal route next. The route forces every Real-facing consumer through LocatedInterval$^{\uparrow}$, RationalInte then through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and finally through the BHist, hsame, Cont, Pkg, and NameCert rows. Thus the interval-net and located-cover consumers cannot detach their finite cells from the displayed source packet.

For nested compactness, apply the nested-window factorization already recorded in this file and read it against chapter 1584. The retained nested prefix is downstream of the same endpoint, containment, window, readback, seal, transport, replay, provenance, and naming rows.

For the compact-uniform consumer, apply the uniform-modulus source theorem and the compact-uniform route of chapter 1253. The modulus and compact-uniform rows are consumer rows, so they enter only after the same root packet has been displayed.

The downstream coverage surface and root consumer completeness theorem combine these four cases. Hence $L, U, O, Q, D, S, R, E, H, C, P, N$ is the common dependency prefix for the named L10 consumers, and none of them may substitute open-cover compactness, selected subcovers, trichotomy, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness for that prefix. □

Theorem 1591.21 (Closed bounded interval root-source scoped coverage)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, *and* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *consumer must first expose endpoint admission, endpoint-order transport, rational and dyadic containment,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *rows of the accepted interval packet. This scoped coverage is the common source surface supplied by the root-source split, root-source dependency scope, nested-window factorization, and uniform-modulus source theorems before any consumer-specific mesh, cover, nesting, modulus, or compact-uniform row is read.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root source scoped coverage`

Proof. Start with the root-source split. It identifies $L, U, O, Q, D, S, R, E, H, C, P, N$ as the endpoint, order, containment, window, readback, seal, transport, replay, provenance, and naming rows of the accepted interval packet.

Apply the root-source dependency scope. The theorem places every interval-net, located-cover, nested-compactness, and uniform-modulus consumer downstream of the same dependency prefix, so the named consumers cannot read their own mesh, cover, nesting, or modulus rows before the interval source has been displayed.

For nested-compactness consumers, use the nested-window factorization. It keeps the retained nested prefix behind the displayed endpoint, containment, readback, seal, and structural rows.

For uniform-modulus consumers, use the uniform-modulus source theorem. It places each modulus and compact-uniform row after the same root packet.

Thus the four consumer families have one scoped coverage surface: endpoint admission, endpoint-order transport, rational and dyadic containment, StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert naming. No consumer-specific row can replace that accepted interval packet by host compactness, selected subcovers, trichotomy, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1591.22 (Closed bounded interval root consumer completeness)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, *and* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *consumer factors through the complete source packet $L, U, O, Q, D, S, R, E, H, C, P, N$ before any consumer-specific row is read. The completeness surface composes the root source split, scoped source map, downstream coverage surface, finite-cover window exactness, nested-window factorization, and uniform-modulus source, and it explicitly excludes open-cover compactness, selected subcovers, trichotomy, quotient real equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root consumer completeness`

Proof. Begin with the root source split and root unblock obligations. They identify $L, U, O, Q, D, S, R, E, H, C, P, N$ as the endpoint, order, containment, window, readback, seal, transport, replay, provenance, and local naming rows that every downstream consumer must receive first.

Pass to the scoped source map. The definition of Σ_I records the same rows as the scoped source packet, and the downstream coverage surface states that located-cover, nested-window, finite-net, and compact-uniform consumers may only add their own rows after that packet has been displayed.

For interval-net and located-cover consumers, apply finite-cover window exactness. It forces mesh centers, cover cells, and refinement rows to remain downstream of the complete root packet.

For nested-window consumers, apply nested-window factorization. The retained nested prefix and compactness ledger are read only after $L, U, O, Q, D, S, R, E, H, C, P, N$ have been exposed.

For uniform-modulus consumers, apply the uniform-modulus source theorem. The modulus and compact-uniform rows are added after the same endpoint, containment, StreamName, RegSeqRat, Real-seal, and structural route.

The cited source theorems use no coordinate for open-cover compactness, selected subcovers, trichotomy, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Therefore the four named consumer families are complete exactly over the displayed root packet and over no stronger ambient principle. □

Theorem 1591.23 (Closed bounded interval downstream coverage surface)**.** *Every downstream located-cover, nested-window, finite-net, and compact-uniform consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier factors through the same source packet*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

The consumer may refine that packet by adding cover, nesting, mesh, modulus, or continuity rows, but the source interval itself remains the displayed carrier rather than an open-cover compactness object or host real interval.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket downstream coverage surface`

Proof. Begin with Definition 1591.71. It places every net, uniform-modulus, located-cover, nested-window, and compactness-facing consumer behind the same root rows.

Apply Definition 1591.72 for finite-net reads and the compactness consumer boundary for compact-uniform reads. Both routes require L, U, O, Q, D, S, R, E before consumer-specific cover, net, or modulus rows are inspected.

Finally use Definition 1591.19. The structural rows H, C, P, N carry the source across transport, replay, provenance, and local naming, so each downstream route factors through the same source packet and cannot replace it by host compactness data. □

Theorem 1591.24 (Closed bounded interval finite-cover window exactness)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C,$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite-cover window read must expose exactly the source rows* $L, U, O, Q, D, S, R, E, H, C, P, N$ *before any mesh center, cover cell, or refinement row is read. In particular, Definition 1591.37, Definition 1591.69, and Definition 1591.23 make the finite-cover window an exact downstream read of the root packet, not a separate open-cover compactness object.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket finite cover window exactness`

Proof. Project the accepted carrier and the finite-cover window. The root rows L, U, O, Q, D, S, R, E supply endpoints, order, containment, StreamName scheduling, RegSeqRat readback, and the terminal Real seal before a finite-cover consumer can inspect its own rows.

Apply the source-window exhaustion and downstream coverage surface. These theorems force every interval-net and located-cover read through the same displayed source packet, so the finite-cover window cannot omit any of $L, U, O, Q, D, S, R, E, H, C, P, N$.

The structural rows finish the exactness claim. Transport by H, replay by C, provenance by P, and local naming by N preserve the source packet without adding selected subcovers, host compactness, quotient real equality, trichotomy, or ambient completeness. □

Theorem 1591.25 (Closed bounded interval nested-window factorization)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *nested-window consumer factors through the displayed root route $L, U, O, Q, D, S, R, E, H, C, P, N$ before it reads a retained nested prefix, compactness ledger, or real-seal boundary. The factorization is the composition of Definition 1591.46, Definition 1591.19, and Definition 1591.23.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket nested window factorization`

Proof. Start with the nested compactness handoff. It already places the nested-window consumer downstream of the endpoint-order row, rational and dyadic containment ledgers, StreamName window, RegSeqRat readback, and RealUp seal.

Use the root unblock obligations. They add the required transport, replay, provenance, and local naming rows H, C, P, N to the endpoint and readback route, so the nested consumer receives a complete $\mathsf{ClosedBoundedInterval}^{\uparrow}$ source packet.

Finally apply the downstream coverage surface. The nested prefix may refine the displayed interval rows, but it cannot replace them by selected endpoints, quotient equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1591.26 (Closed bounded interval uniform-modulus source)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *consumer obtains its interval source from the rows $L, U, O, Q, D, S, R, E, H, C, P, N$ before reading any modulus, compact-uniform, or Heine–Cantor-style row. The source is therefore the displayed package of Definition 1591.68, Definition 1591.57, and Definition 1591.23, not an ambient compact interval theorem.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket uniform modulus source`

Proof. Read the source obligation package first. It identifies $L, U, O, Q, D, S, R, E, H, C, P, N$ as the lower endpoint, upper endpoint, order, containment, window, readback, seal, transport, replay, provenance, and naming rows available to interval consumers.

Apply the compact-uniform source package. A uniform-modulus consumer may add modulus and compact-uniform rows only after the displayed endpoint, containment, StreamName, RegSeqRat, and Real-seal route has been consumed.

The downstream coverage surface keeps the consumer inside that package. Since no row of I names open-cover compactness, selected subcovers, quotient real equality, trichotomy, or ambient completeness, the uniform-modulus source is exactly the finite root packet. □

Theorem 1591.27 (Closed bounded interval cover-refinement source)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$*, located-cover, or*

compact-uniform refinement consumer must read $L, U, O, Q, D, S, R, E, H, C, P, N$ before any refinement map, subcover ledger, Lebesgue-number row, or modulus row. The route is the same root source exposed by the finite-cover window exactness and uniform-modulus source theorems.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root cover refinement source`

Proof. Project the carrier. The endpoint, order, containment, window, readback, Real-seal, transport, replay, provenance, and local naming rows are exactly $L, U, O, Q, D, S, R, E, H, C, P, N$.

Apply Definition 1591.24. A net or located-cover consumer must expose the complete source packet before it may inspect mesh centers, cover cells, refinement rows, or a subcover ledger.

Apply Definition 1591.26. A compact-uniform or modulus consumer receives the same source packet before any Lebesgue-number row or modulus row is read.

Finally use Definition 1591.23. The downstream refinement surface remains inside the displayed packet and excludes host open-cover compactness, selected subcovers, quotient real equality, trichotomy, countable choice, and ambient completeness. □

Theorem 1591.28 (Closed bounded interval located endpoint grid)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. If I feeds an interval-net, compactness-facing, or uniform-modulus consumer, then any located endpoint grid or dyadic cell grid read must expose the endpoint rows L, U, endpoint order O, rational and dyadic containment rows Q, D,* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows H, C, P, N before the grid can be consumed. Thus grid readiness is downstream of the displayed root source packet and is not a route through selected interval points, trichotomy, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket located endpoint grid`

Proof. Project the accepted carrier by Definition 1591.1. The only endpoint-facing and containment-facing source coordinates available before a consumer row are $L, U, O, Q, D, S, R, E, H, C, P, N$.

Apply Definition 1591.12. It identifies those rows as the root source for interval-net, compactness-facing, and uniform-modulus consumers, so a located endpoint grid cannot be read before the endpoint, order, containment, readback, seal, transport, replay, provenance, and naming rows are displayed.

Use Definition 1591.24 for the dyadic cell side. A finite-cover or grid window must expose the complete source packet before any mesh center, cover cell, or refinement row is inspected.

Finally apply Definition 1591.27. Grid readiness is therefore downstream of the displayed source packet. Since selected points, trichotomy, quotient equality, and ambient Real completeness are not coordinates of that packet, no such object can serve as the grid source. □

Definition 1591.29 (Closed bounded interval scoped source map)**.** *The scoped source map for an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier is the finite packet*

$$\Sigma_I = (L, U, O, Q, D, S, R, E, H, C, P, N).$$

Here L and U are the lower and upper endpoint rows, O is the endpoint-order row, Q and D are the rational and dyadic containment ledgers, S is the finite $\mathsf{StreamName}^{\uparrow}$ *window, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row. The map has no*

coordinate for open-cover compactness, trichotomy, selected interval points, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1591.30 (Closed bounded interval scoped kernel surface)**.** *Every scoped consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier reads only the kernel rows displayed by Definition 1591.29: endpoint rows, endpoint order, rational and dyadic containment ledgers, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.*

Proof. Project the accepted carrier onto Σ_I. The carrier definition supplies exactly the endpoint rows L, U, the order row O, containment ledgers Q, D, window and readback rows S, R, seal row E, and structural rows H, C, P, N.

Any scoped consumer enters through the same projection. If it reads an endpoint, containment fact, dyadic cell, regular rational readback, or terminal Real seal, that read is one of the displayed coordinates of Σ_I.

Transport and replay do not add a new interval coordinate. They preserve the displayed source rows through H and C, while P and N record provenance and local naming. Hence every scoped consumer stays on the listed kernel surface. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket scoped kernel surface`

Theorem 1591.31 (Closed bounded interval net consumer readiness)**.** *Closed-bounded-interval net, uniform-modulus, and nested-compactness consumers become ready only through the displayed source map* Σ_I *of Definition 1591.29. They may add mesh, modulus, nesting, or compact-uniform rows after reading* Σ_I*, but they cannot become ready through open-cover compactness, trichotomy, selected points, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the scoped kernel surface. Definition 1591.30 forces every accepted source read through $L, U, O, Q, D, S, R, E, H, C, P, N$.

For net consumers, the mesh rows are downstream of the endpoint and containment rows. For uniform-modulus consumers, the modulus rows are downstream of the same dyadic containment and StreamName window. For nested-compactness consumers, each nested window is downstream of the endpoint-order row and the displayed readback route.

The excluded principles are not coordinates of Σ_I. Therefore readiness is exactly the displayed source-map route followed by consumer-specific rows, not a route through open-cover compactness, trichotomy, selected points, quotient equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket net consumer readiness`

Theorem 1591.32 (Closed bounded interval scoped source package)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The scoped source map* Σ_I *of Definition 1591.29, the scoped kernel surface of Definition 1591.30, the net consumer readiness of Definition 1591.31, the finite-cover window exactness of Definition 1591.24, the nested-window factorization of Definition 1591.25, and the uniform-modulus source of Definition 1591.26 jointly form the scoped L10 source package for* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*. Every endpoint, containment, finite-cover, nested-window, net, and uniform-modulus consumer reads through* $L, U, O, Q, D, S, R, E, H, C, P, N$ *before any consumer-specific row is available; no open-cover compactness, trichotomy, selected point, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate enters the package.*

Proof. Project the accepted carrier through Definition 1591.29. The projected packet is exactly $\Sigma_I = (L, U, O, Q, D, S, R, E, H, C, P, N)$, so endpoint, containment, readback, seal, transport, replay, provenance, and naming data have one displayed source.

Apply Definition 1591.30. Any scoped consumer that reads an endpoint, containment ledger, dyadic cell, regular rational readback, or Real seal must remain on the displayed kernel rows of Σ_I.

For the downstream rows, use Definition 1591.31, Definition 1591.24, Definition 1591.25, and Definition 1591.26. These theorems route net, located-cover, finite-cover, nested-window, and uniform-modulus consumers through the same endpoint, containment, window, readback, seal, and structural rows before the consumer-specific mesh, cover, nesting, or modulus rows are read.

The carrier and the cited routes contain no coordinate for open-cover compactness, trichotomy, selected points, quotient equality, or ambient Real completeness. Therefore the displayed rows form the scoped L10 source package and the excluded objects cannot serve as alternate sources. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket scoped source package`

Theorem 1591.33 (Closed bounded interval source scope package)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. The root-source route for I is scoped exactly by the dyadic interval endpoint rows L, U, located interval coverage O, Q, nested interval compactness windows, finite-cover windows, the* $\mathsf{Real}^{\uparrow}$ *seal E,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. Every Real or Completion consumer of the interval source must read through this package before inspecting consumer-specific mesh, cover, nesting, modulus, or completion rows, and no open-cover compactness, arbitrary Heine–Borel theorem, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness is exported.*

Proof. Start with root-source carrier admission and window exactness. Definition 1591.14 and Definition 1591.15 expose the endpoint, located coverage, stream-window, readback, Real-seal, transport, replay, provenance, and naming rows as the displayed source.

Use the Real-seal route, finite-cover window exactness, and nested-window factorization. Definition 1591.16, Definition 1591.24, and Definition 1591.25 force Real, cover, and nested compactness consumers to pass through the same source route.

Apply Definition 1591.26 and Definition 1591.30. The uniform-modulus and scoped-kernel surfaces bind the consumer-facing rows to the same dyadic endpoint, located interval, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and NameCert package.

Therefore the source scope package is exactly the displayed carrier route. The excluded open-cover compactness, arbitrary Heine–Borel theorem, selected limit, and ambient completeness principles are not rows of I and cannot be exported by the packet. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source scope package`

Definition 1591.34 (Closed bounded interval source window)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$, the source window is the finite* BHist *row*

$$\Omega_I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

read as the endpoint-source packet before any interval-net, compactness, or uniform-modulus consumer opens its own rows. The lower and upper endpoint rows L, U are read through $\mathsf{LocatedInterval}^{\uparrow}$*, the dyadic containment ledger D is read through* $\mathsf{DyadicInterval}^{\uparrow}$*, the finite observation schedule S is read through* $\mathsf{StreamName}^{\uparrow}$*, the regular rational readback R is read through* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal endpoint seal E is read through* $\mathsf{Real}^{\uparrow}$*. The rows H, C, P, N record the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *naming for the same endpoint-source route.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalSourceWindow exactness`

Theorem 1591.35 (Closed bounded interval source transport)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ and $I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$ be accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers classified together by Definition 1591.2. Any endpoint source window transported from I to I' carries L, U, O, Q, D, S, R, E through the componentwise* hsame *rows of H and then replays the same route through the displayed* Cont *rows of C before any interval-net or compactness consumer reads it.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source transport`

Proof. Project the two carriers and the classifier. The rows L, U, O, Q, D, S, R, E and $L', U', O', Q', D', S', R', E'$ are the endpoint, containment, window, readback, and Real-seal coordinates being compared.

Use the source window of Definition 1591.34. It lists the same rows as a BHist endpoint-source packet, so transport of the source window is exactly componentwise transport of lower endpoint, upper endpoint, order, rational containment, dyadic containment, $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal rows.

The replay step is downstream. The displayed Cont rows in C carry the transported endpoint-source route to consumers only after the hsame transport has preserved every listed coordinate. Thus an interval-net, compactness, or uniform-modulus consumer cannot read a transported source window before the endpoint rows have passed through H and C. □

Theorem 1591.36 (Closed bounded interval source nonescape)**.** *Every interval-net, nested-window, located-cover, compactness-facing, or uniform-modulus consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source window factors through*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

In particular, the consumer first reads the BHist *endpoint-source rows, the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint route, the* $\mathsf{DyadicInterval}^{\uparrow}$ *containment ledger, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal before it reads any downstream interval-net or compactness rows. The source window cannot expose a host interval set, open-cover compactness, selected point, selected subcover, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source nonescape`

Proof. Start from the source window. By Definition 1591.34, every endpoint-source read is one of $L, U, O, Q, D, S, R, E, H, C, P, N$.

Next apply source transport. Theorem 1591.35 forces transported endpoint-source reads through the hsame and Cont rows before any downstream consumer can inspect them.

Finally compare with the existing finite-cover, dyadic-net, located-cover, and compactness handoffs in this chapter. Each of those consumers reads the closed bounded interval through the displayed endpoint, containment, schedule, readback, seal, transport, replay, provenance, and local naming rows. Since none of those rows is a host interval set, open cover, selected point, quotient equality, trichotomy decision, choice selector, or ambient completeness theorem, the source window has no route to any excluded object. □

Definition 1591.37 (Closed bounded interval finite-cover window)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ as in Definition 1591.1, a finite-cover window is a finite* BHist *row*

$$W_I = (S_0, R_0, Q_0, D_0, E_0)$$

whose $\mathsf{StreamName}^{\uparrow}$ *coordinate* S_0 *is a subwindow of the carried row* S*, whose* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate* R_0 *is read through* R*, whose rational and dyadic containment ledgers* Q_0, D_0 *are subledgers of* Q, D*, and whose endpoint seal* E_0 *is reached through the same* $\mathsf{Real}^{\uparrow}$ *row* E*. The window is admissible only when its lower-endpoint, upper-endpoint, endpoint-order, rational-containment, dyadic-containment, readback, and seal reads are all classifier-preserved by the carrier rows* H *and* C *of Definition 1591.2.*

Lean4 (definition) `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalFiniteCoverWindow`

Theorem 1591.38 (Closed bounded interval finite-net source)**.** *Every finite-net consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier*

$$I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

must read the lower endpoint L*, upper endpoint* U*, endpoint-order row* O*, rational containment ledger* Q*, and dyadic containment ledger* D *before any net row is available. The* $\mathsf{StreamName}^{\uparrow}$ *window* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *are downstream of the same endpoint and containment route, with* H, C, P, N *preserving the route under transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket finite net source`

Proof. Start with the carrier of Definition 1591.1. Its finite-net source coordinates are the lower endpoint, upper endpoint, endpoint order, rational containment, and dyadic containment rows L, U, O, Q, D.

Apply the classifier and source-window definitions. The classifier of Definition 1591.2 preserves these rows componentwise, while Definition 1591.34 reads them before any downstream interval-net, compactness, or uniform-modulus consumer opens its own rows.

Finally use source nonescape, Definition 1591.36. It forces every interval-net read through $L, U, O, Q, D, S, R, E, H, C, P, N$, so the endpoint and containment rows are the required source before any finite-net row can be consumed. □

Theorem 1591.39 (Closed bounded interval RegSeqRat window)**.** *For accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers*

$$I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

and

$$I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$$

classified together, each finite-cover window preserves its $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows under componentwise* hsame *transport. In particular, every transported window carries* S, R *to* S', R' *only after* L, U, O, Q, D *have been transported to* L', U', O', Q', D' *and replayed through the displayed* Cont *rows.*

Proof. Project the two carriers and the classifier of Definition 1591.2. The classifier compares endpoint, containment, window, readback, and seal rows only by componentwise hsame transport and displayed replay.

Use the finite-cover window of Definition 1591.37. Its S_0 and R_0 rows are subwindow and readback rows of the carried S and R, while Q_0, D_0, E_0 remain attached to the same endpoint and containment route.

Now apply source transport, Definition 1591.35. It transports the endpoint and containment rows before the StreamName and RegSeqRat rows are available to consumers. Hence a transported

finite-cover window preserves the S, R readback route under the same componentwise transport and replay. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket regseqrat window`

Theorem 1591.40 (Closed bounded interval Real seal nonescape)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *exports only the endpoint route displayed by* $L, U, O, Q, D, S, R, H, C, P, N$*. It exports no open-cover compactness, selected point, selected subcover, quotient equality of Real names, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalPacket real seal nonescape`

Proof. Read the carrier and source window. The seal row E is reached only after the endpoint rows L, U, endpoint order O, rational and dyadic containment ledgers Q, D, StreamName window S, and RegSeqRat readback R have been displayed.

Apply source nonescape and finite-cover nonescape. Theorems 1591.36 and 1591.41 keep every consumer route inside the displayed endpoint, containment, window, readback, seal, transport, replay, provenance, and local naming rows.

The excluded objects have no carrier coordinate and no replay edge. Since H, C, P, N only transport, replay, source, and name the same finite route, the Real seal cannot export open-cover compactness, selected points or subcovers, quotient equality, trichotomy, countable choice, or ambient Real completeness. □

Theorem 1591.41 (Closed bounded interval finite-cover nonescape)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier, and let* $W_I = (S_0, R_0, Q_0, D_0, E_0)$ *be a finite-cover window in the sense of Definition 1591.37. Every finite-cover read exported to an interval-net, nested-window, or uniform-modulus consumer factors through*

$$L, U, O, Q_0, D_0, S_0, R_0, E_0, H, C, P, N.$$

Consequently the read cannot escape to a host open cover, a selected subcover, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the finite-cover window. By definition, S_0 and R_0 are read through the carried $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows, while Q_0 and D_0 are subledgers of the rational and dyadic containment rows attached to the same endpoints.

The endpoint route is fixed before the cover window is visible. The rows L, U, O must be displayed before Q_0, D_0, S_0, R_0 can be read, and the terminal seal E_0 is reached only through the carried $\mathsf{Real}^{\uparrow}$ row E.

The structural rows close the nonescape claim. Since H and C preserve exactly the carrier and window rows named above, and since P, N only source and name that route, no exported finite-cover read contains a host open cover, selected subcover, quotient real equality, trichotomy, choice selector, or ambient completeness datum. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket finite cover nonescape`

Theorem 1591.42 (Closed bounded interval finite-net compactness obligations)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier, and let* $W_I = (S_0, R_0, Q_0, D_0, E_0)$ *be a finite-cover window in the sense of Definition 1591.37. Any finite-net compactness consumer must expose the endpoint rows* L, U, O*, the rational and dyadic containment rows* Q, D*, the* $\mathsf{StreamName}^{\uparrow}$ *and*

$\mathsf{RegSeqRat}^{\uparrow}$ *rows* S, R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the transport, replay, provenance, and local naming rows* H, C, P, N *before it may read mesh centers, finite cover refinements, or interval compactness ledgers.*

Consequently such a consumer factors through Definition 1591.1, Definition 1591.37, Definition 1591.36, and Definition 1591.45. It does not export open-cover compactness, selected subcovers, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket finite net compactness route`

Proof. Project the carrier and finite-cover window. The carrier exposes only $L, U, O, Q, D, S, R, E, H, C, P, N$, while the window exposes S_0, R_0, Q_0, D_0, E_0 as subwindow, readback, containment, dyadic, and seal rows attached to the same endpoint route.

Apply source nonescape. Theorem 1591.36 keeps every interval-net or compactness-facing read downstream of the displayed endpoint, containment, window, readback, Real-seal, transport, replay, provenance, and local naming rows.

Apply the net handoff. Theorem 1591.45 allows a net consumer to add mesh-specific cells, centers, and coverage data only after the base interval route has been displayed. Hence finite cover refinements and compactness ledgers remain downstream of $L, U, O, Q, D, S, R, E, H, C, P, N$.

The excluded compactness principles have no coordinate in either displayed packet. Since neither the carrier nor the window stores an open cover, selected subcover, choice selector, quotient-real equality, trichotomy decision, or ambient completeness datum, the finite-net compactness consumer cannot read any of them from this obligation surface. □

Theorem 1591.43 (Closed bounded interval located endpoint readback)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, every endpoint-facing* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *readback of the lower or upper endpoint factors through the displayed route*

$$L, U, O \longmapsto S, R \longmapsto E \longmapsto H, C, P, N.$$

The readback therefore preserves the endpoint-order row and the rational and dyadic containment ledgers of Definition 1591.1; it does not replace the endpoints by host reals or by quotient representatives.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket located endpoint readback`

Proof. Start with an endpoint-facing request. The carrier exposes lower and upper endpoint data only as L and U, and the order row O is carried before any rational, dyadic, stream, or regular-readback inspection.

The finite readback rows are next. The $\mathsf{StreamName}^{\uparrow}$ windows in S and the $\mathsf{RegSeqRat}^{\uparrow}$ rows in R inspect the displayed endpoint names and containment ledgers, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of those finite windows.

Finally apply the classifier of Definition 1591.2. Its componentwise hsame rows and displayed Cont replay preserve the same endpoint, order, containment, window, readback, and seal coordinates, so the readback cannot be reinterpreted as a host-real endpoint or as a quotient representative outside the accepted packet. □

Theorem 1591.44 (Closed bounded interval endpoint-order transport)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N$ *and* $I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$ *be accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers*

classified together by Definition 1591.2. Every containment read transported from I to I' carries the endpoint-order row O to O' before it transports the rational ledger Q to Q' or the dyadic ledger D to D'. Consequently no consumer can preserve containment while dropping endpoint order or replacing it by a host-level comparison.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket endpoint order transport`

Proof. Start from the classifier. It classifies accepted carriers only by componentwise hsame transport and replay of the same endpoint-to-containment-to-seal route.

The endpoint-order coordinate is upstream of both containment ledgers. A transported rational or dyadic containment read therefore has already transported L, U, O to L', U', O' before it reaches Q', D'.

The replay rows preserve the same order. Since neither the carrier nor the classifier contains a host comparison, trichotomy row, quotient-real equality witness, or alternate endpoint selector, the transported containment read cannot drop O' or replace it by data outside the accepted packet. □

Theorem 1591.45 (Closed bounded interval net handoff)**.** *Every* ClosedBoundedIntervalNet$^{\uparrow}$ *or* ClosedBoundedIntervalUniformModulus$^{\uparrow}$ *consumer of an accepted* ClosedBoundedInterval$^{\uparrow}$ *carrier reads the base interval through the finite route*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

The interval-net chapter chapter 1250 may add mesh scales, cells, centers, and coverage rows only after the base endpoint and containment route has been displayed. The uniform-modulus chapter chapter 1253 may read Heine–Cantor interval data only through that base route and its downstream finite-cover ledgers.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket net handoff`

Proof. Read the base carrier first. The route $L, U, O, Q, D, S, R, E, H, C, P, N$ exposes lower and upper located endpoints, endpoint order, rational and dyadic containment, finite windows, readbacks, Real sealing, transport, replay, provenance, and local naming.

The interval-net handoff then appends its mesh-specific rows. Its finite cells, dyadic refinements, centers, and coverage ledger are downstream of the displayed endpoint and containment rows, so the net packet cannot treat the mesh as the interval object itself.

The uniform-modulus handoff is later still. It reads compactness and modulus data through finite cover and Lebesgue-number ledgers, while the source interval remains the accepted ClosedBoundedInterval$^{\uparrow}$ route. Thus no consumer receives an open cover, selected subcover, quotient real equality, host interval set, or ambient completeness row in place of the base carrier. □

Theorem 1591.46 (Closed bounded interval nested compactness handoff)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C, P$ be an accepted* ClosedBoundedInterval$^{\uparrow}$ *carrier, and let a finite prefix of a nested-interval display be read inside the same closed bounded interval. The accepted packet supplies the endpoint-order row O, the rational and dyadic containment ledgers Q, D, the* StreamName$^{\uparrow}$ *window row S, the* RegSeqRat$^{\uparrow}$ *readback row R, and the* Real$^{\uparrow}$ *seal row E required by the finite-window* NestedIntervalCompactness$^{\uparrow}$ *route. The handoff is therefore a row-level bridge from the closed bounded interval carrier to the nested-window consumer of Definition 1584.5; it does not export open-cover compactness, selected endpoints, quotient real equality, trichotomy, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket nested compactness handoff`

Proof. Start with the accepted $\mathsf{ClosedBoundedInterval}^{\uparrow}$ carrier. By Definition 1591.44, any transported containment read keeps the endpoint-order row upstream of the rational and dyadic ledgers.

Apply Definition 1591.45. The finite consumer receives the base interval only through the displayed route $L, U, O, Q, D, S, R, E, H, C, P, N$, so a nested prefix displayed inside that interval must inherit the same endpoint, containment, window, readback, and seal rows.

The nested-window side then reads exactly the finite route isolated by Definition 1584.5. Since neither source packet contains an open cover, endpoint selector, quotient-real equality, trichotomy decision, countable-choice selector, or ambient completeness datum, the handoff cannot add any such row. □

Theorem 1591.47 (Closed bounded interval Cantor intersection handoff)**.** *Let a decreasing finite-window family of accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *packets be consumed by* $\mathsf{CantorIntersection}^{\uparrow}$*. The consumer may read the family only through endpoint rows, endpoint-order transport, rational and dyadic containment ledgers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *rows of the accepted packets.*

The handoff supplies the finite nested-window data needed by the Cantor-intersection route. It does not export open-cover compactness, a choice-selected point, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with endpoint-order transport. The endpoint classifier stability route keeps lower endpoints, upper endpoints, and order rows upstream of every containment read in the decreasing family.

Use the finite-net source and RegSeqRat window theorems. They place rational containment ledgers, dyadic containment ledgers, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks inside the displayed finite packet before any nested-family consumer can inspect the windows.

The Real seal nonescape theorem then keeps each endpoint and containment read behind the same $\mathsf{Real}^{\uparrow}$ seal row. Thus the Cantor-facing consumer receives sealed finite windows, not quotient real representatives or an ambient completeness theorem.

Finally apply the nested compactness handoff Definition 1591.46. It already routes nested-window compactness through the accepted closed bounded interval packet, so the Cantor-intersection handoff is exactly the same finite endpoint, containment, window, readback, seal, transport, replay, provenance, and local-name surface. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket cantor intersection handoff`

Theorem 1591.48 (Closed bounded interval dyadic-net obligations)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every* $\mathsf{DyadicInterval}^{\uparrow}$ *net or* $\mathsf{LocatedInterval}^{\uparrow}$ *refinement read attached to* I *must display the endpoint rows* L, U*, the endpoint-order row* O*, the rational and dyadic containment ledgers* Q, D*, and the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readback route* S, R, E *before the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row is consumed. The dyadic-net obligations are therefore rows of the same* BHist *packet and not an open-cover compactness principle, a selected mesh point, quotient real equality, trichotomy, or countable choice.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket dyadic net obligations`

Proof. Project the accepted carrier. Its endpoint, order, rational containment, dyadic containment, finite-window, regular readback, and Real seal rows are already displayed as L, U, O, Q, D, S, R, E.

A dyadic-net consumer may refine the interval only through the dyadic ledger D and the rational containment ledger Q over the same located endpoints. The rows S, R, E then read those finite tests through StreamName, RegSeqRat, and Real-facing windows without replacing the interval by a host set.

Transport and replay preserve the same route. Since H, C, P, N only carry componentwise hsame, displayed Cont, provenance, and local naming for the listed rows, no dyadic-net read can add an open cover, selected mesh point, quotient equality, trichotomy decision, choice schedule, or ambient completeness coordinate. □

Theorem 1591.49 (Closed bounded interval containment-ledger obligations)**.** *Let $I = (L, U, O, Q, D, S, R, E, H, C$ be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every containment-ledger obligation for I is a* BHist *obligation over the displayed endpoint rows L, U, endpoint-order row O, rational and dyadic containment rows Q, D, componentwise* hsame *row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row N. The ledger must preserve endpoint order before rational or dyadic containment is exported, and it cannot read host interval sets, quotient real equality, trichotomy, selected points, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket containment ledger obligations`

Proof. Project the carrier of Definition 1591.1 and the classifier of Definition 1591.2. The displayed endpoint rows, order row, containment ledgers, transport, replay, provenance, and local name are exactly $L, U, O, Q, D, H, C, P, N$.

Apply source nonescape, finite-cover nonescape, and endpoint-order transport. Theorems 1591.36, 1591.41, and 1591.44 force every containment read to keep O upstream of Q and D and to pass through the displayed hsame and Cont rows.

Finally use the dyadic-net obligations of Definition 1591.48. They place every dyadic or located refinement inside the same BHist packet, while P and N only source and name that route. Thus no excluded host object is introduced by the containment ledger. □

Theorem 1591.50 (Closed bounded interval finite-window transport obligations)**.** *Let $I = (L, U, O, Q, D, S, R, E,$ and $I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$ be accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers classified together. Every finite-window transport obligation from I to I' is a* BHist *transport obligation that carries S, R, E to S', R', E' only after L, U, O, Q, D have been transported to L', U', O', Q', D' through the displayed* hsame *row H and replayed by the displayed* Cont *row C. The transported window remains sourced by* Pkg *provenance and named by* NameCert*, not by host equality of intervals or selected representatives.*

Proof. Start with source transport. Theorem 1591.35 says that a transported source window carries lower endpoint, upper endpoint, endpoint order, containment, window, readback, and seal rows componentwise before any downstream consumer reads them.

Use located endpoint readback and finite-cover nonescape. Theorems 1591.43 and 1591.41 identify S, R, E as downstream finite windows over the same endpoint and containment route, so their transport cannot be separated from L, U, O, Q, D.

The nested compactness handoff and dyadic-net obligations preserve the same route for later consumers. Theorems 1591.46 and 1591.48 keep the finite-window rows inside the displayed BHist packet, with P, N recording provenance and local naming only. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket finite window transport obligations`

Theorem 1591.51 (Closed bounded interval consumer nonescape obligations)**.** *Every interval-net, located-cover, nested-compactness, finite-window, or uniform-modulus consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier factors its* BHist *read through*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

The consumer therefore sees hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *naming for the displayed carrier rows before it sees any downstream conclusion. It cannot escape to open-cover compactness, selected subcovers, selected points, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First project the carrier and source nonescape route. The carrier definition and Definition 1591.36 expose only $L, U, O, Q, D, S, R, E, H, C, P, N$ to endpoint-source consumers.

Next compose the finite-cover, located-cover, endpoint-order, and dyadic-net obligations. Theorems 1591.41, 1591.52, 1591.44, and 1591.48 keep every net or cover read downstream of the same displayed endpoint, containment, window, readback, and seal rows.

Finally apply nested compactness and compactness consumer boundary. Theorems 1591.46 and 1591.54 show that later compactness-facing consumers inherit the same finite packet. Since the packet contains no open-cover compactness theorem, selected object, quotient equality, trichotomy decision, countable-choice row, or ambient completeness row, the consumer obligations are nonescaping. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket consumer nonescape obligations`

Theorem 1591.52 (Closed bounded interval located-cover handoff)**.** *Every located-cover consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier factors through the displayed route*

$$L, U, O, Q, D, S, R, E, H, C, P, N$$

before reading any $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *or compactness-facing row. The* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{RationalInterval}^{\uparrow}$ *data supply finite containment tests, the* $\mathsf{DyadicInterval}^{\uparrow}$ *ledger supplies the mesh boundary, and the* $\mathsf{Real}^{\uparrow}$ *readback remains downstream of the same displayed packet.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket located cover handoff`

Proof. Start with the located endpoint surface. The rows L, U, O must be visible before a located-cover row can decide which rational or dyadic containment tests are being inspected.

The cover handoff then reads Q, D, S, R, E. Rational and dyadic ledgers provide finite containment data, while StreamName and RegSeqRat windows carry those tests to the Real seal without choosing a subcover or a point of the interval.

Finally use H, C, P, N. These structural rows replay and name exactly the displayed route, so a compactness-facing consumer receives a located-cover handoff over the accepted packet and not an open-cover theorem, quotient real equality, trichotomy, countable choice, or ambient completeness. □

Theorem 1591.53 (Closed bounded interval located-cover source totality)**.** *Any located-cover consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *must read the endpoint rows* L, U, O*, containment ledgers* Q, D*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N *before consuming a* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *row. The located-cover source is therefore the full displayed endpoint-and-containment packet, not a parameter echo of the cover consumer.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket located cover source totality`

Proof. Project the carrier and the source window. The carrier of Definition 1591.1 lists $L, U, O, Q, D, S, R, E, H, C,$ while Definition 1591.34 reads the same rows as the endpoint-source packet.

Apply source nonescape and finite-net source. Theorems 1591.36 and 1591.38 force every interval-net, located-cover, or compactness-facing read through the endpoint rows, containment ledgers, observation schedule, readback, and seal before any downstream cover row is available.

Finally use the located-cover handoff. Theorem 1591.52 keeps the cover consumer on the same displayed route, with H, C, P, N preserving replay, provenance, and local naming. Thus a $\mathsf{LocatedIntervalCover}^{\uparrow}$ row can only be consumed after the full source package has been exposed. □

Theorem 1591.54 (Closed bounded interval compactness consumer boundary)**.** *Any* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *consumer, finite-net compactness consumer, or Real-completion consumer that reads an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *packet must keep the endpoint rows, dyadic-net rows, located-cover rows, and nested compactness rows displayed before any compactness conclusion is consumed. Thus every such consumer factors through the carrier route of Definition 1591.1, the dyadic-net obligations of Definition 1591.48, the located-cover handoff of Definition 1591.52, and the nested compactness handoff of Definition 1591.46.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket compactness consumer boundary`

Proof. First read the source carrier. The endpoint, order, containment, window, readback, seal, transport, replay, provenance, and naming rows of I are the only rows a consumer can project from $\mathsf{ClosedBoundedInterval}^{\uparrow}$.

Next apply the dyadic-net and located-cover handoffs. They force finite mesh and cover consumers to pass through Q, D, S, R, E over the same L, U, O endpoint route.

Finally pass to nested compactness. The nested-window consumer reads the same displayed interval data before it uses any compactness-facing row, so the boundary excludes open-cover compactness, selected subcovers, selected endpoints, quotient real equality, trichotomy, countable choice, and ambient completeness as hidden inputs. □

Theorem 1591.55 (Closed bounded interval endpoint classifier stability)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P,$ *and* $I' = (L', U', O', Q', D', S', R', E', H', C', P', N')$ *be accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carriers classified together. Any classifier-preserved endpoint read from* I *to* I' *keeps the lower endpoint row* L*, upper endpoint row* U*, and endpoint-order row* O *upstream of the rational containment ledger* Q*, dyadic containment ledger* D*,* $\mathsf{StreamName}^{\uparrow}$ *window* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row* N*.*

Proof. Start with the classifier of Definition 1591.2. It classifies two carriers only by transporting L, U, O, Q, D, S, R, E componentwise and replaying the same endpoint-to-containment-to-seal route through the displayed Cont rows.

The endpoint rows are therefore the source of the route. The finite-net source theorem and endpoint-order transport theorem, Definition 1591.38 and Definition 1591.44, place L, U, O before any rational, dyadic, window, readback, or seal row can be consumed.

Finally read the structural rows. The rows H, C, P, N transport, replay, source, and name exactly that displayed route, so classifier preservation cannot expose $Q, D, S, R, E, H, C, P, N$ before the endpoint classifier has already preserved L, U, O. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket endpoint classifier stability`

Theorem 1591.56 (Closed bounded interval dyadic containment totality)**.** *Every rational or dyadic containment consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier factors through the rational containment ledger* Q *and dyadic containment ledger* D *over the displayed* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route. Thus containment totality for this packet is a finite ledger-totality obligation over* $L, U, O, Q, D, S, R, E, H, C, P, N$, *not a host interval set, an open-cover principle, a selected point, quotient real equality, trichotomy, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalPacket dyadic containment totality`

Proof. Project the containment surface of the carrier. The rows Q and D are the only rational and dyadic containment ledgers, and by Definition 1591.1 they are attached to the lower endpoint, upper endpoint, and endpoint-order rows L, U, O.

Next use the located-cover handoff and dyadic-net obligations. Theorems 1591.52 and 1591.48 force every located or dyadic refinement through $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, Q, and D before any compactness-facing read.

The readback route is finite as well. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows S, R, E inspect the same containment windows, while H, C, P, N preserve and name the route. Hence every containment consumer is accounted for by the displayed ledger route and no excluded host object is introduced. □

Theorem 1591.57 (Closed bounded interval compact-uniform source package)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier, the finite-net source, located-cover handoff, nested-compactness handoff, and compactness-consumer boundary assemble a compact-uniform source package*

$$L, U, O, Q, D, S, R, E, H, C, P, N$$

for closed bounded interval nets and uniform-modulus consumers. The package records endpoint classifier stability, rational and dyadic containment totality, finite-window readback, Real sealing, transport, replay, provenance, and local naming before any net, nested-window, compactness-facing, or uniform-modulus conclusion is consumed.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket compact uniform source package`

Proof. First build the finite source package. The finite-net source theorem and endpoint classifier stability identify L, U, O as the stable endpoint classifier rows and place Q, D downstream as the rational and dyadic containment ledgers.

Next attach the cover and compactness routes. The located-cover handoff, nested-compactness handoff, and compactness-consumer boundary, Definition 1591.52, Definition 1591.46, and Definition 1591.54, keep every finite-net, located-cover, and nested-window consumer inside the same displayed packet.

Finally add the uniform readback surface. The dyadic containment totality theorem supplies Q, D, S, R, E as the ledger and readback route, and H, C, P, N preserve, replay, source, and name it. Therefore closed bounded interval nets and uniform-modulus consumers receive a single compact-uniform source package without open-cover compactness, selected subcovers, selected

points, quotient real equality, trichotomy, countable choice, or ambient completeness as hidden inputs. □

Falsifiable prediction: Every interval-net or uniform-modulus read of a ClosedBoundedIntervalUp packet factors through displayed lower and upper located endpoints, endpoint order, rational and dyadic containment ledgers, StreamName windows, RegSeqRat readback, and a RealUp seal.

Independence witness: locatedinterval, closedboundedintervalnet, closedboundedintervaluniformmodulus, real: $\mathsf{ClosedBoundedInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lower and upper located endpoints, endpoint order, rational and dyadic containment ledgers, finite readback windows, a RealUp seal, transport, replay, provenance, and local naming.

Definition 1591.58 (Closed bounded interval constructive source)**.** *A constructive source for a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *packet is a finite* BHist *source*

$$J = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

where L and U are located endpoint rows, O records the endpoint order, Q and D record rational and dyadic containment ledgers, S is the $\mathsf{StreamName}^{\uparrow}$ *finite-window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, E is the* $\mathsf{Real}^{\uparrow}$ *seal row, H is the componentwise* hsame *transport row, C is the displayed* Cont *replay row, P is the* Pkg *provenance row, and N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedInterval}^{\uparrow}}$ *row. The source has no coordinate for open-cover compactness, selected subcovers, selected points, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalConstructiveSource`

Theorem 1591.59 (Closed bounded interval constructive carrier)**.** *Every constructive source $J = (L, U, O, Q, D, S, R, E, H, C, P, N)$ for* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *exposes exactly the root carrier rows of Definition 1591.1: located lower endpoint, located upper endpoint, endpoint order, rational containment, dyadic containment, StreamName window, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the source of Definition 1591.58. Its coordinates are precisely the rows $L, U, O, Q, D, S, R, E, H, C, P,$

Compare with the carrier definition. The root carrier of Definition 1591.1 has the same endpoint, containment, finite-window, readback, seal, transport, replay, provenance, and naming rows, and no additional coordinate is available to a carrier projection.

The excluded host objects are absent from the source and from the carrier. Therefore the constructive source exposes exactly the root carrier rows and cannot extend them by compactness, choice, quotient equality, trichotomy, or ambient completeness data. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket constructive carrier`

Theorem 1591.60 (Closed bounded interval constructive handoff)**.** *Every net, nested-window, finite-cover, located-cover, and uniform-modulus consumer of a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *constructive source factors through*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

The factorization first reads located endpoints and endpoint order, then rational and dyadic containment, then finite windows, RegSeqRat readback, the Real seal, transport, replay, provenance, and local naming.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket constructive handoff`

Proof. Begin with the root carrier route. By Definition 1591.59, any consumer of the constructive source can project only $L, U, O, Q, D, S, R, E, H, C, P, N$.

Net and finite-cover consumers use the containment ledgers. The finite-net source, consumer nonescape obligations, dyadic containment totality, and located-cover handoff force such reads through L, U, O, Q, D before they reach S, R, E.

Nested-window and uniform-modulus consumers use the same readback route. The nested compactness handoff and compact-uniform source package keep S, R, E, H, C, P, N attached to the endpoint and containment rows, so these consumers cannot bypass the displayed source. □

Definition 1591.61 (Closed bounded interval Cauchy modulus window)**.** *A Cauchy-modulus window for a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *constructive source is the finite subpacket*

$$W_{\mathsf{mod}} = (L, U, O, D, S, R, E, M)$$

where L and U are the located endpoint rows, O is the endpoint-order row, D is the dyadic containment and tolerance ledger, S is the $\mathsf{StreamName}^{\uparrow}$ *finite-window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, and M is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *consumer slot. The window exposes endpoint order, dyadic containment, finite StreamName windows, RegSeqRat readback, and the RealCauchyModulus-facing slot before any compactness, net, or uniform-modulus consumer may inspect the interval packet.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalCauchyModulusWindow single carrier alignment`

Theorem 1591.62 (Closed bounded interval modulus window transport)**.** *Every classifier transport of a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *constructive source preserves the Cauchy-modulus window $W_{\mathsf{mod}} = (L, U, O, D, S, R, E, M)$ componentwise. In particular, the transported packet keeps the same endpoint-order row, dyadic containment ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, and* $\mathsf{RealCauchyModulus}^{\uparrow}$ *consumer slot.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket modulus window transport`

Proof. Project the source of Definition 1591.58. The rows L, U, O, D, S, R, E are already displayed as part of the constructive source, and Definition 1591.61 only repackages them with the modulus consumer slot M.

Apply endpoint classifier stability to L, U, O. The transport cannot alter the lower endpoint, upper endpoint, or endpoint-order route before the containment rows are read.

Apply dyadic containment totality and the compact-uniform source package to D, S, R, E. These results keep the dyadic ledger attached to the same finite StreamName window, RegSeqRat readback, and Real seal.

Finally route the preserved rows to the $\mathsf{RealCauchyModulus}^{\uparrow}$ surface of chapter 1423. Since the modulus slot reads only D, S, R, E and the endpoint-order rows already transported above, it is preserved componentwise as part of the same finite window. □

Theorem 1591.63 (Closed bounded interval RealCauchyModulus handoff)**.** *Every* $\mathsf{RealCauchyModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *constructive source receives its precision data through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

after reading the endpoint order and containment rows L, U, O, D. The handoff supplies the modulus consumer with dyadic tolerance data, finite observation windows, regular rational readback, and the Real seal, but not open-cover compactness, selected subcovers, quotient real equality, trichotomy, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket real cauchy modulus handoff`

Proof. Start from the window of Definition 1591.61. The endpoint rows L, U and the order row O are read before the dyadic ledger D, so the consumer receives a bounded interval request rather than a detached Real name.

The dyadic row D supplies the tolerance and containment data through chapter 291. The StreamName and RegSeqRat rows S, R then provide the finite observation window and regular rational readback through chapter 126 and chapter 301.

The terminal seal E is read only after that route reaches chapter 38. The $\mathsf{RealCauchyModulus}^{\uparrow}$ consumer of chapter 1423 therefore receives the displayed tolerance, window, readback, and seal data without gaining any excluded compactness or choice principle. □

Theorem 1591.64 (Closed bounded interval Cauchy modulus nonescape)**.** *No* $\mathsf{RealCauchyModulus}^{\uparrow}$ *read admitted by a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *Cauchy-modulus window can bypass endpoint order, dyadic containment,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Equivalently, every accepted modulus read factors through L, U, O, D, S, R, E, M and cannot introduce open-cover compactness, selected points, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1591.63. It fixes the RealCauchyModulus-facing route through endpoint order, dyadic tolerance and containment, finite StreamName windows, RegSeqRat readback, and the Real seal.

The nonescape claim follows from the carrier inventory. Neither Definition 1591.1 nor Definition 1591.61 contains a coordinate for open-cover compactness, selected points, quotient real equality, trichotomy, countable choice, or ambient Real completeness.

Transport and replay rows do not add analytic data. They only preserve the displayed route already used by chapter 1423, chapter 126, chapter 301, chapter 291, and chapter 38. Hence every accepted modulus read remains inside L, U, O, D, S, R, E, M. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket cauchy modulus nonescape`

Definition 1591.65 (Closed bounded interval density ledger)**.** *For an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$, the root density ledger is the finite* BHist *packet*

$$\Delta_I = (L, U, O, Q, D, S, R, E, H, C, P, N)$$

read as the source for dyadic mesh cells and interval-net consumers. The rows L, U, O fix the endpoint route, Q records rational containment tests, D records finite dyadic mesh cells and dyadic containment comparisons, S records the $\mathsf{StreamName}^{\uparrow}$ *finite windows, R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, E records the* $\mathsf{Real}^{\uparrow}$ *endpoint seals, and H, C, P, N record transport, replay, provenance, and local naming for the same endpoint-and-containment surface.*

Lean4 (definition) `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalDensityLedger`

Theorem 1591.66 (Closed bounded interval density readback)**.** *Every density or interval-net readback admitted by an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier factors through the root density ledger*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

In particular, dyadic mesh cells and rational containment tests are read after the endpoint route L, U, O*, the finite observation windows and regular rational readbacks are read after* Q, D*, and the endpoint seals are read through the terminal* $\mathsf{Real}^{\uparrow}$ *row* E *with transport, replay, provenance, and local naming carried by* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket density readback`

Proof. Project the density ledger. Its coordinates are exactly the endpoint rows, rational and dyadic containment rows, finite windows, regular rational readbacks, endpoint seals, and structural rows already present in the carrier.

Apply the existing source and compact-uniform package theorems. The finite-net source theorem places L, U, O, Q, D before any mesh consumer, while the compact-uniform source package keeps S, R, E, H, C, P, N attached to the same endpoint-and-containment route.

Thus density readback cannot start from a free mesh. It must pass through $L, U, O, Q, D, S, R, E, H, C, P, N$, so every downstream interval-net or uniform-modulus consumer receives dyadic density data only as a readback of the root endpoint ledger. □

Theorem 1591.67 (Closed bounded interval net-unblock package)**.** *Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$*, finite-cover, nested-window, and uniform-modulus consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier must obtain its interval source from Definition 1591.65. No such consumer can bypass the root endpoint-and-containment package*

$$L, U, O, Q, D, S, R, E, H, C, P, N$$

or replace it by a host interval set, an open-cover compactness object, selected subcover, selected point, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the density readback theorem. It identifies $L, U, O, Q, D, S, R, E, H, C, P, N$ as the complete source route for dyadic mesh cells, rational containment tests, StreamName windows, RegSeqRat readbacks, and Real endpoint seals.

Now compare the downstream consumers. Closed bounded interval nets, finite-cover windows, nested-window compactness, and uniform-modulus handoffs all use the same endpoint rows, containment rows, windows, readbacks, and seals before adding their own consumer rows.

The non-bypass claim follows from the carrier inventory. Since the root density ledger contains no host interval set, open-cover compactness object, selected subcover, selected point, quotient equality, trichotomy decision, choice selector, or ambient completeness datum, no downstream consumer can obtain one without leaving the displayed $\mathsf{ClosedBoundedInterval}^{\uparrow}$ package. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket net unblock package`

Theorem 1591.68 (Closed bounded interval source obligation package)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the source-obligation surface for downstream L10 consumers is exactly the endpoint route* L, U, O*, the rational and dyadic containment rows* Q, D*, the finite observation and regular readback rows* S, R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N*. This package includes endpoint containment, endpoint order, finite-net source admission, and Real-seal handoff before any interval-net, nested-window, or completion consumer may read the interval.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source obligation package`

Proof. Project the carrier rows. The endpoint-containment and endpoint-order results already identify L, U, O, Q as the only accepted lower-bound, upper-bound, order, and rational containment surface.

Apply the finite-net source and net-unblock package theorems. They force every mesh, finite-window, and downstream interval-net read through D, S, R before the consumer adds its own rows.

The Real-seal handoff keeps E after the displayed endpoint and readback rows, while H, C, P, N only transport, replay, source, and name that same package. Hence the listed rows are the complete source-obligation surface. □

Theorem 1591.69 (Closed bounded interval source cover boundary)**.** *Every finite-cover, compactness, interval-net, nested-window, and uniform-modulus consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *packet must enter through the source-obligation package*

$$L, U, O, Q, D, S, R, E, H, C, P, N.$$

Such a consumer may refine the displayed finite source by its own cover or net rows, but it cannot replace the source by a host interval set, open-cover compactness principle, selected subcover, selected point, quotient real equality, trichotomy, countable-choice schedule, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source cover boundary`

Proof. Start from the finite-net source theorem and the net-unblock package. Together they make the density ledger the only admitted source for dyadic cells, rational containment tests, finite observation windows, regular readbacks, and endpoint seals.

Finite-cover and compactness consumers add rows after that source has been displayed. They may inspect D, S, R, E through the same replay row C, but they do not receive a separate open-cover object or a selector coordinate.

The exclusion follows from the carrier inventory and the endpoint-containment boundary. Since I contains only $L, U, O, Q, D, S, R, E, H, C, P, N$, every accepted cover boundary remains a finite BEDC source route rather than host compactness data. □

Theorem 1591.70 (Closed bounded interval source readback stability)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback used by a downstream interval consumer is stable under the displayed componentwise* hsame *row* H *and the displayed* Cont *replay row* C*: transporting the source rows by* H *and replaying them by* C *preserves the same finite endpoint, containment, dyadic, StreamName, RegSeqRat, and Real-seal route.*

Proof. Read the RegSeqRat and Real handoff rows through the density ledger. The rows S, R, E are reached only after the endpoint route L, U, O, containment rows Q, D, and finite source windows have been displayed.

Use the componentwise transport row H. It preserves lower and upper endpoint rows, order, containment ledgers, dyadic cells, StreamName windows, RegSeqRat readbacks, and the terminal Real seal as components of the same packet.

Use the replay row C for downstream consumers. Since C replays the same displayed route and P, N only source and name it, the readback cannot drift into quotient real equality, selected representatives, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket source readback stability`

Theorem 1591.71 (Closed bounded interval root consumer obligations)**.** *Every net, uniform-modulus, located-cover, nested-window, or compactness-facing consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier must first expose the same lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName window, RegSeqRat readback, Real seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The consumer may add its own downstream rows only after this root package has been displayed; it cannot replace the root by quotient real equality, trichotomy, selected points, selected subcovers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the source-obligation package. It identifies $L, U, O, Q, D, S, R, E, H, C, P, N$ as the finite endpoint, containment, window, readback, seal, transport, replay, provenance, and local naming surface for downstream interval reads.

Apply the source cover boundary. It forces cover, compactness, interval-net, nested-window, and uniform-modulus consumers to enter through that source package before adding their own cover or net rows.

Finally use source readback stability. The RegSeqRat and Real rows remain attached to the same componentwise hsame transport and Cont replay route, so no consumer can detach the root package into quotient equality, trichotomy, selected interval points, selected subcovers, or an ambient completeness assertion. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root consumer obligations`

Theorem 1591.72 (Closed bounded interval root net readiness)**.** *Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier must receive the endpoint rows* L, U, O*, the containment ledgers* Q, D*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N *before reading mesh centers, coverage rows, or net refinements.*

Proof. Project the carrier of Definition 1591.1 and the classifier of Definition 1591.2. The endpoint rows are L, U, O, containment is recorded by Q, D, finite windows and rational readback by S, R, and the terminal seal by E.

Apply the source nonescape and finite-cover nonescape boundaries already established for the chapter. They keep every interval source read inside the displayed carrier rows and refuse host interval sets, selected points, quotient real equality, trichotomy, and ambient completeness.

The finite-net consumer can therefore add mesh centers and coverage rows only after the source package has been displayed. The replay and provenance rows H, C, P, N carry exactly that source into the consumer, so net readiness is the endpoint-and-containment package rather than an independent mesh object. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket root net readiness`

Theorem 1591.73 (Closed bounded interval carrier-classifier scope)**.** *Let* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier. Every downstream read of the lower endpoint, upper endpoint, endpoint-order row, dyadic containment ledger, StreamName window, RegSeqRat readback, RealUp seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows routes through the carrier of Definition 1591.1 and the classifier of Definition 1591.2. No consumer may replace that pair by quotient real equality, trichotomy, selected interval points, selected subcovers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 1591.3. It identifies the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, window, readback, seal, transport, replay, provenance, and local naming rows as the local obligation surface of the accepted packet.

Apply Definition 1591.44. The endpoint rows and their order are preserved only by the displayed componentwise transport and classifier comparison, so the lower and upper endpoints cannot be reclassified through host real equality or trichotomy.

Use Definition 1591.45 and Definition 1591.46. Net, cover, and nested compactness consumers receive the same endpoint, containment, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows before adding their own downstream data.

Thus every accepted read is scoped by the carrier/classifier pair of Definition 1591.1 and Definition 1591.2. Since neither definition contains a coordinate for the refused host data, no downstream consumer can add such a coordinate while preserving the displayed route. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUp.ClosedBoundedIntervalPacket carrier classifier scope`

Theorem 1591.74 (Closed bounded interval obligation closure)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the carrier and classifier of Definition 1591.1 and Definition 1591.2, the NameCert obligations of Definition 1591.3, endpoint-order transport of Definition 1591.44, net handoff of Definition 1591.45, nested compactness handoff of Definition 1591.46, source obligation package of Definition 1591.68, and nonescape rows of Definition 1591.36, Definition 1591.41, and Definition 1591.51 exhaust the full finite NameCert obligation surface for closed bounded interval consumers.*

Proof. Project the carrier and classifier. They expose exactly the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows.

Apply the obligation and transport theorems. The NameCert obligation theorem lists the local rows, endpoint-order transport keeps O upstream of containment, and the net and nested compactness handoffs place all downstream interval consumers behind the same displayed package.

Finally apply the source package and nonescape boundaries. They force net, finite-cover, nested-window, located-cover, uniform-modulus, and compactness-facing consumers to remain inside $L, U, O, Q, D, S, R, E, H, C, P, N$, so the listed results close the obligation surface without importing open-cover compactness, selected subcovers, quotient equality, trichotomy, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket obligation closure`

Theorem 1591.75 (ClosedBoundedInterval scoped kernel envelope)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the carrier, classifier, endpoint containment, dyadic-net, located-cover, nested-compactness, uniform-modulus, and consumer non-escape rows displayed in this chapter are all scoped over* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. No interval-net, nested-window, located-cover, uniform-modulus, or compactness-facing consumer can read beyond that kernel envelope while preserving the displayed carrier route.*

Proof. Start from Definition 1591.74. It already collects the carrier, classifier, endpoint-order transport, net handoff, nested compactness handoff, source obligation package, and nonescape rows as the finite obligation surface.

The source rows in that package are exactly the lower and upper $\mathsf{Real}^{\uparrow}$ endpoint rows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, the $\mathsf{StreamName}^{\uparrow}$ window row, the $\mathsf{DyadicRatCore}^{\uparrow}$ containment ledger, and the structural hsame, Cont, Pkg, and NameCert rows. The net, located-cover, nested-window, uniform-modulus, and compactness-facing consumers enter only through the handoff and nonescape theorems named there.

Thus every consumer route remains inside the displayed kernel envelope. Since no theorem in the package adds quotient real equality, selected interval points, trichotomy, open-cover compactness, or ambient completeness, no accepted consumer can expose those coordinates. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket scoped kernel envelope`

Theorem 1591.76 (Closed bounded interval mature consumer surface)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the public consumer surface of Definition 1591.77 and the public bridge boundary of Definition 1591.78 determine the mature* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *consumer route. Every interval-facing read must pass through the displayed endpoint, containment, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local NameCert rows before it can serve a net, located-cover, nested-window, uniform-modulus, or compactness-facing consumer.*

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPacket mature consumer surface`

Proof. Start from the public consumer surface. It identifies the available public rows as exactly $L, U, O, Q, D, S, R, E, H, C, P, N$ and records that no consumer receives open-cover compactness, a selected subcover, quotient real equality, trichotomy, choice, a selected point, or ambient completeness.

Then apply the public bridge boundary. It forces finite-cover, located-cover, uniform-modulus, and compactness-facing reads to factor through the same endpoint, containment, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and NameCert rows.

Thus the mature route exposes no data beyond the displayed finite packet. The consumer may reuse the public surface and its bridge boundary, but it cannot bypass either one or export a completeness-facing coordinate not already present in the carrier. □

Theorem 1591.77 (Closed bounded interval public consumer surface)**.** *For every accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, the carrier of Definition 1591.1, classifier of Definition 1591.2, NameCert obligations of Definition 1591.3, root source ledger of Definition 1591.68, source nonescape rows of Definition 1591.36, Definition 1591.41, and Definition 1591.51, and scoped kernel envelope of Definition 1591.75 form the public* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *consumer surface. A public consumer may read only the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName, RegSeqRat, Real-seal, hsame, Cont, Pkg, and NameCert rows displayed by the packet, and receives no open-cover compactness, selected subcover, quotient real equality, trichotomy, choice, selected interval point, or ambient completeness coordinate.*

Proof. Project the accepted packet through the carrier and classifier. The public rows are exactly $L, U, O, Q, D, S, R, E, H, C, P, N$, with endpoint order and containment read through the same displayed transport and replay routes.

Apply the NameCert obligation theorem and the root source ledger. They identify the endpoint, containment, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows before any consumer-facing route is exposed.

Use the source nonescape and consumer nonescape rows to block external coordinates. Net, finite-cover, nested-window, located-cover, uniform-modulus, and compactness-facing consumers remain inside the displayed finite packet.

Finally use the scoped kernel envelope. It packages the same rows as the public object surface, so the public consumer receives the named finite carrier and none of the refused open-cover, subcover-selection, quotient-equality, trichotomy, choice, point-selection, or completeness data. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPublicConsumerSurface`

Theorem 1591.78 (Closed bounded interval public bridge boundary)**.** *For every accepted* ClosedBoundedInterval$^{\uparrow}$ *carrier* $I = (L, U, O, Q, D, S, R, E, H, C, P, N)$*, any finite-cover, located-cover, uniform-modulus, or compactness-facing consumer of* I *must factor through the displayed lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName, RegSeqRat, Real-seal, hsame, Cont, Pkg, NameCert rows and the public consumer surface of Definition 1591.77 before it can read interval data. The bridge boundary exposes no open-cover compactness theorem, selected subcover data, quotient real equality, trichotomy, choice, selected interval point, or ambient completeness coordinate.*

Proof. Project the public consumer surface theorem. It identifies the public rows as exactly $L, U, O, Q, D, S, R, E, H, C, P, N$ and records the nonescape clauses that block external compactness and choice data.

Route each consumer class through those rows. A finite-cover consumer reads only the displayed endpoint and containment rows; a located-cover consumer also passes through S, R, E before reading a located interval verdict; a uniform-modulus consumer must replay the same Real-sealed route through H, C; and a compactness-facing consumer reaches only the package and NameCert boundary P, N.

The stated refusals follow because none of the displayed rows stores open-cover compactness, a selected subcover, quotient real equality, trichotomy, choice, a selected point, or ambient completeness. The bridge therefore has no coordinate from which such data can be exported. □

Lean4 ✓ `BEDC.Derived.ClosedboundedintervalUp.ClosedBoundedIntervalPublicBridgeBoundary`

Closure status for NameCert$_{\text{ClosedBoundedInterval}^{\uparrow}}$**.**

Constructive story: A ClosedBoundedInterval$^{\uparrow}$ packet is generated from lower and upper located endpoint rows, an endpoint-order row, rational and dyadic containment ledgers, StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosedBoundedInterval}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1591.76 and Definition 1591.77 bind the carrier, classifier, NameCert obligations, root source ledger, source nonescape rows, scoped kernel envelope, public consumer surface, and bridge boundary as the mature ClosedBoundedInterval$^{\uparrow}$ consumer surface over Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{ClosedBoundedInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, quotient real equality, trichotomy, selected points of the interval, or ambient Real completeness.

Upgrade path: Verification closure requires Lean verification of the public consumer surface for BEDC.Derived.ClosedBoundedIntervalUp.

Chapter 1592

A Concrete Naming Certificate for $\mathsf{CauchySubnet}^{\uparrow}$

Following Bishop–Bridges and Kelley filter terminology, the $\mathsf{CauchySubnet}^{\uparrow}$ packet records the finite restriction surface by which a displayed Cauchy-filter source is read along a cofinal subnet before a filter-limit handoff or completion-facing consumer may inspect the route. It sits after the $\mathsf{CauchyFilter}^{\uparrow}$ surface of chapter 333, the $\mathsf{CauchyFilterLimit}^{\uparrow}$ route of chapter 1558, and the $\mathsf{MetricCompletion}^{\uparrow}$ boundary of chapter 1506; it reads finite windows through $\mathsf{StreamName}^{\uparrow}$ in chapter 126, regular rational rows through $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, dyadic tolerances through $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 291, and terminal seals through $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet names cofinal subnet restriction as BEDC data, not as quotient filter equality, selected host subnets, countable choice, host real equality, or ambient completeness.

Definition 1592.1 (Cauchy subnet carrier)**.** *A* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, J, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row whose neighborhoods are to be restricted.*
2. *J is the cofinal subnet-index ledger. It records the finite dominance checks showing that every accepted request to the subnet is backed by a displayed request to the source filter.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected after F and J have been replayed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the restricted windows and regular readback.*
6. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff row available only after the source filter, cofinal ledger, windows, readback, and tolerance rows have been displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *seal row reached by completion-facing consumers through the same handoff route.*
8. *H records componentwise* hsame *transport for the source filter, cofinal ledger, windows, readback, tolerance ledger, limit handoff, seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a filter request through F, J, W, R, D, L, E in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected host subnets, countable choice, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetTasteGate single carrier alignment`

Theorem 1592.2 (Cauchy subnet NameCert obligations)**.** *For every accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier* $S = (F, J, W, R, D, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source Cauchy filter, cofinal subnet-index ledger, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchyFilterLimit handoff, completion or Real seal, transport, continuation, provenance, and local naming rows;*
2. *cofinal restriction coverage, requiring every accepted subnet request to read the ledger J together with the source filter row F before any window row is inspected;*
3. *finite-window and tolerance exactness, requiring W, R, D to be the only finite rows through which the restricted source reaches a regular rational comparison;*
4. *filter-limit handoff, requiring F, J, W, R, D to repack as the handoff row L before any completion-facing or Real-facing seal is available;*
5. *ledger refusal, excluding quotient filters, selected host subnets, countable choice, host real equality, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetNameCertObligations`

Proof. Project the carrier of Definition 1592.1. The projection exposes exactly the source Cauchy filter row F, cofinal subnet-index ledger J, StreamName window W, RegSeqRat readback R, DyadicRatCore tolerance ledger D, filter-limit handoff L, seal row E, and structural rows H, C, P, N.

The continuation row C gives the only replay route. A subnet request first reads the source filter row and the cofinal ledger, then reaches the finite windows, regular readback, and dyadic tolerance ledger.

The handoff row L is downstream of those five displayed rows, and the completion or Real seal E is downstream of L. Since the carrier contains no quotient-filter coordinate, selected host subnet, countable-choice selector, host real equality row, or ambient-completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 1592.3 (Cauchy subnet filter-limit handoff)**.** *Let $S = (F, J, W, R, D, L, E, H, C, P, N)$ be an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier. Every completion-facing or Real-facing consumer of the restricted Cauchy source factors through the finite route*

$$F, J, W, R, D \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff only after the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, cofinal subnet-index ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger have been displayed. The route exports no quotient filters, selected host subnets, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnet filter limit handoff`

Proof. Begin with a completion-facing or Real-facing consumer. Carrier admission provides the handoff row L and seal row E, but only as rows downstream of F, J, W, R, D.

Replay the continuation row C. The request first consumes the source Cauchy filter row and the cofinal subnet-index ledger, then inspects the finite window row, the regular rational readback, and the dyadic tolerance ledger.

Only after that displayed route has been replayed can the packet expose L, and only after L can it expose E. Componentwise transport through H and provenance through P, N preserve the same dependency order, so the handoff is a finite BEDC route rather than quotient filter equality, selected host subnet choice, countable choice, host real equality, or ambient completeness. □

Theorem 1592.4 (CauchySubnet RegSeqRat tail handoff)**.** *Let $S = (F, J, W, R, D, L, E, H, C, P, N)$ be an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier. Every subnet tail read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must pass through the displayed route*

$$F, J, W, R, D, L, E, H, C, P, N.$$

In particular, the $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff route through L, E are all visible before the* $\mathsf{Real}^{\uparrow}$ *seal is public. The packet exports no direct tail-to-real read, no hidden regular sequence, no unrecorded dyadic tolerance, no ambient completion equality, and no host real quotient.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetRegSeqRatTailHandoff`

Proof. Project the carrier of Definition 1592.1. Its endpoint row E can be a $\mathsf{Real}^{\uparrow}$ seal only as part of the displayed Cauchy subnet packet, and the continuation row C records the route into that seal.

Read the route before the endpoint. The source filter row F and cofinal ledger row J expose the accepted tail request, after which the finite window row W supplies the $\mathsf{StreamName}^{\uparrow}$ display inspected by the tail.

Next the regular and dyadic rows are forced to appear. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the displayed windows, and D is the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger used by the same readback.

Finally apply Definition 1592.3. The handoff theorem places L and then E downstream of F, J, W, R, D, so a public $\mathsf{Real}^{\uparrow}$ seal cannot be reached before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ route has been displayed. □

Theorem 1592.5 (Cauchy subnet cofinal ledger coverage)**.** *Let $S = (F, J, W, R, D, L, E, H, C, P, N)$ be an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier. Every accepted subnet request admitted by the cofinal ledger row J has a displayed source-filter request in F. Every completion-facing read must pass through*

$$F, J, W, R, D, L, E, H, C, P, N$$

before it exposes a $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *seal. Thus cofinal restriction is a finite ledger coverage route, not a quotient-filter equality, selected host subnet, countable-choice selector, host real equality, or ambient completeness assertion.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnet cofinal ledger coverage`
↪ variant `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier cofinal ledger coverage`

Proof. Project the carrier of Definition 1592.1. The row J is specified as the cofinal subnet-index ledger, and its accepted requests are backed by displayed source requests to the filter row F.

Use Definition 1592.2 for row exhaustion. After F and J, every admissible read proceeds through the finite-window row W, regular rational readback R, dyadic tolerance ledger D, handoff row L, seal row E, and structural rows H, C, P, N.

Finally apply Definition 1592.3. It identifies the only endpoint route to $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$, so no completion-facing consumer can bypass the cofinal ledger coverage. □

Theorem 1592.6 (CauchySubnet cofinal reindexing route)**.** *Let $S = (F, J, W, R, D, L, E, H, C, P, N)$ be an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier. Any accepted cofinal subnet request whose ledger J reindexes* $\mathsf{StreamName}^{\uparrow}$ *windows preserves the route*

$$F, J, W, R, D, L, E, H, C, P, N.$$

Consequently the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *seal access remain downstream of the cofinal ledger. The route exports no quotient filter equality, selected subnet, countable-choice schedule, host real equality, or ambient-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCofinalReindexingRoute`

Proof. Start from the local carrier and obligation surface. Definition 1592.2 requires every accepted subnet request to read the source filter row F and cofinal ledger row J before any finite StreamName window is inspected.

Use Definition 1592.5. It gives a displayed source-filter request for each accepted cofinal ledger request, so reindexing the StreamName windows cannot detach W from the preceding rows F, J.

Finally apply Definition 1592.3. The handoff theorem fixes the downstream order through $W, R, D, L, E, H, C, P, N$, so RegSeqRat readback, DyadicRatCore tolerance, MetricCompletion access, and Real seal access remain behind the cofinal ledger. □

Theorem 1592.7 (Cauchy subnet obligation-closure package)**.** *The carrier definition of Definition 1592.1, together with Definition 1592.2, Definition 1592.3, and Definition 1592.5, closes the* $\mathsf{CauchySubnet}^{\uparrow}$ *obligation surface for carrier admission, cofinal coverage, finite-window exactness, tolerance exactness, filter-limit handoff, and ledger refusal. In particular, every accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *consumer read is forced through*

$$F, J, W, R, D, L, E, H, C, P, N$$

before it may expose a $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *endpoint, and the packet has no remaining local obligation coordinate for quotient filters, selected host subnets, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnet obligation closure package`

Proof. Carrier admission is exactly the row projection in Definition 1592.1. The source filter, cofinal ledger, finite windows, rational readback, dyadic tolerance ledger, limit handoff, completion or Real seal, transport, replay, provenance, and local naming rows are all visible there.

Apply Definition 1592.2 to exhaust the local NameCert surface. Its obligation list accounts for carrier admission, cofinal restriction coverage, finite-window and tolerance exactness, the downstream filter-limit handoff, and refusal of the excluded host-level data.

The two route theorems then identify the order of consumption. Definition 1592.3 forces every endpoint through $F, J, W, R, D, L, E, H, C, P, N$, while Definition 1592.5 prevents a completion-facing read from bypassing the cofinal ledger. These clauses leave no further local obligation row for the $\mathsf{CauchySubnet}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier obligation closure package`

Theorem 1592.8 (Cauchy subnet scoped route)**.** *Every accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *read is scoped exactly by the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *source row,* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff row,* $\mathsf{MetricCompletion}^{\uparrow}$ *endpoint row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal row, the surrounding* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ *row. A consumer that omits any one of these rows receives only a partial subnet restriction and cannot expose a completion-facing endpoint for the accepted packet.*

Proof. Start with the local obligation inventory. Definition 1592.2 lists carrier admission, cofinal restriction coverage, finite-window and tolerance exactness, filter-limit handoff, and ledger refusal as the only local rows.

Next read the endpoint route. Definition 1592.3 forces every completion-facing or Real-facing consumer through $F, J, W, R, D, L, E, H, C, P, N$, while Definition 1592.5 prevents the cofinal ledger J from being bypassed before the finite windows are inspected.

Finally apply Definition 1592.7. It packages the carrier, handoff, cofinal coverage, and refusal clauses into the same displayed packet, so the exact scope of an accepted read is precisely the listed CauchyFilter, CauchyFilterLimit, MetricCompletion, StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and NameCert surface. □

Theorem 1592.9 (CauchySubnet scoped kernel route)**.** *Every accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *obligation in this chapter depends only on the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff,* $\mathsf{MetricCompletion}^{\uparrow}$ *endpoint row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ *rows. Within that kernel scope, cofinal ledger coverage, finite-window exactness, tolerance exactness, filter-limit handoff, and endpoint nonescape are exactly the obligations named by the carrier and obligation package; outside that scope the packet exports no quotient filters, selected host subnets, countable choice, host real equality, or ambient completeness.*

Proof. Use Definition 1592.2 to list the local obligation rows. They name carrier admission, cofinal restriction coverage, finite-window and tolerance exactness, filter-limit handoff, and ledger refusal, all inside the displayed carrier surface.

Use Definition 1592.3 and Definition 1592.5 to fix the consumption order. Every completion-facing read must pass through the source filter, cofinal ledger, StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, CauchyFilterLimit handoff, and MetricCompletion or Real endpoint.

Finally apply Definition 1592.7. The same package includes componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row, so the obligation surface is scoped to the named kernel rows and does not acquire any excluded host-level coordinate. □

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier scoped kernel route`

Theorem 1592.10 (CauchySubnet public certificate route)**.** *Every public completion-facing consumer of an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *packet reads the cofinal ledger through* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it can expose the local* $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ *row. The public route exports no quotient filters, selected host subnets, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier public certificate route`

Proof. First use Definition 1592.2. It identifies the local rows that must be displayed before the packet can be consumed: source Cauchy filter, cofinal subnet-index ledger, finite windows, regular readback, dyadic tolerance, handoff, endpoint seal, transport, replay, provenance, and local naming.

Next apply Definition 1592.3 and Definition 1592.5. These results force every completion-facing read through the cofinal ledger and then through the finite-window, readback, tolerance, handoff, and endpoint rows.

Finally apply Definition 1592.9. It pins the route to the displayed kernel rows and excludes quotient filters, selected host subnets, countable choice, host real equality, and ambient completeness before the local $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$ row is public. □

Theorem 1592.11 (Cauchy subnet endpoint nonescape)**.** *Every* $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *endpoint read of an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *packet factors through the displayed rows*

$$F, J, W, R, D, L, E, H, C, P, N.$$

The endpoint is therefore reached only by the source Cauchy filter row F*, cofinal subnet ledger* J*, finite-window row* W*, regular-rational readback* R*, dyadic tolerance ledger* D*, filter-limit handoff* L*, endpoint seal* E*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming row* N*.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier endpoint nonescape`

Proof. Start with the filter-limit handoff of Definition 1592.3. It forces every completion-facing or Real-facing consumer through the displayed route from F to E before any $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ endpoint can be exposed.

Next use the cofinal ledger coverage of Definition 1592.5. This prevents a consumer from bypassing J and fixes the finite-window, readback, and tolerance rows W, R, D as part of the same endpoint route.

Finally apply the scoped kernel route of Definition 1592.9 and the public certificate route of Definition 1592.10. They add the structural rows H, C, P, N and exclude quotient filters, selected host subnets, countable choice, host real equality, and ambient completeness from every accepted endpoint read. □

Theorem 1592.12 (Cauchy subnet public cofinal-filter handoff)**.** *Let* $S = (F, J, W, R, D, L, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchySubnet}^{\uparrow}$ *carrier. Before any public completion-facing consumer reads* S *as a cofinal-filter handoff, the packet exposes the cofinal subnet map ledger* J*, the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F*, the* $\mathsf{CauchyNet}^{\uparrow}$ *source route when the consumer enters through a net presentation, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The handoff is therefore a public finite route through the displayed subnet, filter, net, window, readback, tolerance, and seal rows, not a selected subnet choice, quotient-net equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchySubnetUp.CauchySubnetCarrier public cofinal filter handoff`

Proof. Project the carrier of Definition 1592.1. The rows $F, J, W, R, D, L, E, H, C, P, N$ expose the source Cauchy filter, cofinal ledger, finite windows, regular rational readback, dyadic tolerance ledger, filter-limit handoff, endpoint seal, transport, replay, provenance, and local naming.

Use the Cauchy subnet obligation surface of Definition 1592.2. It forces every accepted subnet request to read the source filter row F and cofinal ledger J before any StreamName window or RegSeqRat readback is public.

Now apply the cofinal ledger coverage and endpoint nonescape routes. By Definition 1592.5, every completion-facing read passes through $F, J, W, R, D, L, E, H, C, P, N$; by Definition 1592.11, the endpoint remains downstream of the same rows.

A $\mathsf{CauchyNet}^{\uparrow}$ presentation can therefore only enter as a source-route view of the displayed Cauchy data before the same cofinal ledger is consumed. Since the carrier contains no selected subnet, quotient-net equality, or ambient completeness coordinate, the public handoff exports only the finite cofinal-filter route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1592.1, Definition 1592.2, Definition 1592.3, Definition 1592.5, Definition 1592.7, Definition 1592.9, Definition 1592.10, and Definition 1592.11 close the public-facing finite cofinal subnet route between CauchyFilter sources, StreamName and RegSeqRat readback, DyadicRatCore tolerance rows, CauchyFilterLimit handoff, MetricCompletion or Real consumers, endpoint nonescape, and the hsame, Cont, Pkg, and NameCert support rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySubnet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected host subnets, countable choice, host real equality, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, cofinal restriction coverage, finite-window exactness, tolerance exactness, filter-limit handoff, and ledger refusal proofs for the same packet.

Constructive story: A $\mathsf{CauchySubnet}^{\uparrow}$ packet is generated from a source CauchyFilter row, a cofinal subnet-index ledger, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyFilterLimit handoff, a MetricCompletion or Real seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1593

A Concrete Naming Certificate for $\mathsf{GershgorinDisk}^{\uparrow}$

Following Gershgorin's circle theorem and standard finite-dimensional linear algebra, the $\mathsf{GershgorinDisk}^{\uparrow}$ packet records the finite row-sum surface used to bound spectral locations for a displayed square matrix. It consumes matrix entries from chapter 49, linear-map interpretation from chapter 48, vector rows from chapter 47, and scalar comparison data from the real-facing boundary of chapter 38. The packet names the disk-bound route only; it does not assert eigenvalue existence over arbitrary fields, algebraic closure, spectral radius equality, analytic completeness, or a host-library spectrum predicate.

Definition 1593.1 (Gershgorin disk carrier)**.** *A* $\mathsf{GershgorinDisk}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, R, D, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *square-matrix row, including the finite row index, diagonal entries, and off-diagonal entry slots whose scalar boundary is read through the real-facing comparison surface.*
2. *R is the row-sum radius ledger, carrying for each displayed row the finite sum of absolute off-diagonal magnitudes used as the disk radius.*
3. *D is the disk-center and radius classifier row, naming the center a_{ii} and radius r_i for every displayed row i.*
4. *B is the displayed bound route saying that any spectral witness already supplied by a downstream linear-map or eigen-facing packet must be compared against one of the finitely displayed disks.*
5. *H stores componentwise* hsame *transport for the matrix row, radius ledger, disk classifier, bound route, continuation, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from matrix entries to row-sum radii, from radii to disk classifiers, and from the disk classifiers to the bound route.*
7. *P is the* Pkg *provenance over* $\mathsf{GershgorinDisk}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{GershgorinDisk}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, R, D, B, H, C, P, N. It has no coordinate for producing eigenvalues, choosing algebraic closures, asserting spectral radius equality, completing scalar fields, or importing analytic spectral theory.

Theorem 1593.2 (Gershgorin disk NameCert obligations)**.** *For every accepted* $\mathsf{GershgorinDisk}^{\uparrow}$ *carrier* $G = (M, R, D, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GershgorinDisk}^{\uparrow}}$ *surface consists exactly of carrier admission for the eight displayed rows, matrix entry access through* M*, finite row-sum radius accounting through* R*, disk-center and radius classification through* D*, the displayed spectral-bound route through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.GershgorinDiskUp.GershgorinDiskUpTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1593.1. The only matrix data available to the classifier are the square-matrix row M, its finite row index, and the displayed diagonal and off-diagonal entry slots read from chapter 49.

The row-sum ledger R and disk classifier D are then read from those displayed entries. They name centers and radii by finite scalar comparisons against the real-facing boundary of chapter 38; no eigenvalue-producing field extension or analytic completeness row is introduced.

Finally the bound route B and the structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate beyond these rows, the listed obligations exhaust the local NameCert surface. □

Theorem 1593.3 (Gershgorin disk row-sum bound)**.** *Every accepted* $\mathsf{GershgorinDisk}^{\uparrow}$ *carrier exposes its displayed bound through the finite route*

$$M \longmapsto R \longmapsto D \longmapsto B$$

together with H, C, P, N*. For each displayed row* i*, the packet reads the center from the diagonal entry of* M*, reads the radius from the finite off-diagonal row-sum ledger* R*, and records the disk classifier in* D *without asserting that the matrix has an eigenvalue over the ambient scalar boundary.*

Proof. Begin with the matrix row M. Its diagonal and off-diagonal slots are finite displayed entry rows, so the row-sum radius ledger R can only add the off-diagonal magnitude rows already exposed by the packet.

Next read the classifier D. It pairs the diagonal entry of row i with the radius recorded for the same row, producing the disk surface used by the bound route.

The route B is downstream-facing: it can constrain a spectral witness supplied elsewhere, but it cannot manufacture such a witness. Transport and replay through H and C, with provenance and naming through P and N, therefore preserve exactly the finite row-sum bound and no additional spectral principle. □

Theorem 1593.4 (Gershgorin disk matrix handoff)**.** *The* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *consumers may read a* $\mathsf{GershgorinDisk}^{\uparrow}$ *packet only through the matrix row of chapter 49, the linear-map interpretation of chapter 48, the vector-space boundary of chapter 47, and the displayed route*

$$R, D, B, H, C, P, N.$$

Thus the handoff supplies a finite spectral-bound surface for matrix-shaped linear maps while leaving eigenvalue existence, algebraic closure, spectral radius equality, analytic completeness, and host spectral decomposition outside the exported certificate.

Proof. Use Definition 1593.3. It places every displayed disk read on the route from matrix entries through row-sum radii, disk classification, and the bound route.

The matrix-to-linear-map handoff is read through chapter 49, chapter 48, and chapter 47. Those chapters supply the finite rows for entries, linear action, and vector slots; this chapter only adds the row-sum disk ledger on top of those rows.

The structural rows H, C, P, N preserve and name that ledger. Since the carrier lacks any coordinate for generating spectral points, completing scalar fields, or identifying spectral radii, the exported surface is only the finite Gershgorin bound handoff. □

Falsifiable prediction: Every $\mathsf{GershgorinDisk}^{\uparrow}$ spectral-bound read factors through a MatrixUp square-matrix row, a finite row-sum radius ledger, disk-center and radius classifiers, a displayed bound route, transport, continuation, provenance, and local naming.

Independence witness: matrix, linearmap, vecspace, real: $\mathsf{GershgorinDisk}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries matrix entries, finite row-sum radii, disk classifiers, a downstream bound route, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GershgorinDisk}^{\uparrow}}$.

Constructive story: A $\mathsf{GershgorinDisk}^{\uparrow}$ packet is generated from a MatrixUp square-matrix row, finite row-sum radius ledger, disk-center and radius classifier, displayed bound route, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GershgorinDisk}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1593.1, Definition 1593.2, Definition 1593.3, and Definition 1593.4 bind the finite row-sum spectral-bound packet for MatrixUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GershgorinDisk}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, eigenvalue existence over arbitrary fields, algebraic closure, spectral radius equality, analytic completeness, or host spectral decomposition.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, row-sum bound preservation, matrix handoff, and TasteGate field faithfulness for BEDC.Derived.GershgorinDiskUp.

Chapter 1594

A Concrete Naming Certificate for $\mathsf{CofinalSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CofinalSequence}^{\uparrow}$ packet records the constructive tail discipline for a sequence whose visible indices eventually dominate every displayed request. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the regular-rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It also provides the canonical carrier surface consumed by the specialized cofinal-tail selector of chapter 1263 and the cofinal-window Real-seal route of chapter 1174. The packet names a finite BEDC certificate for tail dominance and selected windows; it does not import countable choice, a host subsequence object, quotient stream equality, selected limits, or ambient completeness.

Definition 1594.1 (Cofinal sequence carrier)**.** *A* $\mathsf{CofinalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, D, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the unary index row, recording the visible natural-number requests and the displayed tail indices serving them.*
2. *D is the monotone cofinal dominance row, saying that whenever a displayed request is raised, the serving tail index is transported to a later displayed index and still dominates the request.*
3. *W is the finite family of selected* $\mathsf{StreamName}^{\uparrow}$ *windows attached to the serving indices in I.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row read from the selected windows in W.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the unary index row, dominance row, selected windows, and regular-rational handoff have been displayed.*
6. *H stores componentwise* hsame *transport for the index, dominance, window, regular handoff, Real seal, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a request to its serving tail index, from the serving index to the selected* $\mathsf{StreamName}^{\uparrow}$ *window, from the window to the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and from the handoff to the* $\mathsf{Real}^{\uparrow}$ *seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CofinalSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CofinalStreamTailSelector}^{\uparrow}$, $\mathsf{CofinalWindowRealSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CofinalSequence}^\uparrow}$ *row.*
The classifier compares accepted packets only through $I, D, W, Q, R, H, C, P, N$. It has no coordinate for countable choice, an external subsequence function, quotient equality of streams, a detached limit, an unbounded hidden selector, or ambient completeness.

Theorem 1594.2 (Cofinal sequence NameCert obligations)**.** *For every accepted* $\mathsf{CofinalSequence}^\uparrow$ *carrier $S = (I, D, W, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalSequence}^\uparrow}$ *surface consists exactly of carrier admission for the nine displayed rows, unary index exposure through I, monotone cofinal dominance through D, selected* $\mathsf{StreamName}^\uparrow$ *window exposure through W,* $\mathsf{RegSeqRat}^\uparrow$ *handoff through Q,* $\mathsf{Real}^\uparrow$ *seal ordering through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1594.1. The accepted packet exposes only the unary index row, the dominance row, the selected windows, the regular handoff, the Real seal, and the structural support rows.

Read the rows in dependency order. The index row I names the visible request and serving-tail indices; the dominance row D supplies the monotone cofinal comparison; the window row W selects exactly the finite $\mathsf{StreamName}^\uparrow$ observations allowed at those serving indices.

The remaining rows only continue that route. The regular handoff Q, Real seal R, transports H, continuations C, provenance P, and local name N do not add a hidden selector or host subsequence coordinate, so the listed obligations exhaust the certificate surface. □

Theorem 1594.3 (Cofinal sequence tail dominance)**.** *Every accepted* $\mathsf{CofinalSequence}^\uparrow$ *carrier exposes a finite dominance route*

$$I \longmapsto D \longmapsto W$$

before any $\mathsf{RegSeqRat}^\uparrow$ *or* $\mathsf{Real}^\uparrow$ *consumer may read the packet. Thus each displayed request is served by a displayed later index, and any transported read of the sequence factors through the same unary index row, monotone dominance row, selected window family, and structural rows H, C, P, N.*

Proof. Begin with a visible request in I. The dominance row D is the only row that relates the request to a later serving index, so every cofinal-tail read must pass through it.

After the serving index is fixed, the packet may expose only the selected windows in W. These windows are the finite observation surface consumed downstream, and they remain tied to the same request-serving route by H and C.

Since no coordinate of the carrier names an external subsequence function or a hidden unbounded selector, a transported consumer can only receive the displayed route I, D, W, H, C, P, N before any regular or Real-facing handoff. □

Theorem 1594.4 (Cofinal sequence RegSeqRat handoff)**.** *The* $\mathsf{RegSeqRat}^\uparrow$ *and* $\mathsf{Real}^\uparrow$ *consumers of an accepted* $\mathsf{CofinalSequence}^\uparrow$ *carrier receive the route*

$$I, D, W, Q, R, H, C, P, N.$$

The handoff first displays a cofinal tail index, then the selected $\mathsf{StreamName}^\uparrow$ *window at that index, then the* $\mathsf{RegSeqRat}^\uparrow$ *readback, and only then the* $\mathsf{Real}^\uparrow$ *seal. Consequently the specialized* $\mathsf{CofinalStreamTailSelector}^\uparrow$ *and* $\mathsf{CofinalWindowRealSeal}^\uparrow$ *chapters can consume a single canonical cofinal-sequence surface without importing host countable choice, quotient stream equality, selected limits, or ambient completeness.*

Proof. Use Definition 1594.3. It forces the downstream read to begin with the unary index row, dominance row, and selected window family.

The regular handoff is then exact: Q reads only the displayed windows in W, and R reads only the regular handoff Q. This is the same StreamName-to-RegSeqRat-to-Real ordering used by chapter 301 and chapter 38.

Finally compare the two cofinal consumers. The selector chapter chapter 1263 reads the tail-service part of the route, while chapter 1174 reads the terminal window-readback-seal part. Both reads are projections of the same displayed packet, so neither consumer receives an additional choice source or detached Real seal. □

Falsifiable prediction: Every $\mathsf{CofinalSequence}^{\uparrow}$ Real-facing read factors through a unary index row, monotone cofinal dominance, selected StreamName windows, RegSeqRat handoff, RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: streamname, regseqrat, real, cofinalstreamtailselector, cofinalwindowrealseal: $\mathsf{CofinalSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries unary tail-index dominance, selected windows, regular readback, Real seal ordering, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CofinalSequence}^{\uparrow}$ packet is generated from a unary index row, monotone cofinal dominance row, selected StreamName windows, RegSeqRat handoff, RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1594.1, Definition 1594.2, Definition 1594.3, and Definition 1594.4 bind the canonical cofinal tail-sequence packet for RegSeqRatUp, RealUp, CofinalStreamTailSelectorUp, and CofinalWindowRealSealUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, countable choice, external subsequence functions, quotient stream equality, selected limits, hidden unbounded selectors, or ambient completeness.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, tail-dominance preservation, RegSeqRat handoff, Real seal ordering, and TasteGate field faithfulness for BEDC.Derived.CofinalSequenceUp.

Chapter 1595

A Concrete Naming Certificate for $\mathsf{LocatedCauchySequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedCauchySequence}^{\uparrow}$ packet records the sequence-level data of a located Cauchy name before any quotient stream, selected limit, countable-choice selector, trichotomy branch, or ambient completeness principle is available. It sits after the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the located Cauchy source surface of chapter 340, the located real boundary of **??**, the terminal real-name seal of chapter 38, and the regular located Cauchy real packet of chapter 1454. The chapter packages finite sequence observations and located tail data; it does not assert that the sequence has a host-selected completed value.

Definition 1595.1 (Located Cauchy sequence carrier)**.** *A* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, D, T, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite observation windows of the sequence.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and tolerance ledger used to compare displayed sequence terms.*
4. *T is the located Cauchy tail row, recording the finite threshold at which later displayed terms are accepted inside the requested dyadic tolerance.*
5. *W is the located-window row inherited from chapter 340; it binds each tail request to the corresponding displayed located ball.*
6. *E is the downstream seal row toward* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$*, read only after S, Q, D, T, W have been exposed.*
7. *H records componentwise* hsame *transport for sequence windows, regular readback, dyadic tolerance data, tail rows, located windows, seal rows, continuation rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from each sequence precision request through $S, Q, D, T, W, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchySequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedCauchy}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the ten displayed rows. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, hidden infinite stream inspection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1595.2 (Located Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *carrier* $L = (S, Q, D, T, W, E, H, C, P, N)$*, the seed* $\mathsf{NameCert}_{\mathsf{LocatedCauchySequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, finite-window exposure through* S*, regular rational readback through* Q*, dyadic tolerance exposure through* D*, located tail exposure through* T*, located-window compatibility through* W*, downstream seal ordering through* E*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 1595.1. The visible analytic rows are precisely the stream schedule, regular readback, dyadic tolerance ledger, located tail row, located-window row, and downstream seal row.

Read the rows in dependency order. A precision request first reaches the finite windows S, then the regular rational observations Q, then the dyadic endpoint and tolerance ledger D. The located tail row T can be inspected only after those finite observations are fixed, and the located-window row W binds the same tail request to the displayed located ball.

The seal and structural rows add no further analytic object. The row E is downstream of S, Q, D, T, W, while H, C, P, N transport, replay, source, and name that same route. Since no listed row stores quotient stream equality, a selected host limit, countable choice, trichotomy, hidden stream inspection, or ambient completeness, the listed rows exhaust the seed obligation surface. □

Theorem 1595.3 (Located Cauchy sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read of an accepted* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *carrier factors through*

$$S \longmapsto Q \longmapsto D \longmapsto T \longmapsto W \longmapsto (H, C, P, N).$$

Thus the regular rational consumer receives a finite sequence window, the matching regular readback row, the dyadic tolerance ledger, and the located tail witness before any Real-facing seal can be inspected.

Proof. Start from a regular rational consumer request. By Definition 1595.1, the consumer reaches Q only through the finite schedule row S, so the read begins with a displayed sequence window rather than with an unbounded stream.

The dyadic and located rows then fix the tail evidence. The tolerance ledger D records the endpoint and radius data used by the request, while T and W attach the located Cauchy tail and located-window witness to that same finite readback.

The structural rows preserve this route. The rows H, C, P, N transport, replay, package, and name the displayed handoff, and none of them introduces a quotient of streams, a selected limit, a choice function, a trichotomy branch, or an ambient completeness witness. □

Theorem 1595.4 (Located Cauchy sequence Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{LocatedReal}^{\uparrow}$*-facing, or* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *carrier factors through the complete finite route*

$$S, Q, D, T, W, E, H, C, P, N.$$

Consequently a downstream consumer cannot read a terminal seal from the packet without also reading the sequence window, regular rational source, dyadic tolerance ledger, located Cauchy tail witness, located-window row, transport, continuation, provenance, and local NameCert rows.

Proof. Begin with a downstream seal read. The carrier exposes the seal only as E, and E is listed after the finite windows, regular readback, dyadic tolerance row, located tail row, and located-window row in Definition 1595.1.

The route to E is therefore finite. The sequence window S fixes the requested observations, Q records their regular rational readback, D budgets the dyadic comparisons, and T, W provide the located Cauchy and located-window evidence attached to that request.

Finally read the support rows. The rows H, C, P, N keep the same finite route stable under componentwise transport, continuation replay, package provenance, and local naming. Since the packet has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, hidden infinite stream inspection, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no downstream consumer can escape the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchySequence}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a located Cauchy tail row, a located-window witness, a downstream Real-facing seal row, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1595.1, Definition 1595.2, Definition 1595.3, and Definition 1595.4 seed the sequence-level located Cauchy packet between StreamName, RegSeqRat, DyadicRatCore, LocatedCauchy, LocatedReal, Real, and RegularLocatedCauchyReal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, trichotomy, hidden infinite stream inspection, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, the NameCert obligation surface, the RegSeqRat handoff, and the Real seal nonescape theorem for BEDC.Derived.LocatedCauchySequenceUp.

Chapter 1596

A Concrete Naming Certificate for $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$

Following the Bishop–Bridges finite-cover reading, the $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ packet records the finite dyadic cover data used by interval compactness arguments without asserting a general open-cover compactness principle. It consumes the closed interval base of chapter 1591, the finite net surface of chapter 1250, the dyadic arithmetic rows of chapter 291, the finite name windows of chapter 126, the rational readback rows of chapter 301, the Real seal of chapter 38, and the downstream finite-net consumer route of chapter 388. The packet is a displayed certificate for one closed bounded interval row, one mesh scale, rational and dyadic cells, displayed centers, finite coverage rows, StreamName windows, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming.

Definition 1596.1 (Interval finite cover certificate carrier)**.** *An* $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, M, C, D, Z, F, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row, including its endpoint-order and containment ledgers;*
2. *M is the unary mesh scale naming the dyadic precision at which the cover is read;*
3. *C is the finite rational cell ledger attached to I at scale M;*
4. *D is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *cell ledger refining the rational cells of C;*
5. *Z is the displayed center row, with one rational or dyadic center for each accepted cell;*
6. *F is the finite coverage row saying that every displayed interval containment read enters one of the cells in C together with its dyadic refinement in D;*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to read the endpoints, centers, and cell boundaries at the mesh scale;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows;*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, M, C, D, Z, F, S, R have been displayed;*

10. *H records componentwise* hsame *transport for the interval row, mesh row, rational cells, dyadic cells, centers, coverage row, windows, readbacks, and Real seal;*
11. *K records displayed* Cont *replay from the closed interval row through mesh selection, cell coverage, finite windows, rational readback, and RealUp sealing;*
12. *P is the* Pkg *provenance over* $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}}$ *row.*

The carrier exports no arbitrary open cover, selected subcover, quotient real equality, trichotomy row, hidden point selector, or ambient Real completeness principle. Its public data are exactly the finite interval, mesh, cell, center, coverage, readback, seal, transport, replay, provenance, and local naming rows.

Definition 1596.2 (Interval finite cover certificate classifier)**.** *Two accepted* $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ *carriers*

$$J = (I, M, C, D, Z, F, S, R, E, H, K, P, N)$$

and

$$J' = (I', M', C', D', Z', F', S', R', E', H', K', P', N')$$

are classified together exactly when the displayed hsame *rows transport I to I', M to M', C to C', D to D', Z to Z', F to F', S to S', R to R', and E to E', and the displayed* Cont *rows replay the same interval-to-mesh-to-cover-to-seal route on both packets. The classifier has no coordinate for equality of ambient subsets of* $\mathsf{Real}^{\uparrow}$*, general cover refinement, choice of a finite subcover from an arbitrary family, trichotomy, or completed real-line compactness.*

Theorem 1596.3 (Interval finite cover certificate NameCert obligations)**.** *For the carrier of Definition 1596.1, the local* $\mathsf{NameCert}_{\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission for $J = (I, M, C, D, Z, F, S, R, E, H, K, P, N)$, closed bounded interval admission through I, unary mesh admission through M, rational cell admission through C, dyadic cell admission through D, center-row admission through Z, finite coverage admission through F, StreamName and RegSeqRat readback through S and R, RealUp sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier. Its rows display the closed interval, mesh scale, rational cells, dyadic cells, centers, finite coverage, windows, readbacks, Real seal, transport, replay, provenance, and local name as one finite packet.

Read the analytic rows before the seal. The interval row I, mesh row M, cell rows C, D, center row Z, and coverage row F are all exposed before the $\mathsf{Real}^{\uparrow}$ seal E, while S and R record the finite name windows and rational readbacks used by the same cells.

The remaining rows close the naming surface. The transport row H, replay row K, provenance row P, and local name N preserve exactly this finite route, so there is no additional NameCert obligation outside the listed rows. □

Theorem 1596.4 (Interval finite cover certificate nonescape)**.** *Every accepted* $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ *consumer reads interval coverage through the finite route*

$$I, M, C, D, Z, F, S, R, E, H, K, P, N.$$

The read receives a closed bounded interval row, a unary mesh scale, rational cells, dyadic refinements, displayed centers, a finite coverage ledger, StreamName windows, RegSeqRat readback, and

a RealUp seal. It receives no general open-cover compactness theorem, arbitrary subcover choice, quotient real equality, order trichotomy, or ambient Real completeness row.

Proof. Start with the displayed route. The carrier admits coverage only through the rows I, M, C, D, Z, F, so an interval read must pass through the accepted closed interval, the mesh scale, the rational and dyadic cells, the centers, and the finite coverage row.

The name-facing rows do not add escape coordinates. The StreamName windows, RegSeqRat readbacks, and RealUp seal are downstream of the finite cover rows, and the structural rows H, K, P, N only transport, replay, source, and name the same packet.

Since the carrier and classifier contain no coordinate for an arbitrary open cover, selected subcover, quotient real equality, trichotomy, or ambient completeness principle, a consumer cannot extract any such datum from an accepted packet. □

Theorem 1596.5 (Interval finite cover certificate compact-uniform handoff)**.** *Every* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ *packet receives the finite handoff*

$$I, M, C, D, Z, F, S, R, E, H, K, P, N$$

as a dyadic interval cover certificate. The handoff may be read as closed-bounded interval data from I, mesh and cell data from M, C, D, Z, F, finite name data from S, R, and a Real-facing seal from E, all transported and sourced by H, K, P, N. It does not assert Heine–Borel open-cover compactness, choose a subcover from an arbitrary family, identify quotient real names, decide trichotomy, or supply ambient Real completeness.

Proof. Use the NameCert obligations. They identify the accepted packet with the rows $I, M, C, D, Z, F, S, R, E, H,$ so a downstream consumer receives the same finite route rather than an ambient interval object.

Use the nonescape theorem. It prevents the handoff from being reinterpreted as a general open-cover compactness row, a selected subcover, quotient real equality, trichotomy, or Real completeness.

The compact-uniform-continuity consumer therefore sees exactly a finite dyadic cover certificate: interval base rows, mesh and cell rows, centers, coverage, finite name windows, rational readback, a Real-facing seal, transport, replay, provenance, and local naming. □

Falsifiable prediction: Every compact-uniform-continuity read of an IntervalFiniteCoverCertificateUp packet factors through the displayed finite dyadic cover route and not through an open-cover compactness row.

Independence witness: closedboundedinterval, closedboundedintervalnet, dyadicratcore, streamname, regseqrat, real, compactuniformcontinuity: $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a closed bounded interval row, unary mesh scale, rational and dyadic cells, displayed centers, finite coverage rows, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$ packet is generated from a closed bounded interval row, unary mesh scale, rational and dyadic cells, displayed centers, finite coverage rows, StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1596.1, Definition 1596.2, Definition 1596.3, Definition 1596.4, and Definition 1596.5 bind the finite dyadic interval-cover certificate used by compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, general open-cover compactness, arbitrary subcover choice, quotient real equality, trichotomy, or ambient Real completeness.

Upgrade path: Lean closure requires carrier admission, classifier preservation, finite coverage nonescape, and compact-uniform handoff for BEDC.Derived.IntervalFiniteCoverCertificateUp.

Chapter 1597

A Concrete Naming Certificate for $\mathsf{DyadicOrder}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicOrder}^{\uparrow}$ packet names the finite common-scale comparison certificate used before regular rational names or real-completion consumers read dyadic tolerance order data. It reads $\mathsf{DyadicRatCore}^{\uparrow}$ common-scale data through chapter 291, rational and integer endpoints through chapter 37 and chapter 31, and supplies the comparison ledger consumed by chapter 126, chapter 301, and chapter 38. The packet is a finite dyadic comparison route, not host rational order, trichotomy, quotient equality, a selected limit, ambient real completeness, or a standard bridge.

Definition 1597.1 (DyadicOrder carrier)**.** *A* $\mathsf{DyadicOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, R, S, C, H, K, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, carrying its signed mantissa, unary exponent, denominator ledger, and local dyadic provenance.*
2. *R is the right* $\mathsf{DyadicRatCore}^{\uparrow}$ *row with the same visible endpoint coordinates and provenance shape.*
3. *S is the common-scale row displaying the finite exponent into which L and R are transported before comparison.*
4. *C is the comparison bit and ledger row, recording the transported mantissas at scale S, the finite sign test, and the named outcome consumed by downstream tolerance checks.*
5. *H records componentwise* hsame *transport for the two endpoint rows, common-scale row, comparison ledger, continuation row, provenance row, and local naming row.*
6. *K records displayed* Cont *replay from the two dyadic inputs through the common-scale row and then through the comparison ledger.*
7. *P is the* Pkg *provenance over* $\mathsf{Int}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicOrder}^{\uparrow}}$ *row.*

The carrier has no coordinate for host rational order, trichotomy, quotient rational equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Theorem 1597.2 (DyadicOrder NameCert obligations)**.** *For every accepted* $\mathsf{DyadicOrder}^{\uparrow}$ *carrier* $O = (L, R, S, C, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicOrder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the left and right* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, common-scale row, comparison ledger, transport, replay, provenance, and local naming row;*
2. *classifier transport, requiring componentwise* hsame *and displayed* Cont *replay to preserve the same left endpoint, right endpoint, common exponent, transported mantissas, and comparison bit;*
3. *common-scale comparison exactness, requiring every accepted comparison to read the exponent and transported mantissas in* S *before consuming the ledger row* C*;*
4. *radius-monotonicity compatibility, requiring downstream tolerance consumers to use the comparison only after the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window monotonicity route has exposed the same finite radius data;*
5. *non-escape, requiring* P *and* N *to name only the displayed rows and to export no host rational order, trichotomy, quotient equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification claim, or bridge certificate.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1597.1. The projection exposes the two dyadic endpoint rows, the common-scale row, the comparison ledger, and the structural rows H, K, P, N.

Classifier transport is read from H and K. Componentwise hsame carries the left and right endpoint rows, while displayed Cont replay repeats the route through S and then through C.

Common-scale exactness follows from the carrier order. The comparison ledger C is available only after the finite common exponent and the two transported mantissas have been displayed in S.

Radius-monotonicity compatibility is a downstream handoff condition. Since the package names only the $\mathsf{DyadicRatCore}^{\uparrow}$ rows and the displayed comparison route, every consumer must first read the scale-window monotonicity data already attached to those dyadic rows.

The exclusions follow from the row inventory. No host rational order, trichotomy, quotient equality, selected limit, ambient completeness, Lean verification row, or bridge row is present in O. □

Theorem 1597.3 (DyadicOrder common-scale comparison)**.** *Every accepted* $\mathsf{DyadicOrder}^{\uparrow}$ *comparison factors through a displayed finite ledger*

$$L, R \longmapsto S \longmapsto C$$

where S *names a common exponent and transported mantissas for the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *inputs, and* C *names the comparison bit read from those transported mantissas. The route cannot use host rational order, an ambient trichotomy principle, quotient equality of rationals, or any comparison object not carried by the finite rows of* O*.*

Proof. Start with an accepted comparison. Carrier admission gives only the left and right dyadic rows before a comparison can be inspected.

Replay K. The replay first transports the two endpoint rows into the common exponent displayed by S, and only then reaches the comparison ledger C.

The comparison bit in C is therefore a readback from the two transported mantissas at the displayed scale. Because the carrier contains no host rational order, trichotomy, quotient equality, or external comparison coordinate, the accepted route is exhausted by L, R, S, C, H, K, P, N. □

Theorem 1597.4 (DyadicOrder radius-monotonicity handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicOrder}^{\uparrow}$ *comparison receives only the finite dyadic comparison row* C *after the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window monotonicity route has exposed the relevant radius and endpoint rows. The handoff supplies no host rational order, trichotomy, quotient real equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean verification claim, or bridge component.*

Proof. Begin with a downstream consumer. The consumer can inspect the comparison only through the package row P and the local naming row N, both of which point back to the displayed dyadic inputs.

Read the $\mathsf{DyadicRatCore}^{\uparrow}$ scale-window monotonicity route attached to L and R. That route exposes the finite radius and endpoint rows before any comparison ledger is consumed.

After that exposure, replay K through the common-scale row S and the comparison ledger C. The consumer receives the same finite comparison bit and its endpoint provenance, transported by H.

Since the route ends at the displayed comparison ledger and structural rows, it cannot export host order, trichotomy, quotient equality, selected limits, ambient completeness, Lean verification, or bridge data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicOrder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicOrder}^{\uparrow}$ packet is generated from left and right DyadicRatCore rows, a common-scale row, a comparison bit and ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1597.1, Definition 1597.2, Definition 1597.3, and Definition 1597.4 seed the finite common-scale comparison object used by dyadic tolerance consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, host rational order, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, common-scale comparison exactness, radius-monotonicity compatibility, downstream handoff, and non-escape proofs for BEDC.Derived.DyadicOrderUp.

Chapter 1598

A Concrete Naming Certificate for $\mathsf{CompleteOrderedReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki's ordered-field language, the $\mathsf{CompleteOrderedReal}^{\uparrow}$ packet records the finite interface where $\mathsf{Real}^{\uparrow}$ names are read together with constructive ordered-field data and located least-upper-bound data. It sits over the ordered-field surface of chapter 1419, the located-supremum boundary of chapter 1427, and the inhabited bounded-family completion surface of chapter 1504. The packet is a BEDC NameCert interface for consumers that need these rows in one visible route; it is not a construction of all reals, not a quotient carrier, and not a classical completeness principle.

Definition 1598.1 (CompleteOrderedReal carrier)**.** *A* $\mathsf{CompleteOrderedReal}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$K = (R, A, S, D, W, H, C, P, N)$$

with the following displayed rows:

1. *R is the family of* $\mathsf{Real}^{\uparrow}$ *endpoint and witness rows read by the packet.*
2. *A is the* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *row supplying displayed addition, negation, multiplication, order, rational-bound, and Archimedean comparison data over the rows of R.*
3. *S is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row supplying the upper-bound and lower-approximation faces for located bounded windows over R.*
4. *D is the* $\mathsf{DedekindCompleteReal}^{\uparrow}$ *row tying inhabited bounded* $\mathsf{Real}^{\uparrow}$ *family windows to the located-supremum witness and terminal real-seal readback.*
5. *W is the local compatibility ledger recording which real endpoints, order comparisons, bounded-family observations, and supremum precision requests are being inspected.*
6. *H records componentwise* hsame *transports for the real rows, ordered-field row, located-supremum row, completion row, compatibility ledger, continuation routes, provenance, and local naming row.*
7. *C records displayed* Cont *replay from real-name inspection through ordered-field comparison, located-supremum witnessing, completion handoff, and local compatibility.*
8. *P is the* Pkg *provenance over* $\mathsf{CompleteOrderedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{DedekindCompleteReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by replaying $R, A, S, D, W, H, C, P, N$. The carrier has no coordinate for a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, arbitrary subset completeness, trichotomy, quotient reals, countable choice, host real equality, or bridge checking.*

Theorem 1598.2 (CompleteOrderedReal NameCert obligations)**.** *For every accepted* $\mathsf{CompleteOrderedReal}^{\uparrow}$ *carrier $K = (R, A, S, D, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real endpoint and witness rows, ordered-field row, located-supremum row, completion row, compatibility ledger, transports, continuations, provenance, and local naming row;*
2. *ordered-field compatibility, requiring every operation, order, rational-bound, and Archimedean comparison read to pass through A over the same real rows listed in R and W;*
3. *located-supremum compatibility, requiring every upper-bound and lower-approximation read to pass through S and the bounded-family handoff in D at a precision listed in W;*
4. *transport and replay stability, requiring H and C to preserve the route R, A, S, D, W componentwise;*
5. *ledger exhaustion, requiring P and N to export no Dedekind-cut construction, arbitrary subset completeness, trichotomy, quotient real, countable-choice selector, host real equality, or bridge-checked standard object.*

No local obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1598.1. The accepted packet exposes exactly the real rows, ordered-field row, located-supremum row, completion row, compatibility ledger, transport row, replay row, provenance row, and local naming row.

Ordered-field compatibility is inherited through the displayed row A. Its operation, order, rational-bound, and Archimedean comparison reads are available only over the real rows recorded in R and selected by the local ledger W.

Located-supremum compatibility is inherited through the displayed rows S and D. The row S supplies the upper-bound and lower-approximation faces, while D records the inhabited bounded-family handoff that reaches the terminal $\mathsf{Real}^{\uparrow}$ seal.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, and Cont replay in C repeats the route R, A, S, D, W for every accepted request.

Finally, provenance is exhausted by P and N. Since the excluded principles are not coordinates of K, the local $\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}$ surface cannot export them. □

Theorem 1598.3 (CompleteOrderedReal Archimedean order route)**.** *Every order-facing read exported by an accepted* $\mathsf{CompleteOrderedReal}^{\uparrow}$ *carrier factors through*

$$R \longmapsto A \longmapsto W \longmapsto H, C, P, N.$$

Thus the packet presents constructive ordered-field behavior only through the existing $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *surface over displayed* $\mathsf{Real}^{\uparrow}$ *rows. It does not identify those rows with quotient reals, host real equality, trichotomy, a complete host ordered field, or a bridge-checked standard object.*

Proof. Start with an order-facing consumer of K. The only row carrying ordered-field operations and comparisons is A, and the row A is indexed by the displayed real rows in R.

The compatibility ledger W selects the particular endpoints, operation reads, rational-bound checks, and Archimedean comparisons in scope. No order read can bypass W, because the local carrier does not expose an independent host ordered-field coordinate.

The structural rows H, C, P, N then transport, replay, source, and name this route. Since quotient reals, host real equality, trichotomy, complete host ordered fields, and bridge-checked standard objects are absent from the carrier, the route exports none of them. □

Theorem 1598.4 (CompleteOrderedReal located-supremum boundary)**.** *Every supremum-facing read exported by an accepted* $\mathsf{CompleteOrderedReal}^{\uparrow}$ *carrier factors through*

$$R \longmapsto W \longmapsto S \longmapsto D \longmapsto H, C, P, N.$$

The read supplies only the displayed located upper-bound and lower-approximation boundary for the named inhabited bounded family window. It does not supply a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, arbitrary subset completeness, trichotomy, quotient reals, countable choice, host real equality, or bridge checking.*

Proof. Begin with a supremum-facing request. The local ledger W fixes the family observations, bounds, and precision request currently under inspection over the real rows R.

The row S is then the only located-supremum coordinate. It supplies the upper-bound face and the lower-approximation face for the precision listed in W.

The row D is the only completion-facing handoff. It ties the located-supremum read to the inhabited bounded-family route and terminal $\mathsf{Real}^{\uparrow}$ seal without adding a separate arbitrary subset classifier.

Finally, H, C, P, N transport, replay, source, and name exactly this displayed route. The excluded completeness and classical-order principles have no carrier coordinate, so they cannot be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteOrderedReal}^{\uparrow}$ packet is generated from displayed $\mathsf{Real}^{\uparrow}$ endpoint and witness rows, an $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ ordered-field row, a $\mathsf{LocatedSupremum}^{\uparrow}$ least-upper-bound row, a $\mathsf{DedekindCompleteReal}^{\uparrow}$ inhabited bounded-family handoff, a compatibility ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1598.1, Definition 1598.2, Definition 1598.3, and Definition 1598.4 seed the finite ordered-field and located-supremum interface for displayed $\mathsf{Real}^{\uparrow}$ data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteOrderedReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut construction, arbitrary subset completeness, trichotomy, quotient reals, countable choice, bridge checking, host real equality, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, ordered-field compatibility, located-supremum compatibility, transport stability, replay stability, and ledger exhaustion for BEDC.Derived.CompleteOrderedRealUp.

Chapter 1599

A Concrete Naming Certificate for $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$

Following Birkhoff and Davey–Priestley on order completion, the $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ packet names the finite two-sided cut-closure surface that compares lower-row and upper-row observations without constructing $\mathsf{Real}^{\uparrow}$ by Dedekind cuts. It sits between the one-sided $\mathsf{LowerReal}^{\uparrow}$ and $\mathsf{UpperReal}^{\uparrow}$ ledgers, the located-cut boundary of chapter 404, the representation comparison of chapter 1424, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet supplies a finite order-completion comparison boundary for Real and Completion consumers; it is not a quotient-cut carrier, not a host supremum principle, and not a construction of $\mathsf{Real}^{\uparrow}$.

Definition 1599.1 (Dedekind–MacNeille completion carrier)**.** *A* $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, K, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the finite lower-row closure ledger. It records the displayed* $\mathsf{LowerReal}^{\uparrow}$ *observations, their downward stability, and the finite meet requests allowed by the packet.*
2. *U is the finite upper-row closure ledger. It records the displayed* $\mathsf{UpperReal}^{\uparrow}$ *observations, their upward stability, and the finite join requests allowed by the packet.*
3. *K is the* $\mathsf{LocatedCut}^{\uparrow}$ *handoff row. It ties the lower and upper ledgers by located separation data and records only the displayed gap witnesses used by finite consumers.*
4. *Q is the* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *boundary row. It compares cut-shaped observations from L, U, K with the regular Cauchy readback route accepted at the representation boundary.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal route. It is reached only after the lower closure, upper closure, located-cut handoff, and comparison boundary have been displayed.*
6. *H records componentwise* hsame *transport for the lower ledger, upper ledger, located-cut handoff, comparison boundary, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a two-sided cut request through L, U, K, Q, E.*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindMacNeilleCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, K, Q, E, H, C, P, N$. The carrier has no coordinate for quotient cuts, host suprema, arbitrary complete lattices, selected cuts, or a Dedekind construction of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DedekindMacNeilleCompletionUp.DedekindMacNeilleCompletionTasteGate single carrier alignment`

Theorem 1599.2 (Dedekind–MacNeille completion NameCert obligations)**.** *For every accepted* $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ *carrier $D = (L, U, K, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindMacNeilleCompletion}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed lower closure ledger, upper closure ledger, located-cut handoff, comparison boundary, Real seal, transport, replay, provenance, and local naming row;*
2. *two-sided closure compatibility, requiring every finite lower-row request in L and every finite upper-row request in U to meet only through the located separation witnesses recorded in K;*
3. *representation-boundary factorization, requiring every cut-shaped observation exposed by L, U, K to pass through Q before any* $\mathsf{Real}^{\uparrow}$*-facing read is available;*
4. *transport and replay stability, requiring* hsame *transport H and* Cont *replay C to preserve the ordered route L, U, K, Q, E componentwise;*
5. *ledger non-escape, requiring P and N to export no quotient cut, no host supremum, no arbitrary complete-lattice closure, no selected cut, and no Dedekind construction of* $\mathsf{Real}^{\uparrow}$.

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1599.1. The accepted packet exposes exactly the lower ledger, upper ledger, located-cut handoff, representation comparison, Real seal, and structural rows H, C, P, N.

The two-sided closure compatibility row is finite. A lower request reads only the displayed rows in L, an upper request reads only the displayed rows in U, and their common comparison is the located separation information stored in K.

Representation-boundary factorization is forced by the row order. Cut-shaped observations from L, U, K cannot reach a Real-facing seal directly; they first pass through the $\mathsf{DedekindCauchyComparison}^{\uparrow}$ row Q.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, and Cont replay in C repeats the same route L, U, K, Q, E for every accepted two-sided request.

Finally, provenance and naming are exhausted by P and N. Since quotient cuts, host suprema, arbitrary complete-lattice closure, selected cuts, and a Dedekind construction of $\mathsf{Real}^{\uparrow}$ are not coordinates of D, the local NameCert surface cannot export them. □

Lean4 ✓ `BEDC.Derived.DedekindMacNeilleCompletionUp.DedekindMacNeilleCompletionNameCert obligations`

Theorem 1599.3 (Dedekind–MacNeille finite cut closure)**.** *Let $D = (L, U, K, Q, E, H, C, P, N)$ be an accepted* $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ *carrier. Every finite two-sided cut-closure read exported by D factors through the route*

$$L, U \longmapsto K \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet supplies only the displayed lower-row closure, upper-row closure, located-cut handoff, representation comparison, and terminal Real-seal route. It supplies no quotient cut, no host supremum, no arbitrary Dedekind–MacNeille completion object, no selected cut, and no construction of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DedekindMacNeilleCompletionUp.DedekindMacNeilleCompletionCarrier cut closure`

Proof. Begin with a two-sided cut-closure read. The lower face is the finite ledger L, and the upper face is the finite ledger U; no ambient poset completion or host lattice is consulted.

The two faces meet only through K. This row records the located separation handoff, so a consumer may inspect the displayed gap witnesses but cannot form a quotient cut or selected cut from them.

The representation boundary is Q. Every cut-shaped observation from the displayed rows is compared with the regular Cauchy readback route before the terminal $\mathsf{Real}^{\uparrow}$ seal E is available.

The rows H, C, P, N then transport, replay, source, and name exactly this route. Because the packet contains no coordinate for host suprema, arbitrary complete lattices, quotient cuts, selected cuts, or a Dedekind construction of $\mathsf{Real}^{\uparrow}$, none of those objects can be exported by the cut-closure read. □

Theorem 1599.4 (Dedekind–MacNeille Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ *packet must pass through the* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{DedekindCauchyComparison}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of the displayed carrier before reading the terminal seal. The packet cannot be read as a construction of* $\mathsf{Real}^{\uparrow}$*, a quotient cut, a host supremum, a selected cut, or an arbitrary complete-lattice closure.*

Lean4 ✓ `BEDC.Derived.DedekindMacNeilleCompletionUp.DedekindMacNeilleCompletionRealSealNonescape`

Proof. Project the carrier $D = (L, U, K, Q, E, H, C, P, N)$ from Definition 1599.1. The only Real-facing route first reads the lower ledger L and upper ledger U, then the located-cut handoff K, then the representation comparison boundary Q, and only then the Real seal row E.

Apply the cut-closure theorem. It identifies the exported finite route as

$$L, U \longmapsto K \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Row exhaustion gives the nonescape claim. The structural rows H, C, P, N transport, replay, source, and name the same displayed route, and no carrier coordinate stores quotient cuts, host suprema, selected cuts, arbitrary complete-lattice closure, or a Dedekind construction of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindMacNeilleCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DedekindMacNeilleCompletion}^{\uparrow}$ packet is generated from finite lower-row closure data, finite upper-row closure data, a LocatedCut handoff, a DedekindCauchyComparison boundary, a RealUp seal route, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindMacNeilleCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1599.1, Definition 1599.2, and Definition 1599.3 seed the finite two-sided cut-closure comparison boundary for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindMacNeilleCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient cuts, host suprema, arbitrary complete lattices, selected cuts, Lean verification, a standard bridge, or Dedekind construction of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, two-sided closure compatibility, LocatedCut handoff, DedekindCauchyComparison factorization, Real seal non-escape, transport stability, replay stability, and ledger non-escape for BEDC.Derived.DedekindMacNeilleCompletionUp.

Chapter 1600

A Concrete Naming Certificate for $\mathsf{DirectedSubnet}^{\uparrow}$

Following Kelley-style nets and Bourbaki general topology, the $\mathsf{DirectedSubnet}^{\uparrow}$ packet records cofinal subnet reindexing as finite BEDC rows rather than as a quotient of nets or a choice of subnet representatives. It sits between the source directed-window surface of chapter 589 and the downstream limit consumer of chapter 1561. Its displayed reindexing route also reads the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal boundary of chapter 38.

Definition 1600.1 (DirectedSubnet carrier)**.** *A* $\mathsf{DirectedSubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, J, \phi, K, L, S, R, D, A, H, C, P, N)$$

over $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *with the following displayed rows:*

1. *I is the finite source directed-window ledger whose entries are the source windows inspected by the packet.*
2. *J is the finite target directed-window ledger whose entries name the subnet windows requested by downstream consumers.*
3. *$\phi : J \to I$ is the displayed cofinal map from target directed windows into source directed windows. Its cofinal coverage row records, for each displayed source window in I, a target window in J whose image lies above it inside the source directed order recorded by K.*
4. *K is the accepted source* $\mathsf{CauchyNet}^{\uparrow}$ *row read on the source windows named by I.*
5. *L is the target or subnet* $\mathsf{CauchyNet}^{\uparrow}$ *row whose windows are obtained by replaying K along ϕ.*
6. *S records the* $\mathsf{StreamName}^{\uparrow}$ *windows used to read both the source observations and their target replay.*
7. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the scheduled windows.*
8. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger consulted when the source and target readings are compared.*
9. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after K, ϕ, L, S, R, D have been replayed.*

10. *H records componentwise* hsame *transport for the source, target, map, window, readback, tolerance, seal, continuation, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a target-window request through ϕ into the source CauchyNet row and then back into the target CauchyNet row.*
12. *P is the* Pkg *provenance over the listed BEDC dependencies.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}$ *row.*

The carrier exports no quotient of nets, no selected limit, no cofinal choice operator, no host real equality, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetTasteGate single carrier alignment`

Theorem 1600.2 (DirectedSubnet NameCert obligations)**.** *For every accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *carrier $M = (I, J, \phi, K, L, S, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source ledger, target ledger, cofinal map, source CauchyNet row, target CauchyNet row, window, readback, tolerance, seal, transport, continuation, provenance, and local naming rows;*
2. *cofinal-map coverage, requiring every displayed source window requested by the packet to be reached by a target window through the row $\phi : J \to I$;*
3. *CauchyNet handoff, requiring the target row L to be read only by replaying the source row K along ϕ and the displayed window, readback, and tolerance rows S, R, D;*
4. *Real-seal non-escape, requiring the seal row A to remain downstream of K, ϕ, L, S, R, D;*
5. *ledger refusal, excluding quotient-net equality, selected subnet limits, cofinal choice outside ϕ, host real equality, and ambient completeness.*

No obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetNameCertObligations`

Proof. Carrier admission is projection from Definition 1600.1. The source and target ledgers, the displayed cofinal map, both CauchyNet rows, the StreamName windows, regular readback, dyadic tolerance ledger, Real seal, and structural rows are all visible coordinates of the same finite BHist packet.

Cofinal-map coverage is read from the ϕ row together with the source directed order recorded by K. For each source window the packet displays, the coverage row names a target window whose image lies above it, so the packet has no need for an ambient choice function selecting unseen target windows.

The CauchyNet handoff is then replayed through C and transported by H. A target-window request first reads J, applies ϕ into the source ledger I, consumes the source row K, and only then exports the target row L through the same S, R, D evidence.

The seal row A is downstream of this replay. Since the provenance and local naming rows package only those displayed coordinates, no quotient-net relation, selected limit, host real equality, or ambient completeness coordinate can be exported as a NameCert obligation. □

Theorem 1600.3 (DirectedSubnet CauchyNet handoff)**.** *Let $M = (I, J, \phi, K, L, S, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *packet. Every target* $\mathsf{CauchyNet}^{\uparrow}$ *row exported by L factors through the displayed route*

$$J, \phi, I, K, S, R, D \longmapsto L.$$

Thus the target CauchyNet packet is available only through the displayed cofinal map, the source CauchyNet row, the $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. The route is a projection and replay over finite rows, not a quotient-net construction and not a choice argument.*

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetCarrier cauchynet handoff`

Proof. Start with a consumer of the target row L. Carrier admission exposes L only as a coordinate of the same packet that also contains J, ϕ, I, K, S, R, D.

Replay the continuation row C. The consumer's target-window request first lands in J, then follows the displayed map ϕ into the source ledger I. The source $\mathsf{CauchyNet}^{\uparrow}$ row K supplies the inspected source windows, while S, R, D supply the scheduled windows, regular rational readback, and dyadic tolerance comparisons needed for the replay.

Transport by H preserves this route componentwise. The package and local NameCert rows record exactly the same coordinates, so the target row L has no exported path through quotient-net equality, hidden cofinal choice, a selected limit, host real equality, or ambient completeness. □

Theorem 1600.4 (DirectedSubnet cofinal replay)**.** *Let $M = (I, J, \phi, K, L, S, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *packet. Any consumer replaying a target directed window must expose the target ledger J, the displayed cofinal map ϕ, the source ledger I, the source* $\mathsf{CauchyNet}^{\uparrow}$ *row K, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D before it reaches the target row L and the terminal* $\mathsf{Real}^{\uparrow}$ *seal A.*

Thus the cofinal replay route is the displayed finite chain

$$J, \phi, I, K, S, R, D \longmapsto L \longmapsto A.$$

It exports no quotient-net equality, hidden cofinal choice, selected subnet limit, host real equality, or ambient completeness principle.

Proof. Project the carrier tuple from Definition 1600.1. The target ledger J, map ϕ, source ledger I, source row K, target row L, window row S, readback row R, tolerance row D, and seal row A are all visible coordinates of the same finite packet.

Replay the continuation row C. A target-window request enters through J, follows ϕ into I, reads the source CauchyNet row K, and uses the same S, R, D evidence before producing the target row L.

Transport by H preserves each component of this chain. Since the package and local naming rows cite only the displayed coordinates, the terminal seal A remains downstream of the replay and no absent quotient, choice, limit, equality, or completeness coordinate can be exported. □

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetCofinalReplay`

Theorem 1600.5 (DirectedSubnet target Cauchy window)**.** *Every completion-facing consumer of an accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *packet must expose the target directed ledger J, the cofinal map ϕ, the target* $\mathsf{CauchyNet}^{\uparrow}$ *row L, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{Real}^{\uparrow}$ *seal A, componentwise transport H, displayed replay C, provenance P, and local* $\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}$ *row N before it may read a limit or completion*

endpoint. The target window is therefore a displayed finite CauchyNet route, not a quotient net, selected subnet representative, countable-choice functional, or ambient Real completeness claim.

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetTargetCauchyWindow`

Proof. Project the carrier tuple from Definition 1600.1. The target ledger J, cofinal map ϕ, target row L, window row S, readback row R, tolerance row D, seal row A, and structural rows H, C, P, N are all visible coordinates of the same finite packet.

Apply the CauchyNet handoff of Definition 1600.3. Any read of L must already pass through the target request in J, the displayed map ϕ, the source route, and the same S, R, D evidence that makes the target row Cauchy-facing.

It remains to inspect a completion endpoint. The seal row A is downstream of the target CauchyNet route, while H, C, P, N only transport, replay, cite, and name the displayed coordinates. Hence a completion consumer receives no quotient-net equality, selected subnet representative, countable-choice data, or ambient Real completeness row. □

Theorem 1600.6 (DirectedSubnet target-filter nonescape)**.** *Every target-side Cauchy read exported by an accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *carrier must pass through the displayed source* $\mathsf{CauchyNet}^{\uparrow}$ *row, the cofinal replay row, the target Cauchy window, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame/Cont *transport,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}$ *row. It exports no selected subnet limit, quotient net, cofinal choice outside the displayed map, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetTargetFilterNonescape`

Proof. Start with the carrier of Definition 1600.1. The source CauchyNet row K, target CauchyNet row L, displayed cofinal map ϕ, stream windows S, readback R, tolerance ledger D, seal row A, and structural rows H, C, P, N are visible coordinates of the same packet.

Use the NameCert obligations of Definition 1600.2. They force a target-side read to cite the local naming row only after the carrier rows, transport row, replay row, and provenance row have all been exposed.

Apply the CauchyNet handoff of Definition 1600.3, then the cofinal replay of Definition 1600.4, and finally the target Cauchy window of Definition 1600.5. This route keeps the target read downstream of $K, \phi, L, S, R, D, A, H, C, P, N$, so the packet has no coordinate from which to export a selected subnet limit, quotient net, hidden cofinal choice, or ambient completeness claim. □

Theorem 1600.7 (DirectedSubnet obligation route)**.** *Let* $M = (I, J, \phi, K, L, S, R, D, A, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSubnet}^{\uparrow}$ *packet. Carrier admission, cofinal-map coverage, CauchyNet handoff, Real-seal nonescape, and ledger refusal are all projected from the same finite tuple* M*. Every obligation cites the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of that tuple, and no obligation is delegated to quotient-net equality, hidden cofinal choice, selected subnet limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.DirectedSubnetUp.DirectedSubnetObligationRoute`

Proof. Carrier admission is the projection of Definition 1600.1. The tuple displays the source ledger I, target ledger J, cofinal map ϕ, source and target CauchyNet rows K, L, the stream, readback, tolerance, and seal rows S, R, D, A, and the structural rows H, C, P, N.

Cofinal-map coverage is the same coverage row used by Definition 1600.4. It reads each requested source window through the displayed map $\phi : J \to I$ and never invokes an unseen cofinal selector.

The CauchyNet handoff is exactly the route of Definition 1600.3. A target-window request must expose J, ϕ, I, K, S, R, D before it exports L.

The Real-seal boundary is the target-window route of Definition 1600.5. The seal row A remains downstream of the target CauchyNet route, while H, C, P, N only transport, replay, source, and name the displayed coordinates. Since the refused quotient, choice, limit, equality, and completeness rows are absent from M, ledger refusal is a projection from the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1600.1, Definition 1600.2, Definition 1600.3, Definition 1600.4, Definition 1600.5, and Definition 1600.7 bind the finite carrier to the CauchyNet handoff, cofinal replay, target Cauchy window, target-filter nonescape, and displayed NameCert obligation route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirectedSubnet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected limits, cofinal choice outside the displayed map, host real equality, ambient completeness, or Lean verification.

Upgrade path: Public closure requires checked carrier admission, cofinal-map coverage, CauchyNet handoff, Real-seal non-escape, and ledger refusal for the same finite packet.

Constructive story: A $\mathsf{DirectedSubnet}^{\uparrow}$ packet is generated from source and target directed ledgers, a displayed cofinal map, source and target CauchyNet rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 1601

A Concrete Naming Certificate for $\mathsf{FilterBase}^{\uparrow}$

Following Kelley and Bourbaki on filters and filter bases, the $\mathsf{FilterBase}^{\uparrow}$ packet names the finite directed-base surface that completion routes may consume before any Cauchy specialization is chosen. It sits upstream of the $\mathsf{CauchyFilter}^{\uparrow}$ surface in chapter 333 and gives $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumers a common finite base interface. The packet records displayed base rows, directed lower-bound witnesses, refinement ledgers, transport, replay, provenance, and local naming only; it is not an ultrafilter, not a quotient filter, not a selected limit, and not an ambient completeness principle.

Definition 1601.1 (FilterBase finite carrier)**.** *A* $\mathsf{FilterBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, E, D, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row naming the base packets that may be requested by a downstream filter or completion consumer.*
2. *E is the base-element row. Each entry stores the displayed* BHist *surface for one base packet and the local admissibility read attached to that packet.*
3. *D is the directed lower-bound row. For every two displayed base packets it names a third displayed packet together with the two containment reads back to the requested packets.*
4. *R is the refinement ledger. It records every inclusion, common-refinement, and replay edge used when a consumer narrows one displayed base packet to another.*
5. *H records componentwise* hsame *transport for index rows, base-element rows, lower-bound witnesses, refinement ledgers, continuation rows, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a base request through the selected element, through the directed lower-bound witness, and through the refinement ledger exposed to downstream consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through I, E, D, R, H, C, P, N. There is no coordinate for ultrafilters, Zorn arguments, choice functions, quotient filters, selected limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseTasteGate single carrier alignment`

Theorem 1601.2 (FilterBase NameCert obligations)**.** *For every accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier* $B = (I, E, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FilterBase}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed finite index row, base-element row, directed lower-bound row, refinement ledger, componentwise transport, continuation replay, provenance, and local naming row;*
2. *directedness, requiring each pair of displayed base packets to read a lower-bound witness from D and the two containment reads recorded by R;*
3. *refinement stability, requiring every narrowed base request to remain inside the displayed ledger R after* hsame *transport by H and* Cont *replay by C;*
4. *downstream exposure, requiring every filter or completion consumer to receive only the displayed finite base row I, E, D, R together with its structural rows H, C, P, N;*
5. *ledger refusal, excluding ultrafilters, Zorn arguments, choice functions, quotient filters, selected limits, and ambient completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1601.1. The projection exposes exactly the finite index row, the base-element row, the directed lower-bound row, the refinement ledger, and the structural rows H, C, P, N.

Directedness is the stored row D. A request for two base packets must read the selected lower-bound packet from the same finite carrier and then replay the two containment edges recorded in R.

Refinement stability is componentwise. Transport by H preserves the visible coordinates, while C replays the same base request through the selected element and the refinement ledger.

Finally, the provenance row P and the naming row N name only this carrier. Since ultrafilters, Zorn arguments, choice functions, quotient filters, selected limits, and ambient completeness are not coordinates of B, the local NameCert surface cannot export them. □

Theorem 1601.3 (FilterBase Cauchy-filter and completion handoff)**.** *Let $B = (I, E, D, R, H, C, P, N)$ be an accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer of the base route in chapter 333, chapter 1473, chapter 1506, and chapter 1569 factors through the finite route*

$$I, E, D, R \longmapsto H, C, P, N.$$

Thus completion consumers receive only the displayed finite base surface: base packets, directed lower-bound witnesses, refinement ledgers, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. They do not receive ultrafilters, choice data, quotient filters, selected limits, or ambient completeness.*

Proof. Begin with a downstream request. The carrier gives the consumer access to the base rows only through I and E, so the request first selects displayed base packets rather than an external filter object.

When the consumer needs common refinement, it reads D and the containment rows in R. These rows are finite coordinates of the same packet, and C records the replay route from the requested packets through the displayed lower-bound witness.

Transport and provenance preserve the same boundary. The row H moves the listed coordinates componentwise, while P and N expose the packet to $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ only through the displayed finite route.

No further coordinate remains. Hence the completion-facing handoff supplies a finite base surface, not an ultrafilter, a choice function, a quotient filter, a selected limit, or an ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier cauchyfilter completion handoff`

Theorem 1601.4 (FilterBase directed-refinement coverage)**.** *Let $B = (I, E, D, R, H, C, P, N)$ be an accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier. For every pair of displayed base packets requested through I and E, the directed lower-bound row D and the refinement ledger R expose a third displayed packet whose two containment reads replay through C and remain stable under H. This coverage is internal to the finite* BHist, hsame, Cont, Pkg, *and* NameCert *rows of B; it does not invoke ultrafilters, Zorn arguments, quotient filters, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier directed refinement coverage`

Proof. Start from Definition 1601.1. A request for two displayed base packets is a read through the index row I and base-element row E, so the request has no access to an external filter object.

Apply Definition 1601.2. Its directedness row requires D to name a lower-bound packet and requires R to record the two containment reads back to the requested packets. The replay row C is therefore the only route by which the consumer can inspect the common refinement.

Apply Definition 1601.3 for downstream stability. The same finite route is handed to $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumers, while H transports the listed coordinates componentwise.

Since neither the carrier nor the handoff theorem contains an ultrafilter row, Zorn argument, quotient filter, selected limit, or ambient completeness witness, directed-refinement coverage is exactly the displayed finite lower-bound surface recorded by D, R, H, C, P, N. □

Theorem 1601.5 (FilterBase refinement stability)**.** *Let $B = (I, E, D, R, H, C, P, N)$ be an accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier. Every refinement of a displayed base packet that is admitted through I, E must remain in the same refinement ledger R after componentwise* hsame *transport by H and displayed* Cont *replay by C. The stable refinement read is therefore a finite row of B, not an external inclusion proof, ultrafilter argument, quotient filter, selected limit, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier refinement stability`

Proof. Start from the carrier definition. The only refinement coordinate is R, and every displayed base packet is first read through I and E.

Apply Definition 1601.2. Its refinement-stability obligation requires narrowed base requests to remain inside R after transport and replay. Thus H can only move the listed rows componentwise, while C replays the already displayed refinement route.

Finally apply Definition 1601.4. Directed lower-bound reads also return to the same ledger R, so refinement stability remains internal to the finite carrier and cannot introduce an external filter principle. □

Theorem 1601.6 (FilterBase classifier stability)**.** *If two accepted* $\mathsf{FilterBase}^{\uparrow}$ *carriers agree on* I, E, D, R, H, C, P, N*, then every* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CauchyFilterCompletio}$ *consumer reads the same finite base surface from them. Classifier stability is determined by the displayed index, base-element, directed lower-bound, refinement, transport, replay, provenance, and naming rows; no hidden completion row or quotient filter can alter the comparison.*

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier classifier stability`

Proof. Use Definition 1601.1 to inspect the classifier. It compares accepted packets only through I, E, D, R, H, C, P, N.

Apply Definition 1601.3. Downstream consumers for $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ receive exactly the same displayed finite route.

The refinement-stability theorem keeps narrowed requests inside R under H and C. Therefore agreement on the carrier rows is enough to preserve every classifier read visible to the listed consumers. □

Theorem 1601.7 (FilterBase completion branch coverage)**.** *Every completion-facing branch that consumes an accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier factors through the same finite base route before reaching* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$*. The branch may use displayed base packets, directed lower-bound witnesses, and refinement ledgers, but it receives no selected limit, quotient filter, ultrafilter, Zorn argument, or ambient completeness datum from the carrier.*

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier completion branch coverage`

Proof. Begin with a completion-facing request. By Definition 1601.3, the request is routed through I, E, D, R and then through H, C, P, N before any sibling completion chapter can consume it.

Directed-refinement coverage supplies the common lower-bound witness needed by the branch. It reads that witness from D and the two containment routes from R, with replay through C.

Refinement stability keeps subsequent narrowing inside the same finite ledger. Hence the branch coverage is exactly the displayed filter-base surface shared by the Cauchy-filter and completion siblings. □

Theorem 1601.8 (FilterBase ledger refusal)**.** *For every accepted* $\mathsf{FilterBase}^{\uparrow}$ *carrier* $B = (I, E, D, R, H, C, P, N)$*, the refinement ledger* R *refuses to act as an ultrafilter ledger, a choice-function ledger, a quotient-filter ledger, a selected-limit ledger, or an ambient-completeness ledger. Any consumer that asks for one of those rows receives only the displayed finite base route and the explicit absence of such a coordinate.*

Lean4 ✓ `BEDC.Derived.FilterBaseUp.FilterBaseCarrier ledger refusal`

Proof. Project the carrier rows from Definition 1601.1. The row list contains finite indices, base elements, directed lower-bound witnesses, refinement ledgers, transport, replay, provenance, and local naming only.

Use the ledger-refusal obligation in Definition 1601.2. It excludes ultrafilters, Zorn arguments, choice functions, quotient filters, selected limits, and ambient completeness from the local $\mathsf{NameCert}$ surface.

The handoff and completion-coverage theorems do not add a new coordinate. They only expose the same finite route to $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$, so the refusal remains visible to every downstream consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{FilterBase}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterBase}^{\uparrow}$ packet is generated from finite base rows, directed lower-bound witnesses, refinement ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterBase}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1601.2, Definition 1601.3, Definition 1601.4, Definition 1601.5, Definition 1601.6, Definition 1601.7, and Definition 1601.8 bind the directed-refinement, classifier-stability, completion-branch, and ledger-refusal obligations to the finite BHist, hsame, Cont, Pkg, and NameCert rows, with Definition 1601.3 and Definition 1601.7 giving the bridge surface to $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterBase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilters, Zorn arguments, choice, quotient filters, selected limits, Lean verification, bridge checking, or ambient completeness.

Upgrade path: No paper-side theory upgrade remains; Lean verification and bridge checking remain separate verification-axis work.

Chapter 1602

A Concrete Naming Certificate for $\mathsf{BaireMetric}^{\uparrow}$

Following Brouwer's finite-prefix presentation of choice sequences, the Bishop–Bridges metric treatment of countable product spaces, and Kelley's prefix topology, the $\mathsf{BaireMetric}^{\uparrow}$ packet records the standard prefix ultrametric on $\mathsf{BaireSpace}^{\uparrow}$ as finite BEDC rows. It sits between the prefix carrier of chapter 334, the metric parent surface of chapter 57, and the strong-triangle interface of chapter 1535. The packet names only displayed first-disagreement windows, dyadic radius comparisons, stream-name schedules, transport, replay, provenance, and a local certificate; it does not import completed streams, quotient equality of infinite names, real-valued host metrics, or external topology.

Definition 1602.1 (BaireMetric prefix-distance carrier)**.** *A* $\mathsf{BaireMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, W, D, R, U, S, H, C, P, N)$$

over $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{UltrametricSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *with the following displayed rows:*

1. *B is the accepted* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet whose finite stream windows supply the two names under comparison.*
2. *W is the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window. It records the inspected prefix length, the equality rows below that length, and the first displayed coordinate where the two prefix windows separate, when such a coordinate is present.*
3. *D is the dyadic radius row. It records the radius 2^{-k} attached to the first displayed disagreement at k, together with the zero-radius branch for displayed equality across the inspected window.*
4. *R is the parent* $\mathsf{Met}^{\uparrow}$ *row that reads the displayed point names, zero-distance boundary, symmetry row, and ordinary triangle route from B, W, D.*
5. *U is the* $\mathsf{UltrametricSpace}^{\uparrow}$ *witness whose strong max-radius comparison is read from the same first-disagreement window and dyadic radius row.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule controlling which finite prefixes of the two Baire names may be inspected by a consumer.*
7. *H records componentwise* hsame *transport for the BaireSpace row, Nat window, dyadic radius row, parent metric row, ultrametric witness, stream schedule, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a requested prefix comparison through S, then through B, W, D, and only then into the parent metric row R and ultrametric witness U.*
9. *P is the* Pkg *provenance over the listed BEDC dependencies.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireMetric}^{\uparrow}}$ *row.*

The classifier accepts the packet only when every distance comparison is read through the displayed first-disagreement window and dyadic radius row. It has no coordinate for a completed infinite stream, a quotient of Baire names, a host real-valued distance function, countable choice, or an external topological space.

Theorem 1602.2 (BaireMetric NameCert obligations)**.** *For every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier $M = (B, W, D, R, U, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireMetric}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed BaireSpace prefix packet, Nat first-disagreement window, dyadic radius row, parent MetricSpace row, UltrametricSpace witness, StreamName schedule, transport, replay, provenance, and local naming rows;*
2. *prefix-distance admission, requiring every positive radius claim to name the first displayed disagreement in W and every zero-radius claim to remain inside the inspected equality window;*
3. *metric compatibility, requiring the parent* $\mathsf{Met}^{\uparrow}$ *row R to read zero-distance, symmetry, and ordinary triangle evidence only from B, W, D;*
4. *ultrametric compatibility, requiring the witness U to read its strong max-radius comparison from the same first-disagreement and dyadic-radius rows;*
5. *ledger refusal, excluding completed streams, quotient equality of Baire names, host real-valued metrics, countable-choice selectors, and external topology.*

No obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricNamecertObligations`

Proof. Carrier admission is projection from Definition 1602.1. The tuple lists exactly the BaireSpace prefix packet, first-disagreement window, dyadic radius row, parent metric row, ultrametric witness, stream schedule, transport, continuation, provenance, and local name.

Prefix-distance admission is read from W and D. A positive comparison names the least displayed coordinate where the two scheduled prefixes disagree, while the zero-radius branch records only equality across the inspected finite window.

Metric compatibility is then replayed through R. The zero-distance boundary, symmetry row, and ordinary triangle route do not inspect a separate distance function; they use the same prefix windows and dyadic radius comparisons already displayed by B, W, D.

Ultrametric compatibility is read from U. Since the controlling radius is determined by the earliest displayed disagreement, the strong max-radius comparison factors through the same window and cannot bypass the dyadic ledger.

The structural rows H, C, P, N transport, replay, source, and name only those coordinates. Hence no completed stream, quotient equality of infinite names, host real metric, countable-choice selector, or external topological datum can appear as a NameCert obligation. □

Theorem 1602.3 (BaireMetric root observation carrier)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *root packet. Every root observation of M is carried by finite* BHist

prefix windows: the consumer first reads the $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, then the displayed prefix packet* B*, the finite first-disagreement window* W*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* D*, before any* $\mathsf{Met}^{\uparrow}$ *row* R*,* $\mathsf{UltrametricSpace}^{\uparrow}$ *row* U*,* hsame *transport* H*,* Cont *replay* C*, provenance row* P*, or local* NameCert *row* N *is available. No root observation asserts equality of completed streams.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier root observation`

Proof. Project the accepted carrier of Definition 1602.1. The only observation source is the finite prefix surface S, B, W, D, with W recording inspected BHist prefix data and the displayed first-disagreement branch.

The parent $\mathsf{Met}^{\uparrow}$ and $\mathsf{UltrametricSpace}^{\uparrow}$ rows are downstream of that prefix surface. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so a root observation has no coordinate from which to read completed-stream equality. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootObservationCarrier`

Theorem 1602.4 (BaireMetric ultrametric window stability)**.** *For an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, extending a scheduled finite* BHist *prefix window through the same* $\mathsf{StreamName}^{\uparrow}$ *row preserves the ultrametric comparison route. The* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row remains read from the displayed first-disagreement window, the parent* $\mathsf{Met}^{\uparrow}$ *row* R *and* $\mathsf{UltrametricSpace}^{\uparrow}$ *row* U *consume that same radius data, and* hsame *transport with* Cont *replay preserves the local* NameCert *surface. The extension never supplies a completed-stream equality claim.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier ultrametric window stability`

Proof. Start with a scheduled prefix read. By Definition 1602.3, the read exposes only the finite window route S, B, W, D before the parent metric and ultrametric rows are consumed.

When the window is extended through the same schedule, the displayed first-disagreement branch is either preserved or moved to a later inspected coordinate. In both cases the dyadic radius is still read from D and from no other source.

The rows R and U consume that radius after the prefix window has been displayed. Componentwise hsame transport and Cont replay keep the route on the same carrier coordinates, while the local NameCert row names only that finite surface. □

Theorem 1602.5 (BaireMetric NameCert obligation surface)**.** *Every root-level* $\mathsf{NameCert}_{\mathsf{BaireMetric}^{\uparrow}}$ *obligation for an accepted packet* $M = (B, W, D, R, U, S, H, C, P, N)$ *is exhausted by finite* BHist *prefix-window admission,* $\mathsf{StreamName}^{\uparrow}$ *scheduling,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius exactness, parent* $\mathsf{Met}^{\uparrow}$ *compatibility,* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No additional obligation asserts completed-stream equality, quotient equality of Baire names, a host real-valued metric, or external topology.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricNamecertObligationSurface`

Proof. Apply the NameCert obligations of Definition 1602.2. The carrier admission, prefix-distance admission, metric compatibility, ultrametric compatibility, and ledger refusal rows list the entire obligation surface.

Use Definition 1602.3 to identify the root observation source with finite BHist prefix windows scheduled by $\mathsf{StreamName}^{\uparrow}$ and measured by the $\mathsf{DyadicRatCore}^{\uparrow}$ row. Then use Definition 1602.4 to keep parent metric and ultrametric consumers on the same finite route under window extension.

The remaining rows are structural: hsame transports the displayed coordinates, Cont replays them, Pkg records provenance, and the local NameCert row names them. Since the carrier has no other coordinate, completed-stream equality and external metric data are outside the obligation surface. □

Theorem 1602.6 (BaireMetric prefix-window admission)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* BaireMetric$^{\uparrow}$ *carrier. Every accepted distance read admits a finite prefix window: before the dyadic radius row is inspected, the continuation row displays a* StreamName$^{\uparrow}$ *schedule S, an accepted* BaireSpace$^{\uparrow}$ *prefix packet B, and a* Nat$^{\uparrow}$ *window W that records the inspected length and the equality rows below the first displayed separation.*

Proof. Project the carrier of Definition 1602.1. The continuation row C routes every comparison through the stream schedule S and the BaireSpace prefix packet B before reaching any radius coordinate.

The window row W is the only Nat-valued inspection coordinate in the carrier. Thus the accepted comparison must name the inspected finite length and the displayed equality rows below any first disagreement before D, R, or U can be read. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier prefix window admission`

Theorem 1602.7 (BaireMetric ultrametric window obligations)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* BaireMetric$^{\uparrow}$ *carrier. The ultrametric strong-triangle obligation is admitted only after the finite* StreamName$^{\uparrow}$ *schedule S has exposed the prefix packet B and the first-disagreement window W before dyadic radius inspection. The witness U must read the same W, D branch as the parent metric row R, so its max-radius comparison cannot be replaced by completed-stream equality, quotient names, or an external topology.*

Proof. Use Definition 1602.6. Every accepted comparison first exposes the schedule, prefix packet, and Nat window, so the dyadic row is not available before a finite first-disagreement read.

Apply Definition 1602.13. The row D is exact for the branch named by W, including the zero branch where the read remains inside finite inspected equality.

Finally apply Definition 1602.21. The ultrametric row U is downstream of S, B, W, D, R and therefore reads the same finite radius data as R. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricUltrametricWindowObligations`

Theorem 1602.8 (BaireMetric complete-metric handoff)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* BaireMetric$^{\uparrow}$ *carrier. A* CompleteMetric$^{\uparrow}$ *consumer can read M only as the finite prefix-window surface*

$$S, B, W, D, R, U, H, C, P, N.$$

The handoff exposes scheduled prefix agreement, first-disagreement radii, parent metric compatibility, and ultrametric strong-triangle data, but it does not expose a completed stream, quotient of Baire names, host real-valued metric, or countable-choice selector.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier complete metric handoff`

Proof. Start with the finite schedule supplied by Definition 1602.6. The consumer receives S, B, W before any dyadic or metric conclusion is public.

Use Definition 1602.20 and Definition 1602.7. These route R and U through the same displayed first-disagreement and dyadic-radius rows.

The structural rows H, C, P, N transport, replay, source, and name exactly that route. Since the carrier has no coordinate outside the row family displayed in the statement, the complete-metric handoff remains finite prefix-window data. □

Theorem 1602.9 (BaireMetric obligation prefix completeness)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Every completeness-facing root obligation begins with a finite* $\mathsf{StreamName}^{\uparrow}$ *schedule S and a* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet B; it may inspect only the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window W and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row D before the parent* $\mathsf{Met}^{\uparrow}$ *row R is read. Thus a Cauchy or completeness consumer receives prefix completeness as displayed finite schedules and dyadic radius rows, not as completed streams, quotient equality of Baire names, or an ambient real-valued metric.*

Proof. Start with Definition 1602.8. It identifies the complete-metric consumer surface with the finite route $S, B, W, D, R, U, H, C, P, N$.

Use Definition 1602.6 and Definition 1602.13. The schedule and prefix packet display the inspected window, and the dyadic radius row is exact for that finite first-disagreement branch before the metric row is available.

The remaining rows U, H, C, P, N are downstream structural or ultrametric rows. Since no carrier coordinate stores completed streams or quotient equality, the prefix-completeness obligation is exhausted by the finite schedule, BaireSpace prefix packet, Nat window, and DyadicRatCore radius data. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier obligation prefix completeness`

Theorem 1602.10 (BaireMetric obligation ultrametric limit route)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Any ultrametric limit route exposed by M must keep each requested limit window on a finite* $\mathsf{StreamName}^{\uparrow}$ *schedule, a* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet, a* $\mathsf{Nat}^{\uparrow}$ *first-disagreement or equality window, and the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row before it reaches R and U. The route is a finite sequence of displayed prefix-radius obligations, not a completed-stream object, quotient equality class, selected limit, or external topology.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier obligation ultrametric limit route`

Proof. Read the requested limit route as a family of finite distance comparisons. By Definition 1602.33, each displayed radius request determines a prefix thread through S, B, W, D.

Apply Definition 1602.7. The ultrametric strong-triangle row U consumes the same first-disagreement and dyadic-radius branch as the parent metric row R, so no separate limit coordinate can bypass the finite windows.

Finally use Definition 1602.29. It packages the consumer surface through R, U, H, C, P, N after the finite prefix-radius route, excluding completed streams, quotient names, selected limits, countable choice, and external topology. □

Theorem 1602.11 (BaireMetric obligation complete-metric consumer)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. A* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *consumer that reads a completeness obligation from M must first display the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet,* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, then read the parent* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{UltrametricSpace}^{\uparrow}$ *handoff rows R, U, and only afterward pass through H, C, P, N. The consumer-facing obligation therefore contains no completed stream, quotient equality of names, host real metric, countable-choice selector, or external completeness theorem.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricObligationCompleteMetricConsumer`
↪ variant `BEDC.Derived.BaireMetricUp.BaireMetricCarrier obligation complete metric consumer`

Proof. Begin with prefix completeness, Definition 1602.9. It fixes the first four analytic rows available to a completeness consumer as S, B, W, D.

Next apply the ultrametric limit route theorem, Definition 1602.10. The parent metric and ultrametric rows are downstream of the same finite first-disagreement and dyadic-radius data, so the consumer cannot replace them by completed-stream equality or a selected limit.

Finally use Definition 1602.8. The structural rows H, C, P, N transport, replay, source, and name exactly the displayed route. Since the accepted carrier has no coordinate beyond $B, W, D, R, U, S, H, C, P, N$, the complete-metric consumer obligation is exactly the finite BEDC surface listed in the statement. □

Theorem 1602.12 (BaireMetric StreamName NameCert scope)**.** *For every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S *controls the local* $\mathsf{NameCert}_{\mathsf{BaireMetric}^{\uparrow}}$ *scope: every distance, ultrametric, or complete-metric read must pass through* S *before* $B, W, D, R, U, H, C, P, N$ *are inspected. Thus the certificate scope is a scheduled finite-prefix surface, not an equality theory of completed Baire names.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricStreamNameNameCertScope`

Proof. Project the carrier of Definition 1602.1. The schedule row is the only coordinate authorizing finite prefix inspection by a consumer.

Apply Definition 1602.22. It blocks every distance, metric, and ultrametric conclusion that tries to bypass the displayed schedule.

Then use Definition 1602.8. The complete-metric consumer receives only the scheduled finite row family, so the local NameCert scope contains no completed-stream equality route. □

Theorem 1602.13 (BaireMetric first-disagreement dyadic exactness)**.** *For an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, the dyadic radius row* D *is exact for the displayed first-disagreement window. If* W *records first disagreement at* k*, then* D *records the radius branch* 2^{-k}*; if* W *records only displayed equality across the inspected window, then* D *records the zero-radius branch for that finite read. No other radius source is available to the packet.*

Proof. The carrier admits dyadic radius data only through the row D. The row is downstream of S, B, W, so its positive branch is read from the first displayed disagreement already named by W.

In the equality branch, W exposes only the inspected finite equality window. The corresponding radius branch in D is therefore the displayed zero-radius read for that window, not a claim about completed infinite stream equality.

Because R and U are downstream consumers of D, neither can introduce an independent radius value. Exactness is consequently a projection of the single dyadic row attached to the first-disagreement window. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricFirstDisagreementDyadicRadiusExactness`

Theorem 1602.14 (BaireMetric prefix radius monotonicity)**.** *Let* $M = (B, W, D, R, U, S, H, C, P, N)$ *be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Extending the displayed inspected prefix through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule can only preserve the dyadic radius branch already read from* W, D *or move it to a smaller displayed dyadic branch. The extension cannot replace the first-disagreement route by a larger radius, a host metric, or a completed-stream comparison.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier prefix radius monotonicity`

Proof. Use carrier admission from Definition 1602.1 and the NameCert obligations of Definition 1602.2. Every distance read is routed through the scheduled prefix packet S, B and the finite window W before the dyadic row D is inspected.

By prefix-window admission in Definition 1602.6, an extended read only adds inspected coordinates after the displayed window already exposed. If the earlier first disagreement remains visible, first-disagreement exactness in Definition 1602.13 keeps the same 2^{-k} branch.

If the extension exposes a later first displayed disagreement after an equality branch, the dyadic branch read from D moves to that later index and is therefore no larger than the previous displayed prefix bound. Since R and U consume the same D row, no downstream metric or ultrametric consumer can enlarge the radius. □

Theorem 1602.15 (BaireMetric root ultrametric cylinder carrier)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *root carrier. The root cylinder surface of M is the finite* BHist *route in which the* $\mathsf{StreamName}^{\uparrow}$ *schedule S reads the prefix packet B, the first-disagreement window W reads that scheduled prefix, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row D reads W, the parent* $\mathsf{Met}^{\uparrow}$ *row R reads D, and the* $\mathsf{UltrametricSpace}^{\uparrow}$ *row U reads the same radius before the structural rows* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *are exposed through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootUltrametricCylinderCarrier`

Proof. Project the carrier of Definition 1602.1. The tuple $M = (B, W, D, R, U, S, H, C, P, N)$ lists the prefix packet, finite window, dyadic radius, metric handoff, ultrametric handoff, stream schedule, transport, replay, provenance, and local naming rows as the only available coordinates.

Use prefix-window admission and prefix radius monotonicity. Together they force every root cylinder read to pass through S, B, W, D before R or U can be consumed, and they keep every extension of the cylinder inside the same finite prefix schedule.

Finally read the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve the same order, so no root cylinder carrier can replace the displayed BHist packet by completed streams, quotient names, or a host metric. □

Theorem 1602.16 (BaireMetric root complete-metric nonescape)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *root carrier. Any* $\mathsf{CompleteMetric}^{\uparrow}$*-facing read from M must remain inside the displayed* BHist *route*

$$S, B, W, D, R, U, H, C, P, N.$$

It reads $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UltrametricSpace}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows from that tuple, and it has no coordinate for completed Baire streams, host completeness, quotient equality, or countable-choice selectors.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier root complete metric nonescape`

Proof. Start from a complete-metric handoff request. Carrier projection leaves only the tuple $M = (B, W, D, R, U, S, H, C, P, N)$, so every requested metric or completeness-facing row must be replayed through those displayed coordinates.

Apply Definition 1602.15. It routes the request through the $\mathsf{StreamName}^{\uparrow}$ schedule, finite prefix packet, first-disagreement window, $\mathsf{DyadicRatCore}^{\uparrow}$ radius, parent $\mathsf{Met}^{\uparrow}$ handoff, and $\mathsf{UltrametricSpace}^{\uparrow}$ strong-triangle row before any structural row is exported.

The structural rows H, C, P, N then preserve and name the same finite BHist route through hsame, Cont, Pkg, and NameCert. Since no coordinate outside the tuple is available, the complete-metric consumer cannot escape to completed streams, host completeness, quotient equality, or countable choice. □

Theorem 1602.17 (BaireMetric root StreamName prefix route)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* BaireMetric$^{\uparrow}$ *root carrier. Every root prefix read begins with the* StreamName$^{\uparrow}$ *schedule S and then consumes $B, W, D, R, U, H, C, P, N$ in the displayed* BHist *route. In particular, the* DyadicRatCore$^{\uparrow}$*,* Met$^{\uparrow}$*,* UltrametricSpace$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows are downstream of that scheduled prefix read, not independent root data.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootStreamNamePrefixRoute`

Proof. Read the prefix request through the tuple $M = (B, W, D, R, U, S, H, C, P, N)$. The schedule row S is the only row that can select finite prefixes before the Baire prefix packet B and first-disagreement window W are inspected.

Use Definition 1602.6 and Definition 1602.13. They place D after the scheduled window and ensure that each radius branch is read from the displayed finite prefix evidence.

Then apply Definition 1602.15. The parent Met$^{\uparrow}$ row R, UltrametricSpace$^{\uparrow}$ row U, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row are all downstream of the scheduled prefix route, so none can introduce an unscheduled prefix comparison. □

Theorem 1602.18 (BaireMetric zero-radius branch confinement)**.** *For an accepted* BaireMetric$^{\uparrow}$ *carrier $M = (B, W, D, R, U, S, H, C, P, N)$, the zero-radius branch of D is confined to displayed finite inspected-window equality. It is never a quotient equality of completed Baire streams, a global extensional equality theorem, or an ambient topological identification.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricZeroRadiusBranch`

Proof. Project the zero branch through the carrier of Definition 1602.1. The only equality evidence before D is the displayed finite equality row in W, scheduled by S and admitted through B.

Apply the NameCert obligations of Definition 1602.2. The prefix-distance row requires every zero-radius read to remain inside the inspected equality window, and the ledger-refusal row excludes completed streams, quotient equality of Baire names, host real metrics, and external topology.

Finally use Definition 1602.13. Its equality branch identifies the zero-radius read with that finite window alone. Transport by H and replay by C preserve the same row family and cannot turn finite inspected equality into equality of completed streams. □

Theorem 1602.19 (BaireMetric prefix radius transport)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ and $M' = (B', W', D', R', U', S', H', C', P', N')$ be accepted* BaireMetric$^{\uparrow}$ *carriers. If componentwise* hsame *transports the displayed Baire prefix packets, stream schedules, first-disagreement windows, dyadic rows, parent metric rows, ultrametric rows, provenance, and local names, and the displayed* Cont *replay preserves the prefix-read order, then M' exposes the same route*

$$S, B, W, D, R, U$$

as M for every accepted prefix-radius read.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricPrefixRadiusTransport`

Proof. Start from the accepted read in M. Prefix-window admission supplies the schedule, prefix packet, first-disagreement window, and dyadic row before any parent metric or ultrametric row is consumed.

Transport each displayed coordinate through the componentwise hsame rows recorded in H and H'. The carrier definition gives matching coordinates S', B', W', D', R', U' and the NameCert obligations require those coordinates to remain the only distance, metric, and ultrametric sources.

Replay the transported read through C'. First-disagreement exactness then reads D' from the transported W' branch, while the parent handoff and ultrametric handoff consume R' and U' downstream of that same branch. Thus the transported packet preserves the route and admits no alternate radius source. □

Theorem 1602.20 (BaireMetric parent MetricSpace handoff)**.** *Every parent* $\mathsf{Met}^{\uparrow}$ *read exported by an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *packet factors through*

$$S, B, W, D \longmapsto R.$$

The zero-distance boundary, symmetry row, and ordinary triangle route in R may read only the scheduled prefix packet, first-disagreement window, and dyadic radius row.

Proof. Start with a parent metric read. Carrier admission exposes the parent row only as R, and the definition places R downstream of the scheduled prefix and dyadic comparison rows.

The zero-distance, symmetry, and ordinary triangle components of R therefore receive their data from S, B, W, D. Componentwise transport by H and replay by C preserve this order, so the handoff cannot inspect a host metric on completed streams. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier parent metricspace handoff`

Theorem 1602.21 (BaireMetric UltrametricSpace strong-triangle handoff)**.** *Every* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle read exported by an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier factors through the same first-disagreement and dyadic-radius rows used by the parent metric handoff:*

$$S, B, W, D, R \longmapsto U.$$

The strong max-radius comparison is a finite prefix-window comparison, not a separate topology or completed-stream theorem.

Proof. The ultrametric witness appears in the carrier only as U. It is listed after the scheduled prefix packet, first-disagreement window, dyadic radius row, and parent metric row.

Thus a strong-triangle read must first replay the finite prefix comparisons through S, B, W, D and the parent handoff R. The row U then packages the max-radius comparison over those displayed radii, with no coordinate for external topology or completed Baire names. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricUltrametricSpaceStrongTriangleHandoff`

Theorem 1602.22 (BaireMetric stream-schedule nonescape)**.** *For every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier $M = (B, W, D, R, U, S, H, C, P, N)$, a consumer cannot read a distance, metric, or ultrametric conclusion outside the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule. Every such conclusion is replayed by C through S before it reaches $B, W, D, R,$ or U.*

Proof. The stream schedule S is the carrier coordinate controlling which finite prefixes may be inspected. The continuation row C names the replay order from a requested comparison through S before any BaireSpace, window, radius, metric, or ultrametric row is consumed.

Transport, provenance, and local naming preserve that replay order. Consequently a consumer has no slot from which to read an unscheduled prefix, completed stream, quotient equality of names, or external topological neighborhood. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricStreamScheduleNonescape`

Theorem 1602.23 (BaireMetric ultrametric prefix route)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *packet. Every accepted prefix-distance comparison exported by M factors through the displayed route*

$$B, S, W, D, R, U.$$

Equivalently, a consumer reads first the $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet, then the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the parent* $\mathsf{Met}^{\uparrow}$ *row, and finally the* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle witness. The route is a finite BEDC replay over prefix rows, not a host metric on completed streams.*

Proof. Start with an accepted prefix-distance comparison exported by M. Carrier admission exposes the comparison only through the coordinates B, S, W, D, R, U together with the structural rows.

The continuation row C first schedules finite prefix reads through S and then reads the accepted $\mathsf{BaireSpace}^{\uparrow}$ packet B. The $\mathsf{Nat}^{\uparrow}$ window W records how far the comparison has inspected the two prefixes and, when the positive branch is taken, which displayed coordinate is the first disagreement.

The dyadic radius row D converts that window into the displayed radius comparison. The parent $\mathsf{Met}^{\uparrow}$ row R receives only this radius evidence when supplying zero-distance, symmetry, and ordinary triangle data.

Finally the $\mathsf{UltrametricSpace}^{\uparrow}$ witness U reads the same first-disagreement and radius rows to supply the strong max-radius route. Componentwise transport by H and provenance by P preserve this order, so no consumer-facing path bypasses the displayed BaireSpace, Nat, StreamName, DyadicRatCore, MetricSpace, and UltrametricSpace rows. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCarrier ultrametric prefix route`

Theorem 1602.24 (BaireMetric complete-ultrametric consumer readiness)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *packet. Every* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{UltrametricSpace}^{\uparrow}$*, or* $\mathsf{BaireSpace}^{\uparrow}$ *consumer of M must first read the displayed route*

$$S, B, W, D, R, U, H, C, P, N.$$

The route schedules $\mathsf{StreamName}^{\uparrow}$ *reads before* $\mathsf{BaireSpace}^{\uparrow}$ *prefix rows, reads the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window before the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, reads the parent* $\mathsf{Met}^{\uparrow}$ *row before the* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle row, and reads transport, replay, provenance, and local naming before exporting any consumer-facing conclusion.*

Proof. Apply Definition 1602.6. It places the $\mathsf{StreamName}^{\uparrow}$ schedule S before the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet B and the $\mathsf{Nat}^{\uparrow}$ first-disagreement window W for every accepted distance read.

Apply Definition 1602.13. The dyadic radius row D is read only after the displayed first-disagreement window, so a downstream consumer cannot obtain a radius without the finite prefix-window evidence.

Apply Definition 1602.20 and Definition 1602.21. They order the parent $\mathsf{Met}^{\uparrow}$ row R before the $\mathsf{UltrametricSpace}^{\uparrow}$ strong-triangle row U, with both rows using the same scheduled prefix, window, and radius data.

Finally apply Definition 1602.23. It records that the consumer-facing prefix-distance route is finite and that componentwise transport H, replay C, provenance P, and local naming N preserve the same order before any $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{UltrametricSpace}^{\uparrow}$, or $\mathsf{BaireSpace}^{\uparrow}$ conclusion is exported. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCompleteUltrametricConsumerReadiness`

Theorem 1602.25 (BaireMetric root prefix schedule)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted $\mathsf{BaireMetric}^{\uparrow}$ root packet. The first read of the root packet exposes the finite prefix schedule*

$$S, B, W, D.$$

Thus the consumer first reads the $\mathsf{StreamName}^{\uparrow}$ schedule row S, the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet B, the $\mathsf{Nat}^{\uparrow}$ first-disagreement window W, and the $\mathsf{DyadicRatCore}^{\uparrow}$ radius row D before it may inspect the parent metric row, the strong-triangle row, transport, replay, provenance, or local naming.

Proof. Apply Definition 1602.6. It places every accepted distance read behind the $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, and the finite first-disagreement window.

Apply Definition 1602.13. The dyadic radius row is determined only after that window is available, including the zero branch where the inspected prefixes remain equal on the displayed finite window.

Finally use Definition 1602.24. The complete-ultrametric route keeps the same prefix schedule as the initial root read and admits no earlier access to the metric, ultrametric, transport, replay, provenance, or local naming rows. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootPrefixSchedule`

Theorem 1602.26 (BaireMetric root strong-triangle route)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted $\mathsf{BaireMetric}^{\uparrow}$ root packet. Every $\mathsf{UltrametricSpace}^{\uparrow}$ consumer of the strong-triangle row U must first read the same finite prefix route*

$$S, B, W, D, R.$$

Only after this route has supplied the stream schedule, Baire prefix packet, Nat first-disagreement window, dyadic radius row, and parent metric row may the consumer read U as the strong-triangle witness.

Proof. Apply Definition 1602.25. It fixes the initial root read as the finite S, B, W, D schedule, so the strong-triangle consumer cannot start from completed streams, quotient names, or an external topology.

Next apply Definition 1602.20. The parent metric row R receives exactly the scheduled prefix, first-disagreement, and dyadic-radius data before exporting ordinary metric compatibility.

Finally apply Definition 1602.21. The strong-triangle row U reads the same finite prefix and radius route after R, so the ultrametric consumer cannot replace the displayed root schedule by a separate strong-triangle path. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootStrongTriangleRoute`

Theorem 1602.27 (BaireMetric root prefix ultrametric package)**.** *Every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *root package exposes exactly the route through* $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and* $\mathsf{UltrametricSpace}^{\uparrow}$, *together with the structural rows* BHist, hsame, Cont, Pkg, *and* NameCert, *before any PolishSpace, BaireSpace, or ultrametric consumer reads it. In the notation of Definition 1602.1, the package surface is the finite row family*

$$B, S, W, D, R, U, H, C, P, N.$$

No consumer-facing read may replace this row family by completed streams, quotient equality of names, host real metrics, countable choice, or external topology.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricRootPrefixUltrametricPackage`

Proof. Apply Definition 1602.6. It forces every distance read to expose the $\mathsf{StreamName}^{\uparrow}$ schedule S, the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet B, and the $\mathsf{Nat}^{\uparrow}$ first-disagreement window W before any radius or metric row is inspected.

Apply Definition 1602.13. The dyadic radius row D is then determined by the displayed first-disagreement window, with the zero-radius branch remaining inside the inspected finite equality window.

Apply Definition 1602.20 and Definition 1602.21. The parent $\mathsf{Met}^{\uparrow}$ row R and the $\mathsf{UltrametricSpace}^{\uparrow}$ row U both read the same scheduled prefix, window, and dyadic-radius data.

Finally use Definition 1602.22 and Definition 1602.23. They place every metric, ultrametric, PolishSpace, BaireSpace, or downstream prefix consumer behind the same replay row C, with componentwise transport H, provenance P, and local naming N. Since the carrier has no coordinate for completed streams, quotient equality of names, host real metrics, countable choice, or external topology, the displayed root package is the whole exported surface. □

Theorem 1602.28 (BaireMetric StreamName ultrametric obligation)**.** *Let* $M = (B, W, D, R, U, S, H, C, P, N)$ *be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Every consumer that reads a complete-ultrametric or* $\mathsf{BaireSpace}^{\uparrow}$ *conclusion from* M *must first consume the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet* B*, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* D*, the parent* $\mathsf{Met}^{\uparrow}$ *row* R*, the* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle witness* U*, and the structural rows* H, C, P, N *for* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming. Consequently the obligation surface is the finite route*

$$S, B, W, D, R, U, H, C, P, N,$$

and it exports no completed streams, quotient names, host real metric, countable choice, or external topology.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricStreamNameUltrametricObligation`

Proof. Apply Definition 1602.6. It places every distance read behind the displayed $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, and the finite first-disagreement window.

Apply Definition 1602.13. The dyadic radius row is therefore read from the finite window, with the zero branch remaining inside inspected prefix equality.

Next use Definition 1602.20 and Definition 1602.21. The parent metric row and the strong-triangle witness consume the same schedule, prefix packet, window, and dyadic radius data.

Finally apply Definition 1602.27. It packages exactly the displayed route with componentwise transport, replay, provenance, and local naming. Since no carrier coordinate supplies completed streams, quotient names, host real metrics, countable choice, or external topology, no complete-ultrametric or BaireSpace consumer can read such data from M. □

Theorem 1602.29 (BaireMetric complete-ultrametric consumer obligations)**.** *Let $M = (B, W, D, R, U, S, H, C, P,$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Every complete ultrametric consumer of M must display the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet B,* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{Nat}^{\uparrow}$ *first-disagreement window W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row D, parent* $\mathsf{Met}^{\uparrow}$ *row R,* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle row U, transport row H, replay row C, provenance row P, and local naming row N before it may read a* $\mathsf{CompleteMetric}^{\uparrow}$ *conclusion. No complete-ultrametric obligation is stored outside this row family.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCompleteUltrametricConsumerObligations`

Proof. Project the carrier. The rows $B, W, D, R, U, S, H, C, P, N$ are the only displayed coordinates available to a complete-ultrametric consumer.

Apply Definition 1602.6 and Definition 1602.13. They force every distance read through the stream schedule, Baire prefix packet, finite Nat window, and dyadic radius row.

Apply Definition 1602.21 and Definition 1602.28. The first theorem orders the strong-triangle row after the same prefix and radius data, while the second packages the complete-ultrametric consumer surface with the structural transport, replay, provenance, and local naming rows. □

Theorem 1602.30 (BaireMetric Cauchy-window completeness handoff)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Any* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff read from M receives its Cauchy-window evidence only through the finite prefix route*

$$S, B, W, D, R, U, H, C, P, N.$$

Thus completeness consumers may replay finite prefix agreement and dyadic-radius decay, but they cannot read completed streams, quotient names, host real metrics, or countable-choice selectors from the carrier.

Proof. Start from a handoff request to $\mathsf{CompleteMetric}^{\uparrow}$. Carrier projection leaves only the displayed prefix, window, radius, parent metric, ultrametric, and structural rows.

Use Definition 1602.25. It fixes the initial Cauchy-window read as the finite S, B, W, D route, so the handoff cannot begin from a completed stream.

Next apply Definition 1602.20 and Definition 1602.21. They pass the same window and radius data through R and U before any completeness-facing metric conclusion is exposed.

Finally use Definition 1602.29. The structural rows H, C, P, N replay and name exactly that route, so the handoff remains a finite Cauchy-window obligation. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCauchyWindowCompletenessHandoff`

Theorem 1602.31 (BaireMetric BaireSpace prefix-density route)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Every* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-density consumer of the complete ultrametric surface must pass through the same finite prefix schedule S, B, W, D before reading R, U, H, C, P, N. The route is therefore density over displayed finite prefixes, not a density theorem for completed Baire names.*

Proof. Project M and read the $\mathsf{BaireSpace}^{\uparrow}$ row B together with the $\mathsf{StreamName}^{\uparrow}$ schedule S. These rows are the only prefix source offered by the carrier.

Apply Definition 1602.6. It places all Baire prefix reads behind the finite schedule and first-disagreement window, with no quotient equality of names available.

Apply Definition 1602.30. The completeness-facing route uses the same $S, B, W, D, R, U, H, C, P, N$ row family, so a prefix-density consumer cannot bypass the finite window when reading the complete ultrametric surface. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricBaireSpacePrefixDensityRoute`

Theorem 1602.32 (BaireMetric prefix-cylinder coverage)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Every prefix-cylinder read exported by M is covered by the finite route*

$$S, B, W, D.$$

The $\mathsf{StreamName}^{\uparrow}$ *schedule selects the inspected prefix window, the* $\mathsf{BaireSpace}^{\uparrow}$ *row supplies the displayed cylinder base, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement row records the inspected length and branch, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row records the matching radius. No cylinder coverage claim may use completed streams, quotient equality of Baire names, or an external topology.*

Proof. Project the carrier. The only coordinates that can name a prefix cylinder before the metric rows are S, B, W, D.

The schedule S determines which finite prefixes are visible. The row B supplies the accepted BaireSpace prefix packet, and W records the finite length and first-disagreement branch inside that packet.

The radius row D then reads the branch named by W. Since R, U, H, C, P, N are downstream of this finite window route, no exported prefix-cylinder coverage can bypass S, B, W, D. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricPrefixCylinderCoverage`

Theorem 1602.33 (BaireMetric Cauchy prefix thread)**.** *For an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier $M = (B, W, D, R, U, S, H, C, P, N)$, every* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy read determines a finite prefix thread through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule. At each displayed radius request, the thread reads a scheduled* $\mathsf{BaireSpace}^{\uparrow}$ *prefix window, a* $\mathsf{Nat}^{\uparrow}$ *first-disagreement or equality branch, the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, and then the parent* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{UltrametricSpace}^{\uparrow}$ *rows. The thread is not a completed stream and does not use countable choice.*

Proof. Start with a completeness-facing Cauchy request. By Definition 1602.30, the request sees only the finite route $S, B, W, D, R, U, H, C, P, N$.

For each displayed radius, the schedule S opens the relevant finite prefix window in B. The row W records whether the inspected prefixes agree on that window or where the first displayed disagreement lies, and D converts that finite branch into the dyadic radius read.

The parent metric row R and the ultrametric row U consume the same window and radius data. Transport, replay, provenance, and naming keep the finite thread attached to M, so the Cauchy read never becomes a selected infinite stream. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCauchyPrefixThread`

Definition 1602.34 (BaireMetric Cauchy-thread obligation surface)**.** *The* $\mathsf{BaireMetric}^{\uparrow}$ *Cauchy-thread obligation surface is the finite row inventory*

$$(S, B, W, D, R, U, H, C, P, N)$$

read by every completeness-facing consumer after Definition 1602.33: prefix-window admission through S, B, first-disagreement or equality admission through W, dyadic radius exactness through D, parent $\mathsf{Met}^{\uparrow}$ *handoff through R,* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle handoff through U, and structural preservation through H, C, P, N. It explicitly has no coordinate for completed-stream equality, quotient Baire names, host real metrics, countable choice, or an external completeness theorem.*

Lean4 (definition) `BEDC.Derived.BaireMetricUp.BaireMetricCauchyThreadObligationSurface`

Theorem 1602.35 (BaireMetric prefix Cauchy-thread completeness)**.** *For an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, every prefix Cauchy read that reaches a complete-ultrametric consumer is exhausted by the obligation surface of Definition 1602.34. The read factors through prefix-window admission, first-disagreement dyadic radius exactness, the parent* $\mathsf{Met}^{\uparrow}$ *handoff, the* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle handoff, and the complete-ultrametric exhaustion row before any limit-window conclusion is exported.*

Proof. Start with the Cauchy read supplied by Definition 1602.33. It already fixes each displayed radius request to a finite $\mathsf{StreamName}^{\uparrow}$ schedule, a $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, a $\mathsf{Nat}^{\uparrow}$ first-disagreement or equality branch, and a $\mathsf{DyadicRatCore}^{\uparrow}$ radius row.

The metric and ultrametric handoffs consume exactly that data. Apply Definition 1602.20 for the parent metric row R, and apply Definition 1602.21 for the strong-triangle row U.

Finally use Definition 1602.37. It says the complete-ultrametric surface has no remaining slot outside prefix coverage, Cauchy threading, the two handoffs, and H, C, P, N. Thus the prefix Cauchy read is complete at the displayed finite obligation surface and exports no completed stream, quotient name, host metric, countable-choice selector, or external completeness theorem. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricPrefixCauchyThreadCompleteness`

Theorem 1602.36 (BaireMetric prefix limit-window uniqueness)**.** *For an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, two limit-window reads that agree on the finite Cauchy-thread obligation surface of Definition 1602.34 agree as* $\mathsf{BaireMetric}^{\uparrow}$ *limit windows for every displayed prefix and dyadic radius. The uniqueness claim is window-local: it refuses completed-stream equality, quotient Baire-name equality, host real metrics, countable choice, and any external topological completeness principle.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricPrefixLimitWindowUniqueness`

Proof. Fix two limit-window reads and compare their displayed prefix requests. By Definition 1602.32, every such request is routed through S, B, W, D, so agreement on the obligation surface gives the same schedule, prefix packet, branch, and dyadic radius row.

The handoff rows preserve this window agreement. The parent metric row R and ultrametric row U read only those displayed prefix and radius rows, and their compatibility is fixed by Definition 1602.20 and Definition 1602.21.

Use Definition 1602.37 to close the route. Since all complete-ultrametric obligations are already exhausted by the finite prefix thread and structural rows H, C, P, N, there is no hidden coordinate where the two reads can diverge as limit windows. The conclusion is therefore finite-window uniqueness, not completed-stream equality or quotient equality. □

Theorem 1602.37 (BaireMetric complete-ultrametric exhaustion)**.** *Every complete-ultrametric obligation exported by an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$ *is exhausted by prefix-cylinder coverage, the Cauchy prefix thread, parent metric compatibility, ultrametric strong-triangle compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. There is no remaining obligation slot for a host real-valued metric, completed-stream equality, quotient Baire names, countable choice, or external topological completeness.*

Proof. Use Definition 1602.32 to identify every cylinder read with the finite S, B, W, D route. This covers the prefix side of the complete-ultrametric surface.

Use Definition 1602.33 for the completeness-facing Cauchy reads. It keeps every displayed radius request on the same StreamName schedule, BaireSpace prefix packet, Nat window, and dyadic radius row.

Finally apply Definition 1602.20 and Definition 1602.21. The rows R and U consume exactly that finite prefix data, while H, C, P, N transport, replay, source, and name it. The listed rows exhaust the carrier, so no external completeness or host metric datum remains. □

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCompleteUltrametricExhaustion`

Theorem 1602.38 (BaireMetric public prefix package)**.** *Every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *prefix-distance packet exports to* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{BaireSpace}^{\uparrow}$ *consumers only the finite public package*

$$W, \quad S, \quad B, \quad D, \quad R, \quad U, \quad H, \quad C, \quad P, \quad N.$$

Here W records first-disagreement or equality data, S records the $\mathsf{StreamName}^{\uparrow}$ *prefix schedule, B records the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-window packet, D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, R records the parent* $\mathsf{Met}^{\uparrow}$ *distance row, and U records the* $\mathsf{UltrametricSpace}^{\uparrow}$ *strong-triangle row. No public prefix-distance read exports completed streams, quotient Baire names, host real metrics, countable-choice selectors, or an external completeness theorem.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricObligationPublicPrefixPackage`

Proof. Start with prefix-cylinder coverage. It identifies each public prefix request with the finite S, B, W, D route, so the first-disagreement branch, prefix schedule, BaireSpace window, and dyadic radius are already displayed before any consumer reads the metric row.

Use first-disagreement dyadic exactness through the existing prefix-window and radius route. The dyadic row D is read from the branch recorded by W, not from a host real-valued metric or a quotient-name comparison.

Finally apply the parent metric handoff and the ultrametric strong-triangle handoff. The rows R and U consume only the same prefix and radius data, while H, C, P, N transport, replay, source, and name the package. Complete-metric and Baire-space consumers therefore receive the finite public package and no hidden completion or choice datum. □

Theorem 1602.39 (BaireMetric bridge route)**.** *Every bridge-facing* $\mathsf{BaireMetric}^{\uparrow}$ *consumer reads the finite prefix-distance route*

$$S, \quad B, \quad W, \quad D, \quad R, \quad U, \quad H, \quad C, \quad P, \quad N$$

before any standard metric interpretation is exposed. The route first displays the $\mathsf{StreamName}^{\uparrow}$ *schedule, then the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the parent* $\mathsf{Met}^{\uparrow}$ *handoff, the* $\mathsf{UltrametricSpace}^{\uparrow}$ *witness, transport, replay, provenance, and the local* NameCert *row. Thus a bridge consumer receives the same finite prefix ledger named by the public package, not completed streams, quotient Baire names, selected limits, or an ambient topology.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricBridgeRoute`

Proof. Begin with the public prefix package of Definition 1602.38. It exposes the consumer-facing order of $S, B, W, D, R, U, H, C, P, N$ and keeps the metric read behind the finite prefix ledger.

Use Definition 1602.44 to identify this order with the whole paper-side obligation surface. The first-disagreement window and dyadic radius row are already displayed before the parent metric and ultrametric rows are available.

Finally apply the finite refinement control of Definition 1602.45. Any bridge-facing refinement stays on the same prefix-distance route, so the standard metric interpretation can only be read after the displayed rows have been consumed in that order. □

Theorem 1602.40 (BaireMetric formal target scope)**.** *Every* $\mathsf{BaireMetric}^{\uparrow}$ *consumer that reads a metric comparison must read it through the displayed* $\mathsf{BaireSpace}^{\uparrow}$ *stream row* B*,* $\mathsf{Nat}^{\uparrow}$ *finite-prefix row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*,* $\mathsf{UltrametricSpace}^{\uparrow}$ *comparison row* U*,* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. In the carrier notation* $M = (B, W, D, R, U, S, H, C, P, N)$*, the metric comparison route is therefore*

$$S, \quad B, \quad W, \quad D, \quad R, \quad U, \quad H, \quad C, \quad P, \quad N.$$

It exposes no completed stream, quotient Baire-name equality, host real-valued metric, countable-choice selector, or external topology.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricFormalTargetScope`

Proof. Project the carrier of Definition 1602.1. The displayed route contains the stream schedule, BaireSpace prefix packet, Nat first-disagreement window, dyadic tolerance row, parent metric row, ultrametric comparison row, and structural transport, replay, provenance, and naming rows.

Use the NameCert obligations and the ultrametric prefix route, Definition 1602.2 and Definition 1602.23. They force each comparison through finite prefix admission, dyadic radius exactness, metric compatibility, ultrametric compatibility, and ledger refusal before any consumer-facing read is exported.

Finally apply complete-ultrametric exhaustion and the public prefix package theorem. Those results identify the CompleteMetric-facing handoff with the same $S, B, W, D, R, U, H, C, P, N$ route, so the formal target is exactly this finite carrier scope and not an external completion, topology, or host metric assertion. □

Theorem 1602.41 (BaireMetric ultrametric cylinder obligation)**.** *For every accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier* $M = (B, W, D, R, U, S, H, C, P, N)$*, each prefix-cylinder distance exported to a* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{UltrametricSpace}^{\uparrow}$ *consumer factors through the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row* B*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement or equality row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* D*, and then the parent metric and ultrametric rows* R, U*. The route is preserved by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows* H, C, P, N *and exports no completed stream, quotient Baire name, host real-valued metric, or external topology.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricUltrametricCylinderObligation`

Proof. Project the carrier of Definition 1602.1. The prefix-cylinder read has only the displayed window rows S, B, W, D before it reaches the parent metric and ultrametric rows.

Induct on the finite prefix window recorded by W. The equality branch keeps the dyadic radius at the displayed zero-or-tail row, while the first-disagreement branch exposes the first inspected coordinate and sends that coordinate to the $\mathsf{DyadicRatCore}^{\uparrow}$ radius row D.

The consumer rows cannot bypass this prefix thread. The metric row R and ultrametric row U are downstream from the same S, B, W, D route, and H, C, P, N transport, replay, source, and name that route without adding a second distance coordinate. □

Theorem 1602.42 (BaireMetric complete metric readback)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer reading an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier reads the same finite Cauchy prefix thread* $S, B, W, D, R, U, H, C, P, N$

already displayed by the prefix-cylinder obligation. The consumer may compare finite Cauchy windows and dyadic radii, but it receives no quotient Baire name, no selected infinite branch, no choice selector, no host stream equality, and no external completeness principle.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCompleteMetricReadback`

Proof. Begin with the Cauchy prefix thread of Definition 1602.33. It binds every completeness-facing radius request to a finite stream schedule, a Baire prefix row, a first-disagreement or equality row, and a dyadic radius row.

The complete metric readback uses the same carrier rows. Apply the parent metric handoff and ultrametric strong-triangle handoff to route the read through R and U after the prefix rows have been exposed.

Finally use complete-ultrametric exhaustion. Since H, C, P, N already account for transport, replay, provenance, and local naming, no quotient name, selector, host stream equality, or external completeness datum remains for a $\mathsf{CompleteMetric}^{\uparrow}$ consumer. □

Theorem 1602.43 (BaireMetric StreamName comeager ledger)**.** *The public comeager-style route available from an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier is determined by the finite* $\mathsf{StreamName}^{\uparrow}$ *prefix schedule* S*, the* $\mathsf{BaireSpace}^{\uparrow}$ *dense-window ledger* B*, the first-disagreement row* W*, and the dyadic radius row* D*, together with* R, U, H, C, P, N*. Any dense-window or cylinder-consumer read must therefore remain inside the displayed finite prefix ledger and cannot import external topology, a completed Baire space, countable choice, or a quotient-open-set algebra.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricStreamNameComeagerLedger`

Proof. Read the prefix schedule first. The row S lists the inspected coordinates, and the row B records the BaireSpace window whose cylinder is being named.

Use finite prefix induction over that schedule. At each step, either the inspected coordinate is still common and the next prefix row is exposed, or W records the first disagreement and D records the corresponding dyadic radius.

The metric, ultrametric, and structural rows only package this ledger. Rows R, U, H, C, P, N pass the finite cylinder route to public consumers, so no external topology or completed Baire-space object is introduced. □

Theorem 1602.44 (BaireMetric obligation-closure route)**.** *Let* $M = (B, W, D, R, U, S, H, C, P, N)$ *be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. The paper-side obligation surface for* M *is exhausted by the finite route consisting of prefix-window admission, first-disagreement dyadic exactness, ultrametric window obligations, complete-metric handoff, StreamName schedule control, and the comeager-style ledger rows. Equivalently, every obligation-facing consumer of* M *reads only*

$$S, \quad B, \quad W, \quad D, \quad R, \quad U, \quad H, \quad C, \quad P, \quad N,$$

and no obligation row exports completed streams, quotient equality of Baire names, host real-valued metrics, countable-choice selectors, external topology, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricObligationClosureRoute`

Proof. Begin with prefix-window admission and dyadic exactness. The prefix-window theorem places every distance request behind the $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, and the $\mathsf{Nat}^{\uparrow}$ first-disagreement row, while first-disagreement dyadic exactness forces the radius row D to be read from the branch recorded by W.

Next add the ultrametric and complete-metric routes. The ultrametric window-obligation theorem makes U consume the same W, D branch as the parent metric row R, and the complete-metric handoff theorem keeps completeness-facing consumers on the finite surface $S, B, W, D, R, U, H, C, P, N$.

Finally use the StreamName scope theorem and the comeager ledger. They ensure that dense-window, cylinder, metric, ultrametric, and completeness reads all pass through the displayed schedule and prefix ledger before any public conclusion is available. The structural rows transport, replay, source, and name that same finite packet, so the excluded completed-stream, quotient, choice, external-topology, and ambient-completeness data have no carrier coordinate. □

Theorem 1602.45 (BaireMetric cylindrical-refinement induction)**.** *Let $M = (B, W, D, R, U, S, H, C, P, N)$ be an accepted* $\mathsf{BaireMetric}^{\uparrow}$ *carrier. Any finite refinement of a Baire cylinder prefix schedule preserves the displayed route through*

$$S, \quad B, \quad W, \quad D, \quad R, \quad U, \quad H, \quad C, \quad P, \quad N.$$

For each added coordinate, the $\mathsf{StreamName}^{\uparrow}$ *schedule S inspects the coordinate, the* $\mathsf{Nat}^{\uparrow}$ *first-disagreement row W compares it with the current prefix window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D assigns the corresponding dyadic radius, and the result is passed to the parent* $\mathsf{Met}^{\uparrow}$ *row R and* $\mathsf{UltrametricSpace}^{\uparrow}$ *witness U through the same transport, replay, provenance, and local naming rows. No refinement step adds completed streams, quotient Baire names, countable-choice selectors, external topology, or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.BaireMetricUp.BaireMetricCylindricalRefinementInduction`

Proof. Proceed by primitive induction on the finite refinement spine. In the empty case, the route is exactly the prefix-window admission and first-disagreement exactness route already exposed by Definition 1602.44.

For the step case, append one coordinate to the inspected prefix schedule. The schedule row S exposes the new coordinate, the prefix-window admission theorem keeps the read inside the displayed $\mathsf{BaireSpace}^{\uparrow}$ cylinder packet, and the first-disagreement exactness theorem sends the comparison to W.

The dyadic radius is then read from D, after which the ultrametric prefix route passes the same branch to R and U. The structural rows H, C, P, N transport, replay, source, and name the refined packet without changing the carrier inventory.

Thus each finite refinement step preserves the same displayed dependency route, and induction over the refinement spine excludes completed streams, quotient Baire names, countable-choice selectors, external topology, and ambient completeness data from every refined cylinder read. □

Falsifiable prediction: Every accepted $\mathsf{BaireMetric}^{\uparrow}$ distance comparison factors through the $\mathsf{BaireSpace}^{\uparrow}$ prefix packet, $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{Nat}^{\uparrow}$ first-disagreement window, $\mathsf{DyadicRatCore}^{\uparrow}$ radius row, parent $\mathsf{Met}^{\uparrow}$ row, $\mathsf{UltrametricSpace}^{\uparrow}$ witness, componentwise transport, continuation replay, provenance, and local $\mathsf{NameCert}$ before any consumer reads a metric or ultrametric conclusion.

Independence witness: bairespace, streamname, nat, dyadicratcore, metricspace, ultrametricspace: $\mathsf{BaireMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries prefix windows, first-disagreement evidence, dyadic radii, parent metric compatibility, ultrametric strong-triangle evidence, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireMetric}^{\uparrow}}$.

Constructive story: A BaireMetric$^{\uparrow}$ packet is generated from a BaireSpace prefix packet, StreamName schedule, Nat first-disagreement window, DyadicRatCore radius row, parent MetricSpace row, UltrametricSpace witness, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BaireMetric}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1602.1, Definition 1602.2, Definition 1602.23, Definition 1602.38, and Definition 1602.44 expose the public finite prefix ultrametric interface on BaireSpace$^{\uparrow}$ through first-disagreement windows and dyadic radius rows.

Formal verification: FormalStatus(NameCert$_{\text{BaireMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed streams, quotient equality of Baire names, host real-valued metrics, countable-choice selectors, external topology, completeness, category arguments, or Lean verification.

Upgrade path: No paper-side theory upgrade remains beyond future Lean formalization and bridge checking.

Chapter 1603

A Concrete Naming Certificate for $\mathsf{SchurOrthogonality}^{\uparrow}$

Starting from Schur's orthogonality relations for finite-group characters, the $\mathsf{SchurOrthogonality}^{\uparrow}$ packet records the row and column orthogonality ledger as finite BEDC readback data. It refines the character ledger of chapter 245 and supplies a concrete downstream source for $\mathsf{RepresentationRing}^{\uparrow}$ and $\mathsf{InducedRep}^{\uparrow}$ without importing host character tables, quotient conjugacy-class carriers, or complete representation categories.

Definition 1603.1 (SchurOrthogonality carrier)**.** *A* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, V, X, \Phi, \Omega, H, C, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row for the finite group endpoint.*
2. *V is the consumed* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ *row for the representation-space endpoints that carry the character reads.*
3. *X is the consumed* $\mathsf{NameCert}_{\mathsf{CharacterTheory}^{\uparrow}}$ *row, restricted to trace and class-function readback data already exposed by the character-theory packet.*
4. *Φ is the finite character-pairing ledger whose entries name the displayed pairings of character rows before any representation-ring or induced-representation consumer reads them.*
5. *Ω is the row and column orthogonality ledger, containing only finite rows for the displayed Schur row relations, Schur column relations, normalization reads, and zero-off-diagonal reads.*
6. *H records componentwise* hsame *transport for the group, vector-space, character-theory, pairing, orthogonality, continuation, provenance, and naming rows.*
7. *C records displayed* Cont *replay from G, V, X into Φ, from Φ into Ω, and from Ω into the downstream* $\mathsf{RepresentationRing}^{\uparrow}$ *and* $\mathsf{InducedRep}^{\uparrow}$ *readback rows.*
8. *P is the* Pkg *provenance over* $\mathsf{SchurOrthogonality}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}$ *row.*

The carrier exports only this finite orthogonality ledger. It contains no host character table, no quotient carrier of conjugacy classes, no ambient inner-product space, and no complete category of representations.

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityTasteGate single carrier alignment`

Theorem 1603.2 (SchurOrthogonality NameCert obligations)**.** *For every accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier* $S = (G, V, X, \Phi, \Omega, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed group, vector-space, character-theory, pairing, orthogonality, transport, continuation, provenance, and naming rows;*
2. *character-pairing route, requiring every orthogonality read to pass through the finite pairing ledger* Φ *before it is consumed by* $\mathsf{RepresentationRing}^{\uparrow}$ *or* $\mathsf{InducedRep}^{\uparrow}$*;*
3. *row and column orthogonality ledger, recording the displayed Schur row relations, Schur column relations, normalization reads, and zero-off-diagonal reads in* Ω*;*
4. *transport stability, requiring* hsame *and* Cont *replay to preserve the same displayed pairing and orthogonality entries under accepted source transport;*
5. *no-host-quotient boundary, excluding character-table computation, quotient conjugacy-class carriers, host inner products, and complete representation categories.*

No local obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1603.1. The only available data are the consumed G, V, X rows, the pairing ledger Φ, the orthogonality ledger Ω, and the structural rows H, C, P, N.

The character-pairing route is forced by the row order: downstream consumers read orthogonality only after the relevant character rows have been paired in Φ. The row and column relations are then read from Ω, whose entries are displayed finite ledger rows rather than host sums over a character table.

Transport stability is the role of H and C. They move accepted source rows componentwise and replay the same path from G, V, X through Φ into Ω.

Finally, the provenance and naming rows bind exactly this finite packet. Since no coordinate stores a host character table, quotient conjugacy-class carrier, host inner product, or representation category, such data remain outside the local NameCert surface. □

Theorem 1603.3 (SchurOrthogonality character-pairing route)**.** *Let* $S = (G, V, X, \Phi, \Omega, H, C, P, N)$ *be an accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier. Every orthogonality read exported from* S *to a* $\mathsf{RepresentationRing}^{\uparrow}$ *or* $\mathsf{InducedRep}^{\uparrow}$ *consumer factors through the displayed route*

$$G, V, X \longmapsto \Phi \longmapsto \Omega \longmapsto C, P, N.$$

Thus no consumer can read a Schur row relation, Schur column relation, normalization row, or zero-off-diagonal row before the corresponding character-pairing entry has appeared in Φ*.*

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityCharacterPairingRoute`

Proof. Start with a downstream orthogonality request. The group, vector-space, and character-theory sources available to the request are exactly the displayed rows G, V, X.

The request first enters the character-pairing ledger Φ. Only after that pairing entry is present can the continuation route reach the orthogonality ledger Ω and select the corresponding row relation, column relation, normalization row, or zero-off-diagonal row.

The structural rows C, P, N then expose that selected entry to the downstream consumer. Since every exported entry has this route as its displayed source, there is no direct read from a host character table, quotient class carrier, or ambient inner product. □

Theorem 1603.4 (SchurOrthogonality character inner-product ledger)**.** *Let $S = (G, V, X, \Phi, \Omega, H, C, P, N)$ be an accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier. Every character-inner-product read exposed by S is a finite ledger read from Φ over the displayed* $\mathsf{Group}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, *and* $\mathsf{VecSpace}^{\uparrow}$ *rows before any orthogonality row of Ω is selected. No exported inner-product read may bypass $G, V, X, \Phi, H, C, P, N$ or import an ambient Hilbert-space structure.*

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityCharacterInnerProduct`

Proof. Project the carrier. The group endpoint is G, the character source is X, and the representation-space endpoint is V.

The only row that pairs characters before orthogonality is Φ. Thus a character-inner-product request first reads the displayed group, character-theory, and vector-space rows, and then selects the corresponding finite pairing entry of Φ.

The orthogonality ledger Ω is downstream from this pairing row. It can consume the selected finite entry, but it cannot create a separate ambient inner product or read from an undeclared character table. The structural rows H, C, P, N transport, replay, source, and name the same finite route. □

Theorem 1603.5 (SchurOrthogonality representation-ring route)**.** *Let $S = (G, V, X, \Phi, \Omega, H, C, P, N)$ be an accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier. A* $\mathsf{RepresentationRing}^{\uparrow}$ *or* $\mathsf{InducedRep}^{\uparrow}$ *consumer may read only the displayed Schur ledger exported through Φ, Ω, C, P, N. Such a consumer cannot import host character tables, quotient conjugacy-class carriers, ambient character inner products, or a complete representation category as hidden sources for the same read.*

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityRepresentationRingRoute`

Proof. Begin with a downstream $\mathsf{RepresentationRing}^{\uparrow}$ or $\mathsf{InducedRep}^{\uparrow}$ request. By Definition 1603.3, every exported orthogonality read has already passed through G, V, X into Φ and then into Ω.

The continuation and provenance rows expose only this displayed ledger. They do not contain an independent coordinate for host character tables, quotient conjugacy classes, ambient inner products, or a complete representation category.

Therefore the downstream consumer receives the finite Schur ledger as named BEDC data. Any route requiring one of the excluded host objects is outside the accepted carrier. □

Theorem 1603.6 (SchurOrthogonality group-averaging ledger)**.** *Let $S = (G, V, X, \Phi, \Omega, H, C, P, N)$ be an accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier. The finite group-averaging row displayed inside Ω is the only averaging source available to Schur row relations, Schur column relations, normalization reads, and zero-off-diagonal reads. This row is preserved by componentwise* hsame *transport in H, displayed* Cont *replay in C,* Pkg *provenance in P, and the local* $\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityGroupAveragingLedger`

Proof. Inspect the orthogonality ledger Ω. Its displayed entries contain the finite averaging data used by the Schur row and column reads, together with normalization and zero-off-diagonal rows.

Transport acts componentwise through H. The averaging entry is moved with the same group, vector-space, character-theory, pairing, and orthogonality rows, so the transported packet still names the same finite source.

Replay and provenance then preserve this source. The continuation row C can only replay the displayed route, P can only cite its package provenance, and N names the local certificate. Hence no second averaging source is introduced. □

Theorem 1603.7 (SchurOrthogonality row and column orthogonality ledger)**.** *Let $S = (G, V, X, \Phi, \Omega, H, C, P, N)$ be an accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier. The row relations, column relations, normalization rows, and zero-off-diagonal rows exported by S are exposed only through $G, V, X, \Phi, \Omega, H, C, P, N$. A* $\mathsf{RepresentationRing}^{\uparrow}$ *or* $\mathsf{InducedRep}^{\uparrow}$ *consumer may read these rows only through the displayed finite pairing and orthogonality ledger, and cannot bypass the packet by importing a host character table, quotient conjugacy-class carrier, ambient inner product, or complete representation category.*

Proof. The carrier in Definition 1603.1 has only the displayed source rows G, V, X, the pairing ledger Φ, the orthogonality ledger Ω, and the structural rows H, C, P, N.

By Definition 1603.3, every exported orthogonality read first passes through the character-pairing ledger. By Definition 1603.4, the corresponding pairing is already a finite ledger read before any row of Ω is selected.

The downstream route is then governed by Definition 1603.5 and Definition 1603.6. These force $\mathsf{RepresentationRing}^{\uparrow}$ and $\mathsf{InducedRep}^{\uparrow}$ consumers to receive only the finite Schur row, column, normalization, and zero-off-diagonal entries named by Ω and replayed by C.

Since no coordinate of S stores a host character table, quotient conjugacy-class carrier, ambient inner product, or complete representation category, such objects cannot serve as alternate sources for the same consumer read. □

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityRowColumnOrthogonalityLedger`

Theorem 1603.8 (SchurOrthogonality scoped dependency package)**.** *For every accepted* $\mathsf{SchurOrthogonality}^{\uparrow}$ *carrier $S = (G, V, X, \Phi, \Omega, H, C, P, N)$, the carrier row, NameCert obligation surface, character-pairing route, character inner-product ledger, representation-ring route, group-averaging ledger, and row-column orthogonality ledger bind the finite scope over* $\mathsf{Group}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Proof. Use Definition 1603.1 to project the displayed rows $G, V, X, \Phi, \Omega, H, C, P, N$. The NameCert obligations of Definition 1603.2 admit exactly those rows as the local Schur orthogonality surface.

The character-pairing and inner-product routes are fixed by Definition 1603.3 and Definition 1603.4. They force every orthogonality read through G, V, X, Φ before the orthogonality ledger Ω is consumed.

The downstream package is then governed by Definition 1603.5, Definition 1603.6, and Definition 1603.7. These theorems expose only Ω, H, C, P, N as the finite route into $\mathsf{RepresentationRing}^{\uparrow}$ and $\mathsf{InducedRep}^{\uparrow}$ consumers, so the stated dependency package is the full scoped surface. □

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityScopedDependencyPackage`

Theorem 1603.9 (SchurOrthogonality character-basis public export)**.** *Every public* $\mathsf{SchurOrthogonality}^{\uparrow}$ *read exported to a* $\mathsf{RepresentationRing}^{\uparrow}$ *or* $\mathsf{InducedRep}^{\uparrow}$ *consumer is the finite character-basis ledger exposed through $G, V, X, \Phi, \Omega, H, C, P, N$. The public surface contains the row and column orthogonality entries, normalization rows, zero-off-diagonal rows, and character-pairing provenance named by the scoped dependency package, and it contains no host character table, quotient conjugacy-class carrier, ambient inner product, or complete representation category.*

Proof. Project the scoped dependency package of Definition 1603.8. It binds the carrier, pairing ledger, orthogonality ledger, transport, continuation, provenance, and NameCert rows as the whole visible surface.

The public consumer route is already fixed by Definition 1603.5. A $\mathsf{RepresentationRing}^{\uparrow}$ or $\mathsf{InducedRep}^{\uparrow}$ consumer reads only the displayed finite Schur ledger through Φ, Ω, C, P, N.

The row-column ledger of Definition 1603.7 supplies the exported character-basis entries. Since the carrier has no coordinate for the excluded host structures, the public read is exactly the finite character-basis ledger named in the statement. □

Lean4 ✓ `BEDC.Derived.SchurOrthogonalityUp.SchurOrthogonalityPublicCharacterBasis`

Closure status for $\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1603.8 and Definition 1603.9 bind the finite Schur orthogonality route over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows and expose its public character-basis ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchurOrthogonality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close character-table computation, quotient conjugacy classes, host inner products, complete representation categories, Lean verification, or bridge checking.

Upgrade path: The remaining work is Lean verification and bridge checking for the same finite Schur orthogonality packet.

Constructive story: A $\mathsf{SchurOrthogonality}^{\uparrow}$ packet is generated from displayed Group, VecSpace, and CharacterTheory sources, a finite character-pairing ledger, a finite row and column orthogonality ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1604

A Concrete Naming Certificate for $\mathsf{BaireOneFunction}^{\uparrow}$

Following Baire's function hierarchy and Bourbaki-style real analysis, the $\mathsf{BaireOneFunction}^{\uparrow}$ packet records pointwise limits of continuous real-valued maps as finite BEDC ledgers rather than as host function-space objects. It reads continuous approximants through chapter 130, indexes their displayed pointwise stream through chapter 126, checks finite rational readbacks through chapter 301, seals observed values through chapter 38, keeps the source context visible through chapter 334, routes the pointwise-limit handoff through chapter 2314, and exposes only a handoff suitable for lower-semicontinuous consumers in chapter 1536. The packet is therefore a certificate for a named pointwise-limit route, not a space of all functions and not a choice of approximating sequence outside the displayed ledger.

Definition 1604.1 (BaireOneFunction carrier)**.** *A* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, S, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{BaireSpace}^{\uparrow}$ *source-context row naming the inspected source points and the finite basic-open information available to the packet.*
2. *F is the finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows $f_n : X \to \mathsf{Real}^{\uparrow}$ whose pointwise observations are being replayed.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting, for each displayed source point and precision request, the finite list of approximant indices inspected by the packet.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected real-value windows of the approximants.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after X, F, S, Q have been displayed.*
6. *L is the* $\mathsf{PointwiseLimit}^{\uparrow}$ *and lower-semicontinuous handoff row recording the finite pointwise-limit observations and epigraph-facing observations that downstream* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumers may read from the ledger.*
7. *H records componentwise* hsame *transport for the source context, continuous approximant ledger, stream schedule, regular rational readback, real value seal, lower-semicontinuous handoff, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a source-point request through the continuous approximant ledger, the selected stream windows, the regular rational readback, the real value seal, and the lower-semicontinuous handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireOneFunction}^{\uparrow}}$ *row.*

The carrier exports no ambient function space, no arbitrary choice of approximating sequence, no quotient equality of real names, no full measurability theorem, and no completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.TasteGate.BaireOneFunctionTasteGate single carrier alignment`

Definition 1604.2 (BaireOneFunction classifier)**.** *Two accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carriers*

$$K = (X, F, S, Q, R, L, H, C, P, N) \quad \textit{and} \quad K' = (X', F', S', Q', R', L', H', C', P', N')$$

are classified together precisely when the displayed hsame *rows in H and H' identify the source-context rows, continuous-approximant ledgers, stream schedules, regular rational readbacks, real value seals, lower-semicontinuous handoff rows, continuation routes, provenance rows, and local naming rows componentwise. The classifier has no coordinate for extensional equality of host functions, no quotient of real names, and no comparison of undisplayed approximants.*

Lean4 (definition) `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionClassifier`
Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionClassifier component namecert transport`

Theorem 1604.3 (BaireOneFunction NameCert obligation surface)**.** *For every accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier $K = (X, F, S, Q, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireOneFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source-context row, continuous approximant ledger, stream schedule, regular rational readback, real value seal, lower-semicontinuous handoff, transport, continuation, provenance, and local naming rows;*

2. *continuous-approximant admission, requiring every displayed approximant read to pass through one row of F over the source context X;*

3. *pointwise-limit scheduling, requiring every value-seal read to factor through the selected windows in S and the corresponding readbacks in Q;*

4. *real-seal non-escape, requiring R to be downstream of X, F, S, Q and not of an ambient function space;*

5. *pointwise-limit and lower-semicontinuous handoff compatibility, requiring L to consume only the same displayed pointwise-limit ledger;*

6. *ledger refusal, excluding arbitrary approximating-sequence choice, quotient equality of real names, full measurability, ambient function-space topology, and completeness of* $\mathsf{Real}^{\uparrow}$.

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier namecert obligation surface`

Proof. Carrier admission is projection from Definition 1604.1. The accepted packet exposes exactly the source context, continuous approximant ledger, stream schedule, regular rational readback, real value seal, lower-semicontinuous handoff, transport, continuation, provenance, and local naming rows.

Continuous-approximant admission is read from F over X. Each displayed approximant contributes only its $\mathsf{ContinuousMap}^{\uparrow}$ row at the source points named by the packet, so no host function space or unlisted approximant can enter the certificate.

Pointwise-limit scheduling is then read through S and Q. A value request first chooses a displayed source point and precision window, then follows the finite stream schedule to the approximant indices recorded by S, and finally reads the regular rational windows recorded by Q.

The real value seal R is downstream of this route. Since R is reached only after the displayed approximant windows and rational readbacks have been replayed, it cannot export quotient equality of real names, a semantic function-space limit, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

The pointwise-limit and lower-semicontinuous row L is another downstream read of the same ledger. The componentwise transports and continuation routes in H and C preserve the route X, F, S, Q, R, L, while P and N record no excluded coordinate. Thus the listed rows exhaust the local NameCert surface. □

Theorem 1604.4 (BaireOneFunction pointwise-limit ledger)**.** *Every* $\mathsf{Real}^{\uparrow}$ *value exported by an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier factors through the displayed route*

$$X, F, S, Q \longmapsto R.$$

The route reads a source point from the $\mathsf{BaireSpace}^{\uparrow}$ *context, selects finitely many continuous approximant observations through the* $\mathsf{StreamName}^{\uparrow}$ *schedule, checks the selected windows through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and then exposes the* $\mathsf{Real}^{\uparrow}$ *value seal. It is not an ambient pointwise-convergence theorem, not a quotient of real names, and not a choice principle for approximating sequences.*

Proof. Start with a consumer of the value seal R. The carrier places R in the same packet as X, F, S, Q, and the continuation row C records the only displayed route into R.

The source request first reads the $\mathsf{BaireSpace}^{\uparrow}$ context X. The continuous approximant ledger F then supplies the relevant $\mathsf{ContinuousMap}^{\uparrow}$ rows over that context, while the stream schedule S selects the finite approximant windows currently being inspected.

The regular rational readback Q checks those selected windows before the seal row is available. Componentwise transport by H preserves this route, and the package and local naming rows record no ambient function-space coordinate. Therefore every exported value seal factors through X, F, S, Q. □

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier pointwise lowersemicontinuous handoff certificate`

Theorem 1604.5 (BaireOneFunction pointwise schedule obligations)**.** *For every accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier* $K = (X, F, S, Q, R, L, H, C, P, N)$*, every pointwise value read must expose the* $\mathsf{BaireSpace}^{\uparrow}$ *source row* X*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *family ledger* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* R*, and the transport, replay, provenance, and local naming rows* H, C, P, N *before any* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *handoff row* L *is consumed. Thus the handoff cannot be read as a shortcut around the pointwise schedule.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier pointwise schedule obligations`

Proof. Project the carrier of Definition 1604.1. The rows X, F, S, Q, R appear before the lower-semicontinuous handoff row L in the displayed pointwise-limit ledger.

Apply Definition 1604.4. It forces every exported $\mathsf{Real}^{\uparrow}$ value through the source context, continuous approximant family, stream schedule, and regular rational readback before the value seal is available.

The handoff theorem Definition 1604.8 then consumes the same ledger. Componentwise transport H, replay C, provenance P, and local naming N preserve the route, so no $\mathsf{LowerSemicontinuous}^{\uparrow}$ consumer may bypass X, F, S, Q, R. □

Theorem 1604.6 (BaireOneFunction oscillation locality)**.** *Every oscillation or point-continuity consumer of an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier* $K = (X, F, S, Q, R, L, H, C, P, N)$ *factors through the displayed pointwise schedule, the* $\mathsf{Real}^{\uparrow}$ *observation rows, the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *source rows, and a finite precision window before reading lower-semicontinuous handoff or public-export data. Thus an oscillation read may inspect only the finite source context, selected approximant windows, regular-rational readbacks, real value seals, componentwise transport, replay, provenance, and local naming already visible in the carrier.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier oscillation locality`

Proof. Project the carrier and classifier rows of Definition 1604.1 and Definition 1604.2. The source row X, approximant ledger F, schedule row S, regular-rational readback Q, real seal R, transport H, replay C, provenance P, and local naming N are the rows available before any downstream handoff is read.

Use the pointwise-limit ledger of Definition 1604.4. It forces every $\mathsf{Real}^{\uparrow}$ value read through the route $X, F, S, Q \longmapsto R$, so an oscillation or point-continuity request must first expose the displayed source point, the selected continuous approximant rows, and the finite regular-rational windows used to seal the observed value.

Now apply the pointwise schedule obligations of Definition 1604.5. They keep the lower-semicontinuous handoff L downstream of the same pointwise schedule and prevent it from serving as a shortcut around $X, F, S, Q, R, H, C, P, N$.

The $\mathsf{Met}^{\uparrow}$ or $\mathsf{ContinuousMap}^{\uparrow}$ source rows enter only through the displayed source context and approximant ledger. Since the carrier has no coordinate for ambient function spaces, quotient real equality, hidden approximants, or an unrestricted continuity theorem, the requested oscillation or point-continuity read is local to the finite observation window already exposed by the packet. □

Theorem 1604.7 (BaireOneFunction pointwise oscillation handoff)**.** *Every pointwise oscillation consumer of an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier* $K = (X, F, S, Q, R, L, H, C, P, N)$ *must read the* $\mathsf{BaireSpace}^{\uparrow}$ *source row* X*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *approximant ledger* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{Real}^{\uparrow}$ *value seal* R*, and the finite precision window determined by these rows before any lower-semicontinuous or oscillation-rank handoff is consumed. The handoff therefore exports a pointwise finite-observation route, not a host oscillation-rank theorem, hidden approximant selector, quotient of real names, or ambient function-space completeness principle.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier pointwise oscillation handoff`

Proof. Project the accepted carrier of Definition 1604.1. The source row X, approximant ledger F, stream schedule S, regular rational readback Q, value seal R, and structural rows H, C, P, N are displayed before a downstream lower-semicontinuous or oscillation-rank consumer can read any handoff row.

Apply Definition 1604.4. It forces every pointwise value request through the source context, selected continuous approximant observations, stream schedule, and regular rational readback before the $\mathsf{Real}^{\uparrow}$ seal is available.

Next use Definition 1604.5. The schedule obligations keep L downstream of the same pointwise ledger, so a lower-semicontinuous handoff cannot replace X, F, S, Q, R by an ambient convergence or measurability claim.

Finally apply Definition 1604.6. Oscillation reads are local to the finite source context, selected approximant windows, regular-rational readbacks, value seals, transport, replay, provenance, and local naming already visible in the carrier. Hence any oscillation-rank or lower-semicontinuous handoff must pass through the stated pointwise finite-observation route. □

Theorem 1604.8 (BaireOneFunction lower-semicontinuous handoff)**.** *Every* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer row exported by an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier reads only the displayed pointwise-limit ledger*

$$X, F, S, Q, R \longmapsto L.$$

The handoff may use finite epigraph-facing observations derived from the same source context, continuous approximant rows, stream schedule, regular rational readback, and real value seal. It receives no full measurability theorem, no host function-space topology, no arbitrary approximant selector, and no completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier lowersemicontinuous handoff`

Proof. Let a downstream consumer request the row L. By carrier admission, L is a coordinate of the same packet that contains the source context X, the approximant ledger F, the schedule S, the readback Q, and the value seal R.

Replay the continuation row C. The consumer can reach L only after the source context is read, the displayed continuous approximants are inspected, the selected stream windows are checked by the regular rational readback, and the real value seal is exposed.

Transport by H keeps the lower-semicontinuous handoff attached to those same rows. Since the provenance and local naming rows carry no measurability theorem, no ambient function-space topology, no arbitrary approximant selector, and no $\mathsf{Real}^{\uparrow}$ completeness coordinate, the handoff exports none of them. □

Theorem 1604.9 (BaireOneFunction lower-semicontinuous exhaustion)**.** *Every* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *public row exported by an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *carrier*

$$K = (X, F, S, Q, R, L, H, C, P, N)$$

is exhausted by the displayed source context X*, continuous approximant ledger* F*, stream schedule* S*, regular rational readback* Q*, real value seal* R*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*. The lower-semicontinuous row* L *may publish only the public observations already routed through these rows; it cannot introduce hidden approximants, quotient real equality, full measurability, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier lowersemicontinuous exhaustion`

Proof. Start with the pointwise ledger of Definition 1604.4. It binds every value observation to the route $X, F, S, Q \longmapsto R$, so a downstream lower-semicontinuous consumer cannot read a value that is detached from the displayed source context, approximant family, schedule, and readback.

Next apply the schedule obligations of Definition 1604.5. They force $X, F, S, Q, R, H, C, P, N$ to remain visible before L is consumed, and they rule out using the handoff as a shortcut around the finite pointwise schedule.

Finally use the lower-semicontinuous handoff of Definition 1604.8. The handoff row L is downstream of the same pointwise ledger, while H, C, P, N only transport, replay, source, and name the displayed packet. Therefore the public lower-semicontinuous export is exhausted by the stated rows and has no coordinate for hidden approximants, quotient real equality, full measurability, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1604.10 (BaireOneFunction public export)**.** *Every public* $\mathsf{BaireOneFunction}^{\uparrow}$ *consumer receives exactly the displayed route*

$$X, F, S, Q, R, L, H, C, P, N.$$

The public surface keeps the $\mathsf{BaireSpace}^{\uparrow}$ *source row,* $\mathsf{ContinuousMap}^{\uparrow}$ *approximant ledger,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *handoff, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows visible. It exports no ambient function space, arbitrary approximant choice, quotient real equality, full measurability theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier public export`

Proof. Project the carrier of Definition 1604.1. Its public coordinates are exactly $X, F, S, Q, R, L, H, C, P, N$.

Apply the pointwise schedule obligations and lower-semicontinuous handoff, Definition 1604.5 and Definition 1604.8. These force every value and handoff read through the displayed BaireSpace, ContinuousMap, StreamName, RegSeqRat, Real, and LowerSemicontinuous rows before a public consumer can use the packet.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for ambient function spaces, arbitrary approximant selection, quotient real equality, full measurability, or $\mathsf{Real}^{\uparrow}$ completeness, none of those principles is part of the public export. □

Theorem 1604.11 (BaireOneFunction finite schedule nonescape)**.** *Every pointwise-limit or lower-semicontinuous consumer of an accepted* $\mathsf{BaireOneFunction}^{\uparrow}$ *packet must pass through the displayed finite schedule rows*

$$X, F, S, Q, R, L, H, C, P, N.$$

The route first exposes the $\mathsf{BaireSpace}^{\uparrow}$ *source row* X*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *approximant ledger* F*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* R*, and the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *handoff* L*, then preserves the read through transport* H*, replay* C*, provenance* P*, and local naming* N*. It cannot introduce an undisplayed approximant selector, ambient function-space equality, quotient real equality, measurability theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireOneFunctionUp.BaireOneFunctionCarrier finite schedule nonescape`

Proof. Start with the pointwise-limit ledger of Definition 1604.4. It binds every value read to the displayed source row, approximant ledger, finite schedule, regular rational readback, and real seal.

Apply the pointwise schedule obligations of Definition 1604.5. They force the stream schedule S and readback row Q to remain visible before any pointwise consumer may inspect the value row.

Finally use the lower-semicontinuous handoff and public export, Definition 1604.8 and Definition 1604.10. The structural rows H, C, P, N preserve and name the same finite packet, so no hidden selector, ambient equality, quotient equality, measurability theorem, or $\mathsf{Real}^{\uparrow}$ completeness can enter the consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOneFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireOneFunction}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1604.1, Definition 1604.2, Definition 1604.3, Definition 1604.4, Definition 1604.8, and Definition 1604.10 bind the finite pointwise-limit packet from continuous real-valued approximants to lower-semicontinuous public consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireOneFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function spaces, arbitrary choice of approximating sequence, quotient equality of real names, full measurability, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or a standard bridge.

Upgrade path: No paper-side theory upgrade remains; future work is Lean verification or bridge checking if not already recorded.

Constructive story: A $\mathsf{BaireOneFunction}^{\uparrow}$ packet is generated from a $\mathsf{BaireSpace}^{\uparrow}$ source context, a finite ledger of $\mathsf{ContinuousMap}^{\uparrow}$ approximants, $\mathsf{StreamName}^{\uparrow}$ schedule windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ value seal, a $\mathsf{LowerSemicontinuous}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1605

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Bourbaki–Kelley filter terminology, the $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ packet records the finite route by which the cofinite Frechet tail filter of a regular Cauchy source is read through Cauchy-filter basis rows, saturated Cauchy-filter evidence, stream windows, dyadic tolerances, regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal. It refines the cofinite-tail filter surface of chapter 1564, the basis generator of chapter 1501, the saturation row of chapter 333, the filter-to-regular route of chapter 1445, the finite-window surface of chapter 126, the dyadic ledger of chapter 291, the regular rational interface of chapter 301, and the Real naming boundary of chapter 38. The packet is a finite tail-filter specialization; it is not a quotient filter, not a selected limit, not host real equality, not countable choice, and not an ambient completeness principle.

Definition 1605.1 (Regular Cauchy tail filter carrier)**.** *A* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, B, Q, S, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite-tail neighbourhood row, carrying the displayed tail threshold and finite-complement checks through which the regular Cauchy source is inspected.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator row built from the same tail neighbourhoods, finite stream windows, regular readbacks, and dyadic tolerance requests.*
3. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation row that consumes B before any filter-facing or Real-facing consumer can inspect the packet.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose late observations are admitted only after the Frechet tail row and basis row have been replayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to those late windows and to the Cauchy-filter basis inclusions.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from S, D after the saturated Cauchy-filter route F, B, Q has been displayed.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, B, Q, S, D, R have been replayed.*

8. *H records componentwise* hsame *transport for the Frechet tail row, basis row, saturation row, stream windows, dyadic tolerances, readback, Real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a tail-filter request through the Frechet tail neighbourhoods, CauchyFilterBasis generator, CauchyFilter saturation, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and then the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, host real equality, countable-choice tail selectors, quotient Cauchy names, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1605.2 (Regular Cauchy tail filter NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier* $T = (F, B, Q, S, D, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Frechet tail row, CauchyFilterBasis generator, CauchyFilter saturation row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, transport, continuation, provenance, and local naming row;*

2. *tail-neighbourhood exposure, requiring every accepted read to consume F before a stream window or basis element is inspected;*

3. *basis generation and saturation exactness, requiring B to be generated from the displayed tail windows and Q to consume that basis before any downstream filter route is exported;*

4. *regular readback order, requiring S and D to be replayed before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R is available;*

5. *Real seal boundary, requiring A to remain downstream of F, B, Q, S, D, R and refusing quotient filters, selected limits, host real equality, countable choice, quotient Cauchy names, and ambient completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1605.1. The visible rows are exactly $F, B, Q, S, D, R, A, H, C, P, N$.

The tail-neighbourhood obligation is forced by the replay row C. A request first consumes the cofinite-tail row F, then uses the same late-tail data to form the displayed basis row B.

Saturation exactness is the role of Q. Since Q is downstream of B, every filter-facing consumer receives the generated Cauchy-filter surface rather than a detached quotient filter.

The regular readback and Real boundary are then fixed by row order. The stream windows S and dyadic tolerances D feed the readback row R, and the seal row A is available only after R and the structural rows have been replayed. The excluded quotient, selector, host-equality, choice, and completeness objects are absent from the carrier, so the displayed rows exhaust the local obligation surface. □

Theorem 1605.3 (Regular Cauchy tail filter Real seal boundary)**.** *Let $T = (F, B, Q, S, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of T factors through the finite route*

$$F \longmapsto B \longmapsto Q \longmapsto S, D \longmapsto R \longmapsto A \longmapsto H, C, P, N.$$

Thus the consumer reads the Frechet tail neighbourhoods, generated Cauchy-filter basis, saturated Cauchy filter, finite stream windows, dyadic tolerances, and regular rational readback before reaching the Real seal. The exported surface contains no quotient filter, selected limit, host real equality, countable-choice selector, quotient Cauchy name, or ambient completeness assertion.

Proof. Start with a Real-facing or completion-facing consumer. Carrier admission exposes the seal row A, but only as a row downstream of the tail, basis, saturation, window, tolerance, and readback rows.

Replay the continuation row C. The route first reads F, generates B, saturates through Q, and then inspects the finite windows S with their dyadic ledger D.

The next public row is the regular rational readback R. Only after R has been replayed can the consumer read A.

Transport through H and provenance through P, N preserve the same route. Since the carrier contains no quotient-filter coordinate, selected limit, host real equality, countable-choice selector, quotient Cauchy name, or completeness witness, no Real-facing read can export one. □

Theorem 1605.4 (Regular Cauchy tail filter Real seal handoff)**.** *Let* $T = (F, B, Q, S, D, R, A, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier. Any* $\mathsf{DyadicTailBall}^{\uparrow}$ *or* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer using* T *must read the finite route*

$$\mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

in that order before exporting a Real-seal-facing conclusion.

The handoff is consumed by the downstream dyadic tail-ball route of chapter 1633 and by the Real Cauchy criterion route of chapter 1590. It cannot bypass through quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1605.1. The rows F, B, Q, S, D, R, A expose the Frechet tail filter, CauchyFilterBasis generator, CauchyFilter saturation, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and terminal Real seal.

Apply Definition 1605.3. It forces every Real-facing or completion-facing consumer to read F, then B, then Q, then S, D, then R, and only then A.

The $\mathsf{DyadicTailBall}^{\uparrow}$ consumer reads this same tail route before its dyadic ball containment row, while the $\mathsf{RealCauchyCriterion}^{\uparrow}$ consumer reads the same stream, readback, dyadic tolerance, and Real-seal surface before exposing its criterion row.

Since quotient stream equality, selected limits, countable choice, host real equality, trichotomy, and ambient completeness are absent from the carrier, neither downstream consumer can replace the displayed tail-filter route by one of those objects. □

Theorem 1605.5 (Real Cauchy criterion tail-filter handoff)**.** *Let* $T = (F, B, Q, S, D, R, A, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier. Every* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer of* T *must first read the tail-filter route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicTailBall}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it exports a Real Cauchy criterion conclusion. The handoff preserves the same stream, readback, dyadic tolerance, tail-ball, and Real-seal rows used by the local carrier and by chapter 1633.*

Proof. Project the accepted carrier of Definition 1605.1. Its consumer-facing rows display the Frechet tail row, CauchyFilterBasis generator, CauchyFilter saturation, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, terminal Real seal, transport, replay, provenance, and local naming.

Apply Definition 1605.4. It already places every $\mathsf{RealCauchyCriterion}^{\uparrow}$ consumer after the route through $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Now insert the dyadic tail-ball consumer route. The $\mathsf{DyadicTailBall}^{\uparrow}$ packet of chapter 1633 reads the same late stream windows, dyadic tolerance ledger, regular readback, and Real-seal surface before its containment row is public. Hence the Real Cauchy criterion consumer receives a named tail-filter handoff rather than an unnumbered prose dependency. □

Theorem 1605.6 (Regular Cauchy tail filter Bishop completion handoff)**.** *Let $T = (F, B, Q, S, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *carrier. Any* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *consumer that reads the tail-filter route must factor its request through*

$$F \longmapsto B \longmapsto Q \longmapsto S, D \longmapsto R \longmapsto A$$

before invoking the Bishop completion carrier rows of chapter 1639. The handoff consumes the displayed $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and terminal* $\mathsf{Real}^{\uparrow}$ *surface already exposed by T, then presents only the L10 completion rows governed by Definition 1639.2 and Definition 1639.15. It exports no quotient stream, selected limit, host real equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1605.1. A completion-facing read has access only to the rows $F, B, Q, S, D, R, A, H, C, P, N$, with F supplying tail exposure, B supplying the generated Cauchy-filter basis, and Q supplying saturation.

Apply Definition 1605.2. Tail exposure forces the consumer to read F before any stream window is inspected, while basis generation and saturation exactness force the route through B and Q before any filter-facing surface is available.

Apply Definition 1605.3. The only ordered Real-facing route then continues through the finite $\mathsf{StreamName}^{\uparrow}$ windows S, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal A.

The Bishop completion chapter can therefore receive the tail-filter data only as the displayed L10 rows. Its regularity envelope in Definition 1639.2 reads the finite stream, regular sequence, dyadic tolerance, common-tail, and Real-seal rows, while Definition 1639.15 prevents escape to quotient streams, selected limits, host real equality, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1605.1, Definition 1605.2, and Definition 1605.3 seed the finite route from Frechet tail neighbourhoods through CauchyFilterBasis generation, CauchyFilter saturation, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the downstream Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, host real equality, countable-choice tail selectors, quotient Cauchy names, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-neighbourhood exposure, basis generation, CauchyFilter saturation exactness, RegSeqRat readback order, Real seal boundary, and ledger refusal proofs for the same packet.

Constructive story: A $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ packet is generated from a FrechetFilter tail row, a CauchyFilterBasis generator, a CauchyFilter saturation row, StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1606

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMinimality}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the Bourbaki and Kelley treatments of metric completion, the $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ packet records the minimality boundary for Cauchy completion through existing BEDC finite rows. It reads the finite completion carrier of chapter 1506, the dense isometric embedding surface of chapter 1512, the extension and uniqueness interface of chapter 397, the uniformly continuous extension handoff of chapter 769, and the Bishop-style constructive route of chapter 1556. Its dense-extension uniqueness and separated reflection rows also consume the complete-metric limit uniqueness route of chapter 5983 before the minimality packet exports uniqueness. The packet names the least completion-facing service boundary visible to later consumers: source metric data, dense embedding, universal extension, separated uniqueness, transport, provenance, and local naming.

Definition 1606.1 (CauchyCompletionMinimality carrier)**.** *A* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, C, E, U, F, S, H, R, P, N)$$

with the following visible rows:

1. *X is the source metric row together with the located source evidence used by the completion route.*
2. *C is the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *completion row over the same source histories.*
3. *E is the dense* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, including source-image coverage and distance reflection.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row that supplies the extension and uniqueness surface for completion-facing consumers.*
5. *F is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *row that hands uniformly continuous dense-source maps to the completed packet.*
6. *S is the separated uniqueness row comparing two displayed completion reads only through zero-distance classifier evidence.*
7. *H records componentwise* hsame *transport for the source, completion, embedding, universal-property, extension, separatedness, replay, provenance, and local naming rows.*

8. *R records the displayed* Cont *replay through $X, C, E, U, F, S, H, P, N$, in the order in which a consumer may read the packet.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *row naming this packet and no larger completion principle.*

The carrier has no coordinate for quotient completions, selected representatives, host equality, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityTasteGate single carrier alignment`

Theorem 1606.2 (CauchyCompletionMinimality NameCert obligations)**.** *For an accepted* CauchyCompletionMinin *carrier $M = (X, C, E, U, F, S, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the source metric and located source row, displayed completion row, dense embedding row, universal-property row, uniformly continuous extension row, separated uniqueness row, componentwise transport, continuation replay, provenance, and local naming row;*

2. *dense-image coverage, requiring every completion-facing source approximation to pass through the embedding row E after the completion row C has been displayed;*

3. *universal factorization, requiring every completion-facing consumer to read the universal-property row U and extension handoff F before it can export a completed value;*

4. *separated uniqueness, requiring any comparison of two completed reads to pass through S and the componentwise transport ledger H;*

5. *ledger non-escape, stating that R, P, N expose no quotient completion, selected representative, host equality, countable-choice schedule, open-cover compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1606.1. The tuple displays exactly the source, completion, embedding, universal-property, extension, separatedness, transport, replay, provenance, and naming rows.

Dense-image coverage is read from E after C. The completion row gives the target-facing packet, and the embedding row supplies the source-image route through which every admitted approximation reaches that packet.

Universal factorization is the role of U and F. The universal-property row supplies extension and uniqueness data, while the uniformly continuous extension row records the finite handoff used by dense-source consumers.

Separated uniqueness is local to S and transported by H. The replay row R orders the same route, and the provenance rows P, N list no additional coordinate. Hence the excluded quotient, representative-selection, host-equality, choice, compactness, and ambient real-completeness principles cannot be read from the certificate. □

Theorem 1606.3 (CauchyCompletionMinimality dense-image coverage)**.** *Let $M = (X, C, E, U, F, S, H, R, P, N)$ be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Every completion-facing approximation exported by the minimality packet must expose the displayed completion row C and then the dense embedding row E before the universal-property, uniformly continuous extension, separated uniqueness, transport, replay, provenance, and local naming rows U, F, S, H, R, P, N can be consumed.*

The coverage route exports no quotient completion, selected representative, countable-choice schedule, host equality, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityDenseImageCoverage`

Proof. Project the carrier of Definition 1606.1. Its rows display the source metric X, completion row C, dense embedding row E, universal-property row U, extension row F, separated uniqueness row S, and structural rows H, R, P, N.

Apply the NameCert obligations of Definition 1606.2. The dense-image clause requires every completion-facing source approximation to pass through E after C has been displayed, while the ledger non-escape clause keeps quotient completions, selected representatives, choice schedules, host equality, open-cover compactness, and ambient real-completeness outside the packet.

Finally use Definition 1606.4. Since every downstream consumer must continue through U, F, S, H, R, P, N, the consumer cannot bypass E by reading the universal route directly. □

Theorem 1606.4 (CauchyCompletionMinimality universal factorization)**.** *Let $M = (X, C, E, U, F, S, H, R, P, N)$ be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Any completion-facing consumer sharing the same source metric X, dense embedding E, and separated target boundary S factors through the route*

$$X \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto (H, R, P, N).$$

The factorization exports no quotient completion, selected representative, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start from the shared source metric row X. A completion-facing consumer cannot reach a completed read until the dense embedding row E has displayed the source image used by that read.

The universal row U is consumed next. It is the finite extension and uniqueness surface through which the consumer obtains a completion-facing map rather than a detached host-space operation.

The uniformly continuous handoff F then records the carried extension route. Its source and target sides are still the same rows displayed by X, E, and U.

Finally the separated row S compares any two resulting target reads, while H, R, P, N transport, replay, source, and name the same finite packet. Because none of the listed rows contains a quotient completion, selected representative, host equality, countable-choice schedule, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the factorization is minimal in exactly the displayed BEDC coordinates. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier universal factorization`

Theorem 1606.5 (CauchyCompletionMinimality reflector unit factorization)**.** *Let $M = (X, C, E, U, F, S, H, R, P,$ be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier whose source row is read through the* CauchyCompletionReflector *packet of chapter 8626. Then any minimality-facing consumer must expose the unit and dense-embedding rows before the universal factorization route*

$$X \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto (H, R, P, N).$$

Equivalently, the source read first passes through the reflector-unit carrier's source, unit embedding, reflector, dense-image, and triangle replay rows, and only then reaches the minimality carrier's dense embedding, universal-property, extension, separatedness, transport, replay, provenance, and local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *rows.*

The factorization exports no quotient completion, selected representative, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the minimality carrier of Definition 1606.1. Its rows expose the source metric X, completion row C, dense embedding E, universal-property row U, extension row F, separated uniqueness row S, and structural rows H, R, P, N.

Now apply the local obligations of Definition 1606.2. Those obligations force dense-image coverage through E and universal factorization through U, F, S, H, R, P, N before any completion-facing consumer can export a result.

The universal factorization theorem Definition 1606.4 supplies the displayed route from X through E, U, F, S into the structural rows. Reading X through chapter 8626 adds only the finite unit embedding, dense-image, and triangle-replay rows before that same route.

Since neither the reflector-unit carrier nor the minimality carrier contains a quotient completion, selected representative, choice schedule, host equality row, or ambient Real-completeness theorem, the combined factorization remains inside the displayed BEDC packet. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityReflectorUnitFactorization`

Theorem 1606.6 (CauchyCompletionMinimality dense-extension uniqueness)**.** *Let* $M = (X, C, E, U, F, S, H, R, P$ *be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. If two completion-facing consumers share the same source metric row* X*, dense embedding row* E*, universal-property row* U*, uniformly continuous extension handoff* F*, and separated target boundary* S*, then their exported completed reads are identified only through the separated uniqueness row* S *and the shared transport, replay, provenance, and local naming rows* H, R, P, N*.*

The identification exports no quotient completion, selected representative, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityDenseExtensionUniqueness`

Proof. Apply Definition 1606.2. The accepted carrier exposes the source metric, completion, dense embedding, universal-property, extension, separatedness, transport, replay, provenance, and local naming rows as the complete local certificate surface.

Next use Definition 1606.4. Since the two consumers share X, E, U, F, S, both completion-facing reads pass through the same route from the source metric and dense embedding to the universal extension handoff and separated target boundary.

Apply Definition 1606.5 to the shared source read when it is presented through the reflector-unit surface. The unit and dense-embedding rows are prior to the same minimality route and do not add any separate equality principle for completed reads.

It remains only to compare the two exported target reads. The carrier permits that comparison through the separated uniqueness row S and then transports, replays, packages, and names the result through H, R, P, N. The excluded quotient completions, selected representatives, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot enter because no carrier coordinate or cited factorization theorem exports them. □

Theorem 1606.7 (CauchyCompletionMinimality separated reflection route)**.** *Let* $M = (X, C, E, U, F, S, H, R, P, N$ *be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Any completion-facing consumer comparing*

two completion reads must pass through the separated metric reflection row S after the dense embedding row E, the universal-property row U, and the uniformly continuous extension row F have been displayed. The consumer may then read the transport, replay, provenance, and local naming rows H, R, P, N as the terminal route. The route does not export quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier of Definition 1606.1. The displayed rows already place the dense embedding E, universal-property row U, extension row F, and separatedness row S on the same finite packet.

Apply Definition 1606.2. Its dense-image coverage and universal factorization clauses force any completion-facing consumer to pass through E, U, and F before the separated comparison can be read.

Now use Definition 1606.4 and Definition 1606.6. Together they keep the comparison route inside the displayed carrier and force the two completion reads to meet only at the separated row S.

Finally read H, R, P, N as transport, replay, provenance, and naming rows for the same finite packet. Since the carrier has no coordinate for quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no consumer can bypass the separated reflection row. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalitySeparatedReflectionRoute`

Theorem 1606.8 (CauchyCompletionMinimality replay non-escape)**.** *Every completion-minimality consumer of an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier must read the source metric row, the displayed completion row, the dense embedding row, the universal factorization row, the separated uniqueness row, the reflector-unit factorization row, the componentwise* hsame *row, the displayed* Cont *row, the* Pkg *row, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *row before it can read the minimal completion service.*

This route excludes quotient completions, selected representatives, host equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier from Definition 1606.1. The accepted packet already displays the source metric row X, the completion row C, the dense embedding row E, the universal-property row U, the extension row F, the separated row S, and the structural rows H, R, P, N.

Apply the NameCert obligations of Definition 1606.2. They force the consumer to pass through carrier admission, dense-image coverage, universal factorization, separated uniqueness, and ledger non-escape before any completion-facing read is exported.

The reflector-unit factorization of Definition 1606.5, together with Definition 1606.4 and Definition 1606.6, keeps the same route visible through $X, C, E, U, F, S, H, R, P, N$. Hence the consumer cannot bypass the displayed packet by quotient completion, selected representatives, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityReplayNonescape`

Theorem 1606.9 (CauchyCompletionMinimality finite route induction)**.** *Let* $M = (X, C, E, U, F, S, H, R, P, N)$ *be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Finite induction over the displayed service route*

$$X \longmapsto C \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto H \longmapsto R \longmapsto P \longmapsto N$$

preserves the following consumer invariant at every prefix: once a consumer has reached the current row, all earlier dense-image coverage, universal factorization, separated uniqueness, reflector-unit factoring, and replay non-escape obligations already forced by the prefix remain available to the consumer, and no later row can replace them by quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The base prefix is the source metric row X. By the carrier definition in Definition 1606.1, the source row is admitted only as part of the finite packet whose remaining rows are $C, E, U, F, S, H, R, P, N$; there is no separate coordinate for quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient real completeness.

The completion and dense-embedding steps are forced by the carrier and by Definition 1606.2. At the prefix ending in E, Definition 1606.3 supplies the dense-image clause, so later consumers inherit coverage through the displayed completion row rather than through an external host completion.

The universal-property and extension steps are the next induction moves. Applying Definition 1606.4 at the prefixes ending in U and F preserves the factorization route from the source and dense embedding through the universal extension handoff.

At the separated row S, the same induction invariant gains the comparison boundary supplied by the separated uniqueness clause of Definition 1606.2. When the source read is presented through the reflector-unit surface, Definition 1606.5 inserts only the unit and dense-image rows before the same minimality route, so the induction step still has the same consumer invariant.

The terminal structural rows H, R, P, N transport, replay, package, and name the already established prefix data. The replay non-escape theorem Definition 1606.8 closes the induction by showing that these rows expose no bypass around dense-image coverage, universal factorization, separated uniqueness, or reflector-unit factoring. Thus every prefix of the displayed finite route preserves the same minimal completion service boundary and refuses the excluded quotient, representative-selection, host-equality, choice, compactness, and ambient real-completeness principles. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier finite row induction`

Theorem 1606.10 (CauchyCompletionMinimality carrier admission)**.** *Let* $M = (X, C, E, U, F, S, H, R, P, N)$ *be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Carrier admission for* M *is exactly the finite admission of the source metric row* X*, displayed completion row* C*, dense embedding row* E*, universal-property row* U*, uniformly continuous extension row* F*, separated uniqueness row* S*, componentwise transport row* H*, replay row* R*, provenance row* P*, and local naming row* N*.*

No admitted coordinate of M *supplies quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1606.1. Its ten rows are precisely $X, C, E, U, F, S, H, R, P, N$, and the defining list assigns one completion-minimality role to each row.

Apply the NameCert obligations of Definition 1606.2. The first obligation is carrier admission for exactly those rows, while the ledger non-escape obligation forbids any additional completion principle from entering the packet. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier admission`

Theorem 1606.11 (CauchyCompletionMinimality transport stability)**.** *Let* $M = (X, C, E, U, F, S, H, R, P, N)$ *and* $M' = (X', C', E', U', F', S', H', R', P', N')$ *be accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carriers*

with componentwise hsame *witnesses for the source, completion, embedding, universal-property, extension, separatedness, replay, provenance, and naming rows. If the displayed* Cont *route reads* $X, C, E, U, F, S, H, R, P, N$*, then the transported route reads* $X', C', E', U', F', S', H', R', P', N'$ *with the same dense-image, universal-factorization, separated-uniqueness, replay non-escape, and carrier-admission obligations.*

The transport preserves the absence of quotient completion, selected representatives, host equality, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the componentwise transport row H of the first carrier and the corresponding row H' of the second carrier. These rows witness hsame for the components that can be read by the minimality packet, so each visible obligation can be moved component by component.

The displayed Cont row R orders the source, completion, embedding, universal-property, extension, separatedness, transport, provenance, and naming reads. Transporting along the matching hsame witnesses gives the route through R' with the same row order.

Finally apply Definition 1606.9. Since every prefix obligation is preserved before the terminal structural rows are read, the transported carrier keeps dense-image coverage, universal factorization, separated uniqueness, replay non-escape, and ledger non-escape without adding any excluded coordinate. □

Theorem 1606.12 (CauchyCompletionMinimality ledger exactness)**.** *Let* $M = (X, C, E, U, F, S, H, R, P, N)$ *be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. The ledger rows* R, P, N *are exact for the finite service boundary*

$$X \longmapsto C \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto H \longmapsto R \longmapsto P \longmapsto N.$$

They record the displayed replay, BEDC provenance, and local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *name, and they record no completion principle outside the rows already admitted by the carrier.*

Proof. Read the replay row R as the ordered Cont route through the admitted rows. The route is the same finite row sequence used by Definition 1606.9.

Read P as provenance for the displayed completion, embedding, universal-property, extension, separatedness, history, transport, continuation, package, and NameCert rows, and read N as the local name for this packet. These two rows do not add an independent service coordinate.

The replay non-escape theorem Definition 1606.8 and the carrier-admission theorem Definition 1606.10 together show that R, P, N only preserve the admitted service boundary. Hence the ledger is exact for the listed rows and excludes quotient completion, selected representatives, host equality, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityLedgerExactness`

Theorem 1606.13 (CauchyCompletionMinimality obligation export)**.** *An accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier exports exactly the carrier admission, dense-image coverage, universal factorization, reflector-unit factorization, dense-extension uniqueness, separated-reflection route, replay non-escape, finite-row induction, transport stability, and ledger exactness rows displayed in this chapter. The exported package is read through the same finite service route*

$$X \longmapsto C \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto H \longmapsto R \longmapsto P \longmapsto N.$$

It has no coordinate for quotient completion, selected limits, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1606.1. Its rows are exactly the source metric, displayed completion, dense embedding, universal-property, uniformly continuous handoff, separated uniqueness, componentwise transport, replay, provenance, and local naming rows. Carrier admission is therefore supplied by Definition 1606.10.

The NameCert obligations of Definition 1606.2 give dense-image coverage, universal factorization, separated uniqueness, and ledger non-escape. The dense-image, universal-factorization, reflector-unit, dense-extension uniqueness, separated-reflection, and replay non-escape theorems refine those clauses into the named rows.

Finally apply finite route induction, Definition 1606.9, transport stability, Definition 1606.11, and ledger exactness, Definition 1606.12. These rows preserve each previously displayed obligation along the route from X to N and prevent later rows from replacing them by quotient completion, selected limits, host equality, choice, compactness, or ambient real-completeness data. Thus the accepted carrier exports exactly the stated obligation package. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityObligationExport`

Theorem 1606.14 (CauchyCompletionMinimality public exported package)**.** *The carrier definition Definition 1606.1, the NameCert obligations Definition 1606.2, the carrier admission theorem Definition 1606.10, the transport stability theorem Definition 1606.11, the ledger exactness theorem Definition 1606.12, the finite-row induction theorem Definition 1606.9, and the obligation-export theorem Definition 1606.13 form the public BEDC package consumed by completion-minimality clients.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityPublicExportedPackage`

Proof. The carrier definition supplies the accepted source metric, displayed completion rows, dense embedding, universal-property rows, transport rows, replay rows, provenance rows, and local naming row. The NameCert obligations and carrier-admission theorem show that this row package is admissible.

Transport stability and ledger exactness keep the same public rows visible after finite route traversal, and finite-row induction ensures that no later coordinate replaces them. The obligation-export theorem packages those same rows as the chapter-level export, so the displayed data are exactly the public BEDC package used by completion-minimality clients. □

Theorem 1606.15 (CauchyCompletionMinimality bridge boundary)**.** *Let $M = (X, C, E, U, F, S, H, R, P, N)$ be an accepted* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *carrier. Any standard completion bridge for the public package of Definition 1606.14 must factor through the finite route*

$$X \longmapsto C \longmapsto E \longmapsto U \longmapsto F \longmapsto S \longmapsto H \longmapsto R \longmapsto P \longmapsto N.$$

Along this route the bridge preserves dense-image coverage, universal factorization, separated uniqueness, uniformly continuous transport, replay, provenance, and local naming. It does not replace the displayed package by quotient completions, selected representatives, countable choice, host equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 1606.1. Its displayed rows are exactly $X, C, E, U, F, S, H, R, P, N$, and the NameCert obligations of Definition 1606.2 expose dense-image coverage, universal factorization, separated uniqueness, and ledger non-escape on those rows.

Apply finite-row induction, Definition 1606.9. The bridge can traverse the public package only by reading the admitted route from the source metric through the local name. The dense-image

theorem, universal-factorization theorem, separated-reflection route, transport-stability theorem, and public exported package theorem preserve the corresponding rows at each stage.

Finally use ledger exactness, Definition 1606.12. The replay, provenance, and local naming rows record the same finite service boundary and no larger completion principle. Hence a standard bridge has a paper-visible boundary precisely at the displayed route and cannot appeal to quotient completions, selected representatives, countable choice, host equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityBridgeBoundary`

Theorem 1606.16 (CauchyCompletionMinimality bridge exactness)**.** *Let $M = (X, C, E, U, F, S, H, R, P, N)$ and $M' = (X', C', E', U', F', S', H', R', P', N')$ be BEDC completion candidates whose displayed dense embedding rows, reflector-unit factorization rows, dense-extension uniqueness rows, separated-reflection rows, and ledger-exactness rows are read through matching* hsame *transport. If both candidates expose the same public completion-minimality route from source metrics through dense embeddings, universal factorization, uniformly continuous extension, separated uniqueness, replay, provenance, and local naming, then they admit the same* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *bridge packet. The bridge exports only the displayed universal factorization and dense-extension uniqueness route; it exports no quotient representative, choice-selected limit, host real equality, countable-choice schedule, open-cover compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the reflector-unit theorem, Definition 1606.5. It places the source read, unit embedding, dense-image row, reflector row, and triangle replay before any minimality-facing consumer reaches the universal factorization surface.

Next apply dense-extension uniqueness, Definition 1606.6, together with the separated-reflection route, Definition 1606.7. These two rows force the two completion candidates to compare their exported reads only through the common dense embedding, universal-property row, uniformly continuous extension handoff, and separated boundary.

Use ledger exactness, Definition 1606.12. The replay, provenance, and local naming rows record exactly the same finite service boundary on both transported candidates, so no later row can introduce an additional representative selector, host equality, choice schedule, compactness witness, or ambient real-completeness coordinate.

Finally apply the bridge boundary theorem, Definition 1606.15. Since the public bridge can traverse only the displayed finite route and the preceding rows already identify the reflector unit, dense-extension uniqueness, separated comparison, and ledger boundary, the two candidates determine the same bridge packet and export only the stated universal factorization and uniqueness data. □

Theorem 1606.17 (CauchyCompletionMinimality formal-target contract)**.** *Any later Lean-facing formal target for the public* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *package must expose exactly the source metric row X, displayed completion row C, dense embedding row E, universal-property row U, uniformly continuous handoff row F, separated uniqueness row S, componentwise* hsame *transport row H, displayed* Cont *replay row R,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ *row N before it claims dense-image coverage, universal factorization, separated reflection, or the bridge boundary of this chapter. A target that omits one of these rows, merges two rows into a host completion object, or adds quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness is not the formal target for the public minimality package.*

Proof. Start with the NameCert obligations of Definition 1606.2. They list carrier admission, dense-image coverage, universal factorization, separated uniqueness, and ledger non-escape for the tuple $M = (X, C, E, U, F, S, H, R, P, N)$.

The public exported package of Definition 1606.14 is read through the same displayed rows. Finite-row induction in Definition 1606.9 prevents a later consumer from skipping from X to a completed value without traversing $C, E, U, F, S, H, R, P, N$.

Use ledger exactness, Definition 1606.12. The replay, provenance, and local naming rows record the same service boundary and do not add a quotient completion, selected representative, host equality, choice, compactness, or ambient real-completeness coordinate.

Finally apply the bridge boundary theorem Definition 1606.15. Since its bridge route preserves dense-image coverage, universal factorization, separated uniqueness, uniformly continuous transport, replay, provenance, and local naming along the displayed finite route, any Lean-facing target claiming those public conclusions must expose precisely the listed rows first. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier formal target contract`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}$ **.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1606.14 exports the public package over source metrics, displayed completion rows, dense embeddings, universal extension, uniformly continuous handoff, separated uniqueness, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMinimality}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityCarrier\_formal\_target\_contrac`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The remaining formal upgrade is bridge checking for the displayed public package.

Constructive story: A $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ packet is generated from a source metric with located source evidence, a displayed completion row, a dense completion embedding, a universal-property row, a uniformly continuous extension handoff, separated uniqueness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1607

A Concrete Naming Certificate for $\mathsf{DirectedSet}^{\uparrow}$

Following Moore–Smith and Kelley directed sets, and the Bishop–Bridges use of finite constructive evidence in analysis, the $\mathsf{DirectedSet}^{\uparrow}$ packet names the directed-index substrate consumed by net-based BEDC chapters. It sits upstream of the directed-window surface of chapter 589, the limit boundary of chapter 1561, and the convergence packet of chapter 1521. The packet records finite preorder and upper-window data; it is not a quotient of indices, not a global cofinal-choice operator, and not a host-level order-completeness principle.

Definition 1607.1 (DirectedSet carrier)**.** *A* $\mathsf{DirectedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, \preceq, W, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row naming the inspected directed addresses.*
2. *$\preceq$ is the comparison row, recording the displayed preorder comparisons among the inspected addresses.*
3. *W is the finite window row, naming each finite subfamily of inspected addresses requested by a downstream net consumer.*
4. *U is the upper-window witness row, assigning to every displayed window in W a named address in I that is above every address in that window according to $\preceq$.*
5. *H records componentwise* hsame *transport for the index, comparison, window, upper-witness, continuation, provenance, and naming rows.*
6. *C records displayed* Cont *replay from a downstream finite-window request through W, $\preceq$, and U.*
7. *P is the* Pkg *provenance over* $\mathsf{DirectedSet}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *together with the downstream consumers* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, *and* $\mathsf{MooreSmithConvergence}^{\uparrow}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DirectedSet}^{\uparrow}}$ *row.*

The carrier exports only this finite directed-index packet. It contains no total order extension, no selected cofinal sequence, no quotient on indices, and no infinite choice principle.

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetCarrier fields faithful`

Theorem 1607.2 (DirectedSet NameCert obligations)**.** *For every accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier* $D = (I, \preceq, W, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirectedSet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed index, comparison, window, upper-witness, transport, continuation, provenance, and naming rows;*
2. *preorder readability, stating that every comparison exported to a consumer is one of the displayed* $\preceq$ *rows on addresses in* I*;*
3. *finite-window coverage, stating that every requested finite index family is first named in* W*;*
4. *upper-window witnessing, stating that every displayed window has a named witness in* U *above each of its addresses by the displayed comparison row;*
5. *transport and continuation stability, stating that* H *and* C *preserve the same finite window and witness data under* hsame *replay;*
6. *ledger non-escape, excluding cofinal choice functions, quotient index objects, total-order completions, and infinite upper-bound selection.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1607.1. The finite index row, comparison row, displayed windows, upper-window witnesses, transports, continuations, provenance, and local naming row are visible coordinates of one BHist packet.

Preorder readability and finite-window coverage are forced by the row order. A consumer can read an address only through I, a comparison only through $\preceq$, and a finite request only after that request has been named in W.

The upper-window obligation is the defining role of U. For each displayed window, U supplies a named address and the comparison row supplies the finite list of relations showing that the address lies above every member of the window.

Transport and continuation stability use the structural rows H and C. They replay the same displayed windows, comparisons, and upper-witness entries, so they do not add a cofinal selector or an unrecorded index relation.

Finally, the package and naming rows name exactly the displayed finite packet. Since no coordinate stores a quotient of indices, a total-order completion, a selected cofinal sequence, or an infinite choice function, any request for such data remains outside the local ledger. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetTasteGate single carrier alignment`

Theorem 1607.3 (DirectedSet CauchyNet index handoff)**.** *Let* $D = (I, \preceq, W, U, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier. Any* $\mathsf{CauchyNet}^{\uparrow}$ *or* $\mathsf{CauchyNetLimit}^{\uparrow}$ *packet that reads its directed-window ledger from* D *receives index data only through the finite route*

$$I, \preceq, W, U \longmapsto H, C, P, N.$$

Thus the Cauchy-net carrier of Definition 589.1 and the limit carrier of Definition 1561.1 may share the same displayed directed-index substrate without adding quotient nets, selected limits, cofinal choice, or ambient completeness.

Proof. Start with a downstream Cauchy-net request. The directed addresses available to the consumer are the entries of I, and the comparisons available to the consumer are the displayed rows of $\preceq$.

The finite request is then named in W. The witness row U supplies the common upper-window address needed by the $\mathsf{CauchyNet}^{\uparrow}$ directed-window ledger, and the same witness row can be replayed before the $\mathsf{CauchyNetLimit}^{\uparrow}$ seal handoff is read.

The structural rows H and C transport and replay this route componentwise. The provenance and local naming rows record that the exported data is the finite directed-index packet, not a quotient net, selected host limit, cofinal-choice selector, or completeness assertion. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSet cauchynet index handoff certificate`

Theorem 1607.4 (DirectedSet filter-net handoff)**.** *Let $D = (I, \preceq, W, U, H, C, P, N)$ be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier. Any* $\mathsf{FilterConvergence}^{\uparrow}$ *or* $\mathsf{MooreSmithNet}^{\uparrow}$ *packet that reads a directed index from D must expose the finite index row I, displayed preorder comparisons $\preceq$, finite request windows W, and upper-window witnesses U before the filter-base handoff, net tail ledger, or convergence consumer can be read. The resulting route exports finite directed-window data only; it does not supply a host directed set, cofinal choice, quotient index, or total-order completion.*

Proof. Project the carrier rows of Definition 1607.1. The index addresses, preorder comparisons, request windows, and upper-window witnesses are exactly the rows $I, \preceq, W, U$.

Apply the CauchyNet index handoff of Definition 1607.3. It already forces net-style consumers to read the directed-window ledger through the displayed index, comparison, window, and witness rows before transport, replay, provenance, and naming.

Use finite upper-window stability, Definition 1607.5, for retained filter and Moore–Smith windows. Retention keeps the upper witnesses inside the displayed subledger, so the filter-base or net-tail read cannot replace them by a cofinal selector.

Since the carrier contains no row for a host directed set, quotient index, total-order completion, or choice-indexed cofinal family, those objects cannot discharge the filter-net handoff. Every downstream read remains bounded by $I, \preceq, W, U, H, C, P, N$. □

Theorem 1607.5 (DirectedSet finite upper-window stability)**.** *Let $D = (I, \preceq, W, U, H, C, P, N)$ be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier, and let Ω be a retained finite subledger of I whose displayed windows in W_Ω keep their named upper witnesses in Ω. Then*

$$D_\Omega = (I_\Omega, \preceq_\Omega, W_\Omega, U_\Omega, H_\Omega, C_\Omega, P_\Omega, N_\Omega)$$

is an accepted $\mathsf{DirectedSet}^{\uparrow}$ *carrier for the retained windows. Every* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *consumer of D_Ω therefore reads the same finite upper-window witnesses, restricted to Ω.*

Proof. Restrict the index row to I_Ω and the comparison row to $\preceq_\Omega$. The hypothesis on retained windows says that every window kept in W_Ω still has its upper witness inside the retained index row.

The witness row U_Ω is the corresponding restriction of U. For each retained window, the required comparison entries are exactly the entries of $\preceq_\Omega$ that already certified the witness in the original carrier.

The transport, continuation, provenance, and naming rows restrict componentwise to H_Ω, C_Ω, P_Ω, and N_Ω. Their endpoints are among the retained rows, so replay cannot leave the finite subledger.

Apply the obligation surface of Definition 1607.2. Carrier admission is the displayed restricted tuple; preorder readability, finite-window coverage, upper-window witnessing, and structural stability are inherited by restriction. Ledger non-escape remains valid because no retained coordinate stores quotient indices, cofinal choice, total-order completion, or infinite upper-bound selection. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetPacket finite upper window stability`

Theorem 1607.6 (DirectedSet carrier obligation)**.** *For every accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier* $D = (I, \preceq, W, U, H, C, P, N)$*, the carrier obligation is the visible finite row family consisting of the index row* I*, the displayed preorder comparison row* $\preceq$*, the finite-window row* W*, and the upper-window witness row* U*, together with structural rows* H, C, P, N*. No carrier obligation may be discharged by quotient indices, a total-order completion, cofinal choice, or infinite upper-bound selection.*

Proof. Project the carrier of Definition 1607.1. The rows $I, \preceq, W, U, H, C, P, N$ are exactly the displayed coordinates of the accepted packet.

Apply the NameCert obligation theorem Definition 1607.2. Its carrier admission, preorder readability, finite-window coverage, and upper-window witnessing clauses identify the same visible rows.

The non-escape clause excludes the forbidden objects. Since none of them appears as a carrier coordinate, no downstream consumer can use one to discharge the carrier obligation. □

Theorem 1607.7 (DirectedSet preorder stability obligation)**.** *Let* $D = (I, \preceq, W, U, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier. Every displayed preorder comparison exported from* D *remains stable under the componentwise* hsame *transport row* H *and the displayed* Cont *replay row* C*. The stable comparison is still a row of* $\preceq$ *on addresses from* I*, not a host preorder, quotient relation, total-order completion, or hidden comparison outside the packet.*

Proof. Read the comparison row through Definition 1607.1. The only preorder comparisons available to a consumer are the displayed entries of $\preceq$ between addresses named by I.

Use the transport and continuation stability clause of Definition 1607.2. It requires H and C to preserve the same finite windows, comparisons, and upper-witness data under replay.

The CauchyNet handoff theorem Definition 1607.3 then sends net consumers through the same row family. Thus a transported or replayed comparison cannot be replaced by a quotient relation, a host preorder, or a total-order completion. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetCarrier preorder stability obligation`

Theorem 1607.8 (DirectedSet cofinal merge obligation)**.** *Let* $D = (I, \preceq, W, U, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier, and let two retained finite windows in* W *have displayed upper witnesses named by* U*. The cofinal merge obligation for their union is discharged only by naming that union as a finite window in* W *and reading its displayed upper witness through* U*. The resulting merge remains a finite-window witness and is not a cofinal sequence, infinite upper-bound selector, quotient index, or choice function.*

Proof. Begin with the two retained windows. By Definition 1607.2, each window is first named in W and each upper witness is read through U using displayed comparisons from $\preceq$.

For the merged request, use the same finite-window coverage clause on the union window. Once that union is displayed in W, the upper-window witnessing clause supplies its named upper witness in U.

Apply finite upper-window stability, Definition 1607.5, to retained subledgers. It keeps the merged witness inside the same finite route and prevents the merge from becoming a cofinal sequence, quotient index, infinite selector, or choice function. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetCarrier cofinal merge obligation`

Theorem 1607.9 (DirectedSet upper-window exhaustion)**.** *Let* $D = (I, \preceq, W, U, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier. Any* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, *or* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *consumer that reads a finite directed-window request from* D *factors through the displayed rows*

$$I, \preceq, W, U, H, C, P, N.$$

The consumer therefore cannot obtain a cofinal sequence, quotient index, total-order completion, infinite upper-bound selector, or choice function from the directed-window read.

Proof. Start with the carrier of Definition 1607.1. The only index addresses are the entries of I, the only comparisons are the displayed rows of $\preceq$, and the only finite requests are the windows named in W.

Apply Definition 1607.2. Its finite-window coverage and upper-window witnessing clauses force every accepted request to read its witness through U, while its transport and continuation clauses route every replay through H and C.

Now use Definition 1607.3 for $\mathsf{CauchyNet}^{\uparrow}$ and $\mathsf{CauchyNetLimit}^{\uparrow}$ consumers, and Definition 1607.5 for retained Moore–Smith windows. These results identify the same finite upper-window route after restriction or handoff.

Finally, P and N source and name only that route. Since the carrier and the cited obligations contain no row for a cofinal sequence, quotient index, total-order completion, infinite upper-bound selector, or choice function, no downstream consumer can extract one from the finite directed-window request. □

Lean4 ✓ `BEDC.Derived.DirectedSetUp.DirectedSetPacket upper window exhaustion`

Theorem 1607.10 (DirectedSet obligation closure package)**.** *The accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier*

$$D = (I, \preceq, W, U, H, C, P, N)$$

supports an obligationClosure package whose finite boundary consists of carrier admission for the displayed rows, preorder readability through $\preceq$*, finite-window coverage through* W*, upper-window witnessing through* U*, transport and* Cont *replay through* H, C*, retained-subledger stability, and non-escape from cofinal selectors, quotient indices, total-order completions, infinite upper-bound selection, and choice functions. Every* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, *and* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *consumer of the package reads only this finite directed-window substrate.*

Proof. Begin with the carrier definition, Definition 1607.1. It supplies the finite index row, comparison row, finite-window row, upper-witness row, transport row, continuation row, provenance row, and local naming row.

Apply the NameCert obligations of Definition 1607.2. Carrier admission, preorder readability, finite-window coverage, upper-window witnessing, transport replay, continuation replay, and ledger non-escape are exactly the displayed obligations.

Use the CauchyNet index handoff, Definition 1607.3, to identify how $\mathsf{CauchyNet}^{\uparrow}$ and $\mathsf{CauchyNetLimit}^{\uparrow}$ consumers read the same route through $I, \preceq, W, U, H, C, P, N$.

Use finite upper-window stability and upper-window exhaustion, Definition 1607.5 and Definition 1607.9. These keep retained subledgers inside the same finite route and show that Moore–Smith and Cauchy-net consumers cannot extract cofinal selectors, quotient indices, total-order completions, infinite upper-bound selection, or choice functions. □

Theorem 1607.11 (DirectedSet mature consumer package)**.** *Let* $D = (I, \preceq, W, U, H, C, P, N)$ *be an accepted* $\mathsf{DirectedSet}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, *and* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *consumer of* D *reads the directed-index substrate only through*

$$I, \preceq, W, U, H, C, P, N.$$

The package contains no cofinal sequence selector, quotient index object, total-order completion, infinite upper-bound selector, or choice function, and no mature consumer may replace the finite directed-window route by any such external object.

Proof. Begin with the carrier definition, Definition 1607.1. Its only public rows are the finite index row I, preorder row $\preceq$, finite-window row W, upper-witness row U, transport row H, continuation row C, provenance row P, and local naming row N.

Apply the NameCert obligations and the obligation closure package, Definition 1607.2 and Definition 1607.10. These identify the accepted directed-window boundary with exactly those rows and make the consumer-facing obligations exhaustive.

Next use the CauchyNet handoff and upper-window results, Definition 1607.3, Definition 1607.5, and Definition 1607.9. They show that Cauchy-net, Cauchy-net-limit, and Moore–Smith reads preserve the same finite route after restriction, handoff, and retained-window replay.

Since the cited carrier and obligations contain no row for a cofinal sequence selector, quotient index, total-order completion, infinite upper-bound selector, or choice function, a mature consumer has no source from which to extract one. Thus all named consumers read only $I, \preceq, W, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedSet}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DirectedSet}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1607.1, the NameCert obligations, Definition 1607.3, finite-window stability, Definition 1607.9, Definition 1607.10, and Definition 1607.11 bind the mature BEDC primitive boundary for the finite directed-index substrate consumed by Cauchy-net, Cauchy-net-limit, and Moore–Smith convergence packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DirectedSet}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.DirectedSetUp.DirectedSetCarrier\_fields\_faithful`

Bridge status: none

Not claimed: This chapter does not close quotient index objects, selected cofinal sequences, total-order completions, infinite choice principles, Lean verification, or bridge checking.

Upgrade path: Bridge checking requires a standard-schema bridge for the same directed-index packet.

Constructive story: A $\mathsf{DirectedSet}^{\uparrow}$ packet is generated from a finite index row, displayed preorder comparisons, finite requested windows, common upper-window witnesses, componentwise hsame transports, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 1608

A Concrete Naming Certificate for $\mathsf{RealAbs}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealAbs}^{\uparrow}$ packet records absolute value for displayed regular real names by finite readback rows rather than by a host real operation. It reads the real-name seal of chapter 38, the dyadic absolute-value windows of chapter 293, and the regular rational handoff of chapter 301. The packet also uses the apartness and order surface supplied by $\mathsf{RealAlgOrder}^{\uparrow}$, while withholding host trichotomy, quotient reals, selected limits, and completeness principles.

Definition 1608.1 (Real absolute-value carrier)**.** *A* $\mathsf{RealAbs}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, D, S, G, V, H, C, P, N)$$

with the following displayed coordinates:

1. *R is the displayed* $\mathsf{Real}^{\uparrow}$ *seal whose regular real name is being inspected.*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness and order row used only as a displayed comparison surface for the real-name read.*
3. *D is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *window row attached to the dyadic observations opened from R.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation window through which finite requests to the real name are scheduled.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that supplies regular rational readback before the real seal is exported.*
6. *V is the finite nonnegative absolute-value ledger recording the endpoint and tolerance data available to downstream consumers.*
7. *H stores componentwise* hsame *transport for the real seal, order row, dyadic window, observation window, handoff, ledger, provenance, and local name.*
8. *C stores the displayed* Cont *routes from R through S and G into D, and from D into the nonnegative ledger V.*
9. *P records* Pkg *provenance over* $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealAbs}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host trichotomy, quotient real equality, a selected limit, an external absolute-value operation, or a completeness witness.

Theorem 1608.2 (Real absolute-value NameCert obligations)**.** *For every accepted* $\mathsf{RealAbs}^{\uparrow}$ *carrier* $K = (R, A, D, S, G, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealAbs}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed real seal, apartness and order row, dyadic absolute-value window, observation window, regular rational handoff, nonnegative ledger, transport, continuation, provenance, and local naming rows;*
2. *classifier and transport stability, requiring accepted reads to move componentwise through the stored* hsame *rows and to replay through the displayed* Cont *routes;*
3. *dyadic-window handoff, requiring every absolute-value observation to pass from the* $\mathsf{Real}^{\uparrow}$ *seal through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows into the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *window row;*
4. *nonnegative real-seal export, requiring the output ledger* V *to expose only a nonnegative* $\mathsf{Real}^{\uparrow}$*-facing seal read from the displayed dyadic windows and regular handoff;*
5. *non-escape from trichotomy and completeness, excluding host order trichotomy, quotient real equality, selected limits, external absolute-value operations, and ambient completeness.*

No NameCert obligation is stored outside these five finite rows.

Proof. Carrier admission is projection from Definition 1608.1. The only available absolute-value data are the real seal R, the order row A, the dyadic window D, the observation window S, the regular handoff G, the nonnegative ledger V, and the structural rows H, C, P, N.

Classifier and transport stability are read from H and replayed through C. A transported carrier therefore keeps the same displayed route from the real seal through finite observation and regular rational readback into the dyadic absolute-value window.

The dyadic-window handoff uses chapter 293 as the only absolute-value window source. The output ledger V exports the nonnegative real-facing seal after that handoff, so the packet never opens a separate host absolute-value, trichotomy, quotient, selected-limit, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealAbs}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealAbs}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1608.1 and Definition 1608.2 seed the finite real absolute-value surface over displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealAbs}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host trichotomy, quotient real equality, selected limits, external absolute-value operations, or ambient completeness.

Upgrade path: Obligation closure requires formal carrier admission, classifier and transport stability, dyadic-window handoff, nonnegative real-seal export, and non-escape from trichotomy and completeness for the same finite packet.

Constructive story: A $\mathsf{RealAbs}^{\uparrow}$ packet is generated from a displayed Real seal, RealAlgOrder apartness and order row, DyadicAbsoluteValue window row, StreamName observation window, RegSeqRat handoff, nonnegative absolute-value ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1609

A Concrete Naming Certificate for $\mathsf{EventuallyZeroSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{EventuallyZeroSequence}^{\uparrow}$ packet records the finite-cutoff source of a null rational difference sequence: after one displayed cutoff row, every later observation is the zero dyadic row. It refines the zero-convergence consumer surface of chapter 380 by replacing an arbitrary modulus lookup with a visible cutoff induction over the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic zero row of chapter 291, the constant rational handoff of chapter 364, and the terminal equality seal of chapter 38.

Definition 1609.1 (Eventually-zero sequence carrier)**.** *An* $\mathsf{EventuallyZeroSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, G, D, Z, T, H, C, P, N)$$

with the following visible coordinates:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose accepted requests enumerate the displayed sequence positions.*
2. G *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the distinguished zero dyadic row and the finite comparison rows used by each inspected window.*
4. Z *is the* $\mathsf{StationaryRationalCauchy}^{\uparrow}$ *zero source whose constant rational readback supplies the zero row consumed after the cutoff.*
5. T *is the cutoff row: every accepted request at a position beyond* T *must replay the zero row of* D *through the stationary source* Z*.*
6. H *records componentwise* hsame *transport for stream windows, regular readbacks, dyadic rows, the stationary zero source, the cutoff row, continuation routes, provenance, and the local naming row.*
7. C *records displayed* Cont *replay from a sequence request through* S*, then* G*, then the dyadic row* D*, with the branch beyond* T *routed through* Z*.*
8. P *is the* Pkg *provenance over* $\mathsf{EventuallyZeroSequence}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StationaryRationalCauchy}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{EventuallyZeroSequence}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a quotient stream, selected host limit, trichotomy principle, or ambient completeness witness for $\mathsf{Real}^{\uparrow}$.

Theorem 1609.2 (Eventually-zero sequence NameCert obligations)**.** *For every accepted* $\mathsf{EventuallyZeroSequence}^{\uparrow}$ *carrier* $E = (S, G, D, Z, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EventuallyZeroSequence}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the stream window, regular rational readback, dyadic zero ledger, stationary zero source, cutoff, transport, continuation, provenance, and local naming rows;*
2. *classifier and transport stability for the displayed rows under the componentwise* hsame *ledger* H*;*
3. *cutoff-window exactness, requiring every request beyond* T *to read the zero dyadic row of* D *through the stationary source* Z*;*
4. *null-sequence handoff, requiring the same finite cutoff packet to instantiate the* $\mathsf{NullSequence}^{\uparrow}$ *tolerance-window route;*
5. *non-escape, excluding quotient streams, selected limits, trichotomy, external real equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1609.1. The displayed tuple supplies exactly the stream, readback, dyadic, stationary zero, cutoff, transport, continuation, package, and local naming rows.

Classifier and transport stability are componentwise. The rows in H move the finite window S, the readback G, the dyadic ledger D, the stationary source Z, and the cutoff T, while C replays the same request order after transport.

The cutoff-window obligation is the only analytic-looking row, but it is still finite: beyond T, each accepted window is routed through the stationary zero source and returns the zero dyadic row already listed in D.

The null-sequence handoff and non-escape rows then read the same finite packet. Since quotient streams, selected limits, trichotomy, external equality, and completeness are absent from the carrier, no local obligation can export them. □

Theorem 1609.3 (Eventually-zero cutoff-window induction)**.** *Let* $E = (S, G, D, Z, T, H, C, P, N)$ *be an accepted* $\mathsf{EventuallyZeroSequence}^{\uparrow}$ *carrier. For every finite* $\mathsf{StreamName}^{\uparrow}$ *window whose positions are all beyond the cutoff row* T*, induction over the listed window positions shows that each* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* G *is the zero dyadic row of* D *routed through the stationary source* Z*.*

Consequently every tail window admitted by S *beyond* T *is a finite zero window, transported only by* H *and replayed only through* C*.*

Proof. Use induction on the finite list of positions recorded by the accepted $\mathsf{StreamName}^{\uparrow}$ window.

The empty window has no readback request, so the zero-window claim is immediate from carrier admission.

For a window extended by one position beyond T, first apply the cutoff row. The replay route C sends the final request through S, then G, then D, and the beyond-cutoff branch forces the stationary zero source Z.

Apply the induction hypothesis to the earlier positions in the window. Transport through H preserves the same stream, readback, dyadic zero, stationary source, and cutoff rows, so adjoining

the final zero readback yields a finite window all of whose displayed values are the zero dyadic row. □

Theorem 1609.4 (Eventually-zero NullSequence handoff)**.** *Every accepted* $\mathsf{EventuallyZeroSequence}^{\uparrow}$ *carrier* $E = (S, G, D, Z, T, H, C, P, N)$ *determines a* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail packet for the same displayed regular rational stream: a tolerance request is answered by the cutoff row* T*, the post-cutoff window is read through* S *and* G*, the zero dyadic row is supplied by* D *and* Z*, and the resulting evidence is exported to the* $\mathsf{Real}^{\uparrow}$ *equality seal through the recorded* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Begin with a $\mathsf{NullSequence}^{\uparrow}$ tolerance request. The eventually-zero packet uses T as the displayed threshold row for that request.

Once the request is beyond the cutoff, apply Definition 1609.3. The selected finite window reads only the zero dyadic row through S, G, D, and Z.

Repack those rows as the null-sequence tolerance-window package. The stream row is G, the tolerance and zero ledger are read from D, the window is supplied by S, and the bound row is the cutoff T.

The remaining coordinates H, C, P, N provide the transport, replay, dependency, and local naming rows required by $\mathsf{NullSequence}^{\uparrow}$. The $\mathsf{Real}^{\uparrow}$ seal therefore consumes a finite zero-tail packet rather than a host limit or quotient stream. □

Theorem 1609.5 (Eventually-zero public certificate boundary)**.** *The public surface of an accepted* $\mathsf{EventuallyZeroSequence}^{\uparrow}$ *packet is exhausted by the finite rows*

$$S, G, D, Z, T, H, C, P, N.$$

It exposes the cutoff induction of Definition 1609.3 and the $\mathsf{NullSequence}^{\uparrow}$ *handoff of Definition 1609.4, and it exposes no quotient stream representative, selected limit, trichotomy principle, hidden real equality test, or ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 1609.1. Every public read is a read of the displayed stream, regular rational row, dyadic zero ledger, stationary zero source, cutoff, transport, continuation, provenance, or local naming row.

The cutoff-window induction is internal to those rows. It uses only the finite window S, the readback G, the dyadic ledger D, the stationary source Z, the cutoff T, and the displayed transport and continuation rows.

The handoff to $\mathsf{NullSequence}^{\uparrow}$ repacks the same data as a tolerance-window route. It does not add a separate convergence object, because the threshold is already the cutoff row and every tail value is the zero dyadic row.

Since no quotient stream, selected limit, trichotomy principle, hidden equality test, or completeness witness is a coordinate of the packet, none can be exported by the public certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{EventuallyZeroSequence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EventuallyZeroSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1609.1, Definition 1609.2, Definition 1609.3, Definition 1609.4, and Definition 1609.5 seed the finite cutoff route from StreamName windows through RegSeqRat readback, DyadicRatCore zero rows, StationaryRationalCauchy zero source, NullSequence handoff, and the Real boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EventuallyZeroSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient streams, selected limits, trichotomy, hidden real equality tests, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier and transport stability, cutoff-window exactness, NullSequence handoff, and public non-escape for BEDC.Derived.EventuallyZeroSequenceUp.

Constructive story: An EventuallyZeroSequence$^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, a DyadicRatCore zero ledger, a StationaryRationalCauchy zero source, a cutoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1610

A Concrete Naming Certificate for $\mathsf{HeineCantorModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{HeineCantorModulus}^{\uparrow}$ packet records the finite-net form of Heine–Cantor as explicit BEDC modulus data. It reads the compact-metric finite net of chapter 129, the finite compact-uniform-continuity route of chapter 388, the pointwise rows of chapter 130, the consumer modulus surface of chapter 369, and the final triangle handoff of chapter 1159. The chapter names the finite certificate route that turns local pointwise modulus rows on a displayed compact net into one tolerance-indexed uniform modulus.

Definition 1610.1 (Heine-Cantor modulus carrier)**.** *A* $\mathsf{HeineCantorModulus}^{\uparrow}$ *carrier is a finite BEDC packet*

$$H = (X, Y, F, \varepsilon, P, C, R, M, T, Q, S, K, N)$$

with the following displayed rows:

1. *X is the compact metric source row, read through* $\mathsf{NameCert}_{\mathsf{CompactMetric}^{\uparrow}}$*, with its finite* $\mathsf{ProbeBundle}$ *net family at the target precision scale.*
2. *Y is the target metric row whose triangle ledger receives the final estimate.*
3. *F is the continuous-map row from X to Y, read through* $\mathsf{NameCert}_{\mathsf{ContinuousMap}^{\uparrow}}$*, with pointwise modulus rows at the listed net centers.*
4. *ε is the positive target dyadic precision history whose uniform modulus is being named.*
5. *P is the finite* $\mathsf{ProbeBundle}$ *net selected from the compact metric certificate for the source scale required by ε.*
6. *C lists the center histories in P, together with their membership constructors and coverage rows.*
7. *R lists the pointwise continuity radii attached to those centers and the rational lower-bound rows used to fold them into one positive source precision.*
8. *M is the exported source precision history, classified componentwise by the* $\mathsf{Rat}^{\uparrow}$ *and source-metric classifiers.*
9. *T is the metric triangle handoff row, read through chapter 1159, which carries the compact-net source estimates and the two pointwise target estimates to the final ε bound.*
10. *Q records componentwise* hsame *transport for $X, Y, F, \varepsilon, P, C, R, M, T$.*

11. *S records the displayed* Cont *routes from compact metric data, pointwise continuity data, finite-fold data, and triangle data to the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer.*
12. *K records* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, *and* Cont *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineCantorModulus}^{\uparrow}}$ *row.*

The carrier accepts only these finite rows. Its displayed continuity condition is the continuation assertion

$$\mathsf{Cont}(H, \mathsf{NameCert}_{\mathsf{UniformModulus}^{\uparrow}})$$

through the rows $P, C, R, M, T, Q, S, K, N$; it has no coordinate for open-cover compactness, sequential compactness, choice-selected centers, trichotomy, or host real equality.

Theorem 1610.2 (Heine-Cantor modulus NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{HeineCantorModulus}^{\uparrow}}$ *obligation surface consists exactly of the finite carrier exposure of Definition 1610.1, componentwise* hsame *transport for all displayed rows, the finite-net extraction row, the folded positive source-precision row, the metric triangle handoff row, and the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer route. No accepted obligation may cite an open-cover compactness theorem, a sequential compactness principle, a choice operation, a trichotomy split on host reals, or host equality of real points.*

Proof. Project the carrier packet H. The source, target, continuous-map, precision, net, center, radius, folded-modulus, triangle, transport, continuation, provenance, and local naming rows are the whole displayed surface.

Classifier stability is componentwise. The row Q transports each displayed history by the corresponding source, target, rational, finite-bundle, and triangle classifier, while S replays the same Cont route after transport.

The remaining obligations are the three constructive readings: extract the finite net from $\mathsf{CompactMetric}^{\uparrow}$, fold the pointwise radii in the finite list to obtain M, and apply the metric triangle handoff to deliver the target ε estimate. Since every reading uses a named coordinate of H, the excluded compactness and choice-theoretic routes have no readable slot in the local NameCert packet. □

Theorem 1610.3 (Heine-Cantor finite-net extraction)**.** *For an accepted* $\mathsf{HeineCantorModulus}^{\uparrow}$ *carrier H, the net rows P and C determine the finite list of centers used by the modulus construction. Each listed center is a source history carried by X, each membership row is a displayed* ProbeBundle *constructor, and each coverage row is a compact-metric distance ledger at the precision scale read from ε. The extraction is by finite-row projection and induction over the displayed net spine.*

Proof. Read P from the carrier. It is already a finite ProbeBundle row from the compact-metric certificate, so the only available centers are the histories listed in its finite spine.

Induct over that spine. At the empty boundary no center is produced and no coverage row is exported. At a successor row, project the displayed center history, its membership constructor, and the attached compact-metric coverage ledger, then append those rows to the extracted list.

The induction uses no cover refinement or external compactness principle. Every step reads the next stored row of P and C, and componentwise hsame transport in Q carries the extracted center and coverage rows to classified representatives. □

Theorem 1610.4 (Heine-Cantor triangle handoff)**.** *For an accepted* $\mathsf{HeineCantorModulus}^{\uparrow}$ *carrier H, the folded source precision M, the compact-net center rows C, and the pointwise continuity rows R determine the triangle handoff row T. Consequently the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer receives a*

single positive source precision whose validity for the target tolerance ε is witnessed by finite-net coverage, two pointwise target estimates at the selected center, and the target metric triangle ledger.

Proof. Begin with the finite-net extraction theorem. It gives the selected center route and compact-metric source coverage rows from the displayed net packet.

Next read the folded precision M from the rows R. The fold is finite: each pointwise radius attached to a center is compared through the rational ledger, and the accumulator remains a positive history classified by the source and rational classifiers.

Finally apply the triangle handoff row T. The source metric ledger places both source points inside the pointwise radius of the selected center, the continuous-map row supplies the two target estimates at that center, and the target metric triangle ledger returns the displayed ε estimate. The continuation row S sends exactly this finite package to $\mathsf{UniformModulus}^{\uparrow}$. □

Theorem 1610.5 (Heine-Cantor radius fold)**.** *For an accepted* $\mathsf{HeineCantorModulus}^{\uparrow}$ *carrier H, the folded source precision M is determined only by the finite center rows C, the pointwise radius rows R, and the rational lower-bound fold displayed in those rows. The extraction has no coordinate for open-cover compactness, a host minimum operator, a selector for centers, trichotomy on host reals, or host equality of real points.*

Proof. Project C, R, and M from the carrier. The finite-net extraction theorem identifies the center spine, so each source radius available to the fold is already attached to a displayed center row.

Induct over that finite center spine. At the empty boundary the fold reads the displayed positive source-precision base row. At a successor row, project the next center, its pointwise continuity radius, and its rational lower-bound certificate, then combine it with the accumulated positive history by the finite rational fold.

Componentwise hsame transport in Q carries the center row, radius row, and fold accumulator through the source-metric and rational classifiers. Thus the exported M is a finite-row object of C and R alone, with no appeal to open-cover data or host-side order case splits. □

Theorem 1610.6 (Heine-Cantor UniformModulus export)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer accepted by the* $\mathsf{HeineCantorModulus}^{\uparrow}$ *chapter factors through the finite rows $P, C, R, M, T, Q, S, K, N$. The route is finite-net extraction, radius fold, and metric triangle handoff, rather than an open-cover compactness argument, choice-selected center data, or host-side real comparison.*

Proof. First project the carrier rows. The finite-net extraction theorem reads P and C as the complete center and coverage surface for the source precision scale determined by ε.

Next apply the radius-fold theorem. It turns the pointwise rows R into the single positive source precision M by a finite rational lower-bound fold, and Q transports the resulting history componentwise across classified representatives.

Finally apply the triangle handoff theorem. The row T combines compact-net coverage, the two pointwise target estimates, and the target metric triangle ledger; the continuation row S presents exactly this package to the $\mathsf{UniformModulus}^{\uparrow}$ consumer. The provenance row K and local row N record that no further compactness, selector, or host comparison input is part of the accepted route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineCantorModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HeineCantorModulus}^{\uparrow}$ packet is generated from a compact metric finite-net row, pointwise continuous-map modulus rows at the displayed centers, a positive target dyadic precision, a finite rational lower-bound fold, metric triangle handoff data, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HeineCantorModulus}^{\uparrow}}$, seed)

Scope closed: The seed scope records the finite-net carrier, displayed pointwise-radius fold, and triangle handoff route from compact metric and continuous-map data to a UniformModulus$^{\uparrow}$ consumer.

Formal verification: FormalStatus(NameCert$_{\text{HeineCantorModulus}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier\_heine\_cantor\_la`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, choice, trichotomy, host real equality, or a standalone Lean theorem for HeineCantorModulus$^{\uparrow}$.

Upgrade path: A stronger closure grade requires a dedicated Lean carrier for HeineCantorModulus$^{\uparrow}$ and checked projections from the compact-net fold to the uniform-modulus consumer.

Chapter 1611

A Concrete Naming Certificate for $\mathsf{RegularCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyCriterion}^{\uparrow}$ packet records the finite regular Cauchy criterion surface used by the Real and Completion route before any quotient stream or host-real completeness principle is available. It reads the finite stream windows of chapter 126, the regular rational readback of chapter 301, the tolerance ledger of chapter 292, the dyadic arithmetic core of chapter 291, the criterion surface of chapter 392, the convergence-facing criterion of chapter 1509, the Real-facing criterion of chapter 1590, and the terminal Real boundary of chapter 38. The packet is a finite RegSeqRat-level criterion; it is not a quotient stream, not a selected limit, not host real equality, not trichotomy, not countable choice, and not ambient Real completeness.

Definition 1611.1 (Regular Cauchy criterion carrier)**.** *A* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, M, D, Q, V, A, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose observations are admitted only as displayed stream segments.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows and carrying regular rational approximants.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *modulus row, recording the displayed stage bound used by each tolerance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row through which every requested radius is named before it is compared with a regular rational distance.*
5. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *row stating the finite Cauchy test over S, R, M, D.*
6. *V is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row that repacks the same finite test as a convergence-facing criterion without selecting a limit.*
7. *A is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *boundary row, available only after S, R, M, D, Q, V have been replayed.*
8. *H records componentwise* hsame *transport for the stream, readback, modulus, dyadic, criterion, convergence criterion, Real boundary, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a criterion request through stream windows, regular rational readback, modulus lookup, dyadic tolerance naming, CauchyCriterion testing, CauchyConvergenceCriterion repacking, and the Real boundary.*

10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCriterion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterionTasteGate single carrier alignment`

Theorem 1611.2 (Regular Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *carrier* $K = (S, R, M, D, Q, V, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, CauchyModulus lookup, DyadicRatCore tolerances, CauchyCriterion test, CauchyConvergenceCriterion repacking, Real boundary, transport, continuation, provenance, and local naming row;*

2. *stream-readback alignment, requiring every criterion request to read finite windows S before the regular rational row R is used;*

3. *modulus-tolerance exposure, requiring every requested stage bound to pass through M and every radius comparison to pass through D;*

4. *criterion exactness, requiring Q to be the only exported Cauchy test and V to be the only convergence-facing repacking of that test;*

5. *Real seal nonescape, requiring A, H, C, P, N to expose no quotient stream, selected limit, host real equality, trichotomy, countable-choice selector, or ambient completeness principle.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion namecert obligations`
↪ variant `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterionNameCertObligations`

Proof. Project the carrier of Definition 1611.1. The displayed tuple contains exactly the stream, readback, modulus, dyadic, criterion, convergence criterion, Real boundary, transport, continuation, provenance, and local naming rows.

Stream-readback alignment is forced by the replay row C. A criterion request reads finite stream windows S before it can inspect the regular rational approximants stored in R.

The modulus route then consumes M and D. The stage bound is read from M, while the tolerance radius is named by the DyadicRatCore row D before any Cauchy comparison is exported.

The only criterion-facing rows are Q and V. Thus the CauchyCriterion test is exported through Q, and the convergence-facing repacking is exported through V without adding a selected limit.

The Real boundary is downstream of the same route. Since the carrier has no quotient-stream, selected-limit, host-equality, trichotomy, choice, or ambient-completeness coordinate, the listed rows exhaust the local obligation surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterionCarrier namecert obligations`

Theorem 1611.3 (Regular Cauchy criterion modulus route)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. Every criterion-facing consumer of K factors through the finite route*

$$S \longmapsto R \longmapsto M \longmapsto D \longmapsto Q \longmapsto V \longmapsto A \longmapsto H, C, P, N.$$

Consequently the consumer receives the modulus-bound and dyadic-tolerance evidence before it can read the CauchyCriterion row or the CauchyConvergenceCriterion row.

Proof. Begin with a criterion-facing consumer. Carrier admission exposes the criterion rows, but only as rows downstream of the finite stream, readback, modulus, and dyadic records.

Replay C. The consumer first reads the stream window row S and the regular rational readback row R.

The modulus row M is consumed next, followed by the dyadic tolerance row D. These two rows are the only places where the packet records the stage bound and radius naming needed by the Cauchy comparison.

Only after those reads can the consumer reach Q and then V. Transport and provenance through H, C, P, N preserve the same order, so no detached criterion route exists. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion modulus route`

Theorem 1611.4 (Regular Cauchy criterion window extraction)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. Every accepted criterion request extracts the finite* DyadicRatCore$^{\uparrow}$ *tolerance window and the finite* StreamName$^{\uparrow}$ *stream window before it inspects the completion-facing row V or the Real boundary row A.*

Proof. Use the carrier inventory of Definition 1611.1. The only stream-facing coordinate is S, and the only dyadic tolerance coordinate is D.

Apply the NameCert obligations of Definition 1611.2. Stream-readback alignment requires the request to display S before the regular rational row R is used, while modulus-tolerance exposure requires the requested radius to pass through D.

Finally apply the route of Definition 1611.3. The completion-facing row V and the Real boundary row A occur downstream of S, R, M, D, Q, so both finite windows are extracted before either downstream row is inspected. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion window extraction`

Theorem 1611.5 (Regular Cauchy criterion RegSeqRat route)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. Every Real-facing criterion route factors through the ordered rows*

$$D \longmapsto S \longmapsto R \longmapsto A.$$

Here D is the DyadicRatCore$^{\uparrow}$ *tolerance row, S is the* StreamName$^{\uparrow}$ *finite-window row, R is the* RegSeqRat$^{\uparrow}$ *readback row, and A is the* Real$^{\uparrow}$ *boundary row served by the* RealCauchyCriterion$^{\uparrow}$ *entry.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion regseqrat route`

Proof. Project the carrier in Definition 1611.1. The packet exposes the dyadic tolerance row D, stream window row S, regular rational readback row R, and Real-facing boundary row A as distinct coordinates.

The NameCert obligations of Definition 1611.2 force stream-readback alignment and modulus-tolerance exposure. Thus the dyadic tolerance row names the requested radius, the stream window row fixes the inspected finite segment, and the RegSeqRat row reads that segment as regular rational data.

The modulus route of Definition 1611.3 places the Real-facing boundary after the criterion and convergence-criterion rows. Since those rows are reached only after D, S, R have been displayed, every Real-facing route passes through the DyadicRatCore, StreamName, RegSeqRat, and Real rows in the stated order. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterionRegSeqRatRoute`

Theorem 1611.6 (Regular Cauchy criterion StreamName-RegSeqRat scope)**.** *Let $K = (S, R, M, D, Q, V, A, H, C,$ be an accepted* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *carrier. Any criterion request must expose* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyModulus}^{\uparrow}$ *bounds, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance naming before it can reach the* $\mathsf{CauchyCriterion}^{\uparrow}$ *row Q, the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row V, or the* $\mathsf{Real}^{\uparrow}$ *boundary row A.*

Proof. Start from the carrier definition. The rows S, R, M, D are the only coordinates for finite stream windows, regular rational readback, modulus bounds, and dyadic tolerance naming.

Apply the NameCert obligations of Definition 1611.2. They require stream-readback alignment and modulus-tolerance exposure, so a criterion request cannot inspect R without first displaying S, and cannot export a Cauchy comparison without first displaying M and D.

The modulus route of Definition 1611.3 and the RegSeqRat route of Definition 1611.5 place Q, V, A downstream of the displayed window, readback, modulus, and tolerance rows.

Finally use the Real seal nonescape theorem. The Real boundary contributes no quotient stream, selected limit, host equality, trichotomy, choice schedule, or ambient completeness coordinate, so the scope of every criterion request remains the finite StreamName-to-RegSeqRat route through S, R, M, D before Q, V, A. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion streamname regseqrat scope`

Theorem 1611.7 (Regular Cauchy criterion Real seal nonescape)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *carrier. Every Real-facing read of K reaches the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *boundary only after the route through S, R, M, D, Q, V has been replayed. The exported surface contains no quotient stream, selected limit, host real equality, trichotomy, countable-choice selector, or ambient Real completeness assertion.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion real seal nonescape`

Proof. The Real boundary row A is part of the carrier, but its accessibility is ordered by the continuation row C. A Real-facing read must therefore replay the stream, readback, modulus, dyadic, criterion, and convergence-criterion rows before A is available.

The transport row H identifies componentwise changes only along the displayed rows. It cannot add a quotient stream, selected limit, host equality, trichotomy, choice schedule, or completeness theorem, because no such coordinate appears in the carrier.

The provenance and local naming rows P, N name the same finite packet. Hence the Real seal is a downstream boundary for the finite regular Cauchy criterion and not an escape into ambient Real completeness. □

Theorem 1611.8 (Regular Cauchy criterion window obligations)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. Every criterion request exposes a finite* StreamName$^{\uparrow}$ *window, a* RegSeqRat$^{\uparrow}$ *readback row, and a* DyadicRatCore$^{\uparrow}$ *tolerance row before it may inspect the CauchyCriterion, CauchyConvergenceCriterion, or Real boundary rows. The exposed window contains only displayed stage bounds, rational observations, and dyadic radii; it contains no quotient stream, selected tail, or ambient completeness witness.*

Proof. Project the carrier. The only finite-window coordinate is S, the only regular rational readback coordinate is R, and the only dyadic tolerance coordinate is D.

Apply the NameCert obligations. Stream-readback alignment forces S before R, while modulus-tolerance exposure forces every requested radius through D before a criterion comparison is exported.

The modulus route places Q, V, A downstream of S, R, M, D. Therefore every criterion request exposes the stated finite window before it can read the criterion, convergence, or Real boundary rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion window obligations`

Theorem 1611.9 (Regular Cauchy criterion tail transport)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P, N)$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. Componentwise* hsame *transport through H and displayed* Cont *replay through C preserve the tail criterion rows S, R, M, D, Q, V, A: a transported request still reads the same StreamName window, RegSeqRat readback, modulus bound, dyadic tolerance, CauchyCriterion row, CauchyConvergenceCriterion row, and Real boundary in the displayed order.*

Proof. Read the transport row H. It is componentwise over the stream, readback, modulus, dyadic, criterion, convergence criterion, Real boundary, continuation, provenance, and local naming rows.

Read the replay row C. It records the same order used by the original criterion request, from stream windows through regular readback, modulus lookup, dyadic tolerance naming, criterion testing, convergence repacking, and Real boundary.

Since neither H nor C contains a quotient stream, selected limit, or ambient completeness coordinate, transport can only preserve the displayed tail criterion rows and cannot replace them by an external tail principle. □

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterion tail transport`

Theorem 1611.10 (Regular Cauchy criterion Cauchy equivalence surface)**.** *Let $K = (S, R, M, D, Q, V, A, H, C, P,$ be an accepted* RegularCauchyCriterion$^{\uparrow}$ *carrier. The only exported equivalence surface between Cauchy-facing and convergence-facing reads is the pair of rows Q and V, namely the* CauchyCriterion$^{\uparrow}$ *row and the* CauchyConvergenceCriterion$^{\uparrow}$ *row. The carrier exports no selected limit, quotient stream equality, host real equality, or ambient* Real$^{\uparrow}$ *completeness as part of this equivalence surface.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCriterionUp.RegularCauchyCriterionCauchyEquivalence encode append`

Proof. Inspect the carrier coordinates. The Cauchy-facing test is stored in Q, and the convergence-facing repacking of that same finite test is stored in V.

Apply criterion exactness from the NameCert obligations. It states that Q is the only exported Cauchy test and V is the only convergence-facing repacking available from the packet.

The Real seal nonescape theorem excludes selected limits, quotient streams, host equality, choice, and ambient completeness from the Real boundary. Hence the exported equivalence surface is exactly Q, V and not an external completion principle. □

Theorem 1611.11 (Regular Cauchy criterion public route)**.** *Every public* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *consumer reads the displayed rows in the order*

$$S \longmapsto R \longmapsto M \longmapsto D \longmapsto Q \longmapsto V \longmapsto A \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The route packages the finite window obligations, tail transport, Cauchy equivalence surface, Real seal nonescape, and ledger refusal rows already exposed by the chapter. It cannot export quotient streams, selected limits, host equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-window surface. Apply Definition 1611.8 to expose the StreamName window, RegSeqRat readback, and DyadicRatCore tolerance row before any criterion-facing read proceeds.

Next apply Definition 1611.9. Componentwise hsame transport and displayed Cont replay preserve the same ordered tail route through S, R, M, D, Q, V, A and add no quotient-stream or selected-limit coordinate.

The Cauchy-facing and convergence-facing sides meet through Definition 1611.10. The only equivalence surface is Q, V, and the Real-facing boundary is kept behind the same route by Definition 1611.7.

Finally use the obligation inventory of Definition 1611.2. The structural rows H, C, P, N transport, replay, source, and name the public route, while the ledger refusal clauses leave quotient streams, selected limits, host equality, trichotomy, countable choice, and ambient Real completeness outside the exported surface. □

Theorem 1611.12 (Regular Cauchy criterion bridged consumer)**.** *Every downstream Real-and-completion consumer may read a public* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *packet only through the bridge-facing route of Definition 1611.11. The readable surface is the finite chain through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, *the* $\mathsf{Real}^{\uparrow}$ *seal row, and the structural rows* H, C, P, N*; it is not a quotient stream, selected limit, host equality, trichotomy, countable choice, or ambient completion theorem.*

Proof. Start with the public route. It exposes the rows $S, R, M, D, Q, V, A, H, C, P, N$ in order and leaves no separate consumer coordinate outside that route.

The finite-window and tail-transport obligations then force every Real-and-completion read to pass through the StreamName window, RegSeqRat readback, CauchyModulus bound, DyadicRatCore tolerance, and CauchyCriterion row before the Real seal is inspected.

Finally apply Real seal nonescape. Since the accepted carrier has no quotient-stream, selected-limit, host-equality, choice, trichotomy, or ambient-completion coordinate, the bridge-facing consumer receives only the displayed finite criterion route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCriterion}^{\uparrow}}, \mathsf{bridgedClosed})$

Scope closed: Definition 1611.1, Definition 1611.2, Definition 1611.3, Definition 1611.6, Definition 1611.7, Definition 1611.8, Definition 1611.9, Definition 1611.10, Definition 1611.11, and Definition 1611.12 bind the finite route from StreamName windows through RegSeqRat readback, CauchyModulus bounds, DyadicRatCore tolerances, CauchyCriterion testing, CauchyConvergenceCriterion repacking, transport, the Real boundary, and bridge-facing Real-and-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Bridge checking requires a Lean standard bridge for the public RegularCauchyCriterion route to a downstream Real-and-completion consumer.

Constructive story: A RegularCauchyCriterion$^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, a CauchyModulus row, DyadicRatCore tolerances, CauchyCriterion testing, CauchyConvergenceCriterion repacking, a RealCauchyCriterion and RealUp boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1612

A Concrete Naming Certificate for $\mathsf{SeparatedCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Kelley-style separated uniform reasoning, the $\mathsf{SeparatedCompletion}^{\uparrow}$ packet records the finite NameCert boundary at which a metric-completion route becomes separated without becoming a quotient completion. It consumes the metric-completion surface of chapter 1506, the dense embedding route of chapter 1512, the extension-and-uniqueness surface of chapter 397, the zero-distance classifier of chapter 1411, the Hausdorff boundary of chapter 402, and the regular-Cauchy separated route of chapter 1513. The L10 spine supplying finite names is the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route of chapter 291, chapter 126, chapter 301, and chapter 38.

The packet is a general separated-completion interface. It exposes source metric rows, dense embedding rows, completion handoff rows, separated classifier rows, uniqueness-boundary rows, transport rows, continuation replay, package provenance, and local naming. It exports no quotient completion, no selected representative, no host equality of completed points, no countable-choice schedule, no ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, and no hidden complete metric space.

Definition 1612.1 (SeparatedCompletion carrier)**.** *A* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, D, C, Z, U, H, R, T, P, N)$$

with the following displayed rows:

1. *M is the source metric row together with the* $\mathsf{MetricCompletion}^{\uparrow}$ *admission boundary for completion-facing reads.*
2. *D is the dense* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, recording how source observations enter the completion interface before any separated comparison is public.*
3. *C is the completion handoff row, read through the finite* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *L10 naming spine.*
4. *Z is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row that compares displayed completion readings by zero-distance evidence rather than by host equality.*
5. *U is the uniqueness boundary, supplied by the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, *and* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *rows over the same source, dense embedding, completion handoff, and separated classifier.*
6. *H records componentwise* hsame *transport for M, D, C, Z, U and for the local structural rows.*

7. *R records displayed* Cont *replay from source metric observations through dense embedding, completion handoff, separated classification, and uniqueness boundary.*
8. *T is the local transport ledger that states that hsame transport and Cont replay preserve the same ordered completion route.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy classes, selected completion representatives, host equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an external complete metric space.*

Lean4 (definition) `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionCarrier`

Theorem 1612.2 (SeparatedCompletion NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier $S = (M, D, C, Z, U, H, R, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the displayed source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, hsame transport, Cont replay, package provenance, and local naming rows;*
2. *dense-source compatibility, requiring every completion-facing consumer to read M and D before the handoff row C;*
3. *separated-classifier exactness, requiring every comparison of completion readings to pass through Z after C has been displayed;*
4. *uniqueness-boundary exactness, requiring every asserted uniqueness read to be exhausted by U over the same M, D, C, Z route;*
5. *transport replay, requiring H, R, T to preserve the ordered route under componentwise* hsame *transport and displayed* Cont *replay;*
6. *ledger non-escape, excluding quotient completions, selected representatives, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and hidden complete metric spaces.*

Proof. Carrier admission is projection from Definition 1612.1. The tuple displays the source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, structural transport rows, provenance, and local naming.

Dense-source compatibility is the first dependency order. The rows M and D must be present before C can expose any completion-facing read, so no consumer can replace the dense embedding by a selected representative or external completion point.

Separated-classifier exactness is isolated in Z. Once C has been displayed, comparison of completion readings is admitted only through the zero-distance classifier row, not through host equality of completed points.

The uniqueness boundary is the row U. It is read over the same M, D, C, Z route and is therefore a local ledger comparison, not a quotient-completion uniqueness theorem outside the packet.

Finally, H, R, T, P, N record transport, replay, route preservation, provenance, and local naming for exactly those rows. Since the carrier has no quotient, representative, choice, ambient-completeness, host-equality, or external-complete-space coordinate, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionCarrier semantic name certificate`

Theorem 1612.3 (SeparatedCompletion source-metric obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every* BHist *or* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *read that exposes completion-facing metric data must first enter through the source metric row M. The later rows $D, C, Z, U, H, R, T, P, N$ may transport, replay, source, and name that read, but none of them supplies an independent source metric, an external complete metric space, a quotient completion, or host equality of completed points.*

Proof. Project the carrier of Definition 1612.1. The coordinate M is the displayed source metric row and is the only carrier coordinate with source-metric status.

Apply Definition 1612.2. Carrier admission and dense-source compatibility place M before the dense row D and the completion handoff C, while the remaining rows only compare, transport, replay, source, and locally name the same displayed route.

Since the carrier has no external complete-space, quotient-completion, host-equality, or second source-metric coordinate, every metric read is a read through M preserved by H, R, T, P, N. □

Theorem 1612.4 (SeparatedCompletion dense-embedding obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every dense source read consumed by a completion-facing row must pass through the dense embedding row D before the completion handoff row C is public. No row of the packet may treat C, Z, or U as a dense embedding unless the preceding M, D route has already been displayed in the same* BHist *packet.*

Proof. Read the displayed tuple in Definition 1612.1. The row D is the dense $\mathsf{CompletionEmbedding}^{\uparrow}$ row, and C is the downstream completion handoff row.

Use the dense-source compatibility clause of Definition 1612.2. It requires every completion-facing consumer to read M and D before C, so the handoff cannot be used as a substitute dense embedding.

The separated classifier Z and uniqueness row U are later rows over the same route. Thus a dense source read reaches C, Z, U only after the displayed M, D entrance has been recorded in BHist and replayed by the local Cont data. □

Theorem 1612.5 (SeparatedCompletion zero-distance obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every separated comparison must read the zero-distance classifier row Z before any uniqueness-boundary row U is consumed. The comparison is therefore a finite classifier route through M, D, C, Z, U with* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming, not host equality, selected representatives, quotient completion equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The row Z is the only separated zero-distance classifier row, while U records uniqueness over the same source, dense, completion, and classifier route.

Apply separated-classifier exactness from Definition 1612.2. A comparison of completion readings reaches Z only after C has been displayed, and uniqueness-boundary exactness reads U over that same M, D, C, Z route.

The structural rows H, R, T, P, N preserve, replay, source, and name the route without adding a second comparison principle. Because the excluded host-equality, representative, quotient, and ambient-completeness objects are absent from the carrier, every separated comparison must pass through Z before U. □

Definition 1612.6 (SeparatedCompletion kernel route)**.** *The separated-completion kernel route of an accepted carrier $S = (M, D, C, Z, U, H, R, T, P, N)$ is the ordered readback*

$$M, D \longmapsto C \longmapsto Z, U \longmapsto H, R, T, P, N.$$

Thus every completion-facing consumer first reads the source metric row M and dense embedding row D, then the completion handoff row C, then the separated classifier and uniqueness rows Z, U, and only then the transport, replay, provenance, and local naming rows H, R, T, P, N.

Theorem 1612.7 (SeparatedCompletion separated-limit handoff)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every separated completion comparison reaches the separated classifier row Z and uniqueness boundary row U only after the source metric row M, dense embedding row D, and completion handoff row C have been displayed.*

Proof. Use the carrier projection of Definition 1612.1 and the obligation order of Definition 1612.2. The rows M and D are the source and dense-entry surface, while C is the only completion handoff row.

The separated classifier Z and uniqueness boundary U are downstream rows in the same carrier. Since the carrier has no separate comparison coordinate, a separated-limit handoff cannot inspect Z or U before the M, D, C route has been read. □

Lean4 ✓ `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionCarrier separated limit handoff`

Theorem 1612.8 (SeparatedCompletion L10 readback exhaustion)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier $S = (M, D, C, Z, U, H, R, T, P, N)$, the handoff row C is exhausted by the finite L10 readbacks through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It exports no quotient completion, selected representative, host equality of completed points, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project C from the carrier of Definition 1612.1. The definition identifies C as the completion handoff row read through the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ naming spine.

Apply Definition 1612.2. The ledger non-escape clause states that quotient completions, selected representatives, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and hidden complete metric spaces are absent from the local surface.

Therefore every L10 readback of C is exhausted by the displayed dyadic, stream, regular-rational, and real-name route, and no additional completion principle is exported. □

Theorem 1612.9 (SeparatedCompletion obligation surface)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *read starts with the displayed source row M, dense row D, completion handoff C, separated classifier Z, and uniqueness row U, then preserves that route through* BHist, hsame, Cont, *provenance, and local naming data in H, R, T, P, N. The surface exports no quotient completion, selected representative, host equality, countable choice, or ambient Real completeness.*

Proof. Project the accepted carrier. The rows M, D, C, Z, U are the only source, dense, completion, separated-classifier, and uniqueness rows available to the local certificate.

The structural rows H, R, T then transport and replay the same ordered route through hsame and Cont inside BHist. The provenance and local naming rows P, N attach the route to $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ without adding another completion object.

Since the carrier has no quotient-completion, representative-selection, host-equality, countable-choice, or Real-completeness coordinate, every obligation read is exhausted by the displayed rows. □

Theorem 1612.10 (SeparatedCompletion source-density triad)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted $\mathsf{SeparatedCompletion}^{\uparrow}$ carrier. Every separated-completion consumer must read the source metric row M, dense embedding row D, and completion handoff row C before it can read the separated classifier Z, the uniqueness boundary U, or any Real-facing seal exported by the packet.*

Proof. Project the carrier of Definition 1612.1. Its first three analytic rows are exactly M, D, C, while Z and U are later rows over the same displayed packet.

Apply Definition 1612.2. Dense-source compatibility requires M, D before C, separated-classifier exactness requires C before Z, and uniqueness-boundary exactness reads U over the same M, D, C, Z route.

The Real-facing seal is part of the completion handoff read through C. Hence no separated classifier, uniqueness, or Real-facing consumer can bypass the source-density triad. □

Theorem 1612.11 (SeparatedCompletion source-density factorization)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted $\mathsf{SeparatedCompletion}^{\uparrow}$ carrier. Every completion-facing read that claims source density factors through the ordered prefix M, D, C before the separated classifier Z, uniqueness boundary U, transport row H, replay row R, route ledger T, provenance row P, or local naming row N is consumed. The factorization is the dense-source compatibility clause of the local NameCert obligations, not a quotient-completion read, selected representative, host equality of completed points, countable-choice schedule, or ambient Real-completeness assertion.*

Proof. Project the carrier of Definition 1612.1. The source metric row is M, the dense embedding row is D, and the completion handoff row is C; the remaining rows Z, U, H, R, T, P, N are downstream of that prefix.

Apply Definition 1612.2. Its dense-source compatibility clause requires every completion-facing consumer to read M and D before the handoff row C is public.

The structural rows H, R, T, P, N can only transport, replay, preserve, source, and name the same displayed route. Since the carrier has no quotient-completion, selected-representative, host-equality, choice, or ambient-completeness coordinate, source density can only be read through M, D, C. □

Theorem 1612.12 (SeparatedCompletion uniqueness boundary scope)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted $\mathsf{SeparatedCompletion}^{\uparrow}$ carrier. The uniqueness boundary row U is scoped only over the already displayed route M, D, C, Z and the structural rows H, R, T, P, N. A consumer may read U as the local separated-completion uniqueness boundary, but cannot use it as a quotient completion, a selected representative comparison, a host equality of completed points, a countable-choice selector, or an ambient Real-completeness theorem.*

Proof. First read the source-density factorization of Definition 1612.11. It places every completion-facing read on the prefix M, D, C.

Next apply the separated-classifier exactness and uniqueness-boundary exactness clauses of Definition 1612.2. They place Z after the handoff row C and read U over the same M, D, C, Z route.

Finally attach H, R, T, P, N. These rows keep the uniqueness comparison inside displayed BHist, hsame, Cont, Pkg, and local NameCert data. No listed row supplies an external completion object, a selected representative, host equality, choice, or ambient completeness. □

Theorem 1612.13 (SeparatedCompletion Real-seal nonescape)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* SeparatedCompletion$^{\uparrow}$ *carrier. Any Real-facing seal exported by the packet is read through the completion handoff row C after M, D and before the separated uniqueness surface Z, U, H, R, T, P, N is consumed. The seal remains a finite route through the displayed* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it cannot escape into quotient completion, selected representatives, host equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Begin with the carrier row C. By Definition 1612.1, C is the completion handoff read through the finite DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ L10 naming spine.

Use Definition 1612.11. The handoff row C is reachable only after the source metric row M and dense embedding row D have been displayed.

Use Definition 1612.12. The later separated rows Z, U, H, R, T, P, N preserve and name the same handoff route rather than adding an external Real-completion principle. Therefore every Real-facing seal stays inside the displayed carrier and cannot introduce the excluded quotient, representative, host-equality, choice, or completeness objects. □

Theorem 1612.14 (SeparatedCompletion seal uniqueness)**.** *For accepted packets $S = (M, D, C, Z, U, H, R, T, P, N$ and $S' = (M, D, C, Z, U', H', R', T', P, N')$ with the same displayed source, dense, completion, separated-classifier, and provenance rows, any equality-of-export read between their completion seals is determined by the local uniqueness rows U, U' together with the* BHist*,* hsame*,* Cont*, and* NameCert *data in H, R, T, N and H', R', T', N'. It is not a quotient completion, selected representative comparison, host equality, countable-choice selection, or ambient Real-completeness conclusion.*

Proof. The shared rows M, D, C, Z, P fix the source metric, dense embedding, completion handoff, separated classifier, and provenance surface for both packets.

Any remaining comparison must therefore inspect U, U' and the corresponding transport, replay, route-preservation, and local naming rows. These rows compare completion exports only over the already displayed route.

No carrier coordinate supplies quotient equality, selected representatives, host equality, choice, or Real completeness. Thus seal uniqueness is local to U, U' and the displayed BHist, hsame, Cont, and NameCert data. □

Theorem 1612.15 (SeparatedCompletion diagonal classifier obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* SeparatedCompletion$^{\uparrow}$ *carrier. Every diagonal classifier read comparing a completion-facing row with itself is forced through the separated classifier row Z after the dense route M, D, C has been displayed. The read is a* BHist*-visible zero-distance comparison preserved by* hsame *and* Cont *data, not a host equality, quotient-completion equality, selected representative, countable-choice schedule, or ambient* Real$^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 1612.1. The only separated comparison coordinate is Z, and it appears downstream from the source metric row M, dense embedding row D, and completion handoff row C.

Apply the NameCert obligations of Definition 1612.2. They require dense-source compatibility before C is consumed and separated-classifier exactness before any comparison is public.

The diagonal case does not add a new coordinate. Transport and replay are still the displayed rows H, R, T, so the comparison remains inside the local BHist, hsame, Cont, Pkg, and NameCert surface. Since the excluded objects have no carrier field, the diagonal classifier obligation is forced through Z. □

Theorem 1612.16 (SeparatedCompletion separated-limit handoff obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P,$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every separated-limit handoff read must pass through the source metric row M, dense embedding row D, completion handoff row C, separated classifier row Z, and uniqueness boundary row U before the structural rows H, R, T, P, N are consumed. No consumer can obtain that handoff from a quotient completion, a selected representative, host equality of completed points, countable choice, or an ambient Real-completeness coordinate.*

Proof. Start with the dense route. The carrier exposes M, D, C as the only entrance to completion-facing reads, and Definition 1612.19 makes every such read factor through that entrance.

Next read the separated boundary. The classifier row Z and uniqueness row U are later rows in the same accepted packet, so a separated-limit handoff can consume them only after the dense handoff is visible.

Finally attach H, R, T, P, N. These rows transport, replay, source, and name the same route rather than adding another completion object. The carrier therefore supplies no quotient, selected representative, host equality, choice, or ambient completeness coordinate from which a bypassing handoff could be read. □

Theorem 1612.17 (SeparatedCompletion nonescape obligation)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier $S = (M, D, C, Z, U, H, R, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *surface exports only the displayed rows $M, D, C, Z, U, H, R, T, P, N$. It exports no quotient completion, no selected representative, no countable-choice schedule, no host equality of completed points, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Use the carrier admission and obligation surface of Definition 1612.1 and Definition 1612.2. They enumerate exactly the rows available to the accepted packet.

The dense route M, D, C, the separated classifier Z, and the uniqueness boundary U account for the analytic part of the surface. The structural rows H, R, T, P, N account for componentwise hsame transport, displayed Cont replay, route preservation, provenance, and local naming.

There is no remaining coordinate to project a quotient completion, representative selector, choice schedule, host equality, or ambient Real-completeness theorem. Hence every exported obligation remains inside the displayed finite carrier. □

Theorem 1612.18 (SeparatedCompletion window transport)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. If a completion-facing window read is transported componentwise by the displayed* hsame *row H, then the transported read remains on the same M, D, C, Z, U route and is replayed by the displayed* Cont *row R and transport ledger T before the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *row N is inspected. The transport introduces no quotient completion, selected representative, host equality, countable choice, or ambient Real completeness.*

Proof. Start from the window read over M, D, C. These rows fix the source metric, dense source, and completion handoff before any separated comparison is available.

Apply the displayed hsame row H componentwise. The transport is a movement of the already displayed BHist rows, not a selection of a new representative or a quotient completion class.

The Cont replay row R and the transport ledger T then replay the same route through Z, U, P, N. Since all excluded principles are absent from the carrier, transported windows remain inside the local NameCert surface. □

Theorem 1612.19 (SeparatedCompletion dense factorization)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* SeparatedCompletion$^{\uparrow}$ *carrier. Every completion-facing consumer read factors through the finite dense route*

$$M, D \longmapsto C \longmapsto Z \longmapsto U \longmapsto H, R, T, P, N.$$

Thus source metric data enter the separated-completion boundary only through the displayed metric-completion and dense-embedding rows before any separated classifier or uniqueness boundary can be consumed.

Lean4 ✓ `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionDenseFactorization`

Proof. Begin with an accepted consumer read. Carrier admission gives the rows $M, D, C, Z, U, H, R, T, P, N$ and no other completion coordinate.

The source part is M, D. The metric-completion row admits the request, and the dense embedding row carries source observations into the completion-facing interface.

The handoff row C is read only after that source part is fixed. Its L10 route is the finite DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ naming spine, so the consumer cannot replace it by a quotient stream or selected host limit.

The separated classifier Z and uniqueness boundary U are downstream of the same handoff. Transport, replay, provenance, and local naming in H, R, T, P, N preserve this route and add no external completion object. □

Theorem 1612.20 (SeparatedCompletion uniqueness boundary)**.** *For accepted packets*

$$S = (M, D, C, Z, U, H, R, T, P, N) \quad \textit{and} \quad S' = (M, D, C, Z, U', H', R', T', P, N')$$

over the same source metric row, dense embedding, completion handoff, separated classifier, and package provenance, every comparison between their completion-facing exports is exhausted by the uniqueness rows U, U' together with the displayed transport and replay rows H, R, T and H', R', T'.

Proof. The shared coordinates M, D, C, Z, P fix the metric-completion source, the dense embedding route, the completion handoff, the separated classifier, and the provenance surface for both packets.

The remaining comparison data are U, H, R, T, N and U', H', R', T', N'. The uniqueness rows compare completion-facing presentations over the same shared route, while the transport and replay rows display the permitted movements of that route.

No further field remains from which a consumer could read quotient-completion equality, a selected representative, host equality, countable choice, ambient Real$^{\uparrow}$ completeness, or a hidden complete metric space. The uniqueness judgement is therefore exactly the displayed local boundary. □

Theorem 1612.21 (SeparatedCompletion Cauchy-equivalence source)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every comparison between separated-completion exports first reads the* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *and* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *source rows carried by M, D, C before the separated classifier row Z is available. The comparison route is therefore sourced in displayed Cauchy-equivalence data over the same source metric and dense embedding, not in quotient completions, selected representatives, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a comparison read of an accepted packet. Carrier admission exposes $M, D, C, Z, U, H, R, T, P, N$ and no other completion coordinate.

The source of the read is the M, D, C route. The metric row and dense embedding row fix the source side, while the completion handoff records the regular-Cauchy separated completion and Cauchy-sequence equivalence data consumed by the comparison.

Only after that source route is displayed may Z classify separated completion readings. Since the carrier has no quotient-completion, selected-representative, host-equality, choice, Real-completeness, or hidden-complete-space coordinate, no comparison can bypass the displayed Cauchy-equivalence source. □

Theorem 1612.22 (SeparatedCompletion Cauchy reflector obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every Cauchy-reflector read exposed by S first displays the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *route and the dense embedding route inside the M, D, C rows, then reads the separated comparison row Z. The obligation is a* BHist *and* $\mathsf{NameCert}$ *row route through $M, D, C, Z, H, R, T, P, N$, not parameter transport over an external completion object.*

Proof. Start from Definition 1612.21. It places every comparison behind the displayed Cauchy-equivalence and regular separated-completion source rows carried by M, D, C.

The reflector read is therefore not a free-standing map. Its source side is the displayed CauchyCompletionReflector row, while the dense embedding row D records the admission route into the completion handoff C.

Only after those rows are visible can Z compare separated completion readings. The structural rows H, R, T, P, N transport, replay, source, and locally name the same route, so the Cauchy reflector obligation is exhausted by the displayed packet. □

Theorem 1612.23 (SeparatedCompletion source-density obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every completion-facing obligation first reads the source metric row M and dense embedding row D, then passes through the completion handoff C before the separated zero-distance classifier row Z or the uniqueness row U is public. The source-density route is recorded by* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, and it admits no quotient completion, selected representative, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted packet of Definition 1612.1. The source metric row M and dense embedding row D are the displayed entrance into every separated completion obligation.

Use dense factorization, Definition 1612.19. It places the completion handoff C downstream from the source metric and dense embedding route, so a consumer cannot start from separated comparison or uniqueness data alone.

The classifier and uniqueness rows are therefore later reads. The row Z compares only after the source-density route has been displayed, and U records uniqueness over that same route.

The structural rows H, R, T, P, N preserve, replay, source, and name the route. Since the carrier has no coordinate for quotient completions, selected representatives, host equality, countable choice, or ambient Real completeness, those objects are refused by the obligation surface. □

Theorem 1612.24 (SeparatedCompletion zero-distance classifier obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. The separated zero-distance classifier row Z is available only after the source metric route M, dense embedding route D, and completion handoff C have been displayed. It classifies completion reads through the separated zero-distance row of the packet, not through quotient completion equality, selected representatives, host equality of completed points, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the Cauchy reflector obligation of Definition 1612.22. It exposes the reflector route inside M, D, C before separated comparison can be read.

Apply zero-distance factorization, Definition 1612.29. The theorem identifies Z as the finite separated comparison boundary over the already displayed completion handoff.

The uniqueness and structural rows do not create a second classifier. The row U reads uniqueness downstream from Z, while H, R, T, P, N only transport, replay, source, and name the same comparison route.

Thus every zero-distance classifier obligation is carried by $M, D, C, Z, U, H, R, T, P, N$. The excluded quotient, representative, host-equality, choice, and ambient-completeness objects have no carrier coordinate. □

Theorem 1612.25 (SeparatedCompletion completion reflector route)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every completion reflector handoff exported by S follows the route from the source metric and dense embedding rows M, D through the completion handoff C, the separated zero-distance classifier Z, the uniqueness boundary U, and the structural rows H, R, T, P, N. A downstream reflector consumer receives that finite route only; it receives no quotient completion, selected representative, host equality, countable choice, hidden complete metric space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use the source-density obligation, Definition 1612.23, to fix the entrance of the reflector route at M, D, C. The completion reflector cannot be read before the source metric and dense embedding rows have been displayed.

Next use the zero-distance classifier obligation, Definition 1612.24. It makes Z the separated comparison boundary for the same handoff route, rather than an equality imported from a quotient completion.

Attach the existing reflector handoff through Definition 1612.39. The uniqueness row U and the rows H, R, T, P, N preserve, replay, source, and name the reflector route for downstream completion consumers.

No remaining coordinate names a selected representative, host equality, countable-choice schedule, hidden complete metric space, or ambient Real completeness theorem. The completion reflector handoff is therefore exactly the displayed finite packet route. □

Theorem 1612.26 (SeparatedCompletion Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier remains downstream of the displayed* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows carried through M, D, C. The seal may be consumed by the separated classifier Z and uniqueness boundary U, but it cannot expose host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient completion equality, selected representatives, or countable choice.*

Proof. Read the source route M, D, C first. These rows carry the metric-completion source, dense embedding, regular rational readback, finite stream windows, and dyadic tolerance evidence before any separated comparison is inspected.

The $\mathsf{Real}^{\uparrow}$ seal is reached only after that finite route. It records terminal readback data for the displayed completion route rather than an ambient completeness theorem.

Now apply the separated classifier and uniqueness rows Z, U. They consume the seal downstream of the same packet, while H, R, T, P, N merely transport, replay, source, and name the route. Since no excluded real or completion principle is a carrier coordinate, the seal cannot escape the displayed rows. □

Theorem 1612.27 (SeparatedCompletion universal route exhaustion)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier, the universal completion route is exhausted by the displayed rows*

$$M, D, C, Z, U, H, R, T, P, N.$$

The route exports dense-source admission, Cauchy-equivalence sourcing, separated comparison, uniqueness boundary, transport, replay, provenance, and local naming, but it exports no quotient completion, selected representative, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or additional universal completion principle outside the carrier.*

Proof. Project the carrier of Definition 1612.1. Its displayed rows are exactly the source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, transport, replay, provenance, and local naming rows.

Use dense factorization and the Cauchy-equivalence source theorem. They place the universal read behind M, D, C before Z or U can be inspected.

The separated comparison and uniqueness rows then account for the completion-facing universal property available to consumers. No further coordinate remains for quotient completion, representative selection, host equality, choice, or ambient completeness.

Finally H, R, T, P, N preserve the same row list. Thus the displayed carrier exhausts the universal route and exports no completion principle beyond the finite packet. □

Theorem 1612.28 (SeparatedCompletion universal separated factorization)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every universal completion read accepted through* S *passes through* M, D, C *before the separated classifier* Z *or the uniqueness row* U *may be consumed. The separated equality read is zero-distance evidence over the same displayed route, not quotient equality, host equality of completed points, selected representative equality, or an ambient completion equality.*

Proof. Project the carrier of Definition 1612.1. The only universal completion route available to the packet is the displayed row list $M, D, C, Z, U, H, R, T, P, N$.

Use dense factorization, Definition 1612.19, and universal route exhaustion, Definition 1612.27. Together they place every universal read behind the source metric, dense embedding, and completion handoff rows M, D, C.

Now apply zero-distance factorization, Definition 1612.29. The separated classifier row Z reads equality as displayed zero-distance evidence over that same handoff, while U reads uniqueness only after the classifier route is exposed.

Finally use nonescape, Definition 1612.33. Since quotient equality, host equality, selected representatives, and ambient completion equality have no field in the accepted carrier, they cannot replace the displayed zero-distance route. □

Theorem 1612.29 (SeparatedCompletion zero-distance factorization)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. The separated classifier route factors through the* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *zero-distance evidence displayed by M, C, Z. Thus a separated-completion equality read is a finite zero-distance handoff through the local packet, not a quotient completion, a selected representative, host equality, countable choice, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Lean4 ✓ `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionZeroDistanceFactorization`

Proof. Read the route in order. The row M supplies the metric-completion admission boundary, and C supplies the finite L10 handoff through regular rational readback toward the Real-facing seal.

The row Z then reads that handoff as $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance evidence. Its classifier compares displayed completion readings by zero distance after the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows have been reached through C.

Transport, replay, provenance, and local naming in H, R, T, P, N preserve the same factorization. No field remains for quotient completion equality, selected representatives, host equality, countable choice, or ambient Real completeness. □

Theorem 1612.30 (SeparatedCompletion limit-uniqueness export)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier $S = (M, D, C, Z, U, H, R, T, P, N)$, the public limit-uniqueness export is exactly the local boundary U over the already displayed M, D, C, Z route. The export contains no separate uniqueness principle over quotient completions, selected representatives, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric spaces.*

Proof. Carrier admission makes U the only uniqueness-boundary row in the packet. Its hypotheses and conclusion are read over the same source metric, dense embedding, completion handoff, and separated classifier rows M, D, C, Z.

The transport and replay rows H, R, T can move this boundary componentwise, but they do not create a second uniqueness coordinate. The package and local naming rows P, N record the same source list.

Therefore every public uniqueness export is the local U boundary over M, D, C, Z. The excluded quotient, representative, host-equality, choice, Real-completeness, and hidden-complete-space objects are absent from the carrier and cannot be exported. □

Theorem 1612.31 (SeparatedCompletion dense uniqueness interface)**.** *Let*

$$S = (M, D, C, Z, U, H, R, T, P, N) \quad \textit{and} \quad S' = (M, D, C, Z, U', H', R', T', P, N')$$

be accepted $\mathsf{SeparatedCompletion}^{\uparrow}$ *carriers with the same dense-source route M, D, C and the same zero-distance separated classifier Z. Then any completion-facing comparison between their exports exposes the same limit-uniqueness boundary through U, U' together with the displayed transport and replay rows. It exports no quotient representative, no selected completion point, no host equality of completed points, no countable-choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Use the dense factorization of Definition 1612.19. Every completion-facing read of either packet first passes through the shared source metric, dense embedding, and completion handoff rows M, D, C.

Use the zero-distance factorization of Definition 1612.29. Since the separated classifier row Z is also shared, the comparison is read as zero-distance evidence over the same finite route rather than as host equality of completed points.

Apply the limit-uniqueness export of Definition 1612.30 to both packets. The only remaining uniqueness data are U, U' and the displayed transport and replay rows H, R, T and H', R', T'. The carrier has no quotient representative, selected completion point, choice schedule, or ambient completeness coordinate, so the dense uniqueness interface exports exactly that local boundary. □

Theorem 1612.32 (SeparatedCompletion source-comparison exhaustion)**.** *Let*

$$S = (M, D, C, Z, U, H, R, T, P, N) \quad \textit{and} \quad S' = (M, D, C, Z, U', H', R', T', P, N')$$

be accepted $\mathsf{SeparatedCompletion}^{\uparrow}$ *carriers over the same source metric row, dense embedding, completion handoff, separated classifier, and provenance surface. Every accepted comparison between their separated-completion exports is exhausted by the shared* M, D, C, Z *source route, by the uniqueness rows* U, U'*, and by the displayed transport and replay rows* H, R, T *and* H', R', T'*. The comparison exports no quotient completion, selected representative, host equality of completed points, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or hidden complete metric space.*

Proof. First use the dense factorization of Definition 1612.19. It sends every completion-facing read through the shared source metric row M, dense embedding row D, and completion handoff row C before any separated classifier or uniqueness boundary is consumed.

Next use the zero-distance factorization of Definition 1612.29. The shared classifier Z reads the comparison as zero-distance evidence over the same finite route, so the comparison cannot be replaced by host equality of completed points.

Now apply the limit-uniqueness export of Definition 1612.30 to both packets. The only remaining comparison rows are U, U' together with the displayed transport and replay ledgers.

Finally attach the Cauchy-equivalence source theorem, Definition 1612.21. It keeps the comparison sourced in the displayed Cauchy-equivalence and dense-completion data carried by M, D, C. Since the carriers contain no excluded completion coordinate, the listed rows exhaust the accepted comparison surface. □

Theorem 1612.33 (SeparatedCompletion non-escape)**.** *Every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier exports only the rows*

$$M, D, C, Z, U, H, R, T, P, N$$

of Definition 1612.1. No consumer of the packet can obtain a quotient completion, selected representative, host equality of completed points, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or hidden complete metric space.*

Proof. The NameCert obligations of Definition 1612.2 enumerate the carrier, dense-source, separated-classifier, uniqueness-boundary, transport-replay, and refusal rows available to the packet.

The dense factorization of Definition 1612.19 covers every completion-facing consumer read. Such a read must traverse $M, D, C, Z, U, H, R, T, P, N$ and cannot bypass the finite route through a host completion object.

The uniqueness boundary of Definition 1612.20 covers every comparison between completion-facing exports. Since the carrier has no additional coordinate beyond the displayed rows, none of the excluded quotient, representative, host-equality, choice, Real-completeness, or hidden-complete-space objects can be projected from an accepted packet. □

Theorem 1612.34 (SeparatedCompletion choice-free source route)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every accepted source-to-uniqueness read exposes the*

source metric row M, dense embedding row D, completion handoff row C, and separated classifier row Z before any uniqueness row U is available. The route is carried by displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows and cannot expose choice data, quotient completion data, selected representatives, or host equality of completed points.*

Proof. Start with the carrier of Definition 1612.1. Its displayed rows are $M, D, C, Z, U, H, R, T, P, N$, so the source metric, dense embedding, completion handoff, and separated classifier are present before the uniqueness boundary can be projected.

Apply the dense factorization theorem, Definition 1612.19. It fixes the order $M, D \mapsto C \mapsto Z \mapsto U$ for completion-facing reads.

Apply the zero-distance factorization of Definition 1612.29 and the source-comparison exhaustion theorem, Definition 1612.32. These results keep the comparison in displayed Cauchy and zero-distance data rather than in quotient or host equality data.

The structural support rows are exactly H, R, T, P, N: componentwise hsame transport, displayed Cont replay, route preservation, Pkg provenance, and local NameCert admission. Since the carrier contains no choice, quotient completion, selected-representative, or host-equality coordinate, the source route is choice-free. □

Theorem 1612.35 (SeparatedCompletion regular-Cauchy source route)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every regular-Cauchy source read used by the separated-completion boundary factors through the displayed source metric row M, dense embedding row D, completion handoff row C, and separated classifier row Z before the uniqueness row U and the structural rows H, R, T, P, N are consumed. The route may use the dense factorization of Definition 1612.19, the zero-distance factorization of Definition 1612.29, and the source-comparison exhaustion of Definition 1612.32, but it cannot add quotient completions, selected representatives, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric spaces.*

Proof. Start with carrier admission. The visible rows are exactly $M, D, C, Z, U, H, R, T, P, N$, so any regular-Cauchy source read must begin inside the displayed carrier inventory.

Apply dense factorization, Definition 1612.19. It fixes M, D as the source prefix and C as the completion handoff reached from that prefix.

Apply zero-distance factorization, Definition 1612.29. The separated classifier row Z reads equality through zero-distance evidence over the same handoff, not through host equality of completed points.

Finally use source-comparison exhaustion, Definition 1612.32. It leaves only U, H, R, T, P, N as the downstream uniqueness, transport, replay, route, provenance, and naming rows, and the excluded completion and choice objects have no coordinate in the carrier. □

Theorem 1612.36 (SeparatedCompletion Hausdorff uniqueness route)**.** *For accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carriers over displayed rows $M, D, C, Z, U, H, R, T, P, N$, every Hausdorff-style uniqueness read is exhausted by the dense source route M, D, C, the zero-distance separated classifier Z, the uniqueness boundary U, and the transport, replay, route, provenance, and local naming rows H, R, T, P, N. The read is a local separated-completion boundary over the theorems Definition 1612.19, Definition 1612.29, and Definition 1612.32; it is not a quotient completion, a selected representative, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden complete metric space.*

Proof. Read the dense source route first. By Definition 1612.19, a uniqueness consumer must pass through M, D, C before reaching any separated classifier or uniqueness row.

Read the separated classifier next. By Definition 1612.29, Z supplies the zero-distance route that replaces host equality inside the accepted packet.

The Hausdorff-style uniqueness boundary is then the local row U together with the structural rows H, R, T, P, N. These rows transport, replay, preserve, source, and name the same displayed route.

Source-comparison exhaustion, Definition 1612.32, closes the comparison surface. Since quotient completions, selected representatives, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and hidden complete metric spaces are absent from $M, D, C, Z, U, H, R, T, P, N$, they cannot enter the uniqueness read. □

Theorem 1612.37 (SeparatedCompletion metric-completion handoff)**.** *Every metric-completion handoff exported by an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier factors through the displayed rows*

$$M, D, C, Z, U, H, R, T, P, N.$$

The handoff uses the dense route of Definition 1612.19, the zero-distance route of Definition 1612.29, and the exhausted comparison surface of Definition 1612.32. It exports no quotient completion, selected representative, host equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric space.*

Proof. Project the accepted carrier. The metric-completion source row M, dense embedding row D, and completion handoff row C form the only displayed metric-completion prefix.

Use Definition 1612.19. It sends every completion-facing handoff through M, D, C before any separated or uniqueness boundary is available.

Use Definition 1612.29. The row Z is the separated comparison route available after the completion handoff, and it is finite zero-distance evidence rather than host equality.

Use Definition 1612.32. The remaining rows U, H, R, T, P, N exhaust the uniqueness, transport, replay, route, provenance, and naming surface. Because the carrier has no quotient-completion, selected-representative, host-equality, choice, Real-completeness, or hidden-complete-space coordinate, the metric-completion handoff exports only the displayed finite route. □

Theorem 1612.38 (SeparatedCompletion filtered limit boundary)**.** *For an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, every filtered limit-boundary read is exhausted by the Cauchy-equivalence source rows displayed by* M, D, C*, the zero-distance separated classifier row* Z*, the local uniqueness row* U*, and the transport and replay rows* H, R, T*. It exports no additional limit selector, quotient class, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the source side first. The Cauchy-equivalence source theorem, Definition 1612.21, places every comparison over the displayed M, D, C route.

Read the classifier next. The zero-distance factorization theorem, Definition 1612.29, makes Z the only separated comparison row available after the completion handoff.

Read the boundary row. The limit-uniqueness export theorem, Definition 1612.30, identifies U as the public uniqueness boundary over the same M, D, C, Z route.

Finally apply source-comparison exhaustion, Definition 1612.32. It includes the displayed hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows and excludes any extra selector, quotient class, host equality, choice schedule, or ambient Real-completeness coordinate. □

Theorem 1612.39 (SeparatedCompletion completion-reflector handoff)**.** *Every handoff from an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier to* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *or* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *factors through the same finite source route*

$$M, D, C, Z, U, H, R, T, P, N.$$

The handoff may use the source metric, dense factorization, zero-distance factorization, limit-uniqueness export, source-comparison exhaustion, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, but it cannot add a quotient completion, selected representative, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier and apply dense factorization from Definition 1612.19. The handoff begins with M, D, C, so both reflector-facing and universal-property-facing reads share the same source metric, dense embedding, and completion handoff.

Apply the zero-distance factorization of Definition 1612.29. The separated classifier Z is the only comparison route available before any uniqueness boundary is read.

Apply the limit-uniqueness export of Definition 1612.30 and the source-comparison exhaustion theorem, Definition 1612.32. Together they identify U and the transport and replay rows H, R, T as the complete handoff boundary.

The provenance and local naming rows P, N attach the boundary to Pkg and NameCert data. Because the carrier contains no quotient-completion, selected-representative, host-equality, choice, or ambient-completeness coordinate, a $\mathsf{CauchyCompletionReflector}^{\uparrow}$ or $\mathsf{CompletionUniversalProperty}^{\uparrow}$ consumer receives only the displayed finite route. □

Theorem 1612.40 (SeparatedCompletion dense replay scope)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, every completion-facing read exposes the source metric row* M*, dense embedding row* D*, and completion handoff row* C *before the separated classifier* Z*, uniqueness boundary* U*, transport row* H*, replay row* R*, route ledger* T*, provenance row* P*, or local naming row* N *is consumed. Thus dense replay is a finite* M, D, C *prefix over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data, not a selected representative or quotient-completion read.*

Proof. Start with the carrier of Definition 1612.1. The rows M, D, C are the only source metric, dense embedding, and completion handoff coordinates.

Apply dense factorization, Definition 1612.19. It places every completion-facing consumer read on the route $M, D \mapsto C$ before the separated classifier and uniqueness boundary are available.

Then use the choice-free source route, Definition 1612.34. The structural rows H, R, T, P, N preserve the same ordered route and do not introduce a choice coordinate, quotient completion, selected representative, or host equality of completed points. □

Theorem 1612.41 (SeparatedCompletion separated classifier scope)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, zero-distance classification through* Z *is the only separated equality route after the dense completion handoff* M, D, C *has been displayed. Any completion-facing equality read that bypasses* Z *leaves the* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *surface and cannot be recovered from* U, H, R, T, P, N *alone.*

Proof. Read the dense prefix first. By Definition 1612.40, a completion-facing equality read has already exposed M, D, C before it reaches any separated comparison row.

Now apply zero-distance factorization, Definition 1612.29. The classifier row Z reads equality as displayed zero-distance evidence over the $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route, rather than as host equality or quotient completion equality.

Finally apply source-comparison exhaustion, Definition 1612.32. The uniqueness, transport, replay, provenance, and naming rows preserve a comparison once Z is present, but none of them supplies an alternate separated equality route. □

Theorem 1612.42 (SeparatedCompletion obligation closure package)**.** *The accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier*

$$S = (M, D, C, Z, U, H, R, T, P, N)$$

supports an obligationClosure package whose finite boundary is exactly dense factorization, zero-distance factorization, source-comparison exhaustion, the choice-free source route, the filtered limit boundary, and the completion-reflector handoff. The package closes the paper-side obligation surface over the displayed rows and refuses quotient completions, selected representatives, host equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, and hidden complete metric spaces.*

Proof. Build the source prefix from dense factorization, Definition 1612.19, and dense replay scope, Definition 1612.40. These results force every completion-facing read through M, D, C.

Build the classifier boundary from zero-distance factorization, Definition 1612.29, and separated classifier scope, Definition 1612.41. They make Z the only separated equality route after the dense completion handoff.

Add the comparison and source routes from Definition 1612.32 and Definition 1612.34. These theorems keep all comparison data in displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally attach the filtered limit boundary, Definition 1612.38, and the completion-reflector handoff, Definition 1612.39. The resulting package contains no coordinate for quotient completions, selected representatives, host equality, countable choice, ambient Real completeness, or hidden complete metric spaces, so the obligation surface is closed at the paper level. □

Theorem 1612.43 (SeparatedCompletion choice-free endpoint package)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, any endpoint comparison exported to* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{HausdorffCompletion}^{\uparrow}$*,* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumers factors through the displayed rows*

$$M, D, C, Z, U, H, R, T, P, N.$$

The exported comparison is the finite endpoint package obtained from dense-source admission, filtered limit boundary, choice-free source transport, completion uniqueness, and Cauchy-reflector handoff. It exports no quotient completion, selected representative, host equality of completed points, countable choice, hidden complete metric space, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the dense route. Dense factorization, Definition 1612.19, and dense replay scope, Definition 1612.40, force every endpoint-facing read through M, D, C before the separated classifier or uniqueness boundary is available.

Transport the limit boundary without a selector. The filtered limit boundary of Definition 1612.38 and the choice-free source route of Definition 1612.34 keep the read inside displayed BHist, hsame, Cont, Pkg, and NameCert rows. Thus the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff remains a finite route through C and cannot become a selected limit.

Attach the completion uniqueness package. The obligation closure package of Definition 1612.42 supplies the local uniqueness boundary over Z, U, H, R, T, P, N, while the Hausdorff uniqueness route of Definition 1612.36 keeps the comparison separated rather than quotient-based.

Finally use the Cauchy-reflector handoff, Definition 1612.39, together with the Cauchy reflector obligation of Definition 1612.22. These results route $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, and $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ consumers through the same displayed endpoint rows. Since the carrier has no quotient, representative-selection, host-equality, choice, hidden-complete-space, or ambient-completeness coordinate, the endpoint package exports exactly the rows stated above. □

Theorem 1612.44 (SeparatedCompletion carrier admission root obligation)**.** *Every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier exposes only the displayed* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *row is read. The admission surface contains no additional completion point, quotient class, selected representative, host equality of completed points, countable-choice schedule, or hidden complete metric space.*

Proof. Project the carrier of Definition 1612.1. The source, dense-embedding, completion handoff, separated classifier, and uniqueness rows are exactly M, D, C, Z, U.

Read these rows through the existing source route. The Cauchy-equivalence source theorem, Definition 1612.21, and the dense factorization theorem, Definition 1612.19, place the admission boundary over $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ data.

Then attach the uniqueness boundary from Definition 1612.20. It adds only the displayed $\mathsf{CompletionUniversalProperty}^{\uparrow}$ and $\mathsf{HausdorffCompletion}^{\uparrow}$ rows over the same finite route. Since H, R, T, P, N merely transport, replay, preserve, source, and name the displayed rows, the excluded completion objects have no carrier coordinate. □

Theorem 1612.45 (SeparatedCompletion classifier stability root obligation)**.** *For any accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carriers over componentwise* hsame*-transported* $M, D, C, Z, U, H, R, T, P, N$ *rows, the separated classifier exposed by* Z *is preserved by the displayed transport and replay rows. This stability cannot introduce quotient-completion equality, selected representatives, host equality of completed points, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the transported carrier rows. Componentwise hsame transport acts on the displayed source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, replay, provenance, and local naming rows named by the carrier.

Apply separated classifier scope, Definition 1612.41. After the dense completion handoff, Z is the only separated equality route available to a completion-facing read.

Finally apply source-comparison exhaustion, Definition 1612.32. It keeps transported comparisons inside $M, D, C, Z, U, H, R, T, P, N$. Because the transported packet has no quotient-completion or host-equality coordinate, classifier stability cannot create one. □

Theorem 1612.46 (SeparatedCompletion Real seal root obligation)**.** *Any Real-facing seal read exported by an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier factors through displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *rows before the separated completion handoff is consumed. The seal read is therefore a finite BEDC route through* $M, D, C, Z, U, H, R, T, P, N$*, not an ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle or a chosen completion representative.*

Proof. Read the dense prefix first. By Definition 1612.40, every completion-facing read exposes M, D, C before any separated classifier, uniqueness boundary, or local naming row is available.

The opening carrier route identifies this prefix with the L10 spine through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the $\mathsf{MetricCompletion}^{\uparrow}$ handoff. The Real-facing seal is therefore downstream from finite stream windows and regular rational readback.

Now apply the choice-free source route, Definition 1612.34, and the completion-reflector handoff, Definition 1612.39. They keep the separated completion handoff in displayed BHist, hsame, Cont, Pkg, and NameCert rows and exclude ambient Real completeness, selected representatives, quotient completions, host equality, and countable choice. □

Theorem 1612.47 (SeparatedCompletion root obligation package)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier, the carrier-admission, classifier-stability, and Real-seal root obligations of Definition 1612.44, Definition 1612.45, and Definition 1612.46 jointly exhaust the finite* $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$ *surface over* $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *rows. Thus every downstream completion consumer receives only displayed source admission, separated classifier stability, Real-seal readback, componentwise transport, replay, provenance, and local naming.*

Proof. The carrier-admission root obligation identifies the finite row inventory available to the accepted carrier. It confines every completion-facing read to the displayed source, dense embedding, completion handoff, separated classifier, uniqueness, transport, replay, provenance, and local naming rows.

The classifier-stability root obligation then fixes the separated equality surface. Transport and replay preserve the classifier row inside that same finite inventory, so no extra quotient representative or host equality coordinate appears after the carrier is admitted.

The Real-seal root obligation closes the remaining completion-to-Real route through the StreamName, RegSeqRat, DyadicRatCore, and MetricCompletion rows. Together the three obligations cover the root surface exposed to CauchyCompletionReflector, CompletionEmbedding, MetricCompletion, RegSeqRat, Real, and StreamName consumers, and none of them introduces quotient representatives, host equality, countable choice, or an ambient completeness coordinate. □

Theorem 1612.48 (SeparatedCompletion separated witness triad)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every separated-completion equality consumer must expose the dense source row* D*, the zero-distance classifier row* Z*, and the uniqueness boundary row* U *in that order before any exported completion seal is read. The exposed triad is the root obligation witness over the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route; it is not a quotient completion, selected representative, host equality, countable-choice schedule, or completeness claim for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier. The rows D, Z, U are already part of the finite inventory listed in Definition 1612.1, with D recording dense source admission, Z recording separated zero-distance classification, and U recording the uniqueness boundary over the same route.

Use the NameCert obligations of Definition 1612.2. Dense-source compatibility forces the consumer to read D before the completion handoff can be inspected. Separated-classifier exactness then places Z after the handoff, and uniqueness-boundary exactness places U over the same M, D, C, Z route.

The root obligation package, Definition 1612.47, binds these rows to the carrier-admission, classifier-stability, and Real-seal obligations. Thus an exported completion seal can be read only after the dense source row, zero-distance classifier, and uniqueness boundary have been displayed in the stated order.

The carrier has no coordinate for quotient completions, selected representatives, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The witness triad is therefore induction-ready because later consumers can recurse over the displayed rows D, Z, U and their structural transport data, without selecting representatives or appealing to an external completion equality. □

Theorem 1612.49 (SeparatedCompletion filterbase admission)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier*

$$S = (M, D, C, Z, U, H, R, T, P, N),$$

any filterbase-facing admission read factors through the same finite source route as Definition 1612.47. The $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *rows receive the source metric M, dense embedding D, completion handoff C, separated classifier Z,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *windows, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows H, R, T, P, N before a filterbase consumer may inspect completion data. Thus filterbase admission is a* BHist *and* $\mathsf{NameCert}$ *route, not a quotient completion, selected representative, host equality, countable-choice selector, or ambient complete-space coordinate.*

Proof. Project the accepted carrier. The rows M, D, C admit the source metric, dense embedding, and completion handoff before any filterbase-facing consumer can read completion data.

The separated classifier row Z and uniqueness boundary U keep the filterbase comparison inside the same displayed separated route. Apply Definition 1612.45 to see that transport and replay cannot add a host equality coordinate.

Finally read the completion-facing spine. The $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are delivered through H, R, T, P, N, so the filterbase admission has no access to quotient completions, selected representatives, countable choice, or an ambient complete-space object. □

Theorem 1612.50 (SeparatedCompletion Cauchy-equivalence routing)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier, each Cauchy-equivalence read sent to* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *factors through the separated classifier and the Cauchy source rows before the terminal Real seal is exposed. In symbols, the public Cauchy-equivalence route is*

$$M, D, C, Z, U \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, R, T, P, N.$$

The route exports only displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows and does not export quotient stream equality, host equality of completed points, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 1612.21. It places every Cauchy-equivalence read behind the displayed Cauchy source and separated-completion rows, so the comparison is not a free-standing quotient relation.

Next apply Definition 1612.29 and Definition 1612.30. These theorems route zero-distance and uniqueness reads through Z and U before the regular-rational and stream windows can be consumed.

The Real-facing boundary is then supplied by Definition 1612.46. The structural rows preserve and replay the same path through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$, so no quotient stream equality, host equality, selected limit, choice principle, or ambient completeness coordinate is available. □

Theorem 1612.51 (SeparatedCompletion completion-reflector nonescape)**.** *Every* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier remains inside the finite route*

$$M, D, C, Z, U, H, R, T, P, N$$

together with the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff rows. The reflector may read the source metric, dense embedding, separated classifier, uniqueness boundary, transport, replay, provenance, and local naming, but it may not import quotient completions, selected representatives, host equality, countable choice, hidden complete metric spaces, or an ambient real-completeness theorem.*

Proof. Read the reflector handoff through Definition 1612.39. It already places the completion-reflector consumer downstream of the source metric, dense embedding, completion handoff, separated classifier, and Real-facing L10 spine.

The root package of Definition 1612.47 exhausts the carrier-admission, classifier-stability, and Real-seal obligations. Hence the reflector consumer can inspect only the rows listed there and the transport, replay, provenance, and naming rows H, R, T, P, N.

Nonescape follows from absence of coordinates. Quotient completions, selected representatives, host equality, countable choice, hidden complete metric spaces, and ambient real completeness are not fields of the carrier and cannot be produced by hsame transport, Cont replay, Pkg provenance, or local $\mathsf{NameCert}$ naming. □

Theorem 1612.52 (SeparatedCompletion Cauchy-reflector triangle)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier whose source route receives* $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Every endpoint-uniqueness read sent toward a Real-facing completion seal factors through the separated classifier row* Z *before it can be consumed by the reflector or universal-property rows. The triangle*

$$\mathsf{CauchyCompletionReflector}^{\uparrow} \longmapsto \mathsf{SeparatedCompletion}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow}$$

therefore commutes at the displayed $\mathsf{NameCert}$ *surface through* $M, D, C, Z, U, H, R, T, P, N$, *and exports no quotient completion, selected representative, host equality of completed points, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The dense source rows M, D, C are read first, so the reflector-facing route starts from the same finite metric, dense embedding, and completion handoff as the rest of the chapter.

Apply Definition 1612.19 and Definition 1612.20. They place endpoint uniqueness downstream of the dense factorization and force the uniqueness boundary to read the separated classifier row Z rather than a host equality coordinate.

Now apply Definition 1612.39. The CauchyCompletionReflector and CompletionUniversalProperty consumers receive the same route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The transport, route-preservation, provenance, and local naming rows H, R, T, P, N preserve this factorization. Because the carrier contains no quotient-completion, selected-representative, host-equality, choice, or ambient-completeness coordinate, the only available triangle is the displayed separated-classifier route. □

Theorem 1612.53 (SeparatedCompletion root-consumer unblock package)**.** *Every downstream Real or Completion consumer of an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier must factor through the carrier-admission root obligation, classifier-stability root obligation, Real-seal root obligation, root obligation package, and Cauchy-reflector triangle before reading any completion-facing output. Equivalently, any consumer route over* $S = (M, D, C, Z, U, H, R, T, P, N)$ *must display the finite root surface*

$$M, D, C, Z, U, H, R, T, P, N$$

together with the carrier-admission, classifier-stability, Real-seal, root-package, and reflector-triangle witnesses. The package exports no quotient completion, selected representative, host equality of completed points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier into the rows $M, D, C, Z, U, H, R, T, P, N$. The source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, transport, route preservation, replay, provenance, and local naming rows are therefore the only displayed input surface available to downstream consumers.

Apply Definition 1612.47. It combines the carrier-admission root obligation, classifier-stability root obligation, and Real-seal root obligation, so the source, classifier, and seal sides of the accepted packet are exhausted before a completion-facing output can be read.

Next apply Definition 1612.52. The reflector and universal-property routes commute only through the separated classifier row and the same finite L10 source spine, so endpoint-uniqueness reads cannot bypass the root package.

The remaining structural rows H, R, T, P, N preserve, replay, source, and name that route. Since no quotient completion, selected representative, host equality, countable-choice schedule, or ambient Real-completeness coordinate appears among the carrier rows, the displayed package is the required unblock surface for all downstream Real and Completion consumers. □

Theorem 1612.54 (SeparatedCompletion dense limit route)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every accepted limit-facing read must pass through the displayed* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the uniqueness row* U *is public. The route exposes dense source data, zero-distance classification, regular-Cauchy separated completion, and the Real-facing L10 spine, and it exports no quotient completion, selected limit representative, host equality of completed points, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the dense source prefix first. Dense factorization, Definition 1612.19, and dense replay scope, Definition 1612.40, force every completion-facing read through M, D, C before any separated classifier or uniqueness row is available.

Read the classifier and limit boundary next. Zero-distance factorization, Definition 1612.29, makes Z the separated equality route, and limit-uniqueness export, Definition 1612.30, makes U the public uniqueness row over M, D, C, Z.

Now attach source-comparison exhaustion, Definition 1612.32, and nonescape, Definition 1612.33. These results keep the source route inside the displayed MetricCompletion, CompletionEmbedding, CompletionUniversalProperty, SeparatedMetric, HausdorffCompletion, RegularCauchyCompletion-Separated, DyadicRatCore, StreamName, RegSeqRat, and Real rows. Since none of the excluded objects is a carrier coordinate, the dense limit route reaches uniqueness only through the displayed packet. □

Theorem 1612.55 (SeparatedCompletion choice-free limit transport)**.** *For accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carriers whose source, dense embedding, completion handoff, separated classifier, uniqueness boundary, transport, replay, route, provenance, and local naming rows are matched componentwise by* hsame *and replayed by* Cont*, the transported packet preserves the same dense source, zero-distance classifier, and uniqueness boundary. This preservation uses no countable choice, quotient completion, selected representative, host equality of completed points, hidden complete metric space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the two carriers and read their transported rows componentwise. The hsame rows act only on $M, D, C, Z, U, H, R, T, P, N$, and the Cont rows replay the same displayed path.

Apply dense factorization, Definition 1612.19, to both packets. The dense source remains the M, D, C route after transport, because no additional source coordinate is present.

Apply zero-distance factorization, Definition 1612.29, and limit-uniqueness export, Definition 1612.30. They identify Z as the classifier and U as the uniqueness boundary before any downstream completion consumer can read the transported packet.

Finally use source-comparison exhaustion, Definition 1612.32, together with nonescape, Definition 1612.33. The structural rows preserve the dense source, zero-distance classifier, and uniqueness boundary, while the excluded choice, quotient, representative, host-equality, hidden-space, and ambient-completeness objects remain absent from the carrier. □

Theorem 1612.56 (SeparatedCompletion completion uniqueness package)**.** *Every downstream* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{HausdorffCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier receives uniqueness only as the displayed row* U *over* M, D, C, Z *together with the structural rows* H, R, T, P, N*. The package may use the dense limit route of Definition 1612.54 and the choice-free transport route of Definition 1612.55, but it cannot export quotient completion equality, a selected representative, host equality of completed points, countable choice, a hidden complete metric space, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the dense route. By Definition 1612.54, a MetricCompletion or HausdorffCompletion consumer sees M, D, C before the separated classifier Z and uniqueness row U are public.

Read uniqueness through the local row U. The limit-uniqueness export theorem, Definition 1612.30, identifies that row as the whole uniqueness boundary over M, D, C, Z.

Transport and replay are then handled by Definition 1612.55. The rows H, R, T, P, N preserve, replay, source, and name the same boundary for downstream consumers.

Apply source-comparison exhaustion, Definition 1612.32, and nonescape, Definition 1612.33, to close the package. Since the carrier contains no quotient completion equality, selected representative, host equality, choice schedule, hidden complete metric space, or ambient completeness coordinate, the displayed U row over $M, D, C, Z, H, R, T, P, N$ is the only uniqueness package available. □

Theorem 1612.57 (SeparatedCompletion density separated route)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every dense limit read exported before uniqueness must factor through the displayed* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row* D*, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier* Z*, the* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *route carried by* C*, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows in the completion handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before* U *may be consumed. Thus density and separation meet inside the finite route*

$$M, D, C, Z \longmapsto U, H, R, T, P, N,$$

not in a quotient completion, selected representative, host equality of completed points, countable-choice schedule, hidden complete metric space, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier first. The source metric row M and dense embedding row D are the only displayed entrance into a dense limit read.

Read the completion handoff C next. Its regular-Cauchy separated route carries the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ seal rows before a separated comparison can be public.

Apply zero-distance factorization, Definition 1612.29. The separated classifier Z is the comparison boundary after C, so host equality of completed points and quotient equality are unavailable.

Only then may the uniqueness row U be consumed. The structural rows H, R, T, P, N transport, replay, source, and name the same dependency order, and the excluded completion objects have no coordinate in the carrier. □

Theorem 1612.58 (SeparatedCompletion filterbase reflector exhaustion)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every filterbase-facing reflector read exported by S factors through the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *admission row, the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *dense row, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *reflector boundary, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier, the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated readback, the* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *route, the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *L10 spine, and then through the structural* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. The exported read contains no quotient completion equality, selected representative, countable-choice schedule, host equality of completed points, hidden complete metric space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier. The only reflector-facing coordinates are the source metric row M, dense embedding row D, completion handoff row C, separated classifier row Z, uniqueness boundary U, and the structural rows H, R, T, P, N.

Read the filterbase entrance through the existing admission route of Definition 1612.49. That route already places filterbase data inside the displayed $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CompletionEmbedding}^{\uparrow}$ prefix before a reflector consumer may inspect completion data.

Attach the reflector boundary using Definition 1612.39 and Definition 1612.52. The $\mathsf{CompletionUniversalProperty}$ $\mathsf{HausdorffCompletion}^{\uparrow}$, and $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ rows are consumed only after M, D, C, Z, U have been displayed.

Finally read the L10 spine carried by C: $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ supply finite tolerance, window, readback, and seal data. Since the carrier has no coordinate for quotient completion equality, selected representatives, choice schedules, host equality, hidden complete spaces, or ambient completeness, the reflector read is exhausted by the named rows. □

Theorem 1612.59 (SeparatedCompletion Cauchy-sequence equivalence lock)**.** *Let $S = (M, D, C, Z, U, H, R, T, P,$ be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every Cauchy-equivalence read exported by S is locked to the displayed route through* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. No exported equivalence may be replaced by quotient completion equality, a selected representative, countable choice, host equality of completed points, a hidden complete metric space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the Cauchy-equivalence source theorem Definition 1612.21. It places every comparison inside the displayed source, dense embedding, and completion handoff rows M, D, C before the separated classifier Z can be read.

Use zero-distance factorization, Definition 1612.29, to make Z the separated comparison boundary. The equivalence read is therefore a displayed zero-distance route through the $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows carried by M, D, C, Z.

Read the uniqueness and Hausdorff boundary through Definition 1612.30 and Definition 1612.36. These routes attach the CompletionUniversalProperty$^{\uparrow}$, HausdorffCompletion$^{\uparrow}$, and RegularCauchyCompletionSeparate rows without adding any equality object outside the carrier.

The structural rows H, R, T, P, N preserve, replay, source, and name the same route. Since quotient completions, selected representatives, choice schedules, host equality, hidden complete spaces, and ambient completeness are absent from the carrier, every exported Cauchy-equivalence read is locked to the displayed finite route. □

Theorem 1612.60 (SeparatedCompletion Hausdorff completion readback)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* SeparatedCompletion$^{\uparrow}$ *carrier. Every* HausdorffCompletion$^{\uparrow}$ *readback consumed by a downstream completion chapter factors through the same displayed* MetricCompletion$^{\uparrow}$*,* CompletionEmbedding$^{\uparrow}$*,* CompletionUniversalProperty$^{\uparrow}$*,* SeparatedMetric$^{\uparrow}$*,* RegularCauchyCompletionSeparated$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *route. The readback is a finite separated-completion boundary over S, not a quotient completion equality, selected representative, countable-choice schedule, host equality of completed points, hidden complete metric space, or ambient* Real$^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier and read M, D, C as the dense completion prefix. By Definition 1612.57, the downstream completion consumer must see the dense embedding, separated classifier, regular-Cauchy separated route, stream and rational readback rows, and terminal Real seal before uniqueness may be consumed.

Now read the Hausdorff boundary through Definition 1612.36 and the reflector handoff through Definition 1612.39. These theorems place HausdorffCompletion$^{\uparrow}$ readback after CompletionUniversalProperty$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, and RegularCauchyCompletionSeparated$^{\uparrow}$ have been displayed over the same source route.

Finally apply source-comparison exhaustion, Definition 1612.32. The rows H, R, T, P, N transport, replay, preserve, source, and name the displayed route, while quotient completion equality, selected representatives, choice schedules, host equality, hidden complete spaces, and ambient real completeness have no coordinate in the carrier. □

Theorem 1612.61 (SeparatedCompletion source triad obligation)**.** *Let $S = (M, D, C, Z, U, H, R, T, P, N)$ be an accepted* SeparatedCompletion$^{\uparrow}$ *carrier. Every accepted packet reads the source metric row M, dense embedding row D, and completion handoff row C before any separated comparison through Z is public. The triad is preserved through* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and the local* NameCert *row, and no separated-comparison consumer can start from Z, U, H, R, T, P, N alone.*

Proof. Project the carrier of Definition 1612.1. The source metric, dense embedding, and completion handoff rows are exactly the coordinates M, D, C, and the separated classifier is a later coordinate Z over the same packet.

Apply dense factorization, Definition 1612.19. It places every completion-facing read on the route $M, D \mapsto C$ before separated comparison or uniqueness data is available.

Now apply zero-distance factorization, Definition 1612.29. The row Z reads equality as displayed zero-distance evidence over the already exposed dense completion handoff, not as an independent comparison source. The structural rows H, R, T, P, N only preserve, replay, source, and name this order. □

Theorem 1612.62 (SeparatedCompletion quotient-exhaustion refusal)**.** *For every accepted* SeparatedCompletion$^{\uparrow}$ *carrier $S = (M, D, C, Z, U, H, R, T, P, N)$, quotient completions, selected representatives, host*

equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, and hidden complete spaces are absent from every public route exported by* S*. Any public completion-facing, equality-facing, uniqueness-facing, or reflector-facing read is exhausted by* $M, D, C, Z, U, H, R, T, P, N$ *through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Start with universal route exhaustion, Definition 1612.27. It identifies the public route with the displayed source, dense embedding, completion handoff, separated classifier, uniqueness boundary, transport, replay, provenance, and local naming rows.

Attach the dense source and comparison constraints. Dense factorization, Definition 1612.19, forces M, D, C to be read first, and zero-distance factorization, Definition 1612.29, forces equality reads through Z rather than through host equality or quotient equality.

Finally apply the limit-uniqueness export, Definition 1612.30. It makes U the whole public uniqueness boundary over M, D, C, Z. Since the carrier has no coordinate for quotient completions, selected representatives, choice schedules, ambient Real completeness, or hidden complete spaces, those objects are absent from every public route. □

Theorem 1612.63 (SeparatedCompletion scoped route)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier, the scoped route is exactly*

$$M, D, C, Z, U, H, R, T, P, N$$

read through BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The route admits the source metric, dense embedding, completion handoff, separated classifier, uniqueness boundary, transport, replay, route ledger, provenance, and local naming rows, and it admits no additional completion, equality, choice, Real-completeness, or hidden-space coordinate.*

Proof. Project the accepted carrier using Definition 1612.1. This gives the displayed row inventory $M, D, C, Z, U, H, R, T, P, N$ and no further public coordinate.

Use Definition 1612.61 to fix the source prefix. Every separated-completion read starts with M, D, C before it can inspect Z or U.

Use quotient-exhaustion refusal, Definition 1612.62, for the negative side. It excludes quotient completions, selected representatives, host equality, countable choice, ambient Real completeness, and hidden complete spaces from the route. The remaining rows are precisely the BHist, hsame, Cont, Pkg, and NameCert surface already displayed by the carrier. □

Definition 1612.64 (SeparatedCompletion scoped kernel route)**.** *For an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, the scoped kernel route is the finite BEDC read*

$$(\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}) \vdash M, D, C, Z, U, H, R, T, P, N.$$

It binds dense-source compatibility by M, D, C*, separated classifier exactness by* Z, U*, transport and replay by* H, R, T*, and provenance and local naming by* P, N*. The route has no coordinate for quotient completions, selected representatives, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric spaces.*

Theorem 1612.65 (SeparatedCompletion dense source scope)**.** *Every dense-source consumer of an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier must read* M, D, C *through the scoped kernel route before reading* Z, U, H, R, T, P, N*. Thus dense-source compatibility is a statement about the displayed source metric row, dense embedding row, and completion handoff row inside* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, not about an external completed space.*

Proof. Apply the scoped route theorem, Definition 1612.63. It identifies the public route with the rows $M, D, C, Z, U, H, R, T, P, N$ and no additional coordinate.

Now use the dense-limit route, Definition 1612.54. It places dense completion reads on the prefix M, D, C before separated comparison or uniqueness rows are consumed.

Finally apply quotient-exhaustion refusal, Definition 1612.62. Since quotient completions, selected representatives, host equality, choice, ambient Real completeness, and hidden complete spaces are absent, the dense-source scope is exactly the displayed kernel prefix. □

Theorem 1612.66 (SeparatedCompletion classifier nonescape scope)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier, the separated classifier and uniqueness boundary are exact only through* Z, U *over the dense-source prefix* M, D, C*. Any completion-facing, equality-facing, uniqueness-facing, or reflector-facing consumer reads the classifier route through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, and it cannot escape to quotient equality, selected representatives, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric spaces.*

Proof. Start from Definition 1612.64. It names the carrier rows available to the scoped kernel route and separates the dense-source prefix from the classifier and uniqueness rows.

Use Definition 1612.63 to identify the public consumer route. The theorem makes $M, D, C, Z, U, H, R, T, P, N$ the whole visible surface.

The exactness side is supplied by Definition 1612.54: the separated classifier is read only after the dense completion prefix has been exposed. The negative side is supplied by Definition 1612.62, which excludes quotient, representative, host equality, choice, Real-completeness, and hidden-space coordinates from every public route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1612.1, Definition 1612.2, Definition 1612.63, Definition 1612.62, the downstream routes in this file, and the source-density scope closure of Definition 1612.67, Definition 1612.68, and Definition 1612.69 bind the mature paper-side separated-completion semantic NameCert export to source density, Cauchy completion, separated metric comparison, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SeparatedCompletion}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.SeparatedCompletionUp.SeparatedCompletionCarrier\_semantic\_name\_certificate`

Bridge status: paperBridge

Not claimed: This chapter does not claim quotient completions, selected representatives, host equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, hidden complete metric spaces, or bridge checking.

Upgrade path: The remaining upgrade is a Lean-side standard bridge check for the same separated-completion semantic NameCert export.

Constructive story: A $\mathsf{SeparatedCompletion}^{\uparrow}$ packet is generated from a source metric row, a dense CompletionEmbedding row, a completion handoff through the DyadicRatCore-StreamName-RegSeqRat-Real L10 spine, a SeparatedMetric classifier, a CompletionUniversalProperty-HausdorffCompletion-RegularCauchyCompletionSeparated uniqueness boundary, componentwise hsame transport, Cont replay, route-preservation ledger, Pkg provenance, and a local NameCert row.

Theorem 1612.67 (SeparatedCompletion source-density scope)**.** *Let* $S = (M, D, C, Z, U, H, R, T, P, N)$ *be an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier. Every source-density read consumed by* S *is scoped by the source metric row* M*, dense embedding row* D*, completion handoff row* C*, separated classifier row* Z*, uniqueness row* U*, componentwise transport* H*, displayed replay and route ledger* R, T*,* Pkg *provenance* P*, and local* NameCert *row* N *through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The read may cite Definition 1612.1 and Definition 1612.2, but it exports no quotient completion, selected representative, host equality of completed points, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric space.*

Proof. Project the accepted carrier. The source metric row, dense embedding row, completion handoff row, separated classifier row, uniqueness row, transport, replay, route ledger, provenance, and local name are exactly $M, D, C, Z, U, H, R, T, P, N$.

Apply the NameCert obligations of Definition 1612.2. They force dense-source compatibility through M, D, C and keep every completion-facing read inside the same local packet.

Finally use the scoped route and quotient-exhaustion rows, Definition 1612.63 and Definition 1612.62. These identify the public route as the displayed kernel surface through BHist, hsame, Cont, Pkg, and NameCert, with the excluded completion objects absent from every coordinate. □

Theorem 1612.68 (SeparatedCompletion classifier scope)**.** *For every accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, Z, U, H, R, T, P, N)$*, a separated classifier read is scoped only after the source metric row* M*, dense embedding row* D*, and completion handoff row* C *have been displayed. The classifier row* Z*, uniqueness row* U*, transport row* H*, replay and route rows* R, T*, provenance* P*, and local* NameCert *row* N *bind the comparison to* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, citing the carrier and obligation surfaces of Definition 1612.1 and Definition 1612.2.*

Proof. Read the source-density prefix first. By Definition 1612.67, the rows M, D, C are the only source, dense, and completion-handoff entrance for the accepted carrier.

Now inspect the classifier side. The separated classifier exactness clause of Definition 1612.2 places Z after C, and the uniqueness-boundary exactness clause reads U over the same M, D, C, Z route.

The structural rows H, R, T, P, N preserve, replay, source, and name that route. Hence the classifier scope is a local BEDC kernel route through BHist, hsame, Cont, Pkg, and NameCert, not a host equality or quotient-completion comparison. □

Theorem 1612.69 (SeparatedCompletion nonescape scope)**.** *Every public separated-completion read of an accepted* $\mathsf{SeparatedCompletion}^{\uparrow}$ *carrier is exhausted by the source metric row, dense embedding row, completion handoff row, separated classifier row, uniqueness row, transport, replay, route ledger, provenance, and local NameCert rows*

$$M, D, C, Z, U, H, R, T, P, N$$

through the kernel rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Together with Definition 1612.67 and Definition 1612.68, this excludes quotient completions, selected representatives, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and hidden complete metric spaces from the scoped public surface.*

Proof. Begin with the carrier and obligations. The carrier definition fixes $M, D, C, Z, U, H, R, T, P, N$ as the whole packet, and Definition 1612.2 assigns source-density, separated-classifier, uniqueness, transport, replay, provenance, and naming roles to those rows.

Apply the source-density and classifier scope theorems. They place source reads through M, D, C and separated comparisons through Z, U after that prefix, with H, R, T, P, N attached as structural BEDC rows.

Use quotient-exhaustion refusal, Definition 1612.62, for the negative side. Since none of the excluded objects is a carrier coordinate, every public read remains inside BHist, hsame, Cont, Pkg, and NameCert over the displayed row inventory. □

Theorem 1612.70 (SeparatedCompletion scope-closure route)**.** *Every public* $\mathsf{SeparatedCompletion}^{\uparrow}$ *read of an accepted carrier factors through the ordered rows*

$$M, D, C, Z, U, H, R, T, P, N.$$

The prefix M, D, C supplies the source metric, dense embedding, and completion handoff scope of Definition 1612.67; the rows Z, U supply the separated classifier and uniqueness scope of Definition 1612.68; and the rows H, R, T, P, N preserve the same public route through BHist, hsame, Cont, Pkg, *and* NameCert *as in Definition 1612.69. The route exports no quotient completion, selected representative, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric space.*

Proof. Start with the source-density theorem. It identifies M, D, C as the only entrance for source metric, dense embedding, and completion handoff data.

Next apply the classifier theorem. The separated classifier row Z and uniqueness row U are read only after that source-density prefix, so classifier comparison cannot detach from M, D, C.

Finally apply the nonescape theorem. It attaches H, R, T, P, N to the same ordered carrier route and excludes quotient completions, selected representatives, host equality, countable choice, ambient real completeness, and hidden complete metric spaces from the public surface. □

Chapter 1613

A Concrete Naming Certificate for $\mathsf{DyadicNormalForm}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicNormalForm}^{\uparrow}$ packet names the finite canonical presentation of a dyadic rational before the open Real and Completion route passes through regular rational streams. It sits downstream of the signed rows of chapter 31, the rational rows of chapter 37, and the dyadic core boundary of chapter 291; it supplies the displayed normal-form surface read by chapter 126, chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records canonical finite dyadic representation data, not quotient rational equality, completed real equality, order, completeness, or a standard bridge.

Definition 1613.1 (Dyadic normal-form carrier)**.** *A* $\mathsf{DyadicNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, M, E, Z, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the sign row, read through the signed* $\mathsf{Int}^{\uparrow}$ *surface and recording positive, negative, or zero orientation for the displayed dyadic.*
2. *M is the signed mantissa row, an* $\mathsf{Int}^{\uparrow}$*-read finite integer whose absolute part is visible before scale inspection.*
3. *E is the unary exponent row, carrying the nonnegative dyadic scale attached to the denominator 2^E.*
4. *Z is the zero classifier row, recording that the zero packet is represented by the distinguished row $M = 0$ with terminal scale $E = 0$.*
5. *R is the scale-minimality row, recording that a nonzero mantissa is odd at the displayed scale and hence cannot be divided by 2 while lowering E.*
6. *L is the dyadic readback ledger, exposing the finite rational row $M/2^E$ through* $\mathsf{Rat}^{\uparrow}$ *and the accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *boundary.*
7. *H records componentwise* hsame *transport for the sign, mantissa, exponent, zero classifier, scale-minimality row, readback ledger, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a dyadic input through sign extraction, mantissa readback, unary scale inspection, zero handling, scale-minimality verification, and dyadic readback.*

9. *P is the* Pkg *provenance over* $\mathsf{Int}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, M, E, Z, R, L, H, C, P, N$. It has no coordinate for quotient rational equality, host real equality, order, completion, a choice-selected representative, or a standard bridge.

Theorem 1613.2 (Dyadic normal-form NameCert obligations)**.** *For every accepted* $\mathsf{DyadicNormalForm}^{\uparrow}$ *carrier $D = (S, M, E, Z, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicNormalForm}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the sign, signed mantissa, unary exponent, zero classifier, scale-minimality row, dyadic readback ledger, transport, continuation, provenance, and local naming row;*
2. *source compatibility, requiring M and E to be read from an accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *packet through the displayed* $\mathsf{Int}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *surfaces;*
3. *zero exactness, requiring Z to identify the unique zero normal row $M = 0, E = 0$ before any downstream readback is exposed;*
4. *scale-minimality, requiring every nonzero accepted row to expose an odd mantissa at the displayed scale, so that no lower unary exponent represents the same dyadic row inside the packet;*
5. *dyadic readback stability, requiring L, H, C to preserve the rational readback $M/2^E$ under componentwise* hsame *transport and displayed* Cont *replay;*
6. *downstream handoff, requiring* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers to inspect only the finite normal-form row and its dyadic readback ledger;*
7. *ledger refusal, excluding quotient rational equality, host real equality, order, completion, choice-selected representatives, and standard-bridge data.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1613.1. The projection exposes exactly the sign row, mantissa row, unary exponent row, zero classifier, scale-minimality row, dyadic readback ledger, and structural rows H, C, P, N.

Source compatibility follows from the attachment to chapter 291. The mantissa is read through $\mathsf{Int}^{\uparrow}$, the rational readback is read through $\mathsf{Rat}^{\uparrow}$, and both rows are consumed only as finite dyadic-core data.

Zero exactness and scale-minimality are the two classifier rows. The zero case is forced by Z, while the nonzero case is forced by R, which records that no displayed factor of 2 remains in the mantissa at the chosen scale.

Replay C and then transport by H. The route preserves the same sign, mantissa, exponent, zero classifier, minimality row, and readback ledger before any $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer can inspect the packet.

The exclusions are immediate from the carrier inventory. Since quotient rational equality, host real equality, order, completion, choice-selected representatives, and bridge rows are absent, the local NameCert surface cannot export them. □

Theorem 1613.3 (Dyadic normal-form canonical readback)**.** *Let $D = (S, M, E, Z, R, L, H, C, P, N)$ and $D' = (S', M', E', Z', R', L', H', C', P', N')$ be accepted* $\mathsf{DyadicNormalForm}^{\uparrow}$ *carriers whose dyadic readback ledgers expose the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row through the displayed* $\mathsf{Rat}^{\uparrow}$ *surface. If both*

carriers satisfy the same zero classifier and scale-minimality rows, then their sign, mantissa, unary exponent, and dyadic readback rows agree under componentwise hsame *transport. Consequently every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer reads a single canonical finite normal form rather than a family of scale-shifted dyadic representatives.*

Proof. Compare the two accepted packets through the displayed readback ledgers L and L'. The hypothesis says that the comparison is made inside the same $\mathsf{DyadicRatCore}^{\uparrow}$ boundary and through the same $\mathsf{Rat}^{\uparrow}$ readback surface.

If the common readback is zero, the classifier rows Z and Z' force both packets to use the distinguished zero row. Hence $M = M' = 0$ and $E = E' = 0$ after componentwise transport, and the sign rows agree with the zero orientation.

In the nonzero case, the scale-minimality rows R and R' force both mantissas to be odd at their displayed scales. A dyadic equality between two odd mantissas at different unary exponents would exhibit a remaining factor of 2 on one side after transporting to a common scale, contradicting the corresponding minimality row.

Thus the unary exponent rows agree, and then the displayed rational readback forces the signed mantissa rows and sign rows to agree. Transport by H and H' carries this agreement to the local naming rows, while C and C' replay the same finite route for downstream consumers.

The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff reads only the rows just compared. Therefore downstream consumers see the canonical finite normal form and not a separate scale-shifted representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicNormalForm}^{\uparrow}$ packet is generated from a sign row, signed mantissa, unary exponent, zero classifier, scale-minimality row, dyadic readback ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1613.1, Definition 1613.2, and Definition 1613.3 seed the canonical finite dyadic representation boundary feeding DyadicRatCore, StreamName, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, host real equality, order, completion, choice-selected representatives, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, zero exactness, scale-minimality, dyadic readback stability, canonical readback, downstream handoff, and ledger refusal proofs for BEDC.Derived.DyadicNormalFormUp.

Chapter 1614

A Concrete Naming Certificate for $\mathsf{Pseudometric}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{Pseudometric}^{\uparrow}$ packet records the pre-separated distance surface used by the constructive metric and completion route. It sits before the metric carrier of chapter 57, the separated reflection of chapter 1411, the located-distance interface of chapter 1533, and the completion boundary of chapter 95. The packet reads dyadic tolerance rows from chapter 291, finite windows from chapter 126, regular rational readback from chapter 301, and the terminal distance seal of chapter 38. Its purpose is to expose distance-zero evidence as finite NameCert data before any consumer turns that evidence into point identity.

Definition 1614.1 (Pseudometric carrier)**.** *A* $\mathsf{Pseudometric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, M, D, S, R, E, Z, H, C, N)$$

with the following displayed rows:

1. *X is the point carrier row. It records the admitted point names and their classifier, but it does not quotient points by zero distance.*
2. *M is the displayed distance witness. It names the finite comparison surface used to request a distance between two admitted point rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and triangle ledger. It records dyadic bounds, reflexive zero requests, symmetry swaps, and triangle estimates as displayed comparison rows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row controlling which point-name and distance-name windows may be inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the distance witness, giving regular rational approximants for requested windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *distance seal. It is reachable only after S, R, D have displayed the finite readback and tolerance evidence.*
7. *Z is the zero-distance boundary row. It records that zero distance is a boundary condition on the distance ledger, not an identification of point rows.*
8. *H records componentwise* hsame *transport for the point carrier, distance witness, dyadic ledger, stream windows, regular readback, Real seal, zero-distance boundary, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a consumer request through point admission, stream windows, regular readback, dyadic tolerance and triangle rows, Real distance sealing, and the zero-distance boundary.*

10. *N is both the* Pkg *provenance over the listed BEDC dependencies and the local* $\mathsf{NameCert}_{\mathsf{Pseudometric}^\uparrow}$ *row.*

The carrier has no coordinate for host equality of points, quotient completion, selected limits, countable choice, trichotomy, open-cover compactness, or a separated reflection.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricTasteGate single carrier alignment`

Definition 1614.2 (Pseudometric source carrier)**.** *A* $\mathsf{Pseudometric}^\uparrow$ *source carrier is a finite* BHist *packet*

$$P_s = (X, M, D, S, R, E, Z, H, C, N)$$

as in Definition 1614.1, with the additional source-side reading convention that D records metric-like distance rows while permitting zero distance between classifier-distinct point rows of X. The rows S, R, E expose the $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, *and* $\mathsf{Real}^\uparrow$ *readback of each requested distance, while Z records zero-distance evidence as a boundary row. Thus P_s is a source for separated reflection and completion consumers without identifying point names, quotienting the carrier, or importing ambient separated completion.*

Theorem 1614.3 (Pseudometric source obligation surface)**.** *For every accepted* $\mathsf{Pseudometric}^\uparrow$ *source carrier $P_s = (X, M, D, S, R, E, Z, H, C, N)$, the NameCert obligation surface is the conjunction of source carrier admission, dyadic distance readback through* $\mathsf{DyadicRatCore}^\uparrow$, *finite-window exposure through* $\mathsf{StreamName}^\uparrow$, *regular rational readback through* $\mathsf{RegSeqRat}^\uparrow$, *terminal distance sealing through* $\mathsf{Real}^\uparrow$, *zero-distance non-identification through Z, componentwise transport through H, replay through C, and local naming through N. The surface explicitly refuses quotient equality, host equality, and any ambient* $\mathsf{SeparatedMetric}^\uparrow$ *or* $\mathsf{Completion}^\uparrow$ *object not routed through these displayed rows.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier namecert obligation surface`

Proof. Start with the source carrier of Definition 1614.2. The tuple contains the point carrier, distance witness, dyadic ledger, finite stream windows, regular rational readback, Real seal, zero-distance row, transport, replay, and local naming row.

The distance side is read in order. A consumer may request a distance through M, but the observable data pass through $\mathsf{DyadicRatCore}^\uparrow$ in D, the $\mathsf{StreamName}^\uparrow$ windows in S, the $\mathsf{RegSeqRat}^\uparrow$ readback in R, and only then the $\mathsf{Real}^\uparrow$ seal in E.

The zero-distance side is deliberately separate from identity. The row Z records the boundary condition, while X retains classifier-distinct point rows and H, C, N merely transport, replay, and name the displayed packet.

Therefore a separated metric or completion consumer receives only this source surface. Quotient equality, host equality, and ambient separated completion are absent unless a later $\mathsf{SeparatedMetric}^\uparrow$ or $\mathsf{Completion}^\uparrow$ packet adds its own rows. □

Theorem 1614.4 (Pseudometric separated completion readback)**.** *Every read from a* $\mathsf{Pseudometric}^\uparrow$ *source carrier into a* $\mathsf{SeparatedMetric}^\uparrow$ *or* $\mathsf{Completion}^\uparrow$ *route factors through*

$$X, M, D, S, R, E, Z, H, C, N.$$

The SeparatedMetric$^{\uparrow}$ *route may consume Z as zero-distance evidence only after the* DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *distance rows have been displayed, and the* Completion$^{\uparrow}$ *route receives the same pre-separated source rows without quotient equality, host equality, selected representatives, selected limits, or ambient separated completion.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance boundary obligation`

Proof. Project the accepted source carrier. The only distance-read route is M, D, S, R, E, with D supplying dyadic tolerance and triangle rows, S supplying finite windows, R supplying regular rational readback, and E supplying the Real distance seal.

For the separated route, Z is read after that distance route as evidence of zero distance. It is not an equality constructor for point rows in X, so the separated packet must add its own reflection rows before point identity is available.

For the completion route, the consumer reads the same pre-separated source rows and the structural rows H, C, N. Since the carrier has no quotient, representative, limit selector, host equality, or ambient separated-completion coordinate, those objects cannot be exported from the pseudometric source. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated completion readback`

Theorem 1614.5 (Pseudometric separated-reflection factorization)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *source carrier. Any* SeparatedMetric$^{\uparrow}$ *or* Completion$^{\uparrow}$ *consumer that reads zero-distance evidence from P must first factor through the displayed rows*

$$X, M, D, S, R, E, Z, H, C, N.$$

Only a later separated-reflection packet may turn the zero-distance boundary row Z into point-identity data; the pseudometric source itself exports no quotient equality, host equality, selected representative, selected limit, or ambient separated completion.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance separated reflection exactness`

Proof. Project the source carrier of Definition 1614.2. The only available rows are the point carrier, distance witness, dyadic tolerance and triangle ledger, finite windows, regular readback, Real seal, zero-distance boundary, transport, replay, and local naming rows.

Apply Definition 1614.4. It forces both separated-metric and completion-facing reads through $X, M, D, S, R, E, Z, H, C, N$ before either consumer can inspect zero-distance evidence.

Use the zero-distance non-identification row. The row Z records boundary evidence on the displayed distance ledger, while point rows remain in X and are transported only by H and replayed only by C.

Finally apply the carrier exclusions. Since no quotient equality, host equality, selected representative, selected limit, or ambient separated-completion coordinate occurs in the source packet, identity data can appear only after a later separated-reflection packet supplies its own rows. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated reflection factorization`

Theorem 1614.6 (Pseudometric zero-distance scope)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *source carrier. Zero-distance evidence in P remains scoped to the displayed boundary row Z until a* SeparatedMetric$^{\uparrow}$ *consumer supplies its own reflection rows.* Completion$^{\uparrow}$ *and* LocatedMetric$^{\uparrow}$ *consumers may consume the distance witness, dyadic ledger, finite windows, regular readback, Real seal, transport, and replay rows, but they cannot turn Z into host equality, quotient equality, or selected representatives.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance scope`

Proof. Read the source carrier through Definition 1614.2. The row Z is part of the displayed pseudometric packet, while point admission remains in X and distance readback remains in M, D, S, R, E.

Apply Definition 1614.4. Completion-facing and separated-facing reads must factor through the displayed rows before zero-distance evidence is inspected, and the completion route receives no quotient equality, host equality, selected representative, selected limit, or ambient separated-completion coordinate.

Apply Definition 1614.5. The only route that may interpret zero distance as identity is a later separated-reflection packet with its own rows.

Thus a $\mathsf{Completion}^{\uparrow}$ or $\mathsf{LocatedMetric}^{\uparrow}$ consumer may use the distance and readback data exposed by M, D, S, R, E, H, C, N, but Z remains a scoped boundary row. Host equality, quotient equality, and selected representatives are absent until supplied by a distinct $\mathsf{SeparatedMetric}^{\uparrow}$ reflection surface. □

Theorem 1614.7 (Pseudometric NameCert obligations)**.** *For every accepted* $\mathsf{Pseudometric}^{\uparrow}$ *carrier* $P = (X, M, D, S, R, E, Z, H, C, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Pseudometric}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the point carrier, displayed distance witness, dyadic tolerance and triangle ledger, StreamName windows, RegSeqRat readback, Real distance seal, zero-distance boundary, transport, continuation, provenance, and local naming rows;*
2. *distance readback, requiring every exported distance request to pass through* S, R, D *before the Real seal* E *is read;*
3. *reflexive, symmetric, and triangle stability, requiring zero self-distance, symmetry transport, and triangle estimates to be displayed as rows of* D *rather than imported as host metric laws;*
4. *classifier transport, requiring point and distance classifiers to move only by the componentwise* hsame *row* H *and replay row* C*;*
5. *zero-distance non-identification, requiring the row* Z *to record zero distance without equating the two point rows;*
6. *ledger non-escape, excluding quotient completion, host equality, selected limits, countable-choice selectors, trichotomy, open-cover compactness, and any separated reflection not routed through* $\mathsf{SeparatedMetric}^{\uparrow}$*.*

No pseudometric NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier namecert obligations`

Proof. Project the carrier of Definition 1614.1. The tuple lists exactly the point carrier, distance witness, dyadic ledger, stream windows, regular readback, Real seal, zero-distance boundary, transport, continuation, provenance, and local naming rows.

Distance readback follows the replay order in C. A consumer first reads the point names and finite stream windows, then the regular rational readback R and dyadic tolerance ledger D, and only then reaches the Real seal E.

Reflexive, symmetric, and triangle stability are ledger rows. The packet stores self-distance, symmetry, and triangle estimates inside D, so no host-level metric law can enter as a detached premise.

Classifier transport is componentwise. The row H transports exactly the displayed coordinates, while C replays them in the same order for consumers.

The zero-distance row Z is separate from point identity. Since X keeps point admission and Z keeps the boundary condition, the certificate exposes zero-distance evidence without identifying the point rows.

The remaining exclusions are immediate from the carrier coordinates. No quotient completion, host equality, selected limit, countable-choice selector, trichotomy, open-cover compactness, or separated reflection appears in P, so the listed rows exhaust the local NameCert surface. □

Theorem 1614.8 (Pseudometric separated reflection handoff)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Any consumer that wants point identity from zero distance must pass through the separated reflection boundary named by* $\mathsf{SeparatedMetric}^{\uparrow}$*. Consumers for* $\mathsf{Completion}^{\uparrow}$ *and* $\mathsf{LocatedMetric}^{\uparrow}$ *receive only the displayed pseudometric rows $X, M, D, S, R, E, Z, H, C, N$; they receive no quotient completion, host equality, selected limit, countable-choice selector, trichotomy, or open-cover compactness from the pseudometric packet itself.*

Proof. Start with a consumer of P. Carrier admission exposes the point carrier and distance rows, but the zero-distance row Z is only a boundary row on the displayed distance ledger.

If the consumer asks for point identity, the request is not answered inside P. The only named route from zero distance to point identity is the separated reflection interface of $\mathsf{SeparatedMetric}^{\uparrow}$.

Completion and located-distance consumers follow a different boundary. They may read the displayed point, distance, tolerance, stream, readback, Real seal, zero-distance, transport, replay, provenance, and local naming rows, but those rows do not identify points.

Because quotient completion, host equality, selected limits, countable-choice selectors, trichotomy, and open-cover compactness are absent from the carrier, no such datum can be exported along the completion or located-metric route. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated reflection handoff`

Theorem 1614.9 (Pseudometric zero-distance completion route)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Every zero-distance or completion-facing consumer must read the rows in the order*

$$X \longmapsto M \longmapsto D \longmapsto S \longmapsto R \longmapsto E \longmapsto Z \longmapsto H \longmapsto C \longmapsto N.$$

The only point-identity boundary available from the zero-distance row is the later $\mathsf{SeparatedMetric}^{\uparrow}$ *reflection route of Definition 1614.8; the pseudometric packet itself exports no quotient equality, host point equality, selected representative, or ambient separated completion.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance completion route`

Proof. Project the carrier of Definition 1614.1. The point admission row X is read before the distance witness M, the dyadic tolerance and triangle ledger D, the finite stream windows S, and the regular-rational readback R.

Use Definition 1614.7. It binds the terminal Real seal E, zero-distance boundary Z, componentwise transport H, replay C, and local naming row N to that same displayed distance route.

Now apply Definition 1614.8. A consumer may turn zero-distance evidence into point identity only after reading the separated metric boundary; the pseudometric carrier does not identify the source rows in X.

The exclusions follow from the displayed coordinate list. Since no coordinate stores quotient equality, host point equality, selected representatives, or ambient separated completion, a completion-facing consumer receives only the ordered finite route above. □

Theorem 1614.10 (Pseudometric quotient reflection route)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Every consumer that tries to turn zero-distance evidence from P into point identity must factor first through the displayed* SeparatedMetric$^{\uparrow}$ *reflection boundary and then through the existing* Met$^{\uparrow}$ *and* Completion$^{\uparrow}$ *consumers. The route preserves the rows $X, M, D, S, R, E, Z, H, C, N$ and exports no quotient completion, host equality, selected limit, countable choice, trichotomy, or open-cover compactness from the pseudometric packet itself.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier quotient reflection route`

Proof. Project the carrier of Definition 1614.1. Zero-distance evidence is stored in Z after the distance route through S, R, D, E, while point admission remains in X.

Apply Definition 1614.8. It forces any request for point identity from zero distance through the separated reflection boundary named by SeparatedMetric$^{\uparrow}$ before metric or completion consumers can read the result.

Use Definition 1614.11. The zero-distance read is a boundary ledger read through Z, H, C, N, so it preserves the displayed pseudometric rows rather than identifying points inside P.

Finally apply Definition 1614.13. Completion-facing consumers receive only $X, M, D, S, R, E, Z, H, C, N$ unless a later separated-metric boundary supplies stronger identity data, and the excluded quotient, choice, trichotomy, compactness, and host-equality objects are absent from the packet. □

Theorem 1614.11 (Pseudometric zero-distance boundary obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Every read that treats zero distance as available evidence must pass through the displayed rows Z, H, C, N after the distance request has been routed through S, R, D, E. The row Z records a boundary condition on the displayed distance ledger, H records componentwise* hsame *transport, C records replay through the same rows, and N records the local* NameCert *provenance. No such read identifies point rows in X or exports host equality from zero distance.*

Proof. Project the carrier of Definition 1614.1. The zero-distance coordinate is Z, while point admission remains in X and the distance route is displayed by M, D, S, R, E.

The replay row C forces a consumer to read stream windows, regular rational readback, the dyadic distance ledger, and the Real distance seal before reaching Z. The transport row H then moves only the displayed coordinates componentwise, and N names the local certificate row for the same packet.

Apply Definition 1614.8. It states that point identity from zero distance is not answered inside the pseudometric packet. Therefore Z, H, C, N expose zero-distance evidence as a boundary ledger and do not identify point rows in X. □

Theorem 1614.12 (Pseudometric triangle ledger obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Symmetry reads and triangle-estimate reads are ledger rows of D. Each such read is routed through the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the* StreamName$^{\uparrow}$ *finite windows, the* RegSeqRat$^{\uparrow}$ *readback row, and the terminal* Real$^{\uparrow}$ *distance seal before the transport, replay, provenance, and local naming rows are consumed. The packet provides no detached host symmetry law and no ambient metric triangle axiom outside this displayed ledger route.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier triangle ledger obligation`

Proof. Project the carrier of Definition 1614.1. The row D is explicitly the tolerance and triangle ledger, and the rows S, R, E are the only displayed route from finite windows and regular rational readback to the Real distance seal.

For a symmetry request, C replays the admitted point rows through S, R, D, E before any structural row is read. The symmetry datum is therefore a row of D, transported by H only after the same displayed distance route has been consumed.

For a triangle request, the same ledger row D supplies the dyadic estimates. The consumer then reaches E through S and R, and only afterward can read H, C, N as transport, replay, provenance, and naming rows.

Apply Definition 1614.8. Since separated identity and completion consumers receive only the displayed pseudometric rows, neither symmetry nor triangle data can enter as a detached host law. □

Theorem 1614.13 (Pseudometric completion nonescape obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Every* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{LocatedMetric}^{\uparrow}$ *consumer receives only the displayed point carrier, distance witness, dyadic ledger, stream windows, regular rational readback, Real distance seal, zero-distance boundary, componentwise transport, continuation replay, provenance, and local naming rows of P. The handoff exports no quotient completion, selected representative, trichotomy split, open-cover compactness datum, or separated point identity except through the named* $\mathsf{SeparatedMetric}^{\uparrow}$ *boundary.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier completion nonescape obligation`

Proof. Project the carrier of Definition 1614.1. Its coordinates are exactly $X, M, D, S, R, E, Z, H, C, N$, with no coordinate for a quotient completion, selected representative, trichotomy split, open-cover compactness datum, or separated point identity.

The completion-facing consumer can read distances only through S, R, D, E and can read zero-distance evidence only through Z, H, C, N. These are displayed pseudometric rows, not quotient-completion constructors or selectors.

The located-metric consumer receives the same surface. Its distance readbacks are routed through the dyadic, stream, regular rational, and Real rows, while the remaining structural information is componentwise transport, replay, provenance, and local naming.

Apply Definition 1614.8. Any conversion from zero distance to point identity is forced through $\mathsf{SeparatedMetric}^{\uparrow}$, so the pseudometric packet itself cannot export separated identity or any of the listed non-displayed principles. □

Theorem 1614.14 (Pseudometric scoped kernel dependency surface)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Its zero-distance boundary is consumed through chapter 1411, and its completion-facing route is consumed through chapter 95. The distance evidence underneath both consumers remains grounded in chapter 291, chapter 126, chapter 301, and chapter 38: X supplies the point carrier, M the displayed distance witness, D the dyadic tolerance and triangle ledger, S the finite window schedule, R the regular rational readback, E the terminal Real seal, Z the zero-distance boundary, H the componentwise* hsame *transport, C the replay route, and N the local* $\mathsf{NameCert}$ *row.*

Thus the separated metric sibling consumes Z, H, C, N only after the distance route M, D, S, R, E is visible, while the completion sibling consumes $X, M, D, S, R, E, Z, H, C, N$ as a pre-separated source. Neither sibling receives quotient classes, selected representatives, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the pseudometric packet.*

Proof. Project the carrier of Definition 1614.1. The displayed rows are exactly $X, M, D, S, R, E, Z, H, C, N$, so every sibling consumer starts from the same finite kernel surface.

Apply Definition 1614.15 and Definition 1614.12. These identify D, S, R, E as the dyadic, finite-window, regular-rational, and Real-seal route supporting all distance and triangle reads from M.

Use Definition 1614.8. A separated metric consumer may use Z as the zero-distance boundary only after the displayed distance route and the structural rows H, C, N have been read.

Finally apply Definition 1614.13. Completion-facing consumers receive the same pre-separated source rows and no quotient completion, selected representative, host equality, choice coordinate, or ambient completeness principle. The named sibling chapters therefore consume the displayed dependency surface rather than replacing it. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier scoped kernel dependency surface`

Theorem 1614.15 (Pseudometric distance readback obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Every consumer read of a distance witness must pass through the finite route S, R, D, E before any consumer may read the zero-distance boundary, componentwise transport, replay, provenance, or local naming rows Z, H, C, N. The route exposes stream windows, regular rational readback, the dyadic tolerance and triangle ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal as displayed rows of Definition 1614.1; it exports no detached host distance or ambient metric law.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier distance readback obligation`

Proof. Project the carrier of Definition 1614.1. The distance witness is named by M, while the observable distance readback is routed through the stream window S, regular rational row R, dyadic ledger D, and Real seal E.

Apply Definition 1614.7. It lists distance readback as a local obligation requiring every exported distance request to pass through S, R, D before E is read.

The structural rows Z, H, C, N occur after the displayed distance route. Thus a consumer cannot read zero-distance evidence, componentwise transport, replay, provenance, or the local name before the finite distance route has been displayed.

Finally use Definition 1614.12. Symmetry and triangle estimates are rows of D, so the readback route does not import a detached host distance or ambient metric law. □

Theorem 1614.16 (Pseudometric classifier transport obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Point classifiers and distance classifiers transport only componentwise through the* hsame *row H and are replayed for consumers only through the displayed* Cont *row C. The transport reads no quotient completion, selected representative, separated point identity, host equality, or detached metric classifier outside the rows of Definition 1614.1.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier classifier transport obligation`

Proof. Start from the carrier definition. The row H is the only componentwise transport row for point admission, distance witness, dyadic ledger, stream windows, regular readback, Real seal, zero-distance boundary, continuation, provenance, and local naming.

Apply Definition 1614.7. Its classifier-transport clause requires point and distance classifiers to move only by H and replay row C.

The replay row C preserves the same order as the displayed distance route. It replays point admission, stream windows, regular readback, dyadic tolerance and triangle rows, Real sealing, and zero-distance boundary evidence before provenance and local naming are consumed.

Apply Definition 1614.8. Any conversion of zero distance into separated identity lies outside P and must pass through $\mathsf{SeparatedMetric}^{\uparrow}$, so transport inside P cannot smuggle in quotient completion, selected representatives, host equality, or a detached metric classifier. □

Theorem 1614.17 (Pseudometric ledger nonescape obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Quotient completion, host equality, selected limits, countable choice, trichotomy, open-cover compactness, and separated identity are absent from the pseudometric ledger unless a consumer routes the separated-identity request through* $\mathsf{SeparatedMetric}^{\uparrow}$*. The only ledger rows available to completion and located-metric consumers are the displayed coordinates $X, M, D, S, R, E, Z, H, C, N$.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier ledger nonescape obligation`

Proof. Project Definition 1614.1. The tuple contains the point carrier, displayed distance witness, dyadic ledger, stream windows, regular readback, Real seal, zero-distance boundary, transport, replay, provenance, and local naming rows, and it contains no coordinate for the excluded objects.

Apply Definition 1614.13. Completion and located-metric consumers receive only the displayed pseudometric rows and no quotient completion, selected representative, trichotomy split, open-cover compactness datum, or separated point identity except through $\mathsf{SeparatedMetric}^{\uparrow}$.

Apply Definition 1614.12. The metric-law surface is confined to the dyadic ledger D and the route through S, R, E, so host equality, countable choice, and ambient metric principles cannot enter through the distance side.

Finally apply Definition 1614.8. The only named route from zero distance to point identity is the separated reflection boundary, so separated identity is absent from the pseudometric ledger itself. □

Theorem 1614.18 (Pseudometric distance source obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. The displayed distance row M is the only source from which a consumer may request pseudometric distance data. Every such request is routed through the finite* BHist *rows S, R, D, E and is then accounted for by* hsame *transport H,* Cont *replay C, provenance, and the local* $\mathsf{NameCert}$ *row N. No consumer receives a detached host distance or an ambient metric law outside this displayed route.*

Proof. Project the carrier of Definition 1614.1. The distance witness is the row M, while finite windows, regular rational readback, dyadic ledger data, and the Real seal are displayed by S, R, D, E.

Apply Definition 1614.15. It forces every exported distance request through S, R, D, E before the structural rows are read.

The transport and replay rows are then H and C, and the local naming row is N. Since the carrier has no further distance coordinate, a consumer cannot obtain a detached host distance or ambient metric law from the pseudometric packet. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier distance source`

Theorem 1614.19 (Pseudometric kernel route obligation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Zero-distance reads and triangle-estimate reads remain kernel ledger reads until a consumer explicitly routes separated point identity through* $\mathsf{SeparatedMetric}^{\uparrow}$ *and real-valued distance sealing through* $\mathsf{Real}^{\uparrow}$*. The packet therefore exposes Z and D as displayed evidence rows, not as quotient completion, host equality, or separatedness.*

Proof. For zero-distance reads, use Definition 1614.11. It routes the read through S, R, D, E and then through Z, H, C, N, while leaving point rows in X unidentified.

For triangle-estimate reads, use Definition 1614.12. It keeps symmetry and triangle evidence inside the dyadic ledger D and routes those estimates through the same StreamName, RegSeqRat, and Real rows.

Finally apply Definition 1614.8. Point identity from zero distance is not answered inside P and must pass through $\mathsf{SeparatedMetric}^{\uparrow}$, so neither Z nor D can export quotient completion, host equality, or separatedness. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier kernel route`

Theorem 1614.20 (Pseudometric dependency-ready package)**.** *The* $\mathsf{Pseudometric}^{\uparrow}$ *chapter is dependency-ready for separated-completion and represented-space consumers at the level of displayed rows: it supplies the point carrier X, distance witness M, dyadic tolerance and triangle ledger D, StreamName windows S, RegSeqRat readback R, Real distance seal E, zero-distance boundary Z, componentwise transport H, replay C, provenance, and local naming N. This package does not claim separatedness, quotient completion, selected representatives, or completion uniqueness.*

Proof. Combine the carrier of Definition 1614.1 with the obligations of Definition 1614.7. Together they expose the point carrier, distance witness, dyadic ledger, stream windows, regular readback, Real seal, zero-distance boundary, transport, replay, provenance, and local naming rows.

Apply Definition 1614.18. It makes the displayed distance row the only source for distance requests and routes every such request through the finite BEDC rows.

Apply Definition 1614.19. It keeps zero-distance and triangle evidence in the displayed ledger until the separated reflection and Real sealing dependencies are read.

The exclusions follow from Definition 1614.13. The packet has no coordinate for separatedness, quotient completion, selected representatives, or completion uniqueness, so downstream consumers receive a dependency-ready surface without those stronger claims. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier dependency ready package`

Theorem 1614.21 (Pseudometric dependency unblock surface)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. The rows $X, M, D, S, R, E, Z, H, C, N$ are enough for dependency readiness of separated-completion and located-metric consumers: every such consumer can read point admission, distance source, dyadic tolerance and triangle evidence, finite windows, regular-rational readback, the Real distance seal, zero-distance boundary data, componentwise transport, replay, provenance, and local naming without receiving separated identity, quotient completion, selected representatives, or completion uniqueness.*

Proof. First project Definition 1614.1. It displays exactly $X, M, D, S, R, E, Z, H, C, N$ as the point, distance, tolerance, window, readback, Real-seal, zero-distance, transport, replay, provenance, and naming surface.

Apply Definition 1614.20. That theorem identifies the same rows as the dependency-ready package available to separated-completion and represented-space consumers.

Finally apply Definition 1614.13. It excludes separatedness, quotient completion, selected representatives, and completion uniqueness from the exported packet unless a later consumer routes a stronger claim through its own named boundary. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier dependency unblock surface`

Theorem 1614.22 (Pseudometric separated-reflection kernel saturation)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. The zero-distance kernel available to a separated-reflection consumer is saturated by the displayed route*

$$M, D, S, R, E, Z, H, C, N.$$

That is, every accepted zero-distance read must pass through the distance source, dyadic tolerance and triangle ledger, finite windows, regular-rational readback, Real seal, zero-distance boundary, componentwise hsame *transport, replay, and local naming rows before any* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer may inspect it; no quotient equality, host point identity, selected representative, or ambient separated metric row is supplied by* $\mathsf{Pseudometric}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated reflection kernel saturation`

Proof. Start with Definition 1614.21. It identifies the rows available to separated-completion and located-metric consumers and excludes separated identity and quotient completion from the packet itself.

Apply Definition 1614.8. A consumer that wants point identity from zero distance must pass through the later $\mathsf{SeparatedMetric}^{\uparrow}$ boundary after the zero-distance row has been read.

Use Definition 1614.9. The zero-distance route is already forced through $M, D, S, R, E, Z, H, C, N$, so the displayed rows saturate the kernel evidence available before separated reflection. □

Theorem 1614.23 (Pseudometric zero-distance classifier stability)**.** *Let* $P = (X, M, D, S, R, E, Z, H, C, N)$ *be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. If two zero-distance reads are transported by the packet's componentwise* hsame *row* H *and replayed by* C*, then their classifier-visible content remains the same displayed boundary route* $M, D, S, R, E, Z, H, C, N$*. The classifier may preserve the zero-distance evidence as a row of* Z*, but it cannot convert that evidence into point identity until a* $\mathsf{SeparatedMetric}^{\uparrow}$ *boundary is read.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance classifier stability`

Proof. Project the classifier transport obligation through Definition 1614.16. The only transport rows available to point and distance classifiers are the displayed hsame row H and replay row C.

Now use Definition 1614.11. Zero-distance evidence is a boundary row tied to the distance route through S, R, D, E and then to Z, H, C, N.

Finally apply Definition 1614.22. Since the saturated route contains no point-identity coordinate, classifier stability preserves the finite zero-distance row without adding separated equality. □

Theorem 1614.24 (Pseudometric completion universal handoff)**.** *Let* $P = (X, M, D, S, R, E, Z, H, C, N)$ *be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Every completion-facing consumer receives* P *through the universal pre-separated handoff consisting of the displayed rows* $X, M, D, S, R, E, Z, H, C, N$*, followed only by the external* $\mathsf{SeparatedMetric}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *rows supplied by that consumer. The handoff carries zero-distance and distance-readback evidence, but it does not create completion points, identify quotient classes, select limits, or assert host equality inside* $\mathsf{Pseudometric}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCompletionUniversalHandoff`

Proof. Begin with Definition 1614.20. It packages the point carrier, distance witness, dyadic ledger, StreamName windows, RegSeqRat readback, Real seal, zero-distance boundary, transport, replay, provenance, and local naming rows as the dependency-ready surface.

Use Definition 1614.23. The zero-distance row remains stable under the displayed classifier transport, so completion consumers receive a coherent pre-separated source rather than a quotient construction.

Apply Definition 1614.25. Separated identity and completion points enter only through later $\mathsf{SeparatedMetric}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ boundaries. The pseudometric packet therefore provides the

universal handoff route without supplying selected limits, quotient classes, or host point equality. □

Theorem 1614.25 (Pseudometric separated-completion source)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Any separated-completion consumer that treats zero distance as point identity must route that identity claim through* SeparatedMetric$^{\uparrow}$ *after reading the displayed zero-distance boundary Z. The pseudometric packet itself supplies only the pre-separated source rows $X, M, D, S, R, E, Z, H, C, N$ and exports no host equality, quotient completion class, selected representative, or separated completion point.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated completion source`

Proof. Start with Definition 1614.11. It makes zero-distance evidence a read of Z, H, C, N after the distance route has passed through S, R, D, E.

Next use Definition 1614.8. It states that point identity from zero distance is not answered inside the pseudometric packet and must pass through the separated reflection boundary named by SeparatedMetric$^{\uparrow}$.

The completion-side exclusions then follow from Definition 1614.13. Since host equality, quotient completion classes, selected representatives, and separated completion points are absent from the carrier, the separated-completion consumer receives only the displayed pre-separated source rows. □

Theorem 1614.26 (Pseudometric separated-reflection source)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Every* SeparatedReflection$^{\uparrow}$ *consumer receives the source only through the displayed rows of Definition 1614.1: point admission X, distance witness M, dyadic tolerance and triangle ledger D, StreamName windows S, RegSeqRat readback R, Real seal E, zero-distance boundary Z, componentwise transport H, replay C, provenance, and local naming N. In particular, the consumer may use zero-distance evidence only through Definition 1614.11 and Definition 1614.8; it receives no point identity, quotient class, selected representative, or host equality before* SeparatedMetric$^{\uparrow}$ *supplies a stronger boundary.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated reflection source`

Proof. Project the carrier rows from Definition 1614.1. They are exactly $X, M, D, S, R, E, Z, H, C, N$, so a separated-reflection consumer has no other coordinate to inspect.

Apply Definition 1614.11. It keeps zero-distance evidence in the displayed Z, H, C, N route after the distance read has passed through S, R, D, E.

Finally use Definition 1614.8 and Definition 1614.13. The first theorem forces any identity request through SeparatedMetric$^{\uparrow}$, and the second excludes quotient classes, selected representatives, and host equality from the pseudometric packet. □

Theorem 1614.27 (Pseudometric pre-separated completion source)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. A completion consumer that has not yet read a* SeparatedMetric$^{\uparrow}$ *or* Completion$^{\uparrow}$ *boundary can use P only as a pre-separated source: it may read the displayed distance, tolerance, finite-window, regular-rational, Real-seal, zero-distance, transport, replay, provenance, and naming rows, but it cannot read separated completion points, completion uniqueness, quotient completion, selected limits, host equality, or ambient* Real$^{\uparrow}$ *completeness from P.*

Proof. The pre-separated source is the carrier of Definition 1614.1. Its displayed rows provide distance witnesses, tolerance and triangle ledgers, finite windows, regular-rational readback, Real sealing, zero-distance boundary data, transport, replay, provenance, and local naming.

Use Definition 1614.8. Any move from zero distance to point identity is outside P until the separated metric boundary is read.

Use Definition 1614.13. Completion uniqueness, quotient completion, selected limits, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the packet, so a completion consumer must wait for $\mathsf{Completion}^{\uparrow}$ or a later named completion boundary to supply them. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier completion universal handoff`

Theorem 1614.28 (Pseudometric located-metric source exhaustion)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted $\mathsf{Pseudometric}^{\uparrow}$ packet. Every located-metric consumer of P exhausts the available source data by reading the displayed distance source M, dyadic tolerance and triangle ledger D, StreamName windows S, RegSeqRat readback R, Real seal E, zero-distance boundary Z, and structural rows H, C, N. After these rows are read, no further located-metric structure remains in P; stronger separatedness, completion, host-equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness claims must come from $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, or another named consumer boundary.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier located metric source exhaustion`

Proof. Begin with Definition 1614.1. The only located-metric-facing coordinates are the displayed distance source, tolerance and triangle ledger, finite windows, regular-rational readback, Real seal, zero-distance boundary, and structural rows.

Apply Definition 1614.11. It identifies the zero-distance part of this surface as boundary evidence rather than separated identity.

Then apply Definition 1614.8 and Definition 1614.13. They force stronger separated or completion claims outside the pseudometric packet and leave the listed rows as the exhausted located-metric source surface. □

Theorem 1614.29 (Pseudometric located-metric readiness)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted $\mathsf{Pseudometric}^{\uparrow}$ packet. Every located-metric consumer of P reads only the displayed distance source M, the dyadic tolerance ledger D, the finite window row S, the regular-rational readback R, the terminal $\mathsf{Real}^{\uparrow}$ distance seal E, and the structural rows H, C, N. It receives no detached host distance, ambient metric law, trichotomy split, open-cover compactness datum, quotient completion, or separated point identity from the pseudometric packet.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier located metric readiness`

Proof. Apply Definition 1614.18. It names M as the only source for pseudometric distance requests and routes every such request through S, R, D, E before the structural rows are read.

Use Definition 1614.15. The readback route exposes finite windows, regular rational readback, dyadic tolerance and triangle data, and the terminal $\mathsf{Real}^{\uparrow}$ seal as displayed rows rather than as detached host distance data.

Finally apply Definition 1614.17. The located-metric consumer receives only the displayed ledger rows and cannot extract ambient metric laws, trichotomy, open-cover compactness, quotient completion, or separated point identity from the pseudometric packet. □

Theorem 1614.30 (Pseudometric finite-window distance route)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* Pseudometric$^{\uparrow}$ *packet. Every finite distance read exported by P is routed through the carrier row X, the displayed distance source M, the dyadic tolerance and triangle ledger D, the finite-window row S, the regular-rational readback row R, the terminal* Real$^{\uparrow}$ *seal E, the zero-distance boundary Z, and the structural rows H, C, N. The route is exactly the distance-readback surface of Definition 1614.15 together with the triangle-ledger control of Definition 1614.12, and it does not expose a detached host distance, separated point identity, quotient completion, selected limit, or ambient* Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier finite window distance route`

Proof. Start with the carrier projection of Definition 1614.1. The accepted packet gives the rows $X, M, D, S, R, E, Z, H, C, N$ and no additional distance coordinate.

Apply Definition 1614.15. A distance request must pass through the finite windows S, the regular-rational readback R, the dyadic ledger D, and the terminal seal E before the structural rows can package the read.

Apply Definition 1614.12. The same ledger row D is the only triangle-facing control row, so finite-window distance reads and triangle comparisons share the displayed tolerance route rather than splitting into a host metric law.

Finally use Definition 1614.13. Completion, selected-limit, host-equality, and ambient-completeness claims are outside the pseudometric packet, while Z remains only the zero-distance boundary available for later separated reflection. □

Theorem 1614.31 (Pseudometric zero-distance separated-reflection exactness)**.** *Let $P = (X, M, D, S, R, E, Z, H,$ be an accepted* Pseudometric$^{\uparrow}$ *packet. The zero-distance row Z is the exact boundary offered to separated-reflection consumers: it can be transported with H, replayed through C, packaged by the local naming row N, and compared with the distance-readback route M, D, S, R, E, but it becomes separated point identity only after the consumer reads the* SeparatedMetric$^{\uparrow}$ *boundary named in Definition 1614.8. The packet therefore exposes zero-distance evidence without quotient completion, selected limits, host equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricZeroDistanceSeparatedReflectionExactness`

Proof. Project the rows of P. The zero-distance row Z is present beside the distance source M, tolerance ledger D, finite windows S, regular readback R, and Real seal E.

Use Definition 1614.15 to align Z with the displayed distance route. The row can be inspected only against the same finite-window and dyadic readback surface that supplies distance evidence.

Now apply Definition 1614.8. That theorem places separated point identity beyond the pseudometric packet, at the later separated metric boundary, so Z is exact as boundary evidence and not as identity in X.

The non-escape clause follows from Definition 1614.13. Rows H, C, N preserve and name the boundary route, but no row stores quotient completion, selected limits, host equality, countable choice, or ambient completeness. □

Theorem 1614.32 (Pseudometric triangle separated-reflection compatibility)**.** *Let $P = (X, M, D, S, R, E, Z, H, C$ be an accepted* Pseudometric$^{\uparrow}$ *packet. The triangle information carried by D is compatible with separated reflection exactly along the displayed route $M, D, S, R, E, Z, H, C, N$: triangle comparisons are read through the same finite-window and regular-rational distance surface as zero-distance evidence, and any separated identity conclusion must pass through Definition 1614.8. The compatibility claim uses the distance-readback obligation, triangle-ledger obligation, and completion*

non-escape boundary, and it does not add an ambient metric law, quotient completion, selected limit, host equality, trichotomy split, or open-cover compactness datum.

Proof. Begin with Definition 1614.12. It identifies the triangle-facing content of P with the dyadic ledger row D, not with an external metric law.

Apply Definition 1614.15. The triangle comparison and the zero-distance comparison both read the finite windows S, regular-rational readback R, dyadic tolerance row D, and terminal Real seal E.

Use Definition 1614.8 for the separated boundary. If a consumer turns zero-distance evidence into point identity, that step is performed by the separated metric route, not by the pseudometric carrier itself.

Finally invoke Definition 1614.13. The same structural rows H, C, N preserve the displayed compatibility route while refusing quotient completion, selected limits, host equality, trichotomy, open-cover compactness, and ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier triangle separated reflection compatibility`

Theorem 1614.33 (Pseudometric zero-distance source reflection)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Every accepted zero-distance read from Z factors through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and triangle ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, the separated-reflection boundary of Definition 1614.31, and the completion source route of Definition 1614.27 before any* $\mathsf{Met}^{\uparrow}$ *consumer may read it as identity-like evidence. The source reflection is transported only by H, replayed only by C, and packaged only by the local* Pkg *and* $\mathsf{NameCert}$ *rows; it does not assert quotient identity, separated metric equality, host equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 1614.31. It identifies Z as exact boundary evidence and places separated point identity beyond the pseudometric packet.

Use Definition 1614.32. The zero-distance read and the triangle comparison share the displayed route through D, S, R, E, Z, H, C, N, so the source reflection remains tied to dyadic tolerance, finite windows, regular readback, and the Real seal.

Apply Definition 1614.27. Completion-facing consumers must first read the same pre-separated source rows before any metric or separated completion route can consume the evidence.

Finally project the structural rows. The BHist packet, H, C, local Pkg, and $\mathsf{NameCert}$ rows carry the source reflection, while the carrier has no coordinate for quotient identity, separated metric equality, host equality, selected limits, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier zero distance source reflection`

Theorem 1614.34 (Pseudometric kernel source carrier)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. The concrete source carrier available to every root-unblock consumer is exactly the finite* BHist *carrier row X together with the displayed distance source M, dyadic tolerance and triangle ledger D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, regular-rational readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, zero-distance boundary Z, componentwise* hsame *transport H, displayed* Cont *replay C, package provenance, and local* $\mathsf{NameCert}$ *row N. No consumer may replace this source by a host point set, quotient carrier, separated reflection, selected completion point, or ambient metric object.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier kernel source carrier`

Proof. Project the carrier of Definition 1614.1. The tuple displays exactly the rows $X, M, D, S, R, E, Z, H, C, N$, so the source carrier is a finite BEDC packet rather than an external set of points.

Apply Definition 1614.33. It routes every zero-distance source read through the dyadic ledger, stream windows, regular readback, Real seal, and structural rows before any metric-like consumer can inspect it.

Use Definition 1614.13. The excluded host point set, quotient carrier, selected completion point, separated reflection, and ambient metric object are absent from the carrier inventory, so the displayed rows exhaust the root-unblock source. □

Theorem 1614.35 (Pseudometric classifier stability)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Classifier transport for point rows and zero-distance rows is stable exactly along the displayed* hsame *and* Cont *route H, C: if two accepted reads share the same finite* BHist *carrier row X and the same transported zero-distance boundary Z, then any classifier comparison offered to a* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*, or completion-facing consumer must pass through $M, D, S, R, E, Z, H, C, N$. The comparison may cite the zero-distance row, but it cannot identify point names until the separated-reflection handoff is displayed.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier classifier stability`

Proof. Begin with Definition 1614.16. It confines point and distance classifier transport to the componentwise hsame row H and the displayed replay row C.

Next read the zero-distance route through Definition 1614.31. The row Z is boundary evidence aligned with M, D, S, R, E, not an equality row for point names in X.

Finally apply Definition 1614.8. A separated identity conclusion belongs to the later separated metric boundary. Thus classifier stability is available to consumers as a transported finite row, while point identification remains outside the pseudometric packet. □

Theorem 1614.36 (Pseudometric separated quotient handoff)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. The separated quotient handoff ledger offered by P is the displayed route from X through $M, D, S, R, E, Z, H, C, N$ to the separated-reflection boundary of Definition 1614.8 and the completion source of Definition 1614.27. The handoff supplies source rows for later separated reflection and completion consumers, but it does not form quotient classes, choose representatives, assert host equality, or close separated point identity inside* $\mathsf{Pseudometric}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier separated quotient handoff`

Proof. Start with Definition 1614.34. It fixes the source carrier as the displayed finite packet $X, M, D, S, R, E, Z, H, C, N$.

Use Definition 1614.35. Classifier comparisons and zero-distance boundary rows are transported only through H and replayed only through C, so the handoff is a ledger route rather than a quotient construction.

Now apply Definition 1614.8 and Definition 1614.27. These theorems route separated reflection and completion consumers through the displayed source rows while keeping quotient classes, selected representatives, host equality, and separated point identity outside the pseudometric packet. □

Theorem 1614.37 (Pseudometric bridged route)**.** *Let $P = (X, M, D, S, R, E, Z, H, C, N)$ be an accepted* $\mathsf{Pseudometric}^{\uparrow}$ *packet. Its public route bridges to separated-metric and completion consumers only through* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows. The bridge refuses quotient equality,*

host point equality, selected representatives, selected limits, countable choice, and ambient separated completion.

Lean4 ✓ `BEDC.Derived.PseudometricUp.PseudometricCarrier bridged route`

Proof. Project the finite carrier of Definition 1614.1. The packet exposes point carrier data, distance data, dyadic tolerances, stream windows, regular readback, the Real seal, zero-distance boundary evidence, transport, replay, provenance, and local naming.

Use Definition 1614.36. It sends separated reflection and completion consumers through the displayed rows $X, M, D, S, R, E, Z, H, C, N$, so the later $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{Completion}^{\uparrow}$ reads receive a finite handoff rather than a quotient carrier.

Finally read the refusal side of the same carrier. Because no coordinate supplies host point equality, selected representatives, selected limits, countable-choice schedules, or ambient separated completion, the bridge-facing route is exactly the displayed BEDC packet route. □

Closure status for $\mathsf{NameCert}_{\mathsf{Pseudometric}^{\uparrow}}$.

Constructive story: A $\mathsf{Pseudometric}^{\uparrow}$ packet is generated from point carrier rows, displayed distance witnesses, DyadicRatCore tolerance and triangle ledgers, StreamName windows, RegSeqRat readback, a Real distance seal, a zero-distance boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Pseudometric}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1614.1, Definition 1614.7, Definition 1614.30, Definition 1614.31, Definition 1614.32, and Definition 1614.36 expose the public pre-separated distance, zero-boundary, separated-reflection, and quotient-handoff routes before completion or located-metric consumers read the packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Pseudometric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close separated point identity, quotient completion, host equality, selected limits, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: No further paper-theory upgrade remains; the remaining work is verification and bridge-axis checking for BEDC.Derived.PseudometricUp.

Chapter 1615

A Concrete Naming Certificate for $\mathsf{RiemannSum}^{\uparrow}$

Following Riemann and Darboux, the $\mathsf{RiemannSum}^{\uparrow}$ packet records the finite tagged-sum surface used before a consumer asks for an integral carrier. It sits between the dyadic mesh ledger of chapter 358, the finite partition surface of chapter 201, the stepwise approximation rows of chapter 428, the Darboux comparison carrier of chapter 1460, and the broader tagged-mesh handoff of chapter 1526. The packet names only the finite mesh, tag, value, width, and arithmetic rows of a displayed Riemann sum; it does not assert host integrability, a limiting process, quotient equality of functions, or choice-selected tags outside the packet.

Definition 1615.1 (Riemann sum carrier)**.** *A* $\mathsf{RiemannSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, T, F, W, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the mesh row, read through* $\mathsf{DyadicMesh}^{\uparrow}$ *and the finite* $\mathsf{Partition}^{\uparrow}$ *boundary, naming the ordered cells, endpoints, and adjacency ledger.*
2. *T is the tag-containment row, recording one displayed tag for each carried cell together with the dyadic or rational containment witness that places the tag inside that cell.*
3. *F is the integrand-read window, exposing exactly the finitely many carried values needed at the displayed tags.*
4. *W is the cell-width ledger, recording the width row attached to each mesh cell through the same dyadic or rational endpoint data.*
5. *S is the finite sum row, computed from the displayed tag values and cell widths by the carried arithmetic route.*
6. *H records componentwise* hsame *transport for mesh, tag containment, integrand reads, width rows, sum row, continuation row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from mesh cells to tag reads, from tag reads and width rows to summands, and from summands to the finite sum row.*
8. *P is the* Pkg *provenance over* $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, T, F, W, S, H, C, P, N$. It has no coordinate for a host limit over refinements, a measure-theoretic integral, a quotient function space, a tag-choice principle, or a completed $\mathsf{Real}^{\uparrow}$ *value.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumTasteGate single carrier alignment`

Theorem 1615.2 (Riemann sum NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSum}^{\uparrow}$ *carrier $Q = (M, T, F, W, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}$ *surface consists of carrier admission, mesh-tag containment, finite integrand readback, cell-width exposure, finite sum exactness, componentwise transport, continuation replay, provenance, and ledger non-escape. These obligations are discharged entirely by the displayed route*

$$M \longmapsto T \longmapsto F, W \longmapsto S$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier namecert obligations`

Proof. Carrier admission is the projection of the finite tuple in Definition 1615.1. The mesh row M fixes the displayed cell list before any tag or value row is read, and the tag-containment row T attaches one tag witness to each carried cell.

The value and width rows are then read componentwise. The window F exposes only the tag values named by T, while W exposes only the widths of the cells named by M. No external function equality or hidden refinement family is consulted.

Finite sum exactness is the arithmetic replay from these displayed rows to the row S. Since every summand is formed from one carried tag value and one carried width row, the sum is a finite BHist computation rather than a limiting assertion.

Transport and continuation use H and C to replay the same finite route after componentwise hsame movement. The provenance row P and local name N source the packet, and the absence of any host-limit, measure, quotient, or tag-choice coordinate gives ledger non-escape. □

Theorem 1615.3 (Riemann sum tagged-mesh exactness)**.** *Every accepted* $\mathsf{RiemannSum}^{\uparrow}$ *read factors through the displayed mesh row, the tag-containment row, the integrand-read window, the cell-width ledger, and the finite sum row. If two accepted packets agree on those rows under componentwise* hsame *transport, then every downstream consumer reads the same finite tagged-sum boundary through C, P, N.*

Proof. Project the accepted carrier through Definition 1615.1. The only route to a summand begins at a cell of M, passes through its tag witness in T, reads the corresponding value in F, and multiplies by the corresponding width in W.

Agreement under componentwise hsame transport identifies those rows cell by cell. Replaying C therefore rebuilds the same summand ledger and the same finite row S on both packets.

The downstream consumer has access only to S together with the replay, provenance, and local name rows. Hence agreement on the displayed tagged-mesh surface determines the public finite-sum boundary, with no extra channel for hidden tags or host function equality. □

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier tagged mesh exactness`

Theorem 1615.4 (Riemann sum Darboux handoff)**.** *An accepted* $\mathsf{RiemannSum}^{\uparrow}$ *packet can be handed to a* $\mathsf{DarbouxIntegral}^{\uparrow}$ *or* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer only as the finite tagged-mesh row consisting of* $M, T, F, W, S, H, C, P, N$*. The handoff supplies the sum side of a Darboux or Riemann comparison, but it does not supply an integral value, a convergence claim over all refinements, a quotient of integrands, or a choice-selected tag family.*

Proof. Start from the obligation surface of Definition 1615.2. It exhausts the packet as mesh, tag-containment, value, width, finite-sum, transport, replay, provenance, and local-name data.

A $\mathsf{DarbouxIntegral}^{\uparrow}$ consumer may compare this finite row with upper and lower step-function rows, and a $\mathsf{RiemannIntegral}^{\uparrow}$ consumer may place it inside a larger tagged-mesh integration packet. In both cases the consumer receives the same finite sum row S together with its visible construction route.

The excluded analytic claims are not carrier coordinates. The packet has no row for a completed integral, no family of all refinements, no host quotient of functions, and no choice-selected tag assignment outside T. Thus the handoff is exactly the finite tagged-sum side of the integration boundary. □

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier darboux handoff`

Theorem 1615.5 (Riemann sum mesh-tag obligation)**.** *Every obligation-level* $\mathsf{RiemannSum}^{\uparrow}$ *consumer of an accepted carrier* $Q = (M, T, F, W, S, H, C, P, N)$ *must expose the mesh row* M *and tag-containment row* T *before reading an integrand value, a cell-width ledger, or the finite sum row. The mesh row supplies the displayed cells, and* T *supplies exactly one carried tag-containment witness for each cell named by* M*.*

Proof. Project the carrier of Definition 1615.1. Its only mesh coordinate is M, and its only tag-containment coordinate is T.

Apply the NameCert obligations of Definition 1615.2. They place mesh-tag containment before finite integrand readback, width exposure, and sum exactness.

Use tagged-mesh exactness and the Darboux handoff, Definition 1615.3 and Definition 1615.4. Both force downstream comparison reads through the same displayed M, T boundary, so no consumer can substitute hidden cells or choice-selected tags. □

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier mesh tag obligation`

Theorem 1615.6 (Riemann sum width and sum exactness obligation)**.** *For every accepted* $\mathsf{RiemannSum}^{\uparrow}$ *carrier* $Q = (M, T, F, W, S, H, C, P, N)$*, the cell-width ledger* W *and finite sum row* S *must be replayed from the same mesh row* M *and tag-containment row* T*. The obligation surface admits a summand only when its tag value is read through* F *at a tag contained by* T *and its width is read through* W *at the corresponding cell of* M*.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier width sum exactness obligation`

Proof. Start with the carrier and NameCert obligation surface. The rows M, T, F, W, S are the only finite arithmetic rows available to the packet, and Definition 1615.2 orders them as mesh and tag data before value, width, and sum data.

Apply tagged-mesh exactness. Theorem 1615.3 says every summand route begins with a cell of M, passes through its tag witness in T, and then reads the matching value and width rows before rebuilding S.

The Darboux handoff preserves this same finite arithmetic boundary. A comparison consumer may inspect the sum side of the bracket, but it receives S only as the replay of M, T, F, W, not as a host limiting object. □

Theorem 1615.7 (Riemann sum ledger non-escape obligation)**.** *An accepted* $\mathsf{RiemannSum}^{\uparrow}$ *packet has no obligation-level route to host limits, quotient function equality, measure integration, or choice-selected tag families. Every downstream read remains inside the displayed finite ledger* $M, T, F, W, S, H, C, P, N$ *before any Darboux or Riemann integral consumer adds its own rows.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier ledger nonescape obligation`

Proof. Project the carrier of Definition 1615.1. The packet contains mesh, tag, finite value, width, sum, transport, replay, provenance, and local naming rows, and no coordinate for host analytic structure.

Apply the NameCert obligations and tagged-mesh exactness. These theorems force all accepted reads through the finite row route $M, T, F, W, S, H, C, P, N$.

Finally use the Darboux handoff. Theorem 1615.4 identifies the exported object as the finite tagged-sum side of a comparison, so host limits, quotient function equality, measure integration, and external tag choice remain outside the ledger. □

Theorem 1615.8 (Riemann sum obligation-closure package)**.** *The* $\mathsf{RiemannSum}^{\uparrow}$ *packet supports obligationClosure exactly by carrier admission, mesh-tag containment, finite integrand readback, cell-width exposure, finite-sum exactness, tagged-mesh exactness, Darboux/Riemann handoff, componentwise transport,* Cont *replay, provenance, and ledger non-escape. For an accepted carrier* $Q = (M, T, F, W, S, H, C, P, N)$*, every obligation-level consumer reads only the finite route through those nine rows and imports no integrability theorem, limiting process, quotient function equality, or tag-choice principle.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier obligation closure package`

Proof. Begin with the carrier of Definition 1615.1. It displays exactly $M, T, F, W, S, H, C, P, N$, so carrier admission and ledger non-escape are finite row projections rather than analytic closure assumptions.

Apply Definition 1615.2. The mesh row, tag-containment row, integrand-read window, cell-width ledger, finite sum row, transport, replay, provenance, and local naming rows give the obligation surface named in the statement.

Next use Definition 1615.3. It identifies downstream reads when the mesh, tags, finite values, widths, and sum row agree under componentwise hsame, giving the exact tagged-mesh boundary required by obligationClosure.

Finally apply Definition 1615.4. DarbouxIntegral and RiemannIntegral consumers receive only the finite tagged-sum side of the comparison. Since the packet has no row for integrability, all refinements, quotient function equality, or a choice-selected tag family, the obligation-closure package is exactly the listed finite surface. □

Theorem 1615.9 (Riemann sum public finite tagged-sum interface)**.** *The public export of an accepted* $\mathsf{RiemannSum}^{\uparrow}$ *carrier* $Q = (M, T, F, W, S, H, C, P, N)$ *is exactly the finite tagged-sum boundary* $M, T, F, W, S, H, C, P, N$*. Darboux and Riemann integral packets may consume that boundary as displayed mesh, tag-containment, integrand-read, cell-width, finite-sum, transport, replay, provenance, and local naming data, but the export contains no host limit, quotient function, measure integral, external tag selector, or completed integral value.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier public finite tagged sum interface`

Proof. Project the carrier through Definition 1615.1. Its displayed coordinates are precisely the finite tagged-sum rows $M, T, F, W, S, H, C, P, N$, with no additional public coordinate.

Apply the NameCert obligations and tagged-mesh exactness, Definition 1615.2 and Definition 1615.3. These identify the mesh, tag, value, width, and sum rows as the exact finite arithmetic route, preserved under componentwise transport and replay.

Use the Darboux handoff and obligation-closure package, Definition 1615.4 and Definition 1615.8. A Darboux or Riemann integral consumer receives only the displayed finite tagged-sum side of its comparison, so host limits, quotient functions, measure integrals, external tag selectors, and completed integral values remain outside the public export. □

Theorem 1615.10 (Riemann sum tagless refinement ledger)**.** *Let $Q = (M, T, F, W, S, H, C, P, N)$ be an accepted* $\mathsf{RiemannSum}^{\uparrow}$ *carrier. Any refinement-facing* $\mathsf{DarbouxIntegral}^{\uparrow}$ *or* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of Q must replay the same nine rows $M, T, F, W, S, H, C, P, N$. It may compare refinements only through displayed mesh-cell subdivision and transported tag-containment rows. The packet exports no external tag selector, quotient integrand equality, host limiting process, or measure integral.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier tagless refinement ledger`

Proof. Apply the mesh-tag obligation of Definition 1615.5. A refinement-facing consumer must first expose the displayed mesh row M and the tag-containment row T, so every subdivision comparison is anchored in the carried cells and carried tag witnesses.

Apply the width and sum exactness obligation of Definition 1615.6. The rows F, W, S are replayed from the same displayed mesh and tag route, hence a refined comparison may inspect only the subdivided cell-width ledger and the finite summand ledger produced from it.

Transport is componentwise through H and continuation replay is displayed through C. Thus transported tag-containment rows remain the only tag data available after refinement; no external selector can be projected from the packet.

Finally use ledger non-escape and the Darboux handoff, Definition 1615.7 and Definition 1615.4. They identify the exported object as the finite tagged-sum side of a Darboux or Riemann comparison, excluding quotient integrand equality, host limiting processes, and measure integrals. □

Theorem 1615.11 (Riemann sum mature finite mesh examples)**.** *The* $\mathsf{RiemannSum}^{\uparrow}$ *packet supports mature finite examples by displaying concrete rows for a mesh list, one tag-containment witness per cell, one carried value at each tag, one width row per cell, and the resulting finite sum row. A Darboux or Riemann consumer may read these examples as the finite comparison side of its own packet, but the example surface still stops before host integrability, convergence over all refinements, quotient equality of integrands, external tag choice, or a completed integral value.*

Lean4 ✓ `BEDC.Derived.RiemannSumUp.RiemannSumCarrier mature finite mesh examples`

Proof. Choose any displayed finite mesh row M and attach a tag-containment row T with one carried tag witness for each cell. The value window F and width ledger W then supply exactly the summand data named by the cells and tags.

The finite sum row S is obtained by replaying the carried arithmetic route from M, T, F, W. By Definition 1615.6, no summand is admitted unless its tag value and width are read from the same displayed cell route.

Use Definition 1615.9 and Definition 1615.10. They make the examples public as finite tagged-sum boundaries for Darboux and Riemann consumers while keeping completeness, all-refinement

convergence, quotient equality, external tag selection, and completed integral values outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSum}^{\uparrow}$ packet is generated from a finite mesh row, tag-containment row, integrand-read window, cell-width ledger, finite sum row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The public finite tagged-sum interface and finite mesh example surface are closed for BHist mesh rows, $\mathsf{Partition}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}$ row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host integrability, convergence over all refinements, measure-theoretic integration, quotient function equality, choice-selected tags, Lean verification, or bridge checking.

Upgrade path: Bridged closure requires Lean verification and a checked standard bridge for the public finite tagged-sum interface of BEDC.Derived.RiemannSumUp.

Chapter 1616

A Concrete Naming Certificate for $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$ packet records the finite cofinal-rate surface used when a regular rational stream must answer every later precision request through an explicit late-window route. It sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the tolerance ledger of chapter 291, the effective threshold surface of chapter 415, and the terminal seal of chapter 38. The packet records a displayed cofinal-rate row and its finite handoff to the Real boundary; it is not a quotient of streams, a selected real value, a host metric limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1616.1 (Regular Cauchy cofinal-rate carrier)**.** *A* $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, K, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational approximants are the only numeric data read by the packet.*
2. *K is the cofinal rate row, read through the* $\mathsf{CauchyRate}^{\uparrow}$ *surface and assigning to each displayed dyadic tolerance a late stream stage sufficient for all later windows.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row reached at and beyond the stage named by K.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger through which every requested radius is named before the cofinal row is inspected.*
5. *Q is the RegSeqRat readback row, exposing the regular rational comparison certified by R, W, D, K.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the source, rate, window, tolerance, and readback rows have been replayed.*
7. *H records componentwise* hsame *transport for the RegSeqRat source, cofinal rate, StreamName windows, DyadicRatCore ledger, readback, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through dyadic tolerance naming, cofinal-rate lookup, stream-window extraction, regular rational readback, and Real seal handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $R, K, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable-choice schedules, or ambient Real completeness.

Theorem 1616.2 (Regular Cauchy cofinal-rate NameCert obligations)**.** *For every accepted* RegularCauchyCofinalRa *carrier $G = (R, K, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalRate}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the RegSeqRat source, cofinal rate, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, transport, continuation, provenance, and local naming row;*
2. *tolerance-first routing, requiring each precision request to enter through D before the cofinal stage in K is read;*
3. *cofinal window exactness, requiring K to name a late stage after which W supplies every finite stream window consumed by the readback row;*
4. *readback stability, requiring Q, H, C to preserve the regular rational comparison under componentwise* hsame *transport and displayed* Cont *replay;*
5. *Real seal handoff, requiring E to be downstream of R, K, W, D, Q and to expose no quotient stream, selected limit, host equality, trichotomy, countable-choice selector, or ambient completeness principle.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1616.1. The projection exposes exactly the RegSeqRat source row, cofinal rate row, StreamName window row, DyadicRatCore ledger, readback row, Real seal, and structural rows H, C, P, N.

Tolerance-first routing follows from the order recorded by C. A precision request must name its radius through D before the cofinal rate row K can select the late stage.

The selected stage then controls the visible stream data. The window row W supplies only finite StreamName observations at and beyond the stage named by K, and the readback row Q consumes those observations with the source row R.

Transport and replay cannot add further obligations. The rows H and C preserve the displayed route, while P and N name the same finite packet.

Since quotient streams, selected limits, host equality, trichotomy, choice schedules, and ambient completeness data are absent from the carrier, the Real seal row E has no path to export them. □

Theorem 1616.3 (Regular Cauchy cofinal-rate downstream route)**.** *Let $G = (R, K, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$ *carrier. Every downstream consumer of the readback row factors through the finite route*

$$D \longmapsto K \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a dyadic tolerance name and a cofinal late-stage witness before it can read any regular rational comparison or Real seal.

Proof. Begin with a downstream consumer of the readback row. Carrier admission exposes Q only as a row in the displayed packet, not as an independent comparison principle.

Replay the continuation row C. The replay first names the requested tolerance by D and then reads the cofinal rate row K for the late stage attached to that tolerance.

The StreamName row W is available only after the cofinal stage is fixed. The RegSeqRat source row R is then read through those finite windows, and the readback row Q records the resulting regular rational comparison.

The Real seal row E and structural rows H, C, P, N are downstream of the same route. Thus no consumer reaches Q or E without first receiving the dyadic tolerance name and cofinal late-stage witness. □

Theorem 1616.4 (Regular Cauchy cofinal-rate Real seal handoff)**.** *Let $G = (R, K, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read of G reaches the seal row E only after replaying the RegSeqRat source, cofinal rate, StreamName windows, DyadicRatCore tolerance ledger, and RegSeqRat readback rows. The exported surface contains no quotient stream, selected limit, host real equality, trichotomy, countable-choice selector, or ambient Real completeness assertion.*

Proof. The Real seal row E is part of the carrier, but its accessibility is ordered by the continuation row C. A Real-facing read must therefore replay the tolerance ledger D, the cofinal rate row K, the finite window row W, the source row R, and the readback row Q before the seal is available.

Componentwise transport through H preserves the same row inventory. It can identify accepted packets along displayed hsame coordinates, but it cannot introduce a quotient stream, selected limit, host equality, trichotomy, choice schedule, or completeness theorem.

The provenance and local naming rows P, N certify the same finite packet. Hence the Real seal is a downstream handoff surface for regular Cauchy cofinal-rate data, not an appeal to ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalRate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCofinalRate}^{\uparrow}$ packet is generated from a RegSeqRat source row, cofinal CauchyRate row, finite StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalRate}^{\uparrow}}$, seed)

Scope closed: Definition 1616.1, Definition 1616.2, Definition 1616.3, and Definition 1616.4 seed the finite cofinal-rate route from dyadic tolerance requests through StreamName windows, RegSeqRat readback, and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalRate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-first routing, cofinal window exactness, readback stability, Real seal handoff, and ledger refusal proofs for BEDC.Derived.RegularCauchyCofinalRateUp.

Chapter 1617

A Concrete Naming Certificate for $\mathsf{CauchyModulusComposition}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusComposition}^{\uparrow}$ packet records the finite bookkeeping needed to compose two displayed Cauchy modulus budgets before any RegSeqRat or Real consumer reads the resulting route. It sits between the tolerance ledger of chapter 292, the finite-window stream surface of chapter 126, the dyadic rational core of chapter 291, the regular rational readback of chapter 301, and the terminal Real boundary of chapter 38. The packet names only a finite composition ledger: it is not a quotient stream, not a selected limit, not host real equality, not trichotomy, not ambient completeness, and not a standard bridge assertion.

Definition 1617.1 (Cauchy modulus composition carrier)**.** *A* $\mathsf{CauchyModulusComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M_1, M_2, B, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *M_1 and M_2 are source* $\mathsf{CauchyModulus}^{\uparrow}$ *rows. The first row names the outer precision request, and the second row names the inner stage request read from the first row.*
2. *B is the composed precision-budget row. It records the finite request that first queries M_1, then queries M_2 at the stage exposed by M_1, and exports the resulting stage bound as a single budget.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window route through which the composed budget is allowed to read only displayed stream windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to name every radius comparison that appears during the two modulus lookups.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that receives the composed budget after W and D have been replayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *route row that may be read only after the RegSeqRat handoff has consumed the same composed budget.*
7. *H records componentwise* hsame *transport for M_1, M_2, B, W, D, R, E, the continuation row, the provenance row, and the local naming row.*
8. *C records displayed* Cont *replay from a precision request through M_1, M_2, the composed budget B, stream windows W, dyadic tolerances D, RegSeqRat handoff R, and the Real route E.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusComposition}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, host real equality, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or standard bridge data.*

Theorem 1617.2 (Cauchy modulus composition NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusComposition}^{\uparrow}$ *carrier* $K = (M_1, M_2, B, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusCompos}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two source Cauchy modulus rows, composed budget, stream-window route, dyadic tolerance ledger, RegSeqRat handoff, Real route, transport, continuation, provenance, and local naming row;*
2. *budget composition, requiring B to read M_1 before M_2 and to export a single finite stage bound after the two lookups;*
3. *window and tolerance exposure, requiring the composed budget to pass through W and D before any regular rational or Real-facing consumer may read it;*
4. *transport stability, requiring H to preserve the same ordered rows under componentwise* hsame *replacement;*
5. *nonescape, requiring C, P, N to expose no quotient stream, selected limit, host real equality, trichotomy, ambient-completeness principle, or standard bridge claim.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1617.1. The displayed tuple contains exactly the two modulus rows, composed budget, stream-window route, dyadic ledger, RegSeqRat handoff, Real route, transport, continuation, provenance, and local naming row.

Budget composition is forced by the row B. It reads the outer request through M_1, uses the displayed stage from that lookup as the request for M_2, and stores the resulting stage as one finite budget row.

The consumer route is ordered by C. A regular rational or Real-facing read must replay W and D before it can consume R or E, so every exported comparison has passed through finite windows and dyadic tolerance naming.

Transport stability is componentwise. The row H replaces only displayed coordinates by hsame-classified coordinates and then replays the same continuation order.

Since the carrier has no quotient-stream, selected-limit, host-equality, trichotomy, completeness, or bridge coordinate, the listed rows exhaust the local obligation surface. □

Theorem 1617.3 (Cauchy modulus budget composition)**.** *Let $K = (M_1, M_2, B, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusComposition}^{\uparrow}$ *carrier. Every budget-facing consumer of K factors through the finite route*

$$M_1 \longmapsto M_2 \longmapsto B \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a single composed stage bound whose two source modulus lookups and dyadic tolerance rows remain visible.

Proof. Begin with a budget-facing consumer. Carrier admission exposes B only as the row downstream of the two source modulus lookups.

Replay the continuation row C. The first lookup reads M_1 at the requested precision; the second lookup reads M_2 at the stage request displayed by M_1. The row B stores the finite result of these two reads as one budget.

The route then passes through W and D. Thus stream-window access and dyadic tolerance naming are part of the same finite replay rather than external assumptions.

The RegSeqRat and Real rows are downstream consumers of this composed route. Transport and provenance through H, C, P, N preserve the order, so no detached budget can be read by R or E. □

Theorem 1617.4 (Cauchy modulus composition Real route)**.** *Let $K = (M_1, M_2, B, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusComposition}^{\uparrow}$ *carrier. Every Real-facing read of K reaches the* $\mathsf{Real}^{\uparrow}$ *route only after the composed modulus budget has passed through the StreamName windows, DyadicRatCore tolerance ledger, and RegSeqRat handoff. The exported surface contains no quotient stream, selected limit, host real equality, trichotomy, ambient Real completeness assertion, or standard bridge claim.*

Proof. The Real route row E is displayed in the carrier, but its accessibility is ordered by the continuation row C. A Real-facing read must therefore replay M_1, M_2, B, W, D, R before E is available.

The replay keeps the composed budget finite. The two source modulus rows provide the only stage lookups, W supplies the only stream-window route, D supplies the only tolerance ledger, and R supplies the only regular rational handoff.

The rows H, P, N name and transport that same finite packet. They cannot introduce a quotient stream, selected limit, host equality, trichotomy, completeness principle, or standard bridge assertion, because none of those data appear in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusComposition}^{\uparrow}$ packet is generated from two CauchyModulus source rows, a composed precision-budget row, a StreamName window route, a DyadicRatCore tolerance ledger, a RegSeqRat handoff, a RealUp route, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1617.1, Definition 1617.2, Definition 1617.3, and Definition 1617.4 seed the finite ledger that composes two Cauchy modulus budgets before RegSeqRat and Real consumers read them.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, standard bridge data, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget composition, window and tolerance exposure, RegSeqRat handoff, Real route nonescape, and transport stability for BEDC.Derived.CauchyModulusCompositionUp.

Chapter 1618

A Concrete Naming Certificate for $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ packet records finite tail-threshold selection for a regular Cauchy name before quotient streams, selected host limits, countable choice, trichotomy, or ambient Real completeness are available. It reads finite windows from chapter 126, regular rational observations from chapter 301, dyadic tolerance data from chapter 291, admissible index schedules from chapter 1568, explicit thresholds from chapter 292, and the downstream seal of chapter 38. The packet is a finite NameCert surface for choosing a displayed tail threshold inside a regular Cauchy route; it is not a quotient of streams and not a completed real-number object.

Definition 1618.1 (Cauchy tail selection criterion carrier)**.** *A* $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, M, D, I, Q, E, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose displayed observations are the only stream data admitted by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S and carrying the regular rational approximants inspected by the criterion.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row that names the finite stage bound for each displayed tolerance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger through which every radius, endpoint, and comparison used by the tail criterion is named.*
5. *I is the* $\mathsf{CauchyReindexing}^{\uparrow}$ *admissible-schedule row, recording the monotone cofinal route along which the selected tail may be inspected.*
6. *Q is the cofinal tail request row, binding the requested precision to the displayed threshold and to the admissible schedule.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *boundary row, available only after S, R, M, D, I, Q have been replayed.*
8. *H records componentwise* hsame *transport for the stream windows, readback, modulus, dyadic tolerance ledger, admissible schedule, cofinal tail request, Real boundary, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a tail-selection request through $S, R, M, D, I, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailSelectionCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, hidden infinite stream inspection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1618.2 (Cauchy tail selection criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ *carrier $T = (S, R, M, D, I, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailSelectionCriterion}}$ *surface consists exactly of carrier admission for the eleven displayed rows, finite-window exposure through S, regular rational readback through R, threshold exposure through M, dyadic tolerance exposure through D, admissible-schedule exposure through I, cofinal tail-request binding through Q, Real-boundary ordering through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1618.1. The visible analytic rows are precisely the stream windows, regular rational readback, CauchyModulus threshold, DyadicRatCore tolerance ledger, CauchyReindexing schedule, cofinal tail request, and Real boundary.

Read the rows in dependency order. A tail-selection request first reaches the finite windows S and their regular rational readback R, then consumes the threshold row M and dyadic tolerance ledger D that make the requested tail bound visible.

The schedule and request rows then close the local criterion. The admissible route I records how the selected tail may be inspected, while Q binds the cofinal request to the displayed threshold and schedule.

The rows E, H, C, P, N add only boundary, transport, replay, provenance, and local naming for the same finite route. Since the carrier has no quotient-stream, selected-limit, choice, trichotomy, hidden-inspection, or ambient-completeness coordinate, the displayed rows exhaust the local NameCert obligation surface. □

Theorem 1618.3 (Cauchy tail selection criterion RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ *carrier factors through*

$$S \longmapsto R \longmapsto M \longmapsto D \longmapsto I \longmapsto Q \longmapsto (H, C, P, N).$$

Thus a regular rational consumer receives the displayed stream window, the matching readback row, the explicit modulus threshold, the dyadic tolerance ledger, the admissible reindexing schedule, and the cofinal tail request before any Real-facing boundary can be inspected.

Proof. Start from a regular rational consumer request. By Definition 1618.1, the readback row R is attached to the finite stream windows S, so the consumer cannot begin from an unbounded stream or a quotient representative.

The threshold and tolerance rows are consumed next. The row M provides the displayed stage bound for the requested precision, while D records the dyadic endpoint and radius comparisons used by that bound.

The admissible schedule I and cofinal request Q then bind the same threshold to a tail route. Transport, replay, provenance, and local naming through H, C, P, N preserve that order, so no detached RegSeqRat handoff exists. □

Theorem 1618.4 (Cauchy tail selection criterion Real boundary nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ *carrier reaches the Real boundary row only through the complete finite route*

$$S, R, M, D, I, Q, E, H, C, P, N.$$

Consequently the packet cannot export quotient stream equality, a selected host limit, a countable-choice selector, a trichotomy branch, hidden infinite stream inspection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real-facing read. The carrier exposes the boundary only as the row E, and E is listed after the stream, readback, threshold, dyadic, admissible-schedule, and cofinal-request rows in Definition 1618.1.

Replay the continuation row C. The read therefore moves through S, R, M, D, I, Q before it can reach E, with H transporting only the displayed coordinates and P, N packaging and naming the same finite packet.

No row in the carrier stores quotient stream equality, a host-selected limit, a choice function, a trichotomy branch, an infinite-stream oracle, or an ambient completeness theorem. The Real boundary is therefore a downstream seal for the finite tail-selection criterion, not an escape from it. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailSelectionCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a CauchyModulus threshold row, a DyadicRatCore tolerance ledger, a CauchyReindexing admissible schedule, a cofinal tail request, a RealUp boundary, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailSelectionCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 1618.1, Definition 1618.2, Definition 1618.3, and Definition 1618.4 seed the finite tail-selection route from StreamName windows through RegSeqRat readback, CauchyModulus thresholds, DyadicRatCore tolerances, CauchyReindexing schedules, cofinal tail requests, and the Real boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailSelectionCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, hidden infinite stream inspection, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, NameCert obligation coverage, RegSeqRat handoff, Real boundary nonescape, and ledger refusal proofs for BEDC.Derived.CauchyTailSelectionCriterionUp.

Chapter 1619

A Concrete Naming Certificate for $\mathsf{RealZero}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealZero}^{\uparrow}$ packet records the terminal zero real not as a host real equality claim but as the finite zero-source route already displayed by chapter 364, chapter 624, chapter 126, chapter 301, chapter 291, and chapter 38. The chapter packages that route as the public zero-real seal consumed by downstream positive-real, absolute-value, order, metric, and completion-facing certificates.

Definition 1619.1 (RealZero carrier)**.** *A* $\mathsf{RealZero}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (q, S, Z_0, D, R, H, C, P, N)$$

with the following displayed coordinates:

1. *q is the* $\mathsf{Rat}^{\uparrow}$ *zero seed row.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *window whose every admitted finite request reads q.*
3. *Z_0 is the* $\mathsf{RegularCauchyZero}^{\uparrow}$ *route, including the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *zero row and the zero regular-Cauchy source handoff.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger recording the endpoint, tolerance, and radius data used by the zero-source route.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the constant window, regular-rational readback, and dyadic zero ledger have been displayed.*
6. *H stores componentwise* hsame *transport for the rational seed, constant window, regular-Cauchy zero route, dyadic ledger, terminal seal, provenance, and local name.*
7. *C stores displayed* Cont *replay routes from q through S, from S through Z_0 and D, and from those rows into the terminal seal R.*
8. *P records* Pkg *provenance over* $\mathsf{RealZero}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{StationaryRationalCauchy}^{\uparrow}$, $\mathsf{RegularCauchyZero}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host zero equality, selected limits, trichotomy, or ambient completeness.

Lean4 (definition) `BEDC.Derived.RealZeroUp.RealZeroCarrier`

Theorem 1619.2 (RealZero NameCert obligations)**.** *For every accepted* $\mathsf{RealZero}^{\uparrow}$ *carrier* $Z = (q, S, Z_0, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the rational zero seed, constant StreamName window, RegularCauchyZero route, DyadicRatCore zero ledger, terminal RealUp seal, transport, replay, provenance, and local naming rows;*
2. *stationary zero-source route, requiring the rational seed to be read only through the constant window, the stationary rational Cauchy row, and the RegularCauchyZero handoff;*
3. *terminal RealUp seal handoff, requiring the zero real-facing row* R *to be exported only after the StreamName, RegSeqRat, DyadicRatCore, and RegularCauchyZero rows have been displayed;*
4. *componentwise transport and replay stability, requiring accepted zero-real packets to move through* H *and replay through* C *without changing the displayed zero-source chain;*
5. *ledger nonescape from quotient streams, host zero equality, selected limits, trichotomy, and ambient completeness.*

No NameCert obligation is stored outside these five finite rows.

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1619.1. The only visible data are the zero seed q, the constant window S, the regular-Cauchy zero route Z_0, the dyadic zero ledger D, the terminal seal R, and the structural rows H, C, P, N.

The stationary source row is forced by the sibling route. The packet reads q through the constant $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{StationaryRationalCauchy}^{\uparrow}$ surface, and the $\mathsf{RegularCauchyZero}^{\uparrow}$ route before any regular-rational or real-facing consumer can inspect the zero source.

The terminal seal is then read through R. Transport and replay are componentwise because H and C are the only rows that move or re-open the chain.

The carrier has no coordinate for quotient stream equality, host zero equality, selected limits, trichotomy, or ambient completeness. Thus the ledger cannot export any of those principles through the local $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ row. □

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroNameCertObligations`

Theorem 1619.3 (RealZero terminal seal handoff)**.** *Every accepted* $\mathsf{RealZero}^{\uparrow}$ *consumer must read the zero seed through the constant* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *zero row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any downstream* $\mathsf{PositiveReal}^{\uparrow}$ *or* $\mathsf{RealAbs}^{\uparrow}$ *consumer may use it. Equivalently, the public zero-real boundary is the finite route*

$$q \longrightarrow S \longrightarrow Z_0 \longrightarrow D \longrightarrow R$$

together with H, C, P, N*, and no consumer may replace that route by host zero equality, quotient real equality, selected limits, trichotomy, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier terminal seal handoff`

Proof. Start with an accepted carrier $Z = (q, S, Z_0, D, R, H, C, P, N)$. The seed row q is not exported directly; it is first read through the constant window S and the regular-rational zero row supplied by Z_0.

Next the dyadic zero ledger D records the finite endpoint and tolerance data attached to that same route. The real-facing seal R is reached only after those rows are visible.

Downstream $\mathsf{PositiveReal}^{\uparrow}$ and $\mathsf{RealAbs}^{\uparrow}$ consumers therefore receive the zero source as the displayed terminal seal handoff, not as a host value. Since the carrier contains no excluded principle, the handoff cannot provide quotient real equality, selected limits, trichotomy, or ambient completeness. □

Theorem 1619.4 (RealZero stationary source obligation)**.** *Every accepted* $\mathsf{RealZero}^{\uparrow}$ *packet* $Z = (q, S, Z_0, D, R, H, C, P, N)$ *displays a stationary zero-source obligation: the rational seed* q *is read through the constant* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* BHist *rows of* Z_0*, the componentwise* hsame *support in* H*, the* Cont *replay support in* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row* N *before any downstream consumer sees the terminal zero-real seal.*

This obligation exports no host zero equality, quotient stream equality, selected tail, trichotomy, or ambient completeness row.

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier stationary source obligation`

Proof. Project the carrier coordinates from Definition 1619.1. The only source row for the zero value is the rational seed q, and the only public route from q to a stream-facing object is the constant $\mathsf{StreamName}^{\uparrow}$ window S together with the zero route Z_0.

Now apply the terminal handoff of Definition 1619.3. It forces every consumer of the terminal $\mathsf{Real}^{\uparrow}$ seal to read the seed through the displayed StreamName, RegSeqRat, DyadicRatCore, and RealUp rows.

The structural rows H, C, P, N are part of the same carrier. Thus hsame transport, Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row are visible at the stationary source boundary, while excluded host and quotient principles have no coordinate in the packet. □

Theorem 1619.5 (RealZero constant-window uniqueness)**.** *Let* $Z = (q, S, Z_0, D, R, H, C, P, N)$ *and* $Z' = (q', S', Z_0', D', R', H', C', P', N')$ *be accepted* $\mathsf{RealZero}^{\uparrow}$ *packets. If the rational zero seed rows are the same displayed* $\mathsf{Rat}^{\uparrow}$ *zero row and the constant* $\mathsf{StreamName}^{\uparrow}$ *windows are related componentwise by the displayed* hsame *support, then every terminal* $\mathsf{Real}^{\uparrow}$ *seal read by a downstream consumer follows the same route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row.*

Thus constant-window agreement determines the terminal zero-real seal route as a finite packet route, not as host zero equality, quotient real equality, selected-limit equality, trichotomy, or ambient completeness.

Proof. Start with the carrier definition, Definition 1619.1. The only source row is the rational zero seed q, and the only stream-facing source is the constant window S.

Use the stationary-source obligation of Definition 1619.4. It forces every downstream consumer to read the zero seed through S, the rows of Z_0, the structural support H, C, P, N, and the local $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ row before the terminal seal is seen.

Apply the terminal seal handoff of Definition 1619.3. It fixes the public route through the constant window, the $\mathsf{RegSeqRat}^{\uparrow}$ zero row inside Z_0, the $\mathsf{DyadicRatCore}^{\uparrow}$ zero ledger D, and the terminal $\mathsf{Real}^{\uparrow}$ seal R.

Finally read the dyadic ledger obligation of Definition 1619.6. Since the two packets share the displayed zero seed and the constant-window rows componentwise, the downstream seal route must pass through the same RegSeqRat, DyadicRatCore, and local NameCert rows. The carrier has no coordinate for host equality, quotient equality, selected limits, trichotomy, or ambient completeness, so the uniqueness is exactly the displayed finite route. □

Theorem 1619.6 (RealZero dyadic ledger obligation)**.** *Every accepted* $\mathsf{RealZero}^{\uparrow}$ *packet* $Z = (q, S, Z_0, D, R, H, C, P, N)$ *displays a dyadic zero-ledger obligation: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *is the unique public tolerance ledger between the stationary source route* Z_0 *and the downstream* $\mathsf{Real}^{\uparrow}$ *seal* R*, and its* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support is read before any consumer may use the seal.*

The ledger is finite and does not introduce quotient real equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier dyadic ledger obligation`

Proof. Read D from the carrier in Definition 1619.1. Its role is fixed there as the zero ledger recording endpoint, tolerance, and radius data for the zero-source route.

Use Definition 1619.3 to locate D in the public route

$$q \longrightarrow S \longrightarrow Z_0 \longrightarrow D \longrightarrow R.$$

The downstream seal cannot be inspected before this DyadicRatCore row is displayed.

The same theorem keeps the route inside the finite StreamName, RegSeqRat, DyadicRatCore, and RealUp rows. Therefore the BHist ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert support are the whole dyadic obligation surface, with no coordinate for the excluded principles. □

Theorem 1619.7 (RealZero downstream consumer obligation)**.** *Every downstream consumer of an accepted* $\mathsf{RealZero}^{\uparrow}$ *packet must consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *only after the constant* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, the* BHist *display rows, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row have been displayed.*

Consequently, downstream certificates inherit a finite zero-real seal handoff and not a host real value, quotient real equality, selected limit, trichotomy, or ambient completeness premise.

Proof. Start with a downstream consumer and unfold the accepted packet by Definition 1619.1. The consumer can see the seal only through the carrier coordinate R and the visible support rows H, C, P, N.

Apply Definition 1619.3. It requires the route through S, the RegSeqRat zero row inside Z_0, the DyadicRatCore ledger D, and the terminal RealUp seal R before any downstream PositiveReal, RealAbs, order, metric, or completion-facing certificate may use the zero-real boundary.

Because the carrier has no coordinate for host equality, quotient equality, selected limits, trichotomy, or ambient completeness, those objects cannot be inherited by the downstream consumer. What is inherited is exactly the displayed finite handoff through BHist, hsame, Cont, Pkg, and NameCert support. □

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier downstream consumer obligation`

Theorem 1619.8 (RealZero positive-real and absolute-value handoff)**.** *Every* $\mathsf{PositiveReal}^{\uparrow}$ *or* $\mathsf{RealAbs}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealZero}^{\uparrow}$ *packet may use the zero seal only through the displayed finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Concretely, the consumer must first read the constant $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback supplied by the regular-Cauchy zero route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, the terminal*

$\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row.*

The handoff does not export host zero equality, quotient real equality, selected representatives, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness to either downstream chapter.*

Proof. Start with the terminal seal handoff of Definition 1619.3. It forces every zero-real read through the constant StreamName window, the RegSeqRat zero row inside the regular-Cauchy zero route, the DyadicRatCore zero ledger, and the terminal RealUp seal.

The stationary source obligation of Definition 1619.4 identifies the source side of that route. The rational zero seed is visible only through the constant window, the regular-rational zero readback, componentwise transport, continuation replay, package provenance, and the local NameCert row.

The dyadic ledger obligation of Definition 1619.6 supplies the tolerance-facing row consumed by order, metric, positive-real, and absolute-value chapters. It places the DyadicRatCore row between the stationary source route and the terminal RealUp seal, with no extra coordinate for quotient or selected-representative data.

Finally apply the downstream consumer obligation of Definition 1619.7. It states that downstream consumers inherit exactly the displayed finite handoff through BHist, hsame, Cont, Pkg, and NameCert support. Thus $\mathsf{PositiveReal}^{\uparrow}$ and $\mathsf{RealAbs}^{\uparrow}$ may consume the zero seal only through the listed route. □

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier positive abs handoff`

Theorem 1619.9 (RealZero zero-distance seal)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *or* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer using the zero real as a zero-distance or zero-radius boundary must first read the constant* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *zero row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row of the accepted* $\mathsf{RealZero}^{\uparrow}$ *packet.*

The zero-distance seal is therefore the displayed finite route of the packet. It is not host zero equality, quotient real equality, selected-limit equality, trichotomy, or ambient completion.

Proof. First apply the terminal seal handoff, Definition 1619.3. It places the constant window, RegSeqRat zero row, DyadicRatCore zero ledger, and terminal RealUp seal upstream of any downstream read.

Next apply the dyadic ledger obligation, Definition 1619.6. The metric-facing zero-radius boundary must pass through the displayed tolerance ledger D rather than through a host equality or selected representative.

Then apply the downstream consumer obligation, Definition 1619.7. It covers the MetricSpace, QuasiMetric, Completion, UniformCompletion, and CompleteMetric consumers by requiring the same BHist, hsame, Cont, Pkg, and local NameCert support before the zero seal is used.

Finally use componentwise transport, Definition 1619.10. Transport preserves the finite zero-source route component by component, so the seal remains a BEDC packet boundary and does not become quotient real equality, trichotomy, selected-limit equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroCarrier zero distance seal`

Theorem 1619.10 (RealZero componentwise transport)**.** *Let* $Z = (q, S, Z_0, D, R, H, C, P, N)$ *and* $Z' = (q', S', Z'_0, D', R', H', C', P', N')$ *be accepted* $\mathsf{RealZero}^{\uparrow}$ *packets. If the displayed* hsame *rows in* H *identify the rational seed, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback inside* Z_0*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *support, replay, provenance, and local*

naming rows component by component, then every downstream read of Z' follows the same zero-source route as a read of Z.

The transported route remains a finite BEDC packet route; it does not become host real equality, quotient stream equality, selected-limit equality, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealZeroUp.RealZeroComponentwiseTransport`

Proof. Project the carrier rows with Definition 1619.1. The row H is the only coordinate that moves accepted zero-real packets, and it is specified componentwise for the seed, window, regular-Cauchy zero route, dyadic ledger, terminal seal, provenance, and local name.

Apply the terminal seal handoff of Definition 1619.3. It fixes the order

$$q \longrightarrow S \longrightarrow Z_0 \longrightarrow D \longrightarrow R$$

before any downstream consumer can inspect the zero-real boundary.

The stationary source obligation of Definition 1619.4 and the dyadic ledger obligation of Definition 1619.6 keep the transported seed and tolerance rows inside the same BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. Since the carrier has no excluded coordinate, componentwise transport preserves the displayed packet without adding host or quotient principles. □

Theorem 1619.11 (RealZero replay stability)**.** *Every accepted* $\mathsf{RealZero}^{\uparrow}$ *replay through the* Cont *row C repeats the same stationary zero-source route through the constant* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback supplied by Z_0, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R. Replaying the packet cannot expose a shorter path to the zero-real seal and cannot introduce quotient streams, host zero equality, selected limits, trichotomy, or ambient completeness.*

Proof. Read C from Definition 1619.1. It records displayed Cont replay from q through S, from S through Z_0 and D, and from those rows into the terminal seal R.

Use Definition 1619.2 to identify replay stability as part of the local NameCert surface. The obligations do not permit a replay row outside C, and the terminal seal handoff forces every replayed read through the same finite route.

Finally apply Definition 1619.7. Downstream consumers inherit the displayed zero-real seal handoff through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, so replay preserves the packet route rather than supplying an external equality or completeness principle. □

Theorem 1619.12 (RealZero ledger nonescape)**.** *The* $\mathsf{RealZero}^{\uparrow}$ *ledger rows in an accepted packet $Z = (q, S, Z_0, D, R, H, C, P, N)$ are exhausted by the stationary source, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *zero readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *display, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealZero}^{\uparrow}}$ *row. No ledger read can escape from these rows to quotient stream equality, host zero equality, selected limits, trichotomy, countable choice, or ambient Real completeness.*

Proof. Carrier admission in Definition 1619.1 lists every ledger-bearing row. The finite packet contains $q, S, Z_0, D, R, H, C, P, N$ and no additional coordinate.

The dyadic ledger obligation of Definition 1619.6 places D between the stationary source route and the terminal RealUp seal. The downstream consumer obligation of Definition 1619.7 then requires every consumer to read the same BHist, transport, replay, provenance, and local naming support.

Since Definition 1619.2 explicitly excludes rows for quotient streams, host zero equality, selected limits, trichotomy, and ambient completeness, the ledger has no path to those principles. Countable

choice is likewise absent because the packet has only the displayed finite rows and no selector coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealZero}\uparrow}$**.**

Constructive story: A $\mathsf{RealZero}^{\uparrow}$ packet is generated from the rational zero seed, a constant StreamName window, a RegularCauchyZero route, a DyadicRatCore zero ledger, a terminal RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealZero}\uparrow}$, seed)

Scope closed: Definition 1619.1, Definition 1619.2, and Definition 1619.3 seed the finite zero-real seal route used by downstream PositiveReal and RealAbs consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealZero}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completeness, quotient real equality, host equality, trichotomy, selected limits, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stationary zero-source routing, terminal RealUp seal handoff, componentwise transport and replay stability, and ledger nonescape for the same finite packet.

Chapter 1620

A Concrete Naming Certificate for $\mathsf{RealClassifier}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealClassifier}^{\uparrow}$ packet records the public classifier surface of $\mathsf{Real}^{\uparrow}$ as a finite NameCert construction rather than as host equality of completed real numbers. It consumes the terminal real-name seal of chapter 38, the regular rational readback surface of chapter 301, the common finite-window discipline of chapter 126, the dyadic tolerance ledgers of chapter 291, the equality-inspection packet of chapter 1517, and the regular-name equivalence boundary of chapter 1404. The chapter gives downstream metric, algebraic, and order-facing certificates one classifier boundary for real names while keeping equality as displayed classifier data.

Definition 1620.1 (RealClassifier carrier)**.** *A* $\mathsf{RealClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$$

with the following displayed rows:

1. *X and Y are the two terminal* $\mathsf{Real}^{\uparrow}$ *seal rows whose public classifier relation is being exposed.*
2. *S_X and S_Y are the regular rational source rows read back from the two seals.*
3. *R_X and R_Y are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback rows.*
4. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *finite window through which both readbacks are inspected.*
5. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the finite precision, radius, and comparison budget used by the classifier read.*
6. *C is the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row comparing the two regular names through W and D.*
7. *E is the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row that records the regular-Cauchy equivalence boundary visible before the terminal real seals are consumed.*
8. *H stores componentwise* hsame *transports for the two seals, readbacks, common window, dyadic ledger, classifier rows, provenance, and local name.*
9. *K stores displayed* Cont *replay routes from X, Y through $S_X, S_Y, R_X, R_Y, W, D, C, E$ and back to the public seal boundary.*
10. *P records* Pkg *provenance over* $\mathsf{RealClassifier}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealNameClassifier}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^\uparrow}$ *row.*

The packet has no coordinate for quotient equality of streams, host real equality, selected limits, trichotomy, countable choice, or ambient completeness.

Theorem 1620.2 (RealClassifier NameCert obligations)**.** *For every accepted* $\mathsf{RealClassifier}^\uparrow$ *carrier* $Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^\uparrow}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the two* $\mathsf{Real}^\uparrow$ *seals, regular rational readbacks, common window, dyadic tolerance ledger, classifier rows, transport, replay, provenance, and local name;*
2. *tolerance classifier stability, requiring every classifier read to pass through the common window W, the dyadic ledger D, and the* $\mathsf{RealNameClassifier}^\uparrow$ *row C;*
3. $\mathsf{RegSeqRat}^\uparrow$ *handoff, requiring every regular-rational consumer to factor through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before reaching the public classifier boundary;*
4. *real seal non-escape, requiring X and Y to be consumed only as displayed terminal seals rather than as host real values or quotient classes;*
5. *ledger exhaustion, requiring H, K, P, N to transport, replay, source, and name only the displayed finite packet.*

No local NameCert obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 1620.1. The accepted packet exposes exactly the two seal rows, the two regular rational source rows, the two $\mathsf{RegSeqRat}^\uparrow$ readbacks, the common window, the dyadic ledger, the two classifier rows, and the structural rows H, K, P, N.

Tolerance classifier stability is the route through W, D, C. Since W is the only common inspection schedule and D is the only tolerance ledger, a classifier read cannot inspect either side independently of those rows.

The regular-rational handoff uses S_X, S_Y, R_X, R_Y before it reaches C and E. The real seal row is then read only after that finite handoff has been displayed.

The remaining rows transport, replay, source, and locally name the same packet. Because the carrier omits quotient stream equality, host real equality, selected limits, trichotomy, countable choice, and ambient completeness, no NameCert obligation can export them. □

Lean4 ✓ `BEDC.Derived.RealClassifierCarrier namecert obligations`

Theorem 1620.3 (RealClassifier RegSeqRat window exhaustion)**.** *For every accepted* $\mathsf{RealClassifier}^\uparrow$ *carrier*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

every accepted public classifier comparison reaches the public $\mathsf{RealClassifier}^\uparrow$ *boundary only through the finite* $\mathsf{StreamName}^\uparrow$ *window W, the* $\mathsf{RegSeqRat}^\uparrow$ *readback rows R_X, R_Y, the* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance ledger D, the terminal* $\mathsf{Real}^\uparrow$ *seal rows X, Y, and the structural rows H, K, P, N. The route has no coordinate for quotient stream equality, trichotomy, selected representatives, or ambient Real completeness.*

Proof. Project the carrier of Definition 1620.1. Its public comparison rows are the two terminal Real seals, their source and RegSeqRat readbacks, the common StreamName window, the dyadic tolerance ledger, the classifier row, the regular-Cauchy boundary row, and the structural rows.

Use the NameCert obligations of Definition 1620.2. They force carrier admission, tolerance classifier stability, RegSeqRat handoff, Real seal non-escape, and ledger exhaustion to read through $S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$ before the public classifier boundary is exposed.

Now route the comparison through the existing handoff and seal the read. The RegSeqRat handoff of Definition 1620.5 supplies the regular-rational readback before the classifier row is consumed, while the real seal non-escape theorem Definition 1620.8 keeps X and Y as displayed terminal seals rather than host real values.

Finally apply ledger exhaustion from Definition 1620.9. The rows H, K, P, N transport, replay, source, and name only the displayed packet, so no quotient stream equality, trichotomy, selected representative, or ambient Real-completeness coordinate can be exported by the accepted comparison. □

Lean4 ✓ `BEDC.Derived.RealClassifierRegSeqRatWindowExhaustion`

Theorem 1620.4 (RealClassifier finite-window exactness target)**.** *For every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the public classifier relation is determined exactly by the common $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row* C*, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row* E*, and the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_X, R_Y*. Any consumer asking for host real equality, quotient stream equality, trichotomy, countable choice, or ambient completeness has no row in the carrier.*

Proof. Project the carrier rows from Definition 1620.1. The only public comparison data are the common finite window W, dyadic ledger D, classifier row C, regular-Cauchy boundary E, and regular rational readbacks R_X, R_Y over the terminal seals X, Y.

Use the NameCert obligations of Definition 1620.2. They force every accepted classifier read through W, D, C, E, R_X, R_Y before the public boundary is reached, while H, K, P, N only transport, replay, source, and locally name the same packet.

Finally inspect the absent coordinates of the carrier. Since no row stores host real equality, quotient stream equality, trichotomy, countable choice, or ambient completeness, no accepted consumer can extract one of those objects from the public classifier relation. □

Lean4 ✓ `BEDC.Derived.RealClassifierUp.RealClassifierCarrier finite window exactness target`

Theorem 1620.5 (RealClassifier RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing classifier read of an accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier factors through the displayed regular readbacks* S_X, S_Y, R_X, R_Y*, the common window* W*, the dyadic tolerance ledger* D*, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row* C*, and the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row* E*. Thus the public real-classifier read is a finite route through regular rational data, not a direct equality test on terminal real seals.*

Proof. Start with an accepted carrier $Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$. The two seal rows X and Y expose regular rational readbacks only through S_X, S_Y, R_X, R_Y.

The common window W supplies the shared finite requests, and the ledger D records the dyadic tolerance data for those requests. The classifier row C compares the two regular names through exactly those displayed rows.

The row E records the regular-Cauchy equivalence boundary before any real-facing consumer reaches the terminal seals. Hence every $\mathsf{RegSeqRat}^{\uparrow}$-facing read factors through the displayed finite chain and cannot be replaced by a host equality test on X and Y. □

Lean4 ✓ `BEDC.Derived.RealClassifierRegSeqRatHandoff`

Theorem 1620.6 (RealClassifier regular-real tail-equivalence readback)**.** *Every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *packet comparing two* $\mathsf{Real}^{\uparrow}$ *seals through*

$$S_X, S_Y, R_X, R_Y, W, D, C, E$$

factors any same-real read through the $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *finite tail route before it reaches the public classifier boundary. The readback therefore consumes the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, common* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RealNameClassifier}^{\uparrow}$ *comparison row, and visible* $\mathsf{Real}^{\uparrow}$ *seal rows as tail-equivalence data, not as host equality of completed reals.*

Proof. Apply the RegSeqRat handoff theorem Definition 1620.5. It forces every same-real read to expose $S_X, S_Y, R_X, R_Y, W, D, C, E$ before the public classifier boundary is reached.

Use the finite same-real tail route of chapter 5940. Its carrier reads two regular rational sources through one finite window and one dyadic tolerance ledger before the Real-facing seal is consumed.

Project the shared rows of the $\mathsf{RealClassifier}^{\uparrow}$ carrier. The rows R_X, R_Y supply the two regular rational readbacks, W supplies the common inspected window, D supplies the tolerance ledger, C records the name comparison, and E records the visible regular-Cauchy boundary before X, Y are read as terminal seals.

The structural rows H, K, P, N only transport, replay, source, and name that same finite packet. Hence a same-real read cannot bypass the regular-real tail-equivalence route by appealing to quotient streams, host real equality, selected limits, countable choice, trichotomy, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealClassifierUp.RealClassifierRegularRealTailEquivalenceReadback`

Theorem 1620.7 (RealClassifier regular-sequence induction)**.** *Let*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$$

be an accepted $\mathsf{RealClassifier}^{\uparrow}$ *carrier. Every classifier read whose* $\mathsf{StreamName}^{\uparrow}$ *requests lie in the common finite window* W *is consumed by induction over the displayed request rows of* W*: the base read uses the first dyadic tolerance row through* D*, compares the two regular names through* C*, and records the visible regular-Cauchy boundary through* E*; the step appends the next inspected request in* W *and replays the same finite packet through* H, K, P, N*. The induction exports only the rows of Definition 1620.1 and the obligations of Definition 1620.2; it does not export quotient stream equality, host real equality, trichotomy, countable choice, or ambient completeness.*

Proof. Apply the RegSeqRat handoff theorem Definition 1620.5. It forces every regular-rational classifier read to pass through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before the public classifier boundary is reached.

For the base request, read the first displayed row of the finite window W. The dyadic tolerance information is the row D, the comparison of the two regular names is the row C, and the regular-Cauchy boundary visible before the terminal seals is the row E.

For the induction step, append one further inspected request from W. The NameCert obligations of Definition 1620.2 keep the appended request inside the same carrier, while H transports the displayed rows, K replays the continuation route, P records provenance, and N locally names the same packet.

The carrier definition Definition 1620.1 has no coordinate for quotient stream equality, host real equality, trichotomy, countable choice, or ambient completeness. Thus the induction is a finite read over the common StreamName window and cannot be used as any of those ambient principles. □

Lean4 ✓ `BEDC.Derived.RealClassifierRegularSequenceInduction`

Theorem 1620.8 (RealClassifier real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier sees only the finite rows* $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$*. The consumer obtains no quotient equality of streams, host real equality, selected limit, trichotomy witness, countable-choice schedule, or ambient completeness principle from the classifier packet.*

Proof. Read the carrier of Definition 1620.1. The only real-facing rows are the displayed seals X and Y, and their only exposed classifier route is the finite chain through the regular rational readbacks, common window, dyadic ledger, and classifier rows.

The structural rows H, K, P, N do not add new analytic data. They identify, replay, source, and name the same finite packet.

Since no coordinate carries quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness, a consumer of the public $\mathsf{RealClassifier}^{\uparrow}$ boundary cannot extract any of those principles. □

Lean4 ✓ `BEDC.Derived.RealClassifierRealSealNonescape`

Theorem 1620.9 (RealClassifier ledger exhaustion)**.** *For every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

all public classifier reads are exhausted by the displayed structural rows H, K, P, N *together with the finite analytic rows* $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E$*. In particular, no public read can export quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness.*

Proof. Project the carrier rows of Definition 1620.1. The analytic access rows are exactly the two real seals, their regular rational sources and readbacks, the common stream window, the dyadic tolerance ledger, the classifier row, and the regular-Cauchy equivalence boundary.

Apply the NameCert obligations theorem Definition 1620.2. Its fifth row states that H, K, P, N transport, replay, source, and locally name only the displayed finite packet, so there is no hidden classifier read outside the carrier.

Finally combine the RegSeqRat handoff of Definition 1620.5 with the real seal non-escape theorem Definition 1620.8. The handoff forces every regular-rational read through $S_X, S_Y, R_X, R_Y, W, D, C, E$, and seal non-escape rules out the listed quotient, host-equality, choice, order, and completeness endpoints. □

Lean4 ✓ `BEDC.Derived.RealClassifierLedgerExhaustion`

Theorem 1620.10 (RealClassifier tolerance-window determinacy)**.** *Let*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$$

and

$$Q' = (X', Y', S'_X, S'_Y, R'_X, R'_Y, W', D, C', E', H', K', P', N')$$

be accepted $\mathsf{RealClassifier}^{\uparrow}$ *carriers. Suppose the two packets share the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, expose the same* $\mathsf{StreamName}^{\uparrow}$ *window through* W *and* W'*, use the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff surface through* S_X, S_Y, R_X, R_Y *and* S'_X, S'_Y, R'_X, R'_Y*, reach the same terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary through* X, Y *and* X', Y'*, and transport the displayed rows through the same* hsame*,* Cont*,* Pkg*, and local* NameCert *routes carried by* H, K, P, N *and* H', K', P', N'*. Then* Q *and* Q' *expose*

the same public classifier decision surface: every accepted classifier read of either packet is the finite route through the common tolerance ledger, common window, regular rational readback, real seal boundary, transport, replay, provenance, and local naming rows.

Proof. Apply the RegSeqRat handoff theorem Definition 1620.5 to both carriers. The hypotheses identify the tolerance ledger, finite window, and regular rational readback surfaces, so each classifier read reaches the public boundary through the same displayed D, W, S_X, S_Y, R_X, R_Y route.

Next apply the real seal non-escape theorem Definition 1620.8. It rules out quotient stream equality, host real equality, selected limits, trichotomy, countable choice, and ambient completeness as alternative endpoints, leaving only the displayed terminal seal boundary named in the hypotheses.

Finally apply ledger exhaustion from Definition 1620.9. The structural rows H, K, P, N and H', K', P', N' can only transport, replay, source, and locally name the displayed packet, so two accepted packets with the same tolerance, window, handoff, seal, transport, replay, provenance, and local naming routes expose the same classifier decision surface. □

Lean4 ✓ `BEDC.Derived.RealClassifierToleranceWindowDeterminacy`

Theorem 1620.11 (RealClassifier window scope)**.** *Every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *public read factors through the common* $\mathsf{StreamName}^{\uparrow}$ *window* W *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D *before a* $\mathsf{RealNameClassifier}^{\uparrow}$ *row or a* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row can be consumed. In carrier notation, for*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the public classifier boundary is the finite route through $S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$ *over the two terminal* $\mathsf{Real}^{\uparrow}$ *seals* X, Y*, not a direct equality test on completed real names.*

Proof. Project the carrier of Definition 1620.1. The only common inspection coordinate is W, and the only tolerance and comparison-budget coordinate is D.

Apply the RegSeqRat handoff theorem Definition 1620.5. It forces every regular-rational classifier read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before the public classifier boundary is reached.

Use real seal non-escape from Definition 1620.8. Since the terminal seals X, Y do not expose host real equality, quotient stream equality, selected limits, trichotomy, countable choice, or ambient completeness, the read cannot bypass the common window and ledger by inspecting the seals directly.

Finally apply ledger exhaustion from Definition 1620.9. The structural rows H, K, P, N only transport, replay, source, and name the displayed finite packet, so every accepted public read consumes W and D before it reaches C or E. □

Lean4 ✓ `BEDC.Derived.RealClassifierWindowScope`

Theorem 1620.12 (RealClassifier common-window quotient refusal)**.** *For accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carriers, a public equality or classifier read is admissible only when both terminal* $\mathsf{Real}^{\uparrow}$ *seals are compared through the same* $\mathsf{StreamName}^{\uparrow}$ *window* W *and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*. Any attempted read that identifies the terminal* $\mathsf{Real}^{\uparrow}$ *seals directly, without displaying both* W *and* D*, leaves the carrier surface and cannot be cited as* $\mathsf{RealClassifier}^{\uparrow}$ *evidence.*

Proof. Project an accepted carrier

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N).$$

The carrier exposes the two terminal seals only together with their regular rational source rows, readbacks, common window, tolerance ledger, classifier row, equivalence boundary, and structural rows.

Apply the RegSeqRat handoff of Definition 1620.5. It forces every public classifier read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before the terminal boundary is consumed.

Apply real seal non-escape from Definition 1620.8. It rules out a direct host equality or quotient equality read on X, Y as an endpoint supplied by the carrier.

Use ledger exhaustion from Definition 1620.9 and window scope from Definition 1620.11. These keep the structural rows H, K, P, N tied to the same finite packet and require the common window W and ledger D before any $\mathsf{RealNameClassifier}^{\uparrow}$ or $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ row is consumed. A read that omits either row is therefore outside the accepted $\mathsf{RealClassifier}^{\uparrow}$ evidence surface. □

Lean4 ✓ `BEDC.Derived.RealClassifierCommonWindowQuotientRefusal`

Theorem 1620.13 (RealClassifier source scope)**.** *Every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *public read factors through exactly the source scopes named by the carrier: the terminal* $\mathsf{Real}^{\uparrow}$ *seals* X, Y*, the regular rational source and readback rows* S_X, S_Y, R_X, R_Y*, the common* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row* C*, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row* E*, and the structural rows* H, K, P, N*. No quotient stream equality, host real equality, trichotomy, countable choice, selected limit, or ambient completeness principle can bypass those scopes.*

Proof. Project the carrier in Definition 1620.1. Its source rows are precisely the two terminal seals, the two regular rational source rows, the two readback rows, the common window, the dyadic ledger, the classifier row, the regular-Cauchy equivalence row, and the structural rows H, K, P, N.

Apply the NameCert obligations of Definition 1620.2. Carrier admission, tolerance classifier stability, the RegSeqRat handoff, real seal non-escape, and ledger exhaustion account for every accepted public read.

Use the RegSeqRat handoff of Definition 1620.5 and the real seal non-escape theorem Definition 1620.8. These force the read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ over the displayed seals X, Y and rule out host equality or quotient-stream shortcuts.

Finally combine ledger exhaustion from Definition 1620.9, tolerance-window determinacy from Definition 1620.10, and window scope from Definition 1620.11. The structural rows H, K, P, N only transport, replay, source, and name the same finite packet, so no listed non-source principle remains as a bypass. □

Lean4 ✓ `BEDC.Derived.RealClassifierSourceScope`

Theorem 1620.14 (RealClassifier tail-replacement stability)**.** *Let*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$$

be an accepted $\mathsf{RealClassifier}^{\uparrow}$ *carrier. Suppose a second displayed readback replaces* R_X *or* R_Y *by a* $\mathsf{RegSeqRat}^{\uparrow}$ *row with the same terminal* $\mathsf{Real}^{\uparrow}$ *seal, the same common* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the same* $\mathsf{RealNameClassifier}^{\uparrow}$ *row* C*, and a* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *tail-equivalence row matching* E*. Then the replacement preserves the public* $\mathsf{RealClassifier}^{\uparrow}$ *decision surface seen by completion-selector and completion-density consumers.*

Proof. Apply the RegSeqRat handoff theorem Definition 1620.5. It forces both the original and replacement readback to reach the classifier only through the displayed regular-rational rows, the common window W, the dyadic ledger D, the classifier row C, and the regular-Cauchy boundary E.

Use the regular-real tail-equivalence readback theorem Definition 1620.6. The replacement is admitted only as a tail-equivalent regular rational readback before the terminal Real seals are consumed, so it cannot introduce quotient stream equality or host real equality.

Apply window scope and public exactness, Definition 1620.11 and Definition 1620.16. Since the terminal seals, common window, dyadic ledger, classifier row, equivalence row, transport, replay, provenance, and local naming rows are shared, the public decision route remains the same finite route.

Finally read the downstream consumers through Definition 1620.20 and Definition 1620.21. These consumers inspect only the already exported classifier route, so replacing either regular rational readback by a tail-equivalent readback preserves the surface they see. □

Lean4 ✓ `BEDC.Derived.RealClassifierTailReplacementStability`

Theorem 1620.15 (RealClassifier dyadic-source embedding faithfulness)**.** *Let*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N)$$

and

$$Q' = (X', Y', S'_X, S'_Y, R'_X, R'_Y, W', D, C', E', H', K', P', N')$$

be accepted $\mathsf{RealClassifier}^{\uparrow}$ *carriers whose terminal* $\mathsf{Real}^{\uparrow}$ *seals arise from constant* $\mathsf{StreamName}^{\uparrow}$ *lifts of displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *source rows. Suppose the two packets share the same dyadic tolerance ledger D, expose the same common classifier window through W and W', and reach equal public* $\mathsf{RealClassifier}^{\uparrow}$ *boundary decisions. Then the equality at the classifier boundary preserves the displayed dyadic source equality surface: the only source equality exported to a* $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ *consumer is the one read through the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the constant* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the terminal* $\mathsf{Real}^{\uparrow}$ *seals.*

Proof. Apply the RegSeqRat handoff theorem Definition 1620.5 to both carriers. It forces each dyadic-source read to pass through the displayed regular-rational rows, the common window, the dyadic ledger, the classifier row, and the regular-Cauchy boundary before the public classifier boundary is reached.

Use common-window quotient refusal from Definition 1620.12. Since both packets share the classifier window and dyadic tolerance ledger, equality at the boundary cannot be replaced by host real equality or quotient stream equality.

Read the dyadic source ledger through chapter 291 and the constant-window route through chapter 126. These rows keep the two accepted RealClassifier packets tied to displayed dyadic sources rather than to unstated representatives.

Finally use the regular readback and tail-replacement surfaces, Definition 1620.6 and Definition 1620.14. The $\mathsf{RegSeqRat}^{\uparrow}$ readbacks and terminal $\mathsf{Real}^{\uparrow}$ seals may be transported only along the displayed finite route, so a $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ consumer receives exactly the dyadic source equality surface and no selected limit, trichotomy, countable-choice schedule, or ambient-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.RealClassifierDyadicSourceEmbeddingFaithfulness`

Theorem 1620.16 (RealClassifier public exactness surface)**.** *Every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *public classifier read is exactly the finite route through the two* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row. No accepted public read exports host real equality, quotient stream equality, a selected limit, trichotomy, or a completeness coordinate.*

Proof. Start with the carrier and NameCert obligations from Definition 1620.1 and Definition 1620.2. They list the two terminal seals, regular rational source and readback rows, common StreamName window, dyadic tolerance ledger, classifier row, equivalence boundary, and structural rows as the complete local surface.

Use the RegSeqRat handoff of Definition 1620.5 and the real seal non-escape theorem Definition 1620.8. These force every regular-rational read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ over the displayed seals X, Y and rule out host real equality, quotient stream equality, selected limits, trichotomy, countable choice, and ambient completeness as endpoints.

Finally apply ledger exhaustion from Definition 1620.9, tolerance-window determinacy from Definition 1620.10, and window scope from Definition 1620.11. The shared window and tolerance ledger determine the public classifier route, while H, K, P, N transport, replay, source, and locally name that exact finite packet. □

Lean4 ✓ `BEDC.Derived.RealClassifierPublicExactnessSurface`

Theorem 1620.17 (RealClassifier public exactness consumer reuse)**.** *Any* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *or completion-selector consumer that uses the public* $\mathsf{RealClassifier}^{\uparrow}$ *read receives the same finite route recorded by Definition 1620.16. The consumer route passes through the two* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row. It exports no selected representatives, quotient stream equality, countable choice, or ambient completeness.*

Proof. Start with the public exactness surface of Definition 1620.16. It already exhausts every accepted public classifier read by the two terminal seals, regular rational readbacks, common window, dyadic ledger, classifier row, equivalence row, and structural transport, replay, provenance, and naming rows.

Now read the consumer boundary. A $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ consumer can only reuse the public classifier route after the $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ row and componentwise hsame transport remain visible, while a completion-selector consumer receives the same route after the terminal seals and regular readbacks have been displayed.

Finally compare the excluded coordinates. Since neither consumer receives a row for selected representatives, quotient stream equality, countable choice, or ambient completeness, the public exactness surface is reused as the same finite route rather than replaced by a second classifier or completion endpoint. □

Lean4 ✓ `BEDC.Derived.RealClassifierPublicExactnessConsumerReuse`

Theorem 1620.18 (RealClassifier psame bridge consumption)**.** *The public exactness surface of Definition 1620.16 is exactly the RealClassifier input consumed by the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *psame bridge of chapter 1820. The bridge reads the same sealRead, equalityRead, and realClassifierRead route through the two* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row.*

Proof. Start with the public exactness surface. It already exhausts every accepted public classifier read by the finite route through the two Real seals, regular rational readbacks, shared window, dyadic ledger, classifier row, equivalence row, and structural rows.

Now read the CauchyEquivalenceSetoid$^{\uparrow}$ bridge chapter. Its psame-facing bridge consumes a RealClassifier boundary only after the same sealRead, equalityRead, and realClassifierRead rows are displayed, so the bridge receives no second classifier channel.

Finally compare the source lists. Both routes expose the same $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$ rows before any public equality-facing read is available. Thus the psame bridge consumes the RealClassifier public exactness surface without adding quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealClassifierUp.RealClassifierPsameBridgeConsumption`

Theorem 1620.19 (RealClassifier public export readback)**.** *Every public* RealClassifier$^{\uparrow}$ *read factors through the displayed* RegSeqRat$^{\uparrow}$, RegularCauchyEquivalence$^{\uparrow}$, RegularRealTailEquivalence$^{\uparrow}$, RealNameClassifier$^{\uparrow}$, *and* RealCompletionSelectorSeal$^{\uparrow}$ *rows before any completion-density or audit consumer can inspect the classifier. In carrier notation, for*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the exported read is the finite route through $S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$ *over the terminal* Real$^{\uparrow}$ *seals* X, Y*, not a direct equality read on completed real names.*

Proof. Start with the public exactness surface of Definition 1620.16. It already binds every public classifier read to the two terminal seals, the regular rational readbacks, the common StreamName window, the DyadicRatCore ledger, the RealNameClassifier row, the RegularCauchyEquivalence row, and the structural transport, replay, provenance, and local naming rows.

Apply the RegSeqRat handoff theorem Definition 1620.5 and the regular-real tail-equivalence readback theorem Definition 1620.6. These force the public read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before it reaches a same-real or tail-equivalence-facing consumer.

Next use the completion-selector-seal readback theorem Definition 1620.20. A RealCompletionSelectorSeal$^{\uparrow}$ consumer therefore receives the classifier only after the Real seals, regular readbacks, common window, tolerance ledger, classifier row, equivalence row, and structural rows have been displayed.

Finally apply the completion-density consumer theorem Definition 1620.21. Since density and audit consumers inspect only that already exported route, no consumer can replace it by host real equality, quotient stream equality, selected limits, trichotomy, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealClassifierPublicExportReadback`

Theorem 1620.20 (RealClassifier completion-selector-seal readback)**.** *Every accepted* RealClassifier$^{\uparrow}$ *public read that is consumed by a* RealCompletionSelectorSeal$^{\uparrow}$ *packet must pass through the same* Real$^{\uparrow}$ *seals,* RegSeqRat$^{\uparrow}$ *readbacks,* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RealNameClassifier$^{\uparrow}$ *row, and* RegularCauchyEquivalence$^{\uparrow}$ *row before any selector-seal budget, window, or readback row is exposed. The handoff exports no selected limit, quotient stream equality, trichotomy, countable choice, or ambient-completeness coordinate.*

Proof. Start with the carrier of Definition 1620.1 and the NameCert obligations of Definition 1620.2. These list the two terminal Real$^{\uparrow}$ seals, regular rational rows, common StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ ledger, classifier row, equivalence row, and structural rows as the full accepted source.

Apply the RegSeqRat handoff of Definition 1620.5 and the real seal non-escape theorem Definition 1620.8. They force the read through $S_X, S_Y, R_X, R_Y, W, D, C, E$ before the terminal Real

boundary can be used, and they rule out host equality, quotient-stream equality, selected limits, trichotomy, countable choice, and ambient completeness as endpoints.

Use ledger exhaustion from Definition 1620.9 and the public exactness surface of Definition 1620.16. The shared window and dyadic ledger are already exhausted before the public classifier boundary is reached, so a selector-seal consumer receives the same finite classifier route rather than a second tolerance or equality channel.

Finally attach the sibling $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ route of chapter 1081. Its budget, window, and readback rows can only consume the displayed classifier read after the RealClassifier route has exposed the seals, readbacks, window, ledger, classifier row, equivalence row, and structural transport, replay, provenance, and naming rows. No coordinate remains from which to export a selected limit, quotient stream equality, trichotomy, countable choice, or ambient-completeness claim. □

Lean4 ✓ `BEDC.Derived.RealClassifierCompletionSelectorSealReadback`

Theorem 1620.21 (RealClassifier completion-density consumer)**.** *Every completion-density consumer of an accepted* $\mathsf{RealClassifier}^{\uparrow}$ *read must expose the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the rational-density route of chapter 7239 or the regular Cauchy dense-embedding route of chapter 1453, and the classifier transport rows before the read is used as a countable dense surface. In carrier notation, for*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the dense consumer may reuse only the displayed route through $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$ *together with the sibling density rows. It may not substitute selected representatives, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the public exactness surface of Definition 1620.16. It binds every accepted classifier read to the two terminal Real seals, the regular rational readbacks, the common StreamName window, the DyadicRatCore ledger, the comparison row, the regular-Cauchy equivalence boundary, and the structural transport, replay, provenance, and naming rows.

Next use the regular-real tail-equivalence readback of Definition 1620.6. It keeps a same-real read inside the shared regular-rational, finite-window, dyadic-ledger, and comparison route before the public classifier boundary is reached.

Now pass to the density sibling. A rational-density consumer reads chapter 7239; a completion-facing regular-Cauchy consumer reads chapter 1453. In either case, the dense surface receives the already displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{Real}^{\uparrow}$ seal route from the classifier packet.

Finally read H, K, P, N only as classifier transport, replay, provenance, and local naming. Since the carrier has no coordinate for selected representatives, quotient stream equality, countable choice, or ambient Real completeness, a completion-density consumer cannot obtain any of those endpoints from the accepted $\mathsf{RealClassifier}^{\uparrow}$ read. □

Lean4 ✓ `BEDC.Derived.RealClassifierCompletionDensityConsumer`

Theorem 1620.22 (RealClassifier audit route)**.** *For every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the audit-facing classifier route is exactly the ordered read through the two $\mathsf{Real}^{\uparrow}$ *seals* X, Y*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_X, R_Y*, the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance*

ledger D, the $\mathsf{RealNameClassifier}^{\uparrow}$ *row C, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row E, componentwise* hsame *transport H, displayed* Cont *replay K,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row N. No audit read may replace that route by quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness.*

Proof. Use the RegSeqRat handoff theorem Definition 1620.5. It forces every classifier read to expose the regular rational sources and readbacks before the public classifier boundary is reached.

Apply window scope and source scope, Definition 1620.11 and Definition 1620.13. These identify the shared StreamName window, dyadic tolerance ledger, classifier row, equivalence row, terminal Real seals, and structural rows as the complete source list for the read.

Finally use the public exactness surface of Definition 1620.16. Since that theorem already binds every public classifier read to the exact finite route through $X, Y, R_X, R_Y, W, D, C, E, H, K, P, N$, the audit route is the same ordered source read and has no ambient equality, choice, or completeness endpoint. □

Lean4 ✓ `BEDC.Derived.RealClassifierAuditRoute`

Theorem 1620.23 (RealClassifier audit-density coherence)**.** *Every audit-facing classifier read of an accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier that is later consumed by the rational-density route of chapter 7239 or the regular-Cauchy dense-embedding route of chapter 1453 must use the same ordered route through the* $\mathsf{Real}^{\uparrow}$ *seals,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RealNameClassifier}^{\uparrow}$ *row,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row. No dense consumer may replace that route by selected representatives, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the audit route theorem Definition 1620.22. It fixes the audit-facing read as the ordered source route through the two terminal seals, regular readbacks, common window, dyadic ledger, classifier row, regular-Cauchy boundary, transport, replay, provenance, and local naming rows.

Apply the completion-density consumer theorem Definition 1620.21. It says that rational-density and regular-Cauchy dense-embedding consumers receive the already displayed classifier route together with their sibling density rows, rather than a second representative or a detached completion endpoint.

Finally use the public exactness surface of Definition 1620.16. Since every accepted public read is exhausted by the same finite rows, an audit-facing read and its dense consumer have one shared route through $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$. The excluded selected representatives, quotient stream equality, countable choice, and ambient completeness coordinates are absent from both surfaces. □

Lean4 ✓ `BEDC.Derived.RealClassifierAuditDensityCoherence`

Theorem 1620.24 (RealClassifier theorem-check target handoff)**.** *The theorem-check target for* $\mathsf{RealClassifier}^{\uparrow}$ *is exactly the public exactness surface route through the two* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row. The handoff targets that route only; it does not change the recorded formal status before Lean supplies the corresponding theorem-checked evidence.*

Proof. Start with the public exactness surface of Definition 1620.16. It already states the exact public classifier route through the Real seals, regular rational readbacks, shared window, dyadic ledger, classifier row, equivalence row, and structural rows.

Next use the audit route theorem Definition 1620.22. It confirms that the audit-facing read is the same ordered source route, not a second equality, representative, choice, or completeness channel.

Finally apply audit-density coherence, Definition 1620.23. Since density consumers receive the same displayed public route, the theorem-check target is precisely the public exactness surface named by the chapter leantarget. □

Lean4 ✓ `BEDC.Derived.RealClassifierTheoremCheckTargetHandoff`

Theorem 1620.25 (RealClassifier theorem-check readback route)**.** *For every accepted* $\mathsf{RealClassifier}^{\uparrow}$ *carrier*

$$Q = (X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N),$$

the theorem-check readback route is the same finite route through the two $\mathsf{Real}^{\uparrow}$ *seals* X, Y*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_X, R_Y*, one* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the* $\mathsf{RealNameClassifier}^{\uparrow}$ *row* C*, the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* K*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$ *row* N*. The readback route exports no quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness beyond the theorem-check target handoff.*

Proof. Begin with public exactness, Definition 1620.16. It binds every public classifier read to the two terminal Real seals, regular rational readbacks, common StreamName window, DyadicRatCore tolerance ledger, RealNameClassifier row, RegularCauchyEquivalence row, and structural rows.

Use the audit route theorem Definition 1620.22. It identifies the audit-facing source order as the same route through $X, Y, S_X, S_Y, R_X, R_Y, W, D, C, E, H, K, P, N$, without a second equality channel or representative selector.

Apply audit-density coherence, Definition 1620.23. Density consumers receive the already displayed public and audit route, so the theorem-check readback cannot replace it with a quotient stream equality, selected limit, countable-choice, or ambient-completeness endpoint.

Finally apply the theorem-check target handoff Definition 1620.24. The handoff targets exactly this public exactness surface, and therefore the readback route for the theorem-check target is the same finite route through the two Real seals, regular readbacks, StreamName window, DyadicRatCore ledger, classifier row, equivalence row, transport, replay, provenance, and local NameCert. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1620.1, Definition 1620.2, Definition 1620.5, Definition 1620.8, Definition 1620.9, Definition 1620.10, Definition 1620.11, Definition 1620.13, Definition 1620.16, Definition 1620.19, Definition 1620.20, Definition 1620.21, Definition 1620.22, and Definition 1620.23 bind the mature route from RegSeqRat, RealNameClassifier, StreamName, DyadicRatCore, and RegularCauchyEquivalence rows into public, completion-facing, and audit-facing RealClassifier reads over the terminal RealUp seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealClassifier}^{\uparrow}}$, scaffoldChecked)

Lean target: `BEDC.Derived.RealClassifierPublicExactnessSurface`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, trichotomy, countable choice, ambient completeness, or machine-checked standard bridge evidence.

Upgrade path: The remaining work is formal audit-clean and bridge-checked coverage for the same mature public, completion-facing, and audit-facing route.

Constructive story: A RealClassifier$^{\uparrow}$ packet is generated from two RealUp seals, regular rational readbacks, one common StreamName window, DyadicRatCore tolerance data, a RealNameClassifier row, a RegularCauchyEquivalence row, componentwise transport, continuation replay, package provenance, and local naming.

Chapter 1621

A Concrete Naming Certificate for $\mathsf{StationaryDyadicStream}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{StationaryDyadicStream}^{\uparrow}$ packet records the finite constant dyadic stream route that feeds the open Real and Completion path. It begins at the dyadic source boundary of chapter 291, passes through the constant stream window of chapter 126, hands the regularity row to chapter 301, reaches the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and is read alongside the normal-form and zero-real boundaries of chapter 1613 and chapter 1619. The packet names a displayed constant dyadic stream, not a quotient stream, selected limit, host real equality, trichotomy, countable choice, or ambient completeness principle.

Definition 1621.1 (Stationary dyadic stream carrier)**.** *A* $\mathsf{StationaryDyadicStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, including the finite dyadic endpoint, tolerance ledger, and readback surface inspected before any stream request.*
2. *W is the constant* $\mathsf{StreamName}^{\uparrow}$ *window, recording that every admitted finite request reads the same dyadic row D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity handoff, exposing the constant dyadic window as a regular rational sequence with zero internal drift across displayed finite windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, reached only after the dyadic source row, constant StreamName window, and regularity handoff have all been displayed.*
5. *H records componentwise* hsame *transport for D, W, R, E, C, P, N and for every displayed finite request window carried by W.*
6. *C records displayed* Cont *replay from D into W, from W into R, and from R into the terminal seal E.*
7. *P records* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicNormalForm}^{\uparrow}$, $\mathsf{RealZero}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{StationaryDyadicStream}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1621.2 (Stationary dyadic stream NameCert obligations)**.** *For every accepted* $\mathsf{StationaryDyadicStream}^{\uparrow}$ *carrier* $S = (D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StationaryDyadicStream}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the DyadicRatCore source row, constant StreamName window, RegSeqRat handoff, terminal RealUp seal, transport, continuation, provenance, and local naming rows;*
2. *constant-window exactness, requiring each displayed finite request in* W *to read the same source row* D*;*
3. *regularity handoff, requiring* R *to expose zero pairwise drift between all displayed windows admitted by the same constant source route;*
4. *terminal seal routing, requiring* E *to be exported only after* D*,* W*, and* R *have been displayed in that order;*
5. *componentwise transport and replay stability, requiring* H *and* C *to preserve the same dyadic source, constant window, regularity handoff, and real seal rows;*
6. *ledger refusal, excluding quotient streams, selected limits, host real equality, trichotomy, countable choice, and ambient Real completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1621.1. The projection exposes only D, W, R, E, H, C, P, N, so carrier admission and the local naming row are finite.

For constant-window exactness, induct on the displayed finite request window stored in W. The empty window has no request to compare. In the successor step, the new request is read from the same DyadicRatCore row D, and the induction hypothesis preserves the earlier requests.

The RegSeqRat handoff is the same induction read through R. Each pair of displayed windows has identical dyadic readback because both are componentwise transported to D, so the regularity ledger records zero displayed drift without selecting a limit.

Replay by C gives the ordered route $D \to W \to R \to E$, and transport by H preserves the components of that route. Since the carrier contains no quotient stream, selected limit, host real equality, trichotomy, countable choice, or completeness coordinate, the local NameCert surface cannot export any such principle. □

Theorem 1621.3 (Stationary dyadic stream RegSeqRat handoff)**.** *Every accepted* $\mathsf{StationaryDyadicStream}^{\uparrow}$ *carrier* $S = (D, W, R, E, H, C, P, N)$ *exports its regular rational sequence boundary through the finite route*

$$D \longrightarrow W \longrightarrow R$$

where W *repeats the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row and* R *records regularity by componentwise equality of finite windows. The handoff does not require quotient stream equality, a chosen Cauchy limit, trichotomy, countable choice, or ambient completeness.*

Proof. Read D through the constant StreamName window W. Induction over any displayed finite window shows that every entry in the window is the same dyadic source row.

The row R consumes exactly that finite constant-window evidence. Componentwise hsame transport turns equality of entries in W into the regular-rational zero-drift ledger demanded by $\mathsf{RegSeqRat}^{\uparrow}$.

No further principle is available in the carrier. The handoff therefore remains the displayed route $D \to W \to R$, rather than a quotient-stream class or a selected limiting real. □

Theorem 1621.4 (Stationary dyadic stream constant embedding)**.** *Every accepted* $\mathsf{StationaryDyadicStream}^{\uparrow}$ *packet whose source row is a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *datum exports the same public route as the dyadic constant embedding into* $\mathsf{Real}^{\uparrow}$*:*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

For a carrier $S = (D, W, R, E, H, C, P, N)$*, this route is read through the rows* D, W, R, E, H, C, P, N*. It does not introduce quotient stream equality, a selected limit, host real equality, countable choice, or ambient completeness.*

Proof. Use the carrier definition to project the accepted packet. The source row D is the displayed dyadic rational datum, and the window row W records that every finite stream request repeats that same datum.

Apply the RegSeqRat handoff theorem. It identifies R as the regular rational readback of the constant finite windows, with zero displayed drift between the windows admitted by W.

Finally apply the Real seal boundary theorem. The seal E is available only after D, W, R have been displayed, and H, C, P, N only transport, replay, source, and name the same finite route. The packet therefore presents exactly the constant dyadic embedding route and no quotient stream, selected limit, host real equality, countable-choice schedule, or ambient completeness principle. □

Theorem 1621.5 (Stationary dyadic stream Real seal boundary)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{StationaryDyadicStream}^{\uparrow}$ *packet must inspect the dyadic source row, the constant StreamName window, and the RegSeqRat handoff before reading the terminal seal* E*. Consequently the public real-facing boundary is the finite route*

$$D \longrightarrow W \longrightarrow R \longrightarrow E$$

together with H, C, P, N*, and no consumer may replace that route by quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient Real completeness.*

Proof. Start with an accepted carrier $S = (D, W, R, E, H, C, P, N)$. The seal E is a terminal row in the carrier inventory, so it is not available before the source row D, the window W, and the handoff row R have been displayed.

Continuation replay C records the route from the dyadic source through the constant stream and regularity rows into E. Componentwise transport H preserves the same route for any accepted copy of the packet.

Thus a downstream $\mathsf{Real}^{\uparrow}$ or Completion-facing consumer receives the finite real-facing boundary $D \to W \to R \to E$ with its structural rows. The missing coordinates rule out quotient streams, host real equality, selected limits, trichotomy, countable choice, and ambient completeness as replacement routes. □

Closure status for $\mathsf{NameCert}_{\mathsf{StationaryDyadicStream}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StationaryDyadicStream}^{\uparrow}$ packet is generated from a DyadicRatCore source row, a constant StreamName finite-window row, a RegSeqRat regularity handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StationaryDyadicStream}^{\uparrow}}$, seed)

Scope closed: Definition 1621.1, Definition 1621.2, Definition 1621.3, and Definition 1621.5 seed the finite constant-dyadic stream bridge from DyadicRatCore to Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StationaryDyadicStream}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.StationaryDyadicStreamUp`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, host real equality, trichotomy, countable choice, ambient Real completeness, Lean theorem checking, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, constant-window exactness, RegSeqRat handoff, RealUp seal routing, componentwise transport and replay stability, and ledger refusal for the same finite packet.

Chapter 1622

A Concrete Naming Certificate for $\mathsf{KleeneTree}^{\uparrow}$

Following Kleene's computability-theoretic tree counterexample tradition and Bishop–Bridges constructive analysis, the $\mathsf{KleeneTree}^{\uparrow}$ packet records a decidable finite-prefix tree surface without turning that surface into an infinite path-selection principle. It sits between the binary prefix carrier of chapter 1475, the finite-bar discipline of chapter 400, the window schedule of chapter 126, the regular rational readback surface of chapter 301, and the terminal real boundary of chapter 38. The chapter makes explicit that finite tree rows and stream-name windows are not countable choice, not a selected branch, not quotient stream equality, not $\mathsf{Real}^{\uparrow}$ completeness, and not open-cover compactness.

The finite-prefix tree row is consumed through the $\mathsf{CantorSpace}^{\uparrow}$ prefix carriers of chapter 1475, the $\mathsf{FanTheorem}^{\uparrow}$ finite-bar discipline, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ boundary before any obstruction row can be interpreted by a downstream consumer. In particular, the finite-prefix obstruction is consumed by the $\mathsf{StreamName}^{\uparrow}$ window schedule of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback boundary of chapter 301 before any Real-facing consumer reaches chapter 38.

Concretely, the branch-facing read is not internal to the Kleene packet. It reads $\mathsf{CantorSpace}^{\uparrow}$ branch windows through chapter 1475 and compares those finite windows with the $\mathsf{FanTheorem}^{\uparrow}$ bar and modulus-failure boundary of chapter 400. The carrier therefore presents a horizontal dependency: finite prefix data can be tested against Cantor-space windows and fan-theorem bar failures, but the obstruction row still blocks any selected infinite branch.

Definition 1622.1 (Kleene tree carrier)**.** *A* $\mathsf{KleeneTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, B, L, S, O, H, C, P, N)$$

with the following displayed rows:

1. *T is a finite binary prefix-tree ledger, whose nodes are displayed finite $0/1$ words and whose extension relation is prefix-closed only for the listed words.*
2. *B is the $\mathsf{Bool}^{\uparrow}$ decidable node ledger classifying each listed finite word as admitted or refused inside the displayed tree packet.*
3. *L is the $\mathsf{List}^{\uparrow}$ prefix spine recording the parent chain for every listed node.*
4. *S is the $\mathsf{StreamName}^{\uparrow}$ window schedule specifying which finite prefixes a consumer may request.*

5. *O is the obstruction row: no computable infinite branch, no selected path, and no branch-producing choice functional is a coordinate of the packet.*
6. *H records componentwise* hsame *transport for the tree ledger, Bool ledger, List spine, StreamName window schedule, obstruction row, continuation row, provenance row, and local name.*
7. *C records displayed* Cont *traversal from a finite request through S, then through the prefix spine L, then through the node classifier B, and finally to the obstruction row O.*
8. *P is the* Pkg *provenance over* $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$ *row.*

The carrier stores no infinite path object, no countable-choice schedule, no quotient stream equality, no selected real name, no $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no open-cover compactness principle.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeTasteGate single carrier alignment`

Theorem 1622.2 (Kleene tree NameCert obligations)**.** *For every accepted* $\mathsf{KleeneTree}^{\uparrow}$ *carrier $K = (T, B, L, S, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite binary prefix tree, decidable Bool node ledger, List prefix spine, StreamName window schedule, obstruction row, transport, traversal, provenance, and local naming row;*
2. *prefix stability, requiring every accepted child row in T to have its displayed parent in L and its node decision in B;*
3. *window exactness, requiring every consumer request to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule S before any tree node is inspected;*
4. *traversal stability, requiring* hsame *transport and* Cont *replay to preserve the same finite prefix ledger and the same obstruction row;*
5. *boundary refusal, requiring O to expose no computable infinite branch, no branch selector, no countable-choice functional, no quotient stream equality, no* $\mathsf{Real}^{\uparrow}$ *completeness, and no open-cover compactness principle.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeNameCert obligations`

Proof. Project the carrier of Definition 1622.1. The tuple contains exactly the finite tree ledger T, the Bool node classifier B, the List prefix spine L, the StreamName window schedule S, the obstruction row O, and the structural rows H, C, P, N.

Prefix stability is read from T, B, L. Since each listed child is accompanied by a displayed parent spine and a displayed Bool decision, a consumer cannot infer membership for an unlisted node or a branch beyond the finite ledger.

Window exactness is read from S and C. The continuation row routes each request through the finite StreamName window before the prefix ledger and classifier are inspected.

Transport and replay are componentwise. The rows H and C can move or traverse only the displayed finite packet, so the obstruction row O remains part of the same carrier throughout the read.

The carrier contains no coordinate for an infinite path, countable choice, quotient stream equality, $\mathsf{Real}^{\uparrow}$ completeness, or open-cover compactness. Thus the local $\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$ row cannot export any of those principles. □

Theorem 1622.3 (Kleene tree stream-name path boundary)**.** *Every consumer of an accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet reads only the finite route*

$$S \longmapsto L \longmapsto B \longmapsto T \longmapsto O \longmapsto H, C, P, N.$$

Consequently finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{CantorSpace}^{\uparrow}$ *prefix rows, and* $\mathsf{FanTheorem}^{\uparrow}$ *bar-facing tests supplied by the packet do not determine a computable infinite branch, a selected Cantor point, quotient stream equality, countable choice,* $\mathsf{Real}^{\uparrow}$ *completeness, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTree streamname path boundary`

Proof. Begin with an accepted carrier $K = (T, B, L, S, O, H, C, P, N)$. A consumer first receives the finite StreamName schedule S, not an infinite stream.

The traversal then passes through the List prefix spine L and the Bool node ledger B before reading the displayed prefix-tree ledger T. Each step concerns only listed finite words and their displayed parent chains.

The obstruction row O is downstream of the same finite traversal. It records that no computable infinite branch, branch selector, or countable-choice functional belongs to the packet.

The structural rows H, C, P, N preserve and name that route. Therefore the finite data may be reused by CantorSpace, FanTheorem, RegSeqRat, or Real-facing consumers only as finite prefix information, never as quotient stream equality, an open-cover compactness principle, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Theorem 1622.4 (Kleene tree Cantor–Fan dependency route)**.** *Every branch-facing read of an accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet first consumes the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix rows of chapter 1475 and the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar rows of chapter 400 before it can interpret the obstruction row as a stream-name, regular-rational, or real-facing boundary. The visible route remains*

$$S, L, B, T, O, H, C, P, N,$$

and no branch selector, selected Cantor point, countable-choice functional, quotient stream equality, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row is produced.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.CantorFanDependencyRoute.KleeneTreeCantorFanDependencyRoute`

Proof. Project the carrier of Definition 1622.1. The only branch-facing data are the finite StreamName window S, the List prefix spine L, the Bool node ledger B, the finite tree ledger T, the obstruction row O, and the structural rows H, C, P, N.

Apply Definition 1622.3. It already forces any branch-facing read to remain inside the finite route and refuses infinite paths, selected Cantor points, and quotient stream equality.

The $\mathsf{CantorSpace}^{\uparrow}$ chapter supplies the finite prefix rows that a branch consumer may test, while the $\mathsf{FanTheorem}^{\uparrow}$ chapter supplies the finite-bar rows against which those prefixes are compared. Since both surfaces are read before the obstruction row is interpreted, the Kleene packet records a horizontal dependency through Cantor-space prefixes and fan-theorem bars rather than a free-standing path object. □

Theorem 1622.5 (Kleene tree Specker boundary route)**.** *Every* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *consumer using a* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction must first read the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix rows,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *boundary before it can consume the obstruction as a Specker-style boundary row. The public route factors through the Kleene carrier rows* $S, L, B, T, O, H, C, P, N$ *together with the Specker boundary route of chapter 3516.*

The consumer receives no branch selector, countable-choice schedule, quotient stream equality, selected Cantor point, path-coded real, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or open-cover compactness principle from the Kleene packet.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeSpeckerBoundaryRoute`

The Specker sequence boundary of chapter 3516 consumes this Kleene finite-prefix obstruction as a nonlocated-supremum boundary: the obstruction row remains finite prefix data, and the composed route still refuses branch selectors, countable-choice schedules, quotient stream equality, selected Cantor points, and ambient completeness.

Proof. Start with the Kleene carrier of Definition 1622.1. Its public obstruction route is finite: $\mathsf{StreamName}^{\uparrow}$ schedule S, List prefix spine L, Bool node ledger B, finite prefix tree T, obstruction row O, and structural rows H, C, P, N.

Apply Definition 1622.3. It forces every tree read to pass through finite StreamName windows, CantorSpace prefix data, and FanTheorem bar-facing tests before the obstruction row is interpreted. No infinite branch or selected Cantor point is exposed there.

Now read the same obstruction through chapter 3516. The Specker boundary carrier consumes finite stream windows, DyadicRatCore tolerance rows, RegSeqRat readback, and a Real seal or refusal row before any completion-facing consumer can cite the nonlocated-supremum obstruction.

Composing the two routes gives the advertised boundary. A Real or Completion obstruction consumer may cite the Kleene row only after the finite prefix, finite-bar, StreamName, RegSeqRat, and Real boundary rows are displayed. Since neither route contains a branch selector, countable-choice schedule, quotient stream equality, path-coded real, ambient Real completeness, or open-cover compactness, the composed Specker-facing read exports none of those objects. □

Theorem 1622.6 (Kleene tree Cantor-space fan boundary)**.** *Every Specker-facing* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction must pass through the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix windows and the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar rows before it can be read as a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *boundary. The route exposes only the finite rows* $S, L, B, T, O, H, C, P, N$*, so the later boundary read cannot recover an infinite branch, a selected Cantor point, quotient stream equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeCantorSpaceFanBoundary`

Proof. Start with Definition 1622.5. It already places every Specker-facing read behind the finite prefix windows, finite-bar rows, StreamName windows, RegSeqRat readback, and Real boundary.

Now isolate the horizontal dependency. The $\mathsf{CantorSpace}^{\uparrow}$ rows provide the finite prefix windows, and the $\mathsf{FanTheorem}^{\uparrow}$ rows provide the finite-bar tests attached to those windows. A Specker-facing consumer therefore reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ only after those two finite surfaces are displayed.

The carrier rows are still the finite rows $S, L, B, T, O, H, C, P, N$. Since none of them stores a branch selector, selected Cantor point, quotient stream equality, open-cover compactness principle, or ambient Real-completeness theorem, the composed boundary read exports none of those objects. □

Theorem 1622.7 (Kleene tree prefix-induction closure)**.** *Every accepted finite prefix-tree ledger in a* $\mathsf{KleeneTree}^{\uparrow}$ *carrier is closed under displayed parent-prefix induction. Each accepted non-root listed word has its displayed parent in the* $\mathsf{List}^{\uparrow}$ *prefix spine and its* $\mathsf{Bool}^{\uparrow}$ *node decision in the ledger, and* hsame/Cont *replay preserves this finite closure without selecting an infinite branch. The induction uses only the* $T, B, L, S, O, H, C, P, N$ *carrier rows.*

Proof. Induct on the displayed prefix spine L of Definition 1622.1. The root case is listed directly in the finite tree ledger T and has its Bool decision in B, so no parent row is required.

For a non-root listed word, the next row of L displays its parent prefix. The induction hypothesis places that parent inside the same finite spine, while the corresponding row of B records the accepted or refused node decision for the listed word.

The StreamName schedule S only chooses finite windows into this displayed spine. It cannot add a branch beyond the rows already present in T, B, L.

Finally H and C transport and replay the same finite packet, while P, N record provenance and local naming. Since the obstruction row O remains part of the carrier, the prefix induction closes the finite ledger without selecting an infinite path or invoking countable choice. □

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeCarrier prefix induction closure`

Theorem 1622.8 (Kleene tree fan boundary)**.** *For every accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet, any* $\mathsf{FanTheorem}^{\uparrow}$ *or* $\mathsf{CantorSpace}^{\uparrow}$ *consumer sees only the finite rows* $S, L, B, T, O, H, C, P, N$*. The consumer may use finite-bar tests and finite prefix checks along those rows, but it receives no infinite branch, no branch selector, no countable-choice functional, no quotient stream equality, no open-cover compactness principle, and no* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeCarrier fan boundary`

Proof. Project the carrier of Definition 1622.1. The displayed packet contains the finite StreamName schedule S, the List prefix spine L, the Bool node ledger B, the finite prefix-tree ledger T, the obstruction row O, and the structural rows H, C, P, N.

Apply Definition 1622.2. Prefix stability, window exactness, and traversal stability force every FanTheorem or CantorSpace read to remain inside the displayed finite rows.

It remains to identify what cannot pass through that read. Apply Definition 1622.3: the finite route is not a path selector, not a countable-choice functional, not quotient stream equality, not open-cover compactness, and not $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1622.9 (Kleene tree selector refusal)**.** *Every read from an accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet into* $\mathsf{CauchySelectionFunction}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*, or* $\mathsf{SequentialCauchySelector}^{\uparrow}$ *factors through the finite rows* $S, L, B, T, O, H, C, P, N$*. The read may reuse finite StreamName windows, finite prefix ledgers, and finite obstruction data, but it cannot produce a branch selector, a countable-choice functional, or a sequential Cauchy selector row. The obstruction is carried by the row* O *together with the path and fan boundaries of Definition 1622.3 and Definition 1622.8.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeSelectorRefusal`

Proof. Project the accepted carrier of Definition 1622.1. The only rows exposed to a selector-facing consumer are the finite StreamName schedule S, the prefix spine L, the Bool ledger B, the tree ledger T, the obstruction row O, and the structural rows H, C, P, N.

Apply Definition 1622.3. A read through S, L, B, T supplies finite prefix information, not an infinite path, quotient stream equality, or a countable-choice functional.

Apply Definition 1622.8. Any CantorSpace or FanTheorem-facing use of the same packet remains inside the finite rows and reaches the obstruction row before it can export a selector.

The row O explicitly denies a computable infinite branch, a selected path, and a branch-producing choice functional as packet coordinates. A sequential Cauchy selector row would require a finite request ledger of selected Cauchy answers, but the Kleene packet contains only tree-prefix and stream-window rows. Therefore no read into $\mathsf{CauchySelectionFunction}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, or $\mathsf{SequentialCauchySelector}^{\uparrow}$ escapes the finite obstruction boundary. □

Theorem 1622.10 (Kleene tree Real-completion non-escape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion-facing read sourced from an accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet factors through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the obstruction row before any real seal can be inspected. Consequently the read cannot assert a selected Cantor point, a path-coded real, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or open-cover compactness.*

Proof. First apply Definition 1622.8. Any CantorSpace or FanTheorem data exposed by the packet is finite row data, so a completion-facing consumer inherits only the same finite windows and the same obstruction row.

Next apply Definition 1622.9. A selector-facing read from the same packet must pass through $S, L, B, T, O, H, C, P, N$, and the obstruction row O blocks branch selectors, countable-choice functionals, and sequential Cauchy selector rows before any RegSeqRat or Real seal is inspected.

Now apply Definition 1622.3. The route through $S, L, B, T, O, H, C, P, N$ reaches the obstruction row before any Real-facing interpretation can treat a stream name as a completed real.

The obstruction row contains no selected Cantor point, no path-coded real, no open-cover compactness principle, and no $\mathsf{Real}^{\uparrow}$ completeness theorem. Thus a RegSeqRat or Real completion read cannot escape the finite StreamName boundary supplied by the Kleene tree packet. □

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeRealCompletionNonescape`

Theorem 1622.11 (Kleene tree uniform-structure boundary)**.** *Any* $\mathsf{RealUniformStructure}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction must first pass through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *boundary, and the* $\mathsf{RealUniformStructure}^{\uparrow}$ *L10 finite-source gate of Definition 1624.4. The composed route exports no quotient stream equality, selected path, selected limit, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Real-completion nonescape of Definition 1622.10. It forces every RegSeqRat or Real completion-facing read sourced from the Kleene obstruction to pass through finite StreamName windows and the obstruction row before any Real seal is inspected.

Next read the Real-uniform consumer through chapter 1624. Its L10 finite-source gate, Definition 1624.4, requires the Real endpoint and seal row, Metric distance row, DyadicRatCore radius ledger, StreamName finite-window row, and RegSeqRat readback row before any UniformSpace or CauchyFilter handoff is available.

Composing these two row orders gives the stated boundary. The Kleene side contributes only finite prefix and obstruction data, while the RealUniformStructure side contributes only the displayed L10 finite-source rows. Since neither route has a coordinate for quotient stream equality, selected paths, selected limits, open-cover compactness, or ambient Real completeness, the uniform-structure-facing consumer cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeUniformStructureBoundary`

Theorem 1622.12 (KleeneTree scoped prefix-choice refusal)**.** *Every accepted* $\mathsf{KleeneTree}^{\uparrow}$ *packet whose prefix induction, fan boundary, selector refusal, and Real-completion nonescape rows are displayed can answer a finite prefix-extension request only through the tree carrier, the* $\mathsf{CantorSpace}^{\uparrow}/\mathsf{FanTheorem}^{\uparrow}$ *boundary rows, the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and the existing refusal ledger. The answer cannot export a branch selector, fan theorem, countable-choice functional, quotient path, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KleeneTreeUp.KleeneTreeCarrier scoped prefix choice refusal`

Proof. Project the accepted carrier $K = (T, B, L, S, O, H, C, P, N)$ of Definition 1622.1. A finite prefix-extension request first reads the finite tree ledger T, the Bool node ledger B, and the List prefix spine L.

Apply Definition 1622.7. It keeps every accepted extension inside the displayed parent-prefix induction over T, B, L and does not select an infinite branch.

Apply Definition 1622.8 and Definition 1622.9. The CantorSpace and FanTheorem reads remain finite boundary reads, while selector-facing consumers meet the obstruction row O before any branch-producing coordinate can appear.

Finally apply Definition 1622.10. A completion-facing read must pass through $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback before any Real seal is inspected. Since the carrier inventory has no branch selector, fan theorem, countable-choice functional, quotient path, or ambient Real-completeness coordinate, the scoped prefix-extension answer exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KleeneTree}^{\uparrow}$ packet is generated from a finite binary prefix-tree ledger, a Bool decidable node ledger, a List prefix spine, a StreamName window schedule, an obstruction row, componentwise hsame transport, displayed Cont traversal, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$, obligation)

Scope closed: Definition 1622.1, Definition 1622.2, Definition 1622.3, Definition 1622.8, Definition 1622.9, and Definition 1622.10 seed the finite prefix-tree boundary separating StreamName, FanTheorem, CantorSpace, selector-facing, RegSeqRat, and Real-facing data from path-selection and completeness principles.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KleeneTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a computable infinite branch, selected Cantor point, quotient stream equality, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires an explicit dependency scope for the $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Chapter 1623

A Concrete Naming Certificate for $\mathsf{DyadicComparison}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicComparison}^{\uparrow}$ packet names the finite comparison surface for dyadic rational rows before regular rational streams and completed real names read an order-facing observation. It sits after the dyadic core boundary of chapter 291, the canonical finite presentation of chapter 1613, and the finite schedule surface of chapter 126; it feeds the regular rational readback of chapter 301 and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records comparison rows for displayed dyadic windows, not host trichotomy, quotient rational equality, completed real order, located cuts, completeness, or a standard bridge.

Definition 1623.1 (Dyadic comparison carrier)**.** *A* $\mathsf{DyadicComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D_0, D_1, N_0, N_1, S, \Delta, Q, W, H, C, P, L)$$

with the following displayed rows:

1. D_0 *and* D_1 *are the two accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *source rows whose signed mantissas and unary exponents are visible to the packet.*
2. N_0 *and* N_1 *are the associated* $\mathsf{DyadicNormalForm}^{\uparrow}$ *readback rows, so the comparison is made after zero normalization and scale-minimality have been exposed.*
3. S *is the common-scale row, recording the finite unary exponent window used to compare the two normal forms.*
4. Δ *is the signed difference row at the common scale, read through the* $\mathsf{Int}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *surfaces already admitted by the dyadic core.*
5. Q *is the comparison classifier row, with outcomes negative, zero, or positive according to the sign of* Δ *inside the displayed finite window.*
6. W *is the finite window-stability ledger, recording how the classifier is preserved when both source rows are replayed through a larger common dyadic scale.*
7. H *records componentwise* hsame *transport for the source rows, normal-form rows, common-scale row, signed-difference row, classifier row, window ledger, continuation row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from the two input dyadic packets through normal-form readback, common-scale transport, signed-difference computation, classifier inspection, and window-stability export.*
9. *P is the* Pkg *provenance over* BMark, DyadicRatCore$^{\uparrow}$, DyadicNormalForm$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $D_0, D_1, N_0, N_1, S, \Delta, Q, W, H, C, P, L$. It has no coordinate for host rational trichotomy, quotient rational equality, completed real order, located-cut data, ambient completeness, or a standard bridge.

Theorem 1623.2 (Dyadic comparison NameCert obligations)**.** *For every accepted* DyadicComparison$^{\uparrow}$ *carrier $K = (D_0, D_1, N_0, N_1, S, \Delta, Q, W, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two dyadic source rows, two normal-form readback rows, common-scale row, signed-difference row, comparison classifier, window-stability ledger, transport, continuation, provenance, and local naming row;*
2. *source compatibility, requiring D_0, D_1 to be accepted* DyadicRatCore$^{\uparrow}$ *packets and N_0, N_1 to be their displayed* DyadicNormalForm$^{\uparrow}$ *readbacks;*
3. *common-scale exactness, requiring S to transport the two mantissa-exponent pairs to one finite unary scale before Δ is inspected;*
4. *classifier exactness, requiring Q to read only the sign of the displayed finite difference Δ;*
5. *window stability, requiring W, H, C to preserve the classifier under componentwise* hsame *transport and displayed* Cont *replay into larger common dyadic windows;*
6. *regular-rational handoff, requiring* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *consumers to read only the stable classifier and its dyadic source route;*
7. *ledger refusal, excluding host rational trichotomy, quotient rational equality, completed real order, located cuts, ambient completeness, and standard-bridge data.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1623.1. The projection exposes exactly the two dyadic source rows, the two normal-form rows, the common-scale row, the signed-difference row, the classifier row, the window-stability ledger, and the structural rows H, C, P, L.

Source compatibility follows from the attachments to chapter 291 and chapter 1613. The packet never compares hidden representatives: it first reads the accepted dyadic core rows and then reads their zero-normalized, scale-minimal normal forms.

Common-scale exactness is the row S. Once both normal forms are transported to that row, the signed difference Δ is a finite integer-rational readback, and the classifier Q can inspect only its displayed sign.

Replay C and then transport by H. This preserves the same source rows, normal forms, common scale, signed difference, and classifier before any StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, or Real$^{\uparrow}$ consumer can inspect the packet.

The exclusions are immediate from the carrier inventory. Since host trichotomy, quotient equality, completed real order, located cuts, ambient completeness, and bridge rows are absent, the local NameCert surface cannot export them. □

Theorem 1623.3 (Dyadic comparison window stability)**.** *Let $K = (D_0, D_1, N_0, N_1, S, \Delta, Q, W, H, C, P, L)$ be an accepted* $\mathsf{DyadicComparison}^{\uparrow}$ *carrier. If S' is a displayed common dyadic scale extending S and the two normal-form rows are replayed into S' through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{DyadicNormalForm}^{\uparrow}$ *route, then the comparison classifier read at S' agrees with Q under componentwise* hsame *transport. Thus enlarging the finite comparison window changes neither the negative, zero, nor positive outcome exposed by the local* $\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$ *row.*

Proof. Start with the accepted carrier and the larger displayed scale S'. The continuation row C supplies the route from D_0, D_1 through N_0, N_1 to the original common scale S, while the hypothesis supplies the same route into S'.

The normal-form rows are scale-minimal by chapter 1613. Transporting both rows from S to S' multiplies both displayed mantissas by the same visible power of 2, so the signed difference row is multiplied by that same positive dyadic factor.

The sign of the finite difference is therefore unchanged. The zero case remains zero, the negative case remains negative, and the positive case remains positive because no row in the route introduces a hidden quotient or host-level comparison principle.

Apply the window-stability ledger W and componentwise transport H. They identify the classifier read at S' with the original row Q, and the local naming row L exports exactly that stable classifier. □

Theorem 1623.4 (Dyadic comparison RegSeqRat handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicComparison}^{\uparrow}$ *packet factors through the finite route*

$$D_0, D_1 \longmapsto N_0, N_1 \longmapsto S, \Delta, Q \longmapsto W, H, C, P, L.$$

Consequently the regular rational and real-seal phases receive a stable dyadic comparison row, not a direct order on completed real names, not quotient stream equality, not a located-cut comparison, and not an ambient completeness witness.

Proof. Take a consumer in the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ phase. Carrier admission exposes the local comparison row only through the displayed dyadic sources D_0, D_1.

The route then passes through the normal-form rows N_0, N_1. This is the point where zero normalization and scale-minimality are fixed before any regular rational readback can use the comparison.

Next the consumer reads the common-scale row S, the signed-difference row Δ, and the classifier row Q. By Definition 1623.3, any larger finite window used by a regular rational tail request returns the same classifier under hsame transport.

Finally the rows W, H, C, P, L package the stable comparison for the downstream phase. The displayed route is finite and contains no coordinate for direct completed-real order, quotient stream equality, located-cut comparison, selected host limit, ambient completeness, or a standard bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicComparison}^{\uparrow}$ packet is generated from two dyadic source rows, their normal-form readbacks, a common-scale row, a signed-difference row, a comparison classifier, a window-stability ledger, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$, seed)

Scope closed: Definition 1623.1, Definition 1623.2, Definition 1623.3, and Definition 1623.4 seed the finite dyadic comparison surface feeding StreamName, RegSeqRat, and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host rational trichotomy, quotient rational equality, completed real order, located cuts, ambient completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, common-scale exactness, classifier exactness, window stability, RegSeqRat handoff, and ledger refusal proofs for BEDC.Derived.DyadicComparisonUp.

Chapter 1624

A Concrete Naming Certificate for $\mathsf{RealUniformStructure}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges constructive analysis, the $\mathsf{RealUniformStructure}^{\uparrow}$ packet names the uniformity induced by the displayed $\mathsf{Real}^{\uparrow}$ metric surface through finite metric-ball entourage requests. It sits between the endpoint and seal row of chapter 38, the distance witness row of chapter 57, the entourage discipline of chapter 339, and the completion-facing Cauchy-filter route of chapter 333. The chapter records the Real-induced uniform structure as a finite NameCert boundary; it does not assert completeness of $\mathsf{Real}^{\uparrow}$ or choose limits of Cauchy data.

Definition 1624.1 (Real uniform-structure carrier)**.** *A* $\mathsf{RealUniformStructure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and seal row whose named points supply the source of every ball request.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance witness row read from the Real metric surface before any entourage is generated.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row generated by positive dyadic radius requests around the displayed metric balls.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row for completion-facing consumers that read Cauchy data through the induced entourage surface.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger used by the metric-ball generator.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by Real and Cauchy-filter consumers.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
8. *H records componentwise* hsame *transport for the Real, metric, uniform, Cauchy-filter, dyadic, window, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Real endpoint request through distance, positive-radius selection, ball-entourage generation, Cauchy-filter compatibility, finite windows, and regular readback.*

10. *P is the* Pkg *provenance over* $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformStructure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, U, F, D, S, Q, H, C, P, N$. The carrier has no coordinate for quotient real equality, selected limits, trichotomy, countable choice, open-cover compactness, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureTasteGate single carrier alignment`

Theorem 1624.2 (Real uniform-structure NameCert obligations)**.** *For every accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *carrier $U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealUniformStructure}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Real endpoint and seal row, metric distance witness, uniform entourage row, Cauchy-filter compatibility row, dyadic radius ledger, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local naming row;*
2. *metric-ball entourage generation, requiring every entourage request in U to be generated from M by a positive dyadic radius read from D around endpoints displayed by R;*
3. *Cauchy-filter compatibility, requiring every completion-facing Cauchy-filter read in F to consume the induced entourage row U before inspecting stream windows or regular rational readbacks;*
4. *classifier transport, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the route R, M, D, U, F, S, Q;*
5. *ledger non-escape, requiring P and N to export no quotient real equality, selected limit, trichotomy, countable-choice selector, open-cover compactness, or ambient Real completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1624.1. The projection exposes exactly the Real endpoint and seal row, the metric distance witness, the generated uniform entourage row, the Cauchy-filter compatibility row, the dyadic radius ledger, the finite-window and readback rows, and the structural rows H, C, P, N.

Metric-ball entourage generation is forced by the displayed route. An entourage request must first read endpoints from R, then read the distance witness in M, and then choose a positive dyadic radius from D before it can be recorded in the uniform row U.

Cauchy-filter compatibility is downstream of the induced uniformity. The row F is available only as a consumer of U, and the finite observations S and Q are read after that uniform row has been displayed.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, and Cont replay in C repeats the same route R, M, D, U, F, S, Q for every accepted request.

Finally, provenance is exhausted by P and N. Since quotient real equality, selected limits, trichotomy, countable choice, open-cover compactness, and ambient Real completeness are not rows of U_{Real}, the local NameCert surface cannot export them. □

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier namecert obligations`

Theorem 1624.3 (Real metric uniformity handoff)**.** *Every completion-facing or Cauchy-filter consumer of an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *carrier reads the Real uniformity only through the displayed rows*

$\mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{UniformSpace}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Nam}$

Consequently the packet exports no quotient real equality, selected limit, trichotomy, countable-choice selector, open-cover compactness, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier metric uniformity handoff`

Proof. Begin with a completion-facing or Cauchy-filter consumer. Carrier admission gives the consumer access to the local packet only through $R, M, U, F, D, S, Q, H, C, P, N$.

The Real metric uniformity is therefore read through the displayed metric-ball route. The Real row R supplies endpoint names, the metric row M supplies distance evidence, the dyadic row D supplies positive radii, and the uniform row U records the generated entourage.

Any Cauchy-filter use is then a downstream read of F. The window row S and the regular rational row Q expose finite observations only after U and F have been replayed.

The remaining rows do not add mathematical primitives. The BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows transport, replay, source, and name the same finite route, so the packet has no separate place from which quotient real equality, selected limits, trichotomy, countable choice, open-cover compactness, or ambient Real completeness can be exported. □

Theorem 1624.4 (Real uniform-structure L10 finite-source gate)**.** *Every L10 consumer of an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *carrier must inspect the* $\mathsf{Real}^{\uparrow}$ *endpoint and seal row, the* $\mathsf{Met}^{\uparrow}$ *distance row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before any* $\mathsf{UniformSpace}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff is available. No quotient real equality, selected limit, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness row is exported by this gate.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier l10 gate`

Proof. Project the carrier rows of Definition 1624.1. An L10 consumer can see the packet only through $R, M, U, F, D, S, Q, H, C, P, N$.

The finite-source gate is the displayed order of inspection. The Real endpoint and seal row R supplies named endpoints, M supplies distance observations, D supplies positive dyadic radii, S supplies finite windows, and Q supplies regular rational readback.

Only after those rows have been displayed can the existing metric-uniformity route of Definition 1624.3 expose U or F. The NameCert obligations of Definition 1624.2 then force the same route through H, C, P, N.

Since quotient real equality, selected limits, open-cover compactness, and $\mathsf{Real}^{\uparrow}$ completeness are not carrier rows, the L10 gate has no coordinate from which to export them. □

Theorem 1624.5 (Real uniform-structure located-filter compatibility)**.** *Every* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *consumer of the Real-induced uniformity must read the* $\mathsf{Real}^{\uparrow}$ *endpoint row* R*, metric row* M*, dyadic radius ledger* D*, uniform entourage row* U*, Cauchy-filter row* F*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q*, and structural rows* H, C, P, N *before located-tail data is interpreted.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier located filter compatibility`

Proof. Project the carrier of Definition 1624.1. The Real-induced uniformity is available only through $R, M, U, F, D, S, Q, H, C, P, N$, so a located-filter consumer has no independent row from which to interpret located-tail data.

Use the NameCert obligations of Definition 1624.2. Metric-ball entourage generation forces the route through R, M, D, U, and Cauchy-filter compatibility forces the completion-facing filter row F to consume that entourage row before stream windows or rational readbacks are inspected.

Finally apply the L10 finite-source gate of Definition 1624.4. The rows S, Q, H, C, P, N preserve and name the same finite route, so a $\mathsf{LocatedCauchyFilter}^{\uparrow}$ consumer reads the Real-induced uniformity without receiving quotient real equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1624.6 (Real uniform-structure Cauchy-filter basis)**.** *Every accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet exports a* $\mathsf{CauchyFilter}^{\uparrow}$ *basis only through the* $\mathsf{Real}^{\uparrow}$ *endpoint and seal rows,* $\mathsf{Met}^{\uparrow}$ *distance witnesses, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radii, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The Cauchy-filter row is downstream of the metric-ball entourage row, and it cannot export quotient equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier cauchy filter basis`

Proof. Project the carrier of Definition 1624.1. The available coordinates are exactly $R, M, U, F, D, S, Q, H, C, P, N$, so a Cauchy-filter basis read starts from displayed Real endpoints, metric distance data, positive dyadic radii, stream windows, and regular rational readback.

Use the NameCert obligations of Definition 1624.2. They force every entourage request in U to be generated from the metric row M and positive dyadic radius ledger D around endpoints displayed by R.

The row F is therefore downstream of the metric-ball entourage row U. Its finite-window and regular-readback inspections pass through S and Q, while H, C, P, N transport, replay, source, and name the same route.

Since quotient equality, selected limits, and $\mathsf{Real}^{\uparrow}$ completeness are not rows of the carrier, the exported Cauchy-filter basis has no coordinate from which to supply them. □

Theorem 1624.7 (Real uniform-structure cofinal-refinement compatibility)**.** *Suppose an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet supplies its* $\mathsf{CauchyFilter}^{\uparrow}$ *route through a metric-ball entourage basis, and suppose an accepted* $\mathsf{FilterRefinement}^{\uparrow}$ *packet replaces that displayed basis by a cofinal refinement. Then every completion-facing Real-uniform consumer still reads through the same* $\mathsf{Real}^{\uparrow}$ *endpoint row,* $\mathsf{Met}^{\uparrow}$ *distance row, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger,* $\mathsf{CauchyFilter}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The refined route does not export quotient real equality, selected limits, countable choice, quotient filters, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier filter refinement compatibility`

Proof. Start with the Cauchy-filter basis of Definition 1624.6. It forces the Real-uniform route to expose the endpoint row R, metric row M, positive-radius ledger D, generated entourage row U, Cauchy-filter row F, finite windows, regular readbacks, and structural rows before any completion-facing consumer reads the basis.

Apply the Cauchy-preservation theorem for FilterRefinement$^{\uparrow}$, Definition 1626.2. The cofinal refinement replaces a displayed base request by a target-base request and a finite comparison row, while preserving the Cauchy route through the source basis.

Next use the completion route of Definition 1626.3. A completion-facing consumer receives only the refined finite base row, the cofinal refinement row, optional reverse comparison data when needed, and the transport, replay, provenance, and local naming rows.

Composing the two routes leaves the Real-uniform endpoint and metric data unchanged. The refinement acts on the displayed Cauchy-filter basis, so the consumer still reaches the same R, M, D, F, H, C, P, N surface and gains no coordinate for quotient real equality, selected limits, choice, quotient filters, or ambient completeness. □

Theorem 1624.8 (Real uniform-structure subbasis-completion handoff)**.** *Every completion-facing* RealUniformStructure$^{\uparrow}$ *consumer whose* CauchyFilter$^{\uparrow}$ *row is generated from an accepted* CauchyFilterSubbasis$^{\uparrow}$ *packet must read the* Real$^{\uparrow}$ *endpoint rows,* Met$^{\uparrow}$ *distance rows,* DyadicRatCore$^{\uparrow}$ *radius ledger, generated* UniformSpace$^{\uparrow}$ *entourage row, the* CauchyFilterSubbasis$^{\uparrow}$ *generated-base row,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, and the terminal* Real$^{\uparrow}$ *seal before any completion use. The handoff exports no quotient filters, selected limits, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureSubbasisCompletionHandoff`

Proof. Start with the Cauchy-filter basis theorem Definition 1624.6. It forces the Real-uniform consumer to read endpoint rows R, metric data M, positive-radius ledger D, generated entourage row U, Cauchy-filter row F, windows S, readback Q, and structural rows before a completion-facing basis is available.

Apply the cofinal-refinement compatibility of Definition 1624.7. Cofinal replacement of the displayed basis preserves the same Real endpoint, metric, radius, Cauchy-filter, transport, replay, provenance, and local naming surface.

Now use the CauchyFilterSubbasis$^{\uparrow}$ generated-base route, Definition 4232.4 and Definition 4232.6. These force the subbasis-generated filter to expose finite intersections, generated events, the generation ledger, and the generated FilterBase$^{\uparrow}$ row before the CauchyFilter, StreamName, DyadicRatCore, RegSeqRat, and Real seal rows are read.

Composing the Real-uniform route with the subbasis route leaves a single finite handoff: Real endpoints and metric distances generate entourages, the subbasis packet supplies the cofinal generated base, and the windows, rational readback, and Real seal are inspected before completion use.

Since neither packet carries quotient filters, selected limits, countable choice, host equality, or ambient Real completeness, the combined handoff cannot export those objects. □

Theorem 1624.9 (Real uniform-structure subbasis refinement envelope)**.** *Every completion-facing* RealUniformStructure$^{\uparrow}$ *consumer whose* CauchyFilter$^{\uparrow}$ *row is generated from a* CauchyFilterSubbasis$^{\uparrow}$ *packet and then replaced by a displayed* FilterRefinement$^{\uparrow}$ *row still factors through Real endpoints,* Met$^{\uparrow}$ *distance,* DyadicRatCore$^{\uparrow}$ *radius data,* UniformSpace$^{\uparrow}$ *entourage generation, generated finite subbasis base,* CauchyFilter$^{\uparrow}$ *row,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, and the terminal* Real$^{\uparrow}$ *seal. The envelope exports no quotient filters, selected limits, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier subbasis refinement envelope`

Proof. Start with the subbasis-completion handoff of Definition 1624.8. It forces the Real-uniform consumer to read Real endpoints, metric distances, dyadic radii, generated entourages, generated subbasis-base data, windows, readbacks, and the terminal Real seal before completion use.

Apply cofinal-refinement compatibility, Definition 1624.7. The displayed FilterRefinement$^{\uparrow}$ row may replace the generated base by a cofinal base request, but it preserves the same Real endpoint, metric, radius, Cauchy-filter, transport, replay, provenance, and local naming surface.

Now use the CauchyFilterSubbasis$^{\uparrow}$ route. The generated-base cofinality theorem Definition 4232.4 and the refinement stability theorem Definition 4232.6 keep finite subbasis tokens, finite intersections, generated events, the generation ledger, and the generated FilterBase$^{\uparrow}$ row visible before downstream Cauchy-filter and completion rows are read.

Composing these three routes leaves a single envelope through Real endpoints, Metric distance, DyadicRatCore radius data, UniformSpace entourages, generated finite subbasis bases, CauchyFilter rows, StreamName windows, RegSeqRat readbacks, and the Real seal. None of the displayed packets carries quotient filters, selected limits, countable-choice schedules, host real equality, or ambient Real completeness, so the envelope exports none of those objects. □

Theorem 1624.10 (Real uniform-structure finite-intersection subbasis)**.** *Any finite intersection of displayed* RealUniformStructure$^{\uparrow}$ *subbasis rows generated from an accepted* CauchyFilterSubbasis$^{\uparrow}$ *packet still factors through the same* Real$^{\uparrow}$ *endpoint row,* Met$^{\uparrow}$ *distance row, positive* DyadicRatCore$^{\uparrow}$ *radius ledger, generated* UniformSpace$^{\uparrow}$ *entourage row,* CauchyFilterSubbasis$^{\uparrow}$ *generated-base row,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The finite-intersection route exports no selected limits, quotient filters, open-cover compactness, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureFiniteIntersectionSubbasis`

Proof. Start with the subbasis-completion handoff of Definition 1624.8. It forces every completion-facing subbasis consumer to read the Real endpoints, metric distances, positive dyadic radius ledger, generated entourage row, generated-base row, finite windows, regular readbacks, and structural rows before completion use.

Apply the completion entourage basis theorem, Definition 1624.14. The Real-uniform basis route remains attached to the same endpoint, metric, positive-radius, generated-entourage, Cauchy-filter, window, readback, transport, replay, provenance, and local naming surface.

Now use the generated-base and cofinality rows of CauchyFilterSubbasis$^{\uparrow}$, namely Definition 4232.4 and Definition 4232.6. A finite intersection is read as a displayed generated-base event, not as a new filter quotient or selected completion object.

Composing the three routes leaves the same finite Real-uniform surface. Since none of the displayed packets contains selected limits, quotient filters, open-cover compactness, countable choice, host equality, or ambient Real completeness, the finite-intersection route cannot export those objects. □

Theorem 1624.11 (Real uniform-structure cover-read handoff)**.** *Every compact-uniform or finite-cover consumer of an accepted* RealUniformStructure$^{\uparrow}$ *packet must read the* Real$^{\uparrow}$ *endpoint row,* Met$^{\uparrow}$ *distance row, positive* DyadicRatCore$^{\uparrow}$ *radius ledger, generated* UniformSpace$^{\uparrow}$ *entourage row,* CauchyFilter$^{\uparrow}$ *compatibility row,* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *readbacks, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before it can hand data to* CompactUniformCoverRead$^{\uparrow}$ *or* UniformModulus$^{\uparrow}$*. The handoff exports no quotient real equality, selected limits, open-cover compactness, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCoverReadHandoff`

Proof. Project the carrier of Definition 1624.1. The compact-uniform consumer can see only the rows $R, M, U, F, D, S, Q, H, C, P, N$, so its cover read starts from named Real endpoints, metric distances, positive dyadic radii, generated entourages, Cauchy-filter compatibility, finite windows, and regular rational readbacks.

Apply the Cauchy-filter basis theorem Definition 1624.6. It places the Cauchy-filter row downstream of the metric-ball entourage row generated from R, M, D, and it keeps the window and readback rows S, Q attached to the same basis route.

Now use the cofinal-refinement compatibility of Definition 1624.7. A finite-cover consumer may refine the displayed basis, but the refinement remains attached to the same Real endpoint, metric, dyadic-radius, Cauchy-filter, and structural rows.

Therefore a $\mathsf{CompactUniformCoverRead}^{\uparrow}$ or $\mathsf{UniformModulus}^{\uparrow}$ handoff receives exactly the finite Real-uniform route already displayed by the packet. Since no carrier coordinate stores quotient real equality, selected limits, open-cover compactness, countable choice, or ambient Real completeness, none of those objects can be exported by the cover-read handoff. □

Theorem 1624.12 (RealUniformStructure basis refinement uniqueness)**.** *Any cofinal refinement accepted by the* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet must still factor through the same Real endpoint row, Metric distance row, positive DyadicRatCore radius ledger, generated UniformSpace entourage row, CauchyFilter row, StreamName windows, RegSeqRat readbacks, and structural rows. Thus a refined basis preserves the unique Real-induced basis route and exports no quotient real equality, selected limit, countable choice, quotient filter, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier basis refinement uniqueness`

Proof. Begin with the L10 finite-source gate of Definition 1624.4. It forces every Real-uniform consumer to inspect the Real endpoint row, Metric distance row, positive dyadic radius ledger, StreamName window row, and RegSeqRat readback before any UniformSpace or CauchyFilter handoff is available.

Apply the Cauchy-filter basis theorem Definition 1624.6. The CauchyFilter row is downstream of the generated metric-ball entourage row, and the structural rows transport, replay, source, and name that same route.

Now use the cofinal-refinement compatibility theorem Definition 1624.7. A cofinal refinement may replace the displayed basis request by a finite refined request, but it preserves the Real endpoint, metric, dyadic radius, CauchyFilter, and structural rows.

Combining the three routes leaves only one admitted Real-induced basis path:

$$R, M, D, U, F, S, Q \longmapsto H, C, P, N.$$

Since no carrier coordinate stores quotient real equality, selected limits, countable choice, quotient filters, open-cover compactness, or ambient Real completeness, no cofinal refinement can export those objects. □

Theorem 1624.13 (Real uniform-structure RealEquality filter boundary)**.** *Every completion-facing Cauchy-filter comparison over an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet must pass through the same* $\mathsf{Real}^{\uparrow}$ *endpoint row,* $\mathsf{Met}^{\uparrow}$ *distance row, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and then the* $\mathsf{RealEquality}^{\uparrow}$ *classifier boundary before any completion read is available. The route exports no quotient real equality, selected limit, countable-choice schedule, quotient filter, open-cover compactness, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureRealEqualityFilterBoundary`

Proof. Begin with the L10 finite-source gate of Definition 1624.4. It forces a Real-uniform consumer to inspect the Real endpoint row, Metric distance row, positive dyadic radius ledger, finite StreamName windows, and RegSeqRat readbacks before a uniform or filter-shaped read can occur.

Apply the Cauchy-filter basis theorem Definition 1624.6. The CauchyFilter row is downstream of the metric-ball entourage generated from the same Real endpoint, metric, and positive dyadic radius data.

Use the basis-refinement uniqueness theorem Definition 1624.12. Any completion-facing refinement keeps the same Real-induced basis route and cannot replace it by a quotient filter or a selected completion datum.

Finally apply the RealEquality classifier and NameCert boundary of Definition 1636.2 and Definition 1636.3. A Cauchy-filter comparison can read equality only through displayed finite windows, RegSeqRat readbacks, dyadic tolerance data, and the terminal Real boundary, so no hidden host equality or ambient completeness principle enters before the completion read. □

Theorem 1624.14 (Real uniform-structure completion entourage basis)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet reads an entourage basis only through the* $\mathsf{Real}^{\uparrow}$ *endpoint row, the* $\mathsf{Met}^{\uparrow}$ *distance row, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, the generated* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the structural rows* H, C, P, N*. The exported basis does not supply quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCompletionEntourageBasis`

Proof. Start with the NameCert obligations of Definition 1624.2. They admit exactly the rows $R, M, U, F, D, S, Q, H, C, P, N$, with every entourage request generated from Real endpoints, metric distance data, and a positive dyadic radius.

Apply the Cauchy-filter basis theorem Definition 1624.6. It places the $\mathsf{CauchyFilter}^{\uparrow}$ row downstream of the generated metric-ball entourage row and keeps the StreamName and RegSeqRat readbacks downstream of that same basis.

Finally use the cofinal-refinement compatibility of Definition 1624.7. A completion-facing consumer may replace a displayed basis by a cofinal finite refinement, but the route still reads through $R, M, D, U, F, S, Q, H, C, P, N$ and gains no coordinate for quotient real equality, selected limits, quotient filters, choice, open-cover compactness, or ambient Real completeness. □

Theorem 1624.15 (Real uniform-structure completion entourage subbasis)**.** *Every completion-facing subbasis request for an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet factors through the displayed Real endpoint row* R*, Metric row* M*, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger* D*, UniformSpace entourage row* U*, CauchyFilter row* F*, StreamName window row* S*, RegSeqRat readback row* Q*, and the structural rows* H, C, P, N *before any completion consumer reads it. Thus a subbasis request is only a finite entry point into the completion entourage basis; it cannot bypass the finite entourage basis, the positive-radius refinement route, or the Cauchy-filter basis rows.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCompletionEntourageSubbasis`

Proof. Start with the completion entourage basis theorem Definition 1624.14. It already orders every completion-facing entourage read through $R, M, D, U, F, S, Q, H, C, P, N$ before any completion consumer can inspect the basis.

Next apply the finite-entourage basis of Definition 1624.16. A subbasis request may name one generating metric-ball shape, but that shape is admitted only as a finite read of the same Real endpoint, metric, positive-radius, uniform, Cauchy-filter, window, readback, and structural rows.

Finally use the positive-radius entourage refinement of Definition 1624.17. Refining a subbasis request can narrow the positive radius in D, but it cannot add quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Therefore every completion-facing subbasis read remains a finite entrance to the displayed entourage and Cauchy-filter basis route. □

Theorem 1624.16 (Real uniform-structure finite entourage basis)**.** *Every accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet generates its entourage basis from finite reads of the* $\mathsf{Real}^{\uparrow}$ *endpoint row R, the* $\mathsf{Met}^{\uparrow}$ *distance row M, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger D, the generated* $\mathsf{UniformSpace}^{\uparrow}$ *row U, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and the structural rows H, C, P, N. A completion-facing or Real-uniform consumer receives no basis element outside those displayed rows.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureFiniteEntourageBasis`

Proof. Start with the NameCert obligations of Definition 1624.2. They admit exactly the Real endpoint, metric distance, positive radius, uniform entourage, Cauchy-filter, finite-window, readback, transport, replay, provenance, and local naming rows.

Apply the metric-uniformity handoff of Definition 1624.3. It forces every entourage request to read endpoints from R, distance data from M, and a positive dyadic radius from D before the generated uniform row U is public.

Use the Cauchy-filter basis theorem Definition 1624.6. The row F is downstream of the metric-ball entourage row, while S and Q provide only finite windows and regular rational readbacks for that same basis.

Finally compose with the completion-entourage basis of Definition 1624.14. Completion-facing consumers may inspect the displayed basis, but the structural rows H, C, P, N only transport, replay, source, and name it. Thus no basis element is generated outside $R, M, D, U, F, S, Q, H, C, P, N$. □

Theorem 1624.17 (Real uniform-structure positive-radius entourage refinement)**.** *When an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet exposes two positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius rows in the same D ledger and the second is displayed as a refinement of the first, every refined entourage read still factors through the same* $\mathsf{Real}^{\uparrow}$ *endpoint row,* $\mathsf{Met}^{\uparrow}$ *distance row,* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row,* $\mathsf{CauchyFilter}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and structural rows. The refined request may narrow the finite metric-ball basis but cannot add quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructurePositiveRadiusEntourageRefinement`

Proof. Start with the NameCert obligations of Definition 1624.2. Both positive radii are read from the same D ledger, so the refinement remains attached to the displayed Real endpoint and Metric distance rows.

Apply the metric-uniformity handoff of Definition 1624.3. It sends the refined positive-radius request to the generated entourage row U without changing the endpoint row R or the distance row M.

Use the Cauchy-filter basis theorem Definition 1624.6 and the finite-entourage basis of Definition 1624.16. The refined request may narrow the finite metric-ball basis, but it remains downstream of $R, M, D, U, F, S, Q, H, C, P, N$.

Since none of those rows stores quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient Real completeness, no positive-radius refinement can export those objects. □

Definition 1624.18 (Real uniform-structure entourage shrink row)**.** *For an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet* $U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N)$*, an entourage-shrink row is a finite* BHist *entry*

$$\mathrm{shrink}(r, r', W)$$

read from the same positive-radius ledger D*, where* r *is the displayed positive Real uniform entourage radius,* r' *is a smaller positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *radius row, and* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window on which the metric-ball request is inspected. The row is admitted only when the generated entourage for* r' *is recorded in the same* $\mathsf{UniformSpace}^{\uparrow}$ *row* U *and is replayed through the same* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row* F*.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureEntourageShrink route closure`

Theorem 1624.19 (Real uniform-structure entourage shrink stability)**.** *Let* $U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N$ *and* $U'_{\mathsf{Real}} = (R', M', U', F', D', S', Q', H', C', P', N')$ *be accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packets. If an entourage-shrink row* $\mathrm{shrink}(r, r', W)$ *is displayed for* U_{Real} *and the endpoint, metric, radius-ledger, entourage, Cauchy-filter, finite-window, and readback rows transport componentwise under* hsame*, then the transported packet admits the corresponding shrink row through* D', U', F', S', Q' *and the same metric-uniformity handoff. The shrink cannot add quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the shrink row of Definition 1624.18. Its data are only the displayed positive radius r, the smaller dyadic or regular-rational radius r', and the finite window W read through D, S, Q before the generated entourage is recorded in U.

Transport the displayed rows componentwise under hsame. The transported radius ledger D' carries the smaller positive radius row, while S' and Q' carry the finite inspection window and readback. The displayed Cont replay through C' keeps the shrink request downstream of the same endpoint and metric rows.

Finally apply the metric-uniformity handoff of Definition 1624.3 together with the positive-radius refinement of Definition 1624.17. These force the transported shrink to land in U' and to remain compatible with F'. Since the carrier still has no coordinate for quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient Real completeness, the transported shrink exports none of those objects. □

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureEntourageShrinkStability`

Theorem 1624.20 (Real uniform-structure Cauchy-entourage shrink induction)**.** *Let* $U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N)$ *be an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet, and suppose a finite chain of entourage-shrink rows is displayed from the same positive-radius ledger* D*. Then iterated shrink rows preserve the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis* F*, the positive-radius entourage refinement through* D *and* U*, and the completion-entourage basis before any Real completion consumer reads a limit-shaped claim.*

The induction exports no quotient real equality, selected limits, quotient filters, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier cauchy entourage shrink induction`

Proof. Project the shrink definition of Definition 1624.18. Each shrink row is a finite read of a displayed positive radius, a smaller dyadic or regular-rational radius, and a finite StreamName window before the generated entourage is recorded in U and replayed through F.

Use shrink stability, Definition 1624.19, for the induction step. Transporting one shrink row preserves the endpoint, metric, radius-ledger, entourage, Cauchy-filter, finite-window, and readback rows componentwise.

Now apply the finite-entourage basis of Definition 1624.16 and the completion-entourage basis of Definition 1624.14. These keep every later entourage inside the same route through $R, M, D, U, F, S, Q, H, C, P, N$.

Induction over the finite shrink chain therefore preserves the Cauchy-filter basis, the positive-radius refinement, and the completion-entourage basis together. Since the carrier contains no quotient real equality, selected limit, quotient filter, choice schedule, open-cover compactness, or ambient Real-completeness coordinate, no limit-shaped completion claim can be read before those displayed rows are visible. □

Theorem 1624.21 (Real uniform-structure located Cauchy-filter handoff)**.** *Every* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *packet must read the* $\mathsf{Real}^{\uparrow}$ *endpoint row, the* $\mathsf{Met}^{\uparrow}$ *row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the structural rows* H, C, P, N *before any located-tail interpretation is available. The handoff exports no quotient filter, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier located cauchy filter handoff`

Proof. Start with the Cauchy-filter basis theorem Definition 1624.6. It places every filter-facing read downstream of the Real endpoint row, Metric row, positive dyadic radius ledger, generated entourage row, CauchyFilter row, StreamName windows, RegSeqRat readback, and the structural rows.

Apply the L10 finite-source gate Definition 1624.4. A located-tail consumer cannot inspect a tail predicate before the Real endpoint, metric distance, radius ledger, finite window, and regular readback rows have been displayed.

Finally use the positive-radius refinement route Definition 1624.17. Refining the entourage radius preserves the same $R, M, D, U, F, S, Q, H, C, P, N$ surface and adds no quotient filter, selected limit, choice schedule, host equality, or ambient completeness coordinate. Thus located-tail interpretation is a consumer of the displayed Real-uniform packet, not an independent completion principle. □

Theorem 1624.22 (Real uniform-structure obligation-closure package)**.** *For every accepted* $\mathsf{RealUniformStructure}^{\uparrow}$ *carrier*

$$U_{\mathsf{Real}} = (R, M, U, F, D, S, Q, H, C, P, N),$$

the displayed finite rows close carrier admission, metric-ball entourage generation, Cauchy-filter compatibility, classifier transport, and ledger non-escape for the Real-induced uniformity boundary. Every completion-facing, located-filter, or L10 consumer reads the packet through the same $R, M, U, F, D, S, Q, H, C, P, N$ *surface, and no quotient real equality, selected limit, countable-choice schedule, open-cover compactness, quotient filter, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row is exported.*

Lean4 ✓ `BEDC.Derived.RealUniformStructureUp.RealUniformStructureCarrier obligation closure package`

Proof. Carrier admission is the carrier definition, Definition 1624.1. It exposes exactly the Real endpoint row, Metric row, generated UniformSpace row, CauchyFilter row, DyadicRatCore radius ledger, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local naming rows.

Metric-ball entourage generation and the L10 inspection order are already fixed by Definition 1624.2, Definition 1624.3, and Definition 1624.4.

Together these theorems force every entourage request to pass through R, M, D, U and every finite-source consumer to display R, M, D, S, Q before using U or F.

Cauchy-filter compatibility is supplied by Definition 1624.6 and Definition 1624.21. These theorems place every Cauchy or located-tail read downstream of the same generated entourage surface and keep the finite window and readback rows visible.

Finally, classifier transport and ledger non-escape are the structural part of the same carrier. The rows H, C, P, N transport, replay, source, and name only the displayed route.

The packet therefore has no coordinate from which quotient real equality, selected limits, countable choice, open-cover compactness, quotient filters, or ambient Real completeness can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformStructure}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformStructure}^{\uparrow}$ packet is generated from a RealUp endpoint and seal row, a MetricUp distance witness row, a UniformSpace entourage row generated by positive DyadicRatCore radius requests, a CauchyFilter compatibility row, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformStructure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1624.1, Definition 1624.2, and Definition 1624.3 seed the Real-induced uniformity boundary for completion-facing and Cauchy-filter consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealUniformStructure}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RealUniformStructureUp`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, countable-choice selectors, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires carrier admission, metric-ball entourage generation, Cauchy-filter compatibility, classifier transport, and ledger non-escape proofs for the same packet.

Chapter 1625

A Concrete Naming Certificate for $\mathsf{RealIntervalEnclosure}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealIntervalEnclosure}^{\uparrow}$ packet names finite lower and upper rational or dyadic windows around a $\mathsf{Real}^{\uparrow}$ name. It sits after the dyadic finite arithmetic surface of chapter 291, the finite observation gateway of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the endpoint-ledger interface of chapter 394. The packet records an enclosure read for one real name through displayed finite windows; it is not a host interval, quotient real equality, trichotomy, a selected endpoint pair, or a completeness principle.

Definition 1625.1 (Real interval enclosure carrier)**.** *A* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, S, Q, D, L, U, A, W, H, C, P, N)$$

with the following displayed rows:

1. *R is the accepted* $\mathsf{Real}^{\uparrow}$ *name whose finite enclosure is being read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row specifying the finite observations of the real name used by the packet.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose dyadic radius bounds the displayed readback error.*
5. *L and U are the lower and upper rational or dyadic bound rows displayed in the packet.*
6. *A is the admission row saying that the readback Q and tolerance D place the inspected real-name window between L and U.*
7. *W is the window-stability ledger, recording that later finite windows refine the same enclosure route instead of replacing it by a host endpoint choice.*
8. *H records componentwise* hsame *transport for the real name, stream window, regular readback, dyadic tolerance, lower bound, upper bound, admission row, stability ledger, continuation row, provenance row, and local naming row.*
9. *C records the displayed* Cont *replay from the real-name seal through the finite window, regular readback, dyadic tolerance, bound rows, admission row, and stability ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalEnclosure}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite enclosure packet. It has no coordinate for host interval endpoints, quotient real equality, trichotomy, a selected limit value, open-cover compactness, Heine–Borel compactness, or Real completeness.

Theorem 1625.2 (Real interval enclosure NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *carrier $E = (R, S, Q, D, L, U, A, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealIntervalEnclosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real-name seal, stream window, regular rational readback, dyadic tolerance, lower bound, upper bound, admission, stability, transport, continuation, provenance, and local naming rows;*
2. *source compatibility, requiring S, Q, D to be read through the same* $\mathsf{Real}^{\uparrow}$ *route named by R;*
3. *bound admissibility, requiring L and U to be displayed rational or dyadic rows rather than selected host endpoint values;*
4. *enclosure exactness, requiring A to witness that the inspected regular-rational window with tolerance D lies between L and U;*
5. *window stability, requiring W, H, C to preserve the enclosure under componentwise transport and later finite-window replay;*
6. *located-interval handoff, allowing a* $\mathsf{LocatedInterval}^{\uparrow}$ *consumer to read only the displayed bound rows and the same real-name window route;*
7. *ledger refusal, excluding Heine–Borel compactness, open-cover compactness, trichotomy, quotient real equality, selected limits, host endpoint values, and Real completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1625.1. The projection exposes exactly the real-name seal, stream window, regular-rational readback, dyadic tolerance, lower and upper bound rows, admission row, stability ledger, and structural rows H, C, P, N.

Source compatibility follows by reading S, Q, D through the sibling route of chapter 126, chapter 301, and chapter 291. Since all three rows are attached to the same R, no second real-name route is available.

Bound admissibility and enclosure exactness are the rows L, U, A. The lower and upper rows are displayed rational or dyadic data, and A binds them to the inspected readback and tolerance window rather than to host endpoint values.

Replay C and transport by H. The replay preserves the same finite route into later windows, while W records that those later windows refine the displayed enclosure service. A $\mathsf{LocatedInterval}^{\uparrow}$ consumer therefore receives the same lower and upper rows through the same finite route.

The exclusions are immediate from the carrier inventory. The packet contains no row for Heine–Borel compactness, open-cover compactness, trichotomy, quotient real equality, selected limits, host endpoint values, Real completeness, or a standard bridge. □

Theorem 1625.3 (Real interval enclosure RegSeqRat window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{LocatedInterval}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *carrier factors through the finite*

route

$$R \longmapsto S \longmapsto Q, D \longmapsto L, U, A \longmapsto W, H, C, P, N.$$

Consequently the consumer receives a finite enclosure row around a real-name window, not a direct host interval, not quotient equality of real names, not trichotomy, not selected endpoint values, and not a completeness witness.

Proof. Start with an accepted carrier $E = (R, S, Q, D, L, U, A, W, H, C, P, N)$. The only terminal real-name coordinate is R, and the only finite observation coordinate attached to it is the stream window S.

The regular-rational readback Q and dyadic tolerance row D are then read from that same window. Thus any regular-rational consumer reaches the bound rows only after passing through the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route.

The lower and upper rows L, U are admitted through A. A $\mathsf{LocatedInterval}^{\uparrow}$ consumer may use them as displayed interval data, but only together with the same admission row and the same real-name source route.

Finally W, H, C, P, N package the handoff. Stability, transport, continuation replay, provenance, and local naming keep the consumer inside the finite packet, so no host interval, quotient real equality, trichotomy, selected endpoint value, completeness theorem, or bridge row can be inserted into the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalEnclosure}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalEnclosure}^{\uparrow}$ packet is generated from a real-name seal, stream window, regular rational readback, dyadic tolerance, displayed lower and upper rational or dyadic bounds, an enclosure admission row, a window-stability ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealIntervalEnclosure}^{\uparrow}}$, seed)

Scope closed: Definition 1625.1, Definition 1625.2, and Definition 1625.3 seed the finite interval-enclosure surface around Real, StreamName, RegSeqRat, DyadicRatCore, and LocatedInterval consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealIntervalEnclosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, open-cover compactness, trichotomy, quotient real equality, selected limits, host endpoint values, Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, bound admissibility, enclosure exactness, window stability, located-interval handoff, and ledger refusal proofs for BEDC.Derived.RealIntervalEnclosureUp.

Chapter 1626

A Concrete Naming Certificate for $\mathsf{FilterRefinement}^{\uparrow}$

Following Kelley and Bourbaki on finer filters, cofinal subfilters, and refinement of directed bases, the $\mathsf{FilterRefinement}^{\uparrow}$ packet names the finite L10 bridge by which a completion route replaces one displayed filter base by a cofinal refinement. It sits after the finite base surface of chapter 1601, refines the Cauchy-filter route of chapter 333, and keeps the completion-facing consumers of chapter 1473, chapter 1506, and chapter 1569 on the displayed finite route. The packet records cofinal comparison rows only; it is not a quotient filter, not an ultrafilter, not a selected limit, not countable choice, and not an ambient completeness principle.

The same cofinal replacement row is consumed horizontally by the Real-induced uniformity route of chapter 1624 and by the generated-base route of chapter 4232. A $\mathsf{RealUniformStructure}^{\uparrow}$ packet and a $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ consumer both read the displayed $\mathsf{FilterRefinement}^{\uparrow}$ source, target, refinement, and finite generated-base rows before any completion-facing route sees the replacement basis.

Definition 1626.1 (FilterRefinement NameCert surface)**.** *A* $\mathsf{FilterRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, \rho, \lambda, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{FilterBase}^{\uparrow}$ *row naming the base packets through which the original* $\mathsf{CauchyFilter}^{\uparrow}$ *or completion-facing route is read.*
2. *T is the target* $\mathsf{FilterBase}^{\uparrow}$ *row naming the refined base packets that will be exposed to downstream consumers.*
3. *ρ is the cofinal refinement map. For each displayed target base packet it names a source base packet and the containment read from the target packet into that source packet.*
4. *λ is the reverse comparison ledger when present. It records the displayed return comparisons needed for equivalence of two routes, but the carrier may leave this row empty when only one-way refinement is asserted.*
5. *H records componentwise* hsame *transport for the source base, target base, cofinal refinement map, optional reverse ledger, continuation rows, provenance row, and local naming row.*
6. *C records displayed* Cont *replay from an original base request through the cofinal refinement map and, when present, through the reverse comparison ledger.*

7. *P is the* Pkg *provenance over* $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

8. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, \rho, \lambda, H, C, P, N$. There is no coordinate for quotient filters, ultrafilters, selected limits, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementTasteGate single carrier alignment`

Theorem 1626.2 (FilterRefinement Cauchy preservation)**.** *Let $R = (S, T, \rho, \lambda, H, C, P, N)$ be an accepted* $\mathsf{FilterRefinement}^{\uparrow}$ *carrier. If a* $\mathsf{CauchyFilter}^{\uparrow}$ *route is Cauchy through the displayed source base row S, then the route obtained by replaying every base request through the cofinal refinement map ρ is Cauchy through the displayed target base row T.*

The preserved Cauchy route uses only the finite refinement display

$$T \xrightarrow{\rho} S \longmapsto H, C, P, N.$$

It does not use a quotient filter, ultrafilter, selected limit, countable-choice selector, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinement cauchy preservation`

Proof. Project the accepted carrier of Definition 1626.1. The source and target bases are displayed $\mathsf{FilterBase}^{\uparrow}$ rows, and the cofinal map ρ is a finite row of the same packet.

Start with a Cauchy request on the refined route. The target base packet requested from T is sent by ρ to a source base packet in S, together with the displayed containment read from the refined packet into the source packet.

Apply the Cauchy evidence already available on the source route. Because the source route is Cauchy through S, every precision or late-window request is discharged by a displayed source base packet and its $\mathsf{CauchyFilter}^{\uparrow}$ evidence.

Replay the result along the containment read recorded by ρ. The componentwise hsame row H transports the visible base, refinement, continuation, provenance, and naming coordinates, while the Cont row C replays the request through the displayed target packet.

Thus every refined request is answered by a finite target-row request followed by the finite source-row Cauchy witness. No excluded filter, limit, choice, or completeness coordinate is available in the carrier, so Cauchy preservation remains internal to S, T, ρ, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCauchyPreservation`

Theorem 1626.3 (FilterRefinement completion route)**.** *Let $R = (S, T, \rho, \lambda, H, C, P, N)$ be an accepted* $\mathsf{FilterRefinement}^{\uparrow}$ *carrier. Every* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer that receives the refined route sees only the finite target base row T, the cofinal refinement row ρ, the optional reverse comparison ledger λ when finite route equivalence is required, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FilterRefinement}^{\uparrow}}$ *row.*

Equivalently, completion-facing reads factor through

$$S \xleftarrow{\rho} T \longmapsto \lambda, H, C, P, N,$$

with λ omitted for one-way refinement claims. When present, λ records only the finite return comparisons needed to identify the displayed source and target routes; it is not quotient-filter equality, an ultrafilter row, a limit selector, a selected completion point, countable choice, host equality, or ambient completeness.

Proof. Begin with a completion-facing consumer. Its route is required to read the refined base row T before it can inspect Cauchy-filter or completion data, so the first public object is a displayed finite $\mathsf{FilterBase}^{\uparrow}$ row.

The row ρ supplies the only mandatory comparison back to the source route. When a consumer must compare the refined route with the original route, it reads the optional ledger λ as a finite list of return comparisons for route equivalence; otherwise the one-way cofinal refinement row is the entire comparison surface.

Transport and replay do not enlarge the route. The row H moves the listed coordinates componentwise, and C replays base requests through the same displayed refinement rows. The provenance row P names the allowed completion consumers, while N names the local certificate surface.

Consequently $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumers receive a finite refinement route and no hidden completion object. Quotient-filter equality, ultrafilter data, selected completion points, limit selectors, countable-choice selectors, host equality, and ambient completeness are not coordinates of R, and S, T, ρ, H, C, P, N remain the only mandatory route rows. □

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCompletionRoute`

Theorem 1626.4 (FilterRefinement reverse-ledger comparison)**.** *Let $R = (S, T, \rho, \lambda, H, C, P, N)$ be an accepted* $\mathsf{FilterRefinement}^{\uparrow}$ *carrier. When λ is present, it supplies only finite return comparisons from the source route back to the target route. Thus source and target completion-facing reads may be compared through $S, T, \rho, \lambda, H, C, P, N$ without quotient-filter equality, ultrafilter data, selected limits, countable choice, host equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCarrier reverse ledger comparison`

Proof. Project the carrier surface of Definition 1626.1. The rows S and T are displayed filter-base rows, ρ is the cofinal refinement map, and λ is explicitly the optional reverse comparison ledger.

Use the completion route theorem Definition 1626.3. It identifies λ as route-equivalence data read only when a finite comparison between the source and target completion-facing routes is required.

Apply Cauchy preservation and the Cauchy-basis consumer, Definition 1626.2 and Definition 1626.6. Both directions remain inside displayed $\mathsf{FilterBase}^{\uparrow}$ and $\mathsf{CauchyFilterBase}^{\uparrow}$ rows, while H, C, P, N transport, replay, source, and name the same finite packet. No quotient filter, ultrafilter, selected limit, choice schedule, host equality, or ambient completeness row is available to the comparison. □

Theorem 1626.5 (FilterRefinement Cauchy base dependency)**.** *Every refinement accepted by* $\mathsf{FilterRefinement}^{\uparrow}$ *consumes the finite Cauchy filter base carrier of chapter 1915 before it may replay completion-facing cofinality. The refined route therefore exposes a* $\mathsf{CauchyFilterBase}^{\uparrow}$ *basis row, a cofinal comparison through ρ, and the same transport, replay, provenance, and local naming rows H, C, P, N before any* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer reads the refinement.*

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCarrier cauchy base dependency`

Proof. Start from the accepted carrier $R = (S, T, \rho, \lambda, H, C, P, N)$ of Definition 1626.1. The source and target rows are displayed filter-base rows, so a completion-facing refinement can only be consumed after the relevant Cauchy-filter base has been exposed.

Use the Cauchy-base carrier of chapter 1915 as the finite basis row read by the Cauchy route. The cofinal map ρ then sends target-base requests back to the source Cauchy base, while H and C transport and replay the same finite comparison.

Finally apply Definition 1626.3. It permits completion consumers to read only $T, \rho, \lambda, H, C, P, N$, so the Cauchy-base dependency is a displayed prerequisite for cofinality replay rather than a quotient filter, selected limit, countable-choice selector, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCauchyBaseDependency`

Theorem 1626.6 (FilterRefinement Cauchy-basis consumer)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer using a* $\mathsf{FilterRefinement}^{\uparrow}$ *route must first expose the* $\mathsf{FilterBase}^{\uparrow}$ *row* S*, the* $\mathsf{CauchyFilterBase}^{\uparrow}$ *row supporting the Cauchy route, and the cofinal comparison row* ρ *before any completion-facing read. The consumer then factors through the same transport, replay, provenance, and local naming rows* H, C, P, N*, with the optional return ledger* λ *read only when finite route equivalence is required.*

Lean4 ✓ `BEDC.Derived.FilterRefinementUp.FilterRefinementCauchyBasisConsumer`

Proof. Project the carrier $R = (S, T, \rho, \lambda, H, C, P, N)$ from Definition 1626.1. The source row S and target row T are displayed $\mathsf{FilterBase}^{\uparrow}$ rows, and ρ is the only mandatory cofinal comparison between them.

Use the Cauchy-base dependency theorem Definition 1626.5. It forces the Cauchy-filter route to expose its $\mathsf{CauchyFilterBase}^{\uparrow}$ basis before cofinality replay can be consumed.

Finally apply the completion route theorem Definition 1626.3. Completion-facing consumers therefore see the basis rows and ρ before they read any $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ boundary, and the structural rows H, C, P, N add no quotient filter, selected limit, countable choice, host equality, or ambient completeness coordinate. □

The completion-route theorem is read as a sibling dependency rule: a $\mathsf{FilterRefinement}^{\uparrow}$ packet consumes the $\mathsf{FilterBase}^{\uparrow}$ carrier of chapter 1601 and the $\mathsf{CauchyFilter}^{\uparrow}$ route of chapter 333 before any $\mathsf{UniformCompletion}^{\uparrow}$ consumer from chapter 1473, $\mathsf{MetricCompletion}^{\uparrow}$ consumer, or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumer may read the refined route.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1626.1, Definition 1626.2, and Definition 1626.3 seed the finite filter-refinement bridge for Cauchy-filter and completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, ultrafilters, selected limits, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal refinement coverage, optional reverse comparison compatibility, Cauchy preservation, completion-route exposure, and ledger-refusal proofs for BEDC.Derived.FilterRefinementUp.

Constructive story: A $\mathsf{FilterRefinement}^{\uparrow}$ packet is generated from source and target FilterBase rows, a cofinal refinement map, an optional reverse comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1627

A Concrete Naming Certificate for $\mathsf{LocatednessModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatednessModulus}^{\uparrow}$ packet names the finite budget by which a positive rational tolerance request is turned into displayed interval and real-name window data. It sits between the endpoint surface of chapter 394, the rational-cell ledger of chapter 354, the dyadic tolerance rows of chapter 291, the finite observation gateway of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The locatedness-modulus budget is consumed by chapter 1646 as the locatedness request row in the Real metric bracket route. The packet records an explicit locatedness service for constructive Real completion; it is not a host trichotomy, quotient real equality, selected endpoint functional, or ambient completeness theorem.

Definition 1627.1 (Locatedness modulus carrier)**.** *A* $\mathsf{LocatednessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (q, L, I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *q is the positive rational tolerance request supplied to the locatedness service.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint surface whose lower and upper endpoint rows are inspected under that request.*
3. *I is the finite* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger that records the rational windows admitted for the requested tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *or dyadic-interval refinement ledger that records the dyadic rows used to tighten the rational cells.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the endpoint names and the real-name route at precision q.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected stream window.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the readback and refinement budget have been displayed.*
8. *H records componentwise* hsame *transport for the tolerance request, located interval, rational cells, dyadic refinements, stream windows, readbacks, real-seal rows, continuation routes, provenance rows, and local naming row.*

9. *C records the displayed* Cont *replay from the tolerance request through the located interval, rational cells, dyadic refinement ledger, stream window, regular readback, and real-name seal.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatednessModulus}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite locatedness-budget packet. It has no coordinate for a host order trichotomy, quotient real equality, selected endpoints, a global apartness oracle, or ambient Real completeness.

Theorem 1627.2 (Locatedness modulus NameCert obligations)**.** *For every accepted* $\mathsf{LocatednessModulus}^{\uparrow}$ *carrier $M = (q, L, I, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatednessModulus}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission, requiring the displayed tolerance request, located interval, rational-cell ledger, dyadic refinement rows, stream windows, regular readbacks, real-seal rows, transport, continuation, provenance, and local naming data to inhabit one* BHist *packet;*

2. *tolerance-cell compatibility, requiring every rational cell in I to be admitted for the request q and for the endpoint surface L;*

3. *dyadic refinement stability, requiring every dyadic row in D to refine a displayed rational cell rather than replace it by a host endpoint choice;*

4. *window transport, requiring S, R, E, H, C to preserve the same tolerance request through finite endpoint windows and real-seal readbacks;*

5. *non-escape, excluding host trichotomy, quotient real equality, selected endpoints, global apartness choice, and ambient completeness from the exported certificate.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.TasteGate.LocatednessModulusTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.LocatednessModulusTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1627.1. The projection exposes exactly the tolerance request, located interval, rational cells, dyadic refinements, stream windows, readbacks, real-seal row, and structural rows H, C, P, N.

Carrier admission is the finite tuple M itself. Tolerance-cell compatibility is the assertion that the rational cells in I are displayed as the cells admitted for q and for the endpoint surface L.

Dyadic refinement stability reads the rows of D only through the rational cells in I. Thus a dyadic refinement tightens the displayed finite budget and cannot introduce a selected host endpoint.

Window transport is supplied by S, R, E, H, C. The stream window, regular readback, and real-seal replay preserve the same request route through componentwise transport.

The exclusions follow from the carrier inventory. Since M contains no coordinate for host trichotomy, quotient real equality, selected endpoints, a global apartness choice, or Real completeness, none can be exported by the local certificate. □

Theorem 1627.3 (Locatedness modulus window transport)**.** *Every finite consumer of an accepted* $\mathsf{LocatednessModulus}^{\uparrow}$ *carrier transports the tolerance request and endpoint windows through the route*

$$q \longmapsto L \longmapsto I, D \longmapsto S, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently a $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the same requested tolerance together with its finite endpoint-window route, not a new host comparison of completed real values.*

Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.LocatednessModulusCarrier window transport`

Proof. Start with an accepted carrier $M = (q, L, I, D, S, R, E, H, C, P, N)$. The only tolerance coordinate is q, and the only interval coordinate attached to it is the displayed $\mathsf{LocatedInterval}^{\uparrow}$ surface L.

The rational cells I and dyadic refinements D are then read as the finite response to that request. Their transport keeps each cell and refinement attached to q and L because no other request or interval row is present.

The stream window S and regular readback R inspect the endpoint data through that same route. The real-seal row E is reached only after those finite observations have been displayed.

Finally H, C, P, N package the transport. Componentwise hsame, continuation replay, provenance, and local naming keep the consumer inside the requested finite budget, so no host comparison of completed real values can be inserted. □

Theorem 1627.4 (Locatedness modulus Real-seal non-escape)**.** *For every accepted* $\mathsf{LocatednessModulus}^{\uparrow}$ *carrier* $M = (q, L, I, D, S, R, E, H, C, P, N)$*, every Real-facing read factors through the displayed tolerance request, located interval surface, rational-cell ledger, dyadic refinement rows, stream window, regular readback, real-seal row, transport row, continuation row, provenance row, and local naming row. It cannot export host trichotomy, quotient real equality, selected endpoints, a global apartness oracle, or ambient completeness.*

Proof. Read the Real-facing part of Definition 1627.1. The only real-name boundary is the seal row E, and it is preceded by the finite window S, readback R, dyadic refinement ledger D, rational cells I, located interval surface L, and tolerance request q.

Transport does not add a second Real-facing source. The componentwise rows H and displayed replay C move the same listed data through the same packet, while P and N record the package and local certificate provenance.

It remains to rule out non-displayed Real data. The carrier has no field for host trichotomy, quotient real equality, selected endpoints, a global apartness oracle, or ambient completeness; every Real-facing read is therefore a projection from M. □

Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.LocatednessModulusCarrier real seal non escape`

Theorem 1627.5 (Locatedness modulus window decision budget)**.** *For every accepted* $\mathsf{LocatednessModulus}^{\uparrow}$ *carrier* $M = (q, L, I, D, S, R, E, H, C, P, N)$*, a locatedness request at tolerance* q *is discharged only by the displayed route through* $L, I, D, S, R, E, H, C, P, N$*. Every rational-cell decision reads the dyadic refinement ledger* D *before the* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and every Real-facing output is sealed only after that budget is displayed. The route exports no host trichotomy, selected endpoints, quotient real equality, global apartness choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.LocatednessModulusObligationWindowDecisionBudget`

Proof. Project the carrier of Definition 1627.1. The tolerance request q is attached to the located interval L, rational-cell ledger I, dyadic refinement ledger D, StreamName window S, RegSeqRat readback R, Real seal E, and structural rows H, C, P, N.

Apply Definition 1627.3. It routes the request through L, then through the rational cells and dyadic refinements, and only then through S, R, E, H, C, P, N. Thus a rational-cell decision cannot bypass the displayed dyadic budget before the StreamName and RegSeqRat handoff.

Now apply Definition 1627.4. The Real-facing read factors through the same finite budget and reaches the seal row E only after the request, interval, cells, refinements, stream window, and readback are displayed.

The carrier has no coordinate for host trichotomy, selected endpoints, quotient real equality, global apartness choice, or ambient Real completeness. Therefore the locatedness request is discharged exactly by the displayed window decision budget and exports none of the excluded data. □

Theorem 1627.6 (Locatedness modulus public export)**.** *Every Real or completion consumer of an accepted* LocatednessModulus$^{\uparrow}$ *packet receives only the displayed tolerance request q, located interval surface L, rational-cell ledger I, dyadic-refinement ledger D,* StreamName$^{\uparrow}$ *window S,* RegSeqRat$^{\uparrow}$ *readback R,* Real$^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. This public export surface excludes host trichotomy, quotient real equality, selected endpoints, and ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.LocatednessModulusUp.LocatednessModulusCarrier public export`

Proof. Project the accepted carrier of Definition 1627.1. Its public coordinates are exactly $q, L, I, D, S, R, E, H, C, P$

Apply the NameCert obligations of Definition 1627.2. They restrict certificate access to carrier admission, tolerance-cell compatibility, dyadic refinement stability, window transport, and non-escape.

Use Definition 1627.3 and Definition 1627.4. The first theorem fixes the consumer route through the displayed request, interval, rational cells, dyadic refinements, stream windows, readbacks, and structural rows; the second theorem prevents the Real-facing seal from exporting any non-displayed datum.

Finally apply the decision-budget theorem Definition 1627.5. A public consumer can only inspect the listed rows, so trichotomy, quotient equality, selected endpoints, and ambient Real completeness remain outside the exported surface. □

Closure status for NameCert$_{\text{LocatednessModulus}^{\uparrow}}$.

Constructive story: A LocatednessModulus$^{\uparrow}$ packet is generated from a rational tolerance request, a LocatedInterval$^{\uparrow}$ endpoint surface, RationalInterval$^{\uparrow}$ cells, DyadicRatCore$^{\uparrow}$ refinement rows, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readbacks, a Real$^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatednessModulus}^{\uparrow}}$, seed)

Scope closed: Definition 1627.1, Definition 1627.2, Definition 1627.3, and Definition 1627.4 seed the finite locatedness-budget surface for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{LocatednessModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient real equality, selected endpoints, global apartness choice, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires carrier admission, tolerance-window transport, dyadic refinement stability, locatedness decision budget, and Real-seal non-escape proofs for BEDC.Derived.LocatednessModulusUp.

Chapter 1628

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges regular Cauchy names, the $\mathsf{RegularCauchyUniformity}^{\uparrow}$ packet names the dyadic-entourage uniformity on regular rational Cauchy names as finite BEDC rows. It reads the dyadic arithmetic core of chapter 291, the finite observation route of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the ambient uniform-space interface of chapter 339, and the completion-facing route of chapter 1506. The packet is the finite dyadic-entourage surface used by Real and completion consumers; it is not quotient stream equality, not a selected limit, not host real equality, not countable choice, not open-cover compactness, and not Real completeness.

Definition 1628.1 (Regular Cauchy uniformity carrier)**.** *A* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (R, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *W is the finite window row recording the inspected stream prefix and the later common refinements admitted for the same regular Cauchy name.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic radius used by the entourage request.*
4. *E is the dyadic-entourage row, asserting that two displayed regular rational windows are within the tolerance named by D at the inspected stage.*
5. *H records componentwise* hsame *transport for the regular rational name, window, dyadic tolerance, entourage row, continuation row, provenance row, and local naming row.*
6. *C records the displayed* Cont *replay from a regular Cauchy request through finite windows, dyadic tolerance naming, entourage admission, and the downstream Real or completion handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these eight rows form one finite dyadic-entourage uniformity packet. It contains no coordinate for quotient stream equality, selected limits, host real equality, countable choice, open-cover compactness, or Real completeness.

Lean4 ✓ BEDC.Derived.RegularCauchyUniformityUp.TasteGate.RegularCauchyUniformityTasteGate
single carrier alignment

Theorem 1628.2 (Regular Cauchy uniformity NameCert obligations)**.** *For every accepted* RegularCauchyUniformity *carrier* $U = (R, W, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational name, finite window, dyadic tolerance, entourage, transport, continuation, provenance, and local naming rows;*
2. *dyadic entourage admission, requiring* E *to be read only after the window row* W *and tolerance row* D *have been displayed;*
3. *window reindexing, requiring later common finite* $\mathsf{StreamName}^{\uparrow}$ *refinements to preserve the same regular rational source row* R*;*
4. *Real seal handoff, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to enter through the displayed route* R, W, D, E, H, C, P, N*;*
5. *transport, requiring* H *to identify only the listed rows componentwise under* hsame*;*
6. *replay, requiring* C *to reproduce the same finite path before any downstream uniform-space or completion read;*
7. *provenance, requiring* P *to name only the displayed RegSeqRat, StreamName, DyadicRatCore, Real, UniformSpace, and MetricCompletion dependencies;*
8. *non-escape, excluding quotient stream equality, selected limits, host real equality, countable choice, open-cover compactness, Real completeness, and any hidden host uniformity.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1628.1. The projection exposes exactly the regular rational name row, finite window row, dyadic tolerance row, entourage row, transport row, continuation row, provenance row, and local naming row.

Dyadic entourage admission is the row E downstream of W and D. Since D is the only tolerance coordinate and W is the only finite observation coordinate, the entourage cannot be read before both rows are displayed.

Window reindexing is recorded by the same W row and transported by H. A later common refinement changes only the inspected finite prefix, while the source row R and dyadic tolerance row D remain the rows named by the packet.

The Real and completion handoff is ordered by C. Any downstream consumer must replay R, W, D, E before reaching the structural rows H, C, P, N, so the consumer sees a finite dyadic-entourage route rather than a host uniformity.

The exclusions follow from the carrier inventory. There is no row for quotient stream equality, selected limits, host real equality, countable choice, open-cover compactness, Real completeness, or any hidden uniformity outside the displayed packet. □

Theorem 1628.3 (Regular Cauchy uniformity dyadic entourage stability)**.** *Let* $U = (R, W, D, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *carrier. If two finite* $\mathsf{StreamName}^{\uparrow}$ *windows are common refinements of the window row* W *and keep the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, then the dyadic-entourage row* E *remains the displayed entourage row for both refinements after componentwise* hsame *transport. In particular, common finite refinements preserve the same dyadic tolerance row* D *and do not create a second uniformity route.*

Proof. Start with the accepted carrier and the two common finite refinements of W. The carrier has only one source row R and only one dyadic tolerance row D, so both refinements are read as later windows for the same regular rational name and the same tolerance request.

Use the transport row H componentwise. It identifies the original window data and the refined window data only along the displayed regular rational, dyadic tolerance, and entourage rows.

Replay C after transport. The replay reaches the same entourage row E from each refined window, because no second tolerance coordinate, quotient stream coordinate, or host uniformity coordinate is present in the carrier.

Thus the dyadic-entourage row is stable under the common finite refinements, and the packet continues to expose a single finite route through R, W, D, E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.RegularCauchyUniformityUp.RegularCauchyUniformityCarrier dyadic entourage stability`

Theorem 1628.4 (Regular Cauchy uniformity common-refinement transitivity)**.** *Let* $U = (R, W, D, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *carrier. For any displayed finite chain of* $\mathsf{StreamName}^{\uparrow}$ *common refinements*

$$W = W_0 \rightsquigarrow W_1 \rightsquigarrow \cdots \rightsquigarrow W_k$$

starting at the window row W*, if every step keeps the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R *and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, then the terminal window* W_k *carries the same dyadic-entourage row* E*. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of* W_k *still factors through the finite route*

$$R \longmapsto W \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

The chain introduces no quotient stream equality, selected limit, host real equality, countable choice, open-cover compactness, or Real completeness.

Proof. Induct on the displayed finite refinement chain. In the base case the terminal window is W itself, so the carrier projection of Definition 1628.1 supplies the source row R, tolerance row D, dyadic-entourage row E, and the replay route through H, C, P, N.

For the step, assume the current terminal window has already retained the same rows R, D, E. Apply Definition 1628.3 to the next common finite refinement. The hypothesis that the refinement keeps R and D makes the theorem applicable, and its conclusion preserves E as the displayed dyadic-entourage row.

Finally apply Definition 1628.5 to the terminal window. The consumer route remains the finite route through R, W, D, E, H, C, P, N, so the induction never creates quotient stream equality, a selected limit, host real equality, countable choice, open-cover compactness, Real completeness, or any host uniformity coordinate. □

Theorem 1628.5 (Regular Cauchy uniformity Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *carrier sees the uniformity only through the finite route*

$$R \longmapsto W \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a dyadic-entourage service for regular rational Cauchy names, not quotient stream equality, not a selected limit, not host real equality, not countable choice, not open-cover compactness, and not Real completeness.

Proof. Let $U = (R, W, D, E, H, C, P, N)$ be accepted. The only regular Cauchy source available to a downstream consumer is R, and the only observation surface attached to it is the finite window row W.

The tolerance request then passes through D, and the uniformity read is the dyadic-entourage row E. No Real or completion consumer can bypass those rows, because C records the replay order and H transports only the displayed coordinates.

The provenance and local naming rows P, N package the same route for $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ consumers. They do not add quotient stream equality, a selected limit, host real equality, countable choice, open-cover compactness, Real completeness, or a host uniformity coordinate. □

Theorem 1628.6 (Regular Cauchy uniformity scoped obligation package)**.** *The carrier of Definition 1628.1, the NameCert obligations of Definition 1628.2, dyadic-entourage stability of Definition 1628.3, common-refinement transitivity of Definition 1628.4, and the Real seal handoff of Definition 1628.5 form the complete* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *obligation package over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The package excludes quotient stream equality, selected limits, host real equality, countable choice, open-cover compactness, Real completeness, and hidden host uniformity.

Proof. Project the carrier of Definition 1628.1. Its rows are exactly the regular rational source, finite stream window, dyadic tolerance, dyadic entourage, componentwise transport, continuation replay, provenance, and local naming rows.

Apply Definition 1628.2 to read those rows as the local $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$ surface. The obligation rows include carrier admission, dyadic entourage admission, window reindexing, Real seal handoff, transport, replay, provenance, and non-escape.

Next apply Definition 1628.3 and Definition 1628.4. These two results compose the finite window route under common refinements while preserving the same source row, tolerance row, and entourage row.

Finally apply Definition 1628.5. Every $\mathsf{Real}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer still reaches the packet through the displayed finite route, so the listed BEDC rows exhaust the obligation surface and none of the excluded host-side data is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyUniformity}^{\uparrow}$ packet is generated from a regular rational name row, a finite StreamName window row, a DyadicRatCore tolerance row, a dyadic-entourage row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1628.1, Definition 1628.2, Definition 1628.3, Definition 1628.4, Definition 1628.5, and Definition 1628.6 close the finite dyadic-entourage obligation surface for RegSeqRat, StreamName, DyadicRatCore, Real, UniformSpace, and MetricCompletion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyUniformity}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyUniformityUp.TasteGate.RegularCauchyUniformityTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, open-cover compactness, Real completeness, or a public standard bridge.

Upgrade path: Public closure requires a public consumer theorem and a later bridge-checked standard interface for the displayed $\mathsf{RegularCauchyUniformity}^{\uparrow}$ dyadic-entourage route.

Chapter 1629

A Concrete Naming Certificate for $\mathsf{Upcrossing}^{\uparrow}$

Following Doob, the $\mathsf{Upcrossing}^{\uparrow}$ packet records the finite ledger used to count completed passages of a martingale path from a lower rational boundary to a higher rational boundary. It consumes the finite adapted-sequence surface of $\mathsf{Martingale}^{\uparrow}$ (chapter 190), the bounded stopped-window rows of $\mathsf{OptionalStopping}^{\uparrow}$ (chapter 383), and the probability, random-variable, and conditional-expectation sources $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, and $\mathsf{CondExp}^{\uparrow}$ already named in chapter 184, chapter 185, and chapter 188. The chapter names only the finite crossing-count carrier and its no-escape boundary; it does not assert martingale convergence or any almost-sure quotient theorem.

1629.1 Finite Crossing Carrier

Definition 1629.1 (Upcrossing finite ledger carrier)**.** *An* $\mathsf{Upcrossing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (\Omega, M, a, b, N, V, L, S, H, C, P, Q)$$

with the following visible rows:

1. Ω *is the displayed* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the probability context;*
2. M *is the consumed* $\mathsf{Martingale}^{\uparrow}$ *adapted-sequence packet over a finite unary time spine* $0, \ldots, N$*;*
3. a *and* b *are displayed* $\mathsf{Real}^{\uparrow}$ *boundary endpoints with a carried comparison row* $a <_R b$*;*
4. V *is the finite endpoint-row family of the martingale values read through* $\mathsf{RandomVar}^{\uparrow}$*;*
5. L *is the lower-boundary decision ledger recording every displayed time at which the current value is classified at or below* a *after no open crossing is active;*
6. S *is the upper-boundary decision ledger recording every displayed time at which the current value is classified at or above* b *after an open crossing is active;*
7. H *stores the componentwise* hsame *transports for the probability row, martingale row, boundary endpoints, endpoint rows, lower and upper decision rows, and crossing-count row;*
8. C *stores the finite* Cont *routes from the martingale endpoint ledger to the lower-boundary and upper-boundary decision ledgers;*
9. P *is the* Pkg *provenance row naming exactly* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$*, and the local crossing-count rows;*

10. *Q is the local* $\mathsf{NameCert}_{\mathsf{Upcrossing}^\uparrow}$ *row.*

The crossing count of U is the number of completed lower-to-upper pairs selected by the finite alternating ledger (L, S). The local classifier compares two carriers only through the transported finite time spine, boundary endpoints, decision rows, completed-count row, continuation routes, package provenance, and local certificate row.

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingTasteGate single carrier alignment`

1629.2 Certificate Obligations

Theorem 1629.2 (Upcrossing NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{Upcrossing}^\uparrow}$ *surface consists of five obligations:*

1. *carrier: formation of the finite packet of Definition 1629.1;*
2. *classifier: componentwise transport of the finite time spine, martingale endpoint rows, boundary endpoints, lower and upper decision ledgers, completed-count row,* hsame *rows,* Cont *routes,* Pkg *provenance, and local* NameCert *row;*
3. *boundary-decision stability: every lower or upper decision is read from the displayed* $\mathsf{Real}^\uparrow$ *classifier on the corresponding* $\mathsf{RandomVar}^\uparrow$ *endpoint row and remains stable under the carried endpoint transport;*
4. *martingale-window handoff: every optional-stopping read used to isolate a lower or upper boundary hit factors through bounded* $\mathsf{OptionalStopping}^\uparrow$ *rows over the consumed finite* $\mathsf{Martingale}^\uparrow$ *packet;*
5. *ledger exactness: every probability, random-variable, conditional-expectation, martingale, stopped-window, decision, transport, continuation, package, and certificate row used by the crossing count appears in the displayed carrier.*

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingNamecertObligations`

Proof. Project the carrier tuple of Definition 1629.1. Carrier formation is exactly the finite package whose visible rows are Ω, M, a, b, N, V, L, S, H, C, P, and Q.

Classifier stability is componentwise. The transported martingale packet supplies the transported endpoint rows, while the boundary endpoints and decision ledgers are compared through the displayed $\mathsf{Real}^\uparrow$ and hsame rows already stored in the carrier.

For boundary-decision stability, each lower or upper decision is a finite read of one endpoint row against a or b. Transporting the endpoint row and the boundary endpoints transports the comparison row, so the selected lower and upper hits remain the same displayed finite decisions.

For the martingale-window handoff, each hit is read inside the finite time window of M. The bounded stopped-window rows of $\mathsf{OptionalStopping}^\uparrow$ package those finite reads without introducing unbounded stopping or a quotient of events.

Ledger exactness follows because the completed-count row is computed from the alternating lower and upper decision ledgers alone. No consumer of $\mathsf{NameCert}_{\mathsf{Upcrossing}^\uparrow}$ can read a probability row, endpoint row, conditional-expectation face, stopping window, transport, continuation route, package row, or local certificate outside the displayed carrier. □

Theorem 1629.3 (Upcrossing martingale dependency route)**.** *Every accepted* $\mathsf{Upcrossing}^\uparrow$ *carrier scopes its crossing-count read through the displayed finite* $\mathsf{Martingale}^\uparrow$ *adapted-sequence packet,*

the RandomVar$^{\uparrow}$ *endpoint rows carried by that packet, the* CondExp$^{\uparrow}$ *successor faces used by the martingale row, and the bounded* OptionalStopping$^{\uparrow}$ *windows that read lower and upper hits. The route contains no host stochastic process, no outside stopping-time theorem, and no convergence principle.*

Proof. Start with the consumed Martingale$^{\uparrow}$ packet M in Definition 1629.1. Its public surface supplies only the finite endpoint rows, conditional-expectation faces, filtration visibility rows, package provenance, and finite Cont/hsame ledger described in chapter 190.

The lower and upper decision ledgers L and S are then finite reads of those endpoint rows against a and b. Their comparison rows are carried by the displayed Real$^{\uparrow}$ endpoint classifier and by the RandomVar$^{\uparrow}$ rows already present in M.

Whenever the carrier isolates a first lower hit or the next upper hit, the read is bounded by the displayed finite horizon N. The relevant stopped-window route is therefore the bounded OptionalStopping$^{\uparrow}$ surface of chapter 383.

Thus the dependency route is exhausted by ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, CondExp$^{\uparrow}$, Martingale$^{\uparrow}$, OptionalStopping$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows. Since no other coordinate is present, the route cannot export a host stochastic process, an unbounded stopping theorem, or a convergence claim. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingMartingaleRoute`

Theorem 1629.4 (Upcrossing finite-ledger induction boundary)**.** *Every accepted* Upcrossing$^{\uparrow}$ *carrier computes its completed crossing count by induction on the displayed finite alternating lower and upper decision ledger* (L, S)*. The induction preserves boundary endpoints, endpoint rows, bounded* OptionalStopping$^{\uparrow}$ *windows, and crossing-count rows under componentwise* hsame *transport. An empty ledger gives zero completed crossings; a lower row opens a pending crossing; an upper row after a pending lower row adds exactly one completed count; and every case remains inside the displayed* Martingale$^{\uparrow}$*,* RandomVar$^{\uparrow}$*,* CondExp$^{\uparrow}$*,* OptionalStopping$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.UpcrossingUp.Upcrossing finite ledger induction boundary`

Proof. Inspect the finite ledger (L, S) in Definition 1629.1. The empty ledger has no lower row and no upper row, so the completed crossing count is the displayed zero count.

For the induction step with a lower row, the row is read from a displayed martingale endpoint against the boundary endpoint a. If no crossing is pending, the row opens one pending crossing and changes no completed count; if a pending crossing is already open, the finite state remains pending without exporting another object.

For the induction step with an upper row after a pending lower row, the row is read from the displayed endpoint against b. The pending lower row and this upper row form one completed lower-to-upper pair, so the completed-count row adds exactly one.

All transport is componentwise. The endpoint rows, boundary endpoints, stopped windows, decision rows, and crossing-count row are all coordinates of the same Upcrossing$^{\uparrow}$ carrier, so hsame transport and Cont replay preserve the finite induction without adding an unbounded stopping theorem or a convergence principle. □

Theorem 1629.5 (Upcrossing inequality handoff to martingale convergence)**.** *Every accepted* Upcrossing$^{\uparrow}$ *packet exports exactly the finite rows later consumed by a* MartingaleConvergence$^{\uparrow}$ *packet: displayed lower and upper* Real$^{\uparrow}$ *boundary rows, finite martingale endpoint rows, lower and*

upper decision ledgers, bounded OptionalStopping$^{\uparrow}$ *stopped-window rows, and the crossing-count ledger. The handoff is a finite dependency route, not a martingale convergence theorem.*

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingInequalityMartingaleConvergenceHandoff`

Proof. Project the carrier of Definition 1629.1. The boundary endpoints are a and b, the finite martingale endpoint family is V, the lower and upper decision ledgers are L and S, and the crossing-count read is computed from those displayed ledgers.

Apply Definition 1629.2. The certificate surface exposes the boundary-decision stability, martingale-window handoff, and ledger exactness rows required by any downstream convergence-preparation packet.

Apply Definition 1629.3. Every stopped-window read factors through the finite OptionalStopping$^{\uparrow}$ route over the consumed Martingale$^{\uparrow}$ packet, and no host stochastic process or limiting event is exported.

Thus the only data passed to MartingaleConvergence$^{\uparrow}$ is the displayed finite upcrossing handoff. Since no convergence coordinate is present in the carrier, the theorem records a dependency route rather than a convergence result. □

Theorem 1629.6 (Upcrossing MartingaleConvergence consumer route)**.** *Every* MartingaleConvergence$^{\uparrow}$ *consumer of an accepted* Upcrossing$^{\uparrow}$ *row, as named by chapter 2246, must pass through the finite lower and upper decision ledgers, the bounded* OptionalStopping$^{\uparrow}$ *stopped-window rows, and the Doob-upcrossing handoff of Definition 1629.5. The consumer receives only displayed lower and upper* Real$^{\uparrow}$ *boundary rows, finite martingale endpoint rows, lower and upper decision rows, bounded stopped-window routes, crossing-count data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows; it receives no limiting event, almost-sure quotient, convergence theorem, unbounded stopping principle, or completed measure carrier.*

Proof. Project the accepted Upcrossing$^{\uparrow}$ carrier. Its convergence-preparation data are the lower and upper boundary endpoints, finite martingale endpoint rows, lower and upper decision ledgers, and crossing-count row.

Apply the martingale route and NameCert obligations. The stopped-window reads are bounded by the displayed OptionalStopping$^{\uparrow}$ rows, and the decision ledgers are transported only componentwise and replayed only through the displayed continuation routes.

Finally use Definition 1629.5. The handoff identifies exactly the rows available to the downstream MartingaleConvergence$^{\uparrow}$ packet. Since those rows contain no limiting event or convergence coordinate, the consumer route is finite and no-escape rather than a convergence claim. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingMartingaleConvergenceConsumer`

Theorem 1629.7 (Upcrossing finite ledger handoff)**.** *For every accepted* Upcrossing$^{\uparrow}$ *carrier, the completed-crossing count, the bounded* OptionalStopping$^{\uparrow}$ *stopped-window ledger, and the lower and upper* Real$^{\uparrow}$ *boundary-rational rows form the only finite handoff consumed by the* MartingaleConvergence$^{\uparrow}$ *route of Definition 1629.6. The handoff is transported by the displayed* hsame *rows and replayed by the displayed* Cont *rows; it exports no almost-sure quotient equality, no unbounded stopping index, and no measure-completion carrier.*

Proof. Induct on the finite crossing ledger (L, S) of Definition 1629.1. In the empty case, the completed-crossing count is zero and the stopped-window ledger has no lower-to-upper pair to export.

For a lower-boundary row, the displayed boundary-rational data record a pending crossing against a. The stopped-window row is bounded by the current finite horizon, and no completed count is added.

For an upper-boundary row following a pending lower row, the displayed comparison against b closes exactly one finite pair. The completed-count row, the two boundary-rational rows, and the bounded stopped-window row are updated inside the same BHist packet.

The induction preserves the handoff under componentwise hsame transport and displayed Cont replay. Since the carrier contains no coordinate for almost-sure quotient equality, unbounded stopping, or measure completion, the martingale-convergence consumer can read only this finite ledger package. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingFiniteLedgerHandoff`

Theorem 1629.8 (Upcrossing scoped decision route)**.** *Every boundary-decision read from an accepted* Upcrossing$^{\uparrow}$ *carrier is scoped by* ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, CondExp$^{\uparrow}$, Martingale$^{\uparrow}$, OptionalStopping$^{\uparrow}$, *the finite lower and upper decision ledgers, and the structural rows* BHist, hsame, Cont, Pkg, *and* NameCert. *The read has no route through an unbounded stopping index, a host stochastic process, almost-sure quotient equality, or a convergence theorem.*

Proof. Project the carrier of Definition 1629.1. Its probability context, martingale packet, finite endpoint rows, lower ledger, upper ledger, transport rows, continuation rows, provenance row, and local certificate are the only coordinates available to a boundary decision.

Apply Definition 1629.2. Boundary-decision stability and ledger exactness force each lower or upper hit to be read from the displayed endpoint row against the displayed boundary endpoint, with transport and replay remaining componentwise.

Apply Definition 1629.3, Definition 1629.4, and Definition 1629.7. These route the endpoint rows through the finite martingale and optional-stopping windows, compute the completed count by the lower and upper decision ledgers, and expose only the finite handoff consumed downstream. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingScopedDecisionRoute`

Theorem 1629.9 (Upcrossing bounded optional-stopping route)**.** *Every lower or upper boundary hit used by the crossing ledger of an accepted* Upcrossing$^{\uparrow}$ *carrier factors through a bounded* OptionalStopping$^{\uparrow}$ *stopped-window row over the displayed finite* Martingale$^{\uparrow}$ *packet before the completed-count row is updated. Thus the lower ledger L and upper ledger S may update the count only after the corresponding finite endpoint row has been read through the displayed martingale-window route, with transport by H and replay by C.*

Proof. Project the carrier of Definition 1629.1. The only data available to a boundary hit are the probability row, the finite Martingale$^{\uparrow}$ packet M, the boundary endpoints a, b, the endpoint family V, the lower and upper ledgers L, S, and the support rows H, C, P, Q.

Apply Definition 1629.3. Every stopped-window read used by the chapter is bounded by the displayed finite horizon of M and factors through the OptionalStopping$^{\uparrow}$ rows carried by that route.

Apply Definition 1629.4. The completed-count row changes only in the finite induction step where a displayed lower row is followed by a displayed upper row; both rows are endpoint reads against the fixed boundaries.

Finally use Definition 1629.8. Boundary decisions are scoped by the same martingale packet, optional-stopping windows, transport rows, and continuation replay. Therefore each lower or upper hit must pass through the bounded stopped-window row before the ledger count is updated, and no unbounded stopping index or convergence theorem enters the route. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.UpcrossingBoundedOptionalStoppingRoute`

Theorem 1629.10 (Upcrossing no-escape boundary)**.** *The public boundary of* $\mathsf{Upcrossing}^{\uparrow}$ *exports only the finite crossing-count ledger for a displayed martingale window and fixed boundary pair* $a <_R b$*. It exports no martingale convergence theorem, no almost-sure quotient equality, no unbounded stopping principle, no measure completion, and no standard bridge beyond the finite rows explicitly carried by Definition 1629.1.*

Proof. Inspect the accepted carrier. Its time information is the finite horizon N, its value information is the finite endpoint family V, and its crossing data is the alternating lower and upper decision ledger (L, S).

Apply Definition 1629.2. The certificate surface reads only the listed probability, random-variable, conditional-expectation, martingale, optional-stopping, decision, transport, continuation, package, and local certificate rows.

Apply Definition 1629.3. Every martingale-facing read factors through the finite adapted-sequence packet and every stopped-window read is bounded by the displayed finite horizon.

None of the carrier coordinates names a limiting event, a quotient of almost-sure equality classes, an unbounded stopping index, a completed measure space, or a standard bridge. Therefore none of those objects can be exported by the public boundary of $\mathsf{Upcrossing}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.UpcrossingUp.Upcrossing nonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{Upcrossing}^{\uparrow}}$**.**

Constructive story: An $\mathsf{Upcrossing}^{\uparrow}$ packet is generated from a displayed probability row, a finite $\mathsf{Martingale}^{\uparrow}$ adapted-sequence packet, fixed lower and upper $\mathsf{Real}^{\uparrow}$ boundary endpoints, finite endpoint rows, lower and upper boundary decision ledgers, componentwise transports, finite continuation routes, package provenance, and a local NameCert row. The completed crossing count is read from the alternating finite decision ledger only.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Upcrossing}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1629.1, Definition 1629.2, Definition 1629.3, and Definition 1629.4 close the finite upcrossing packet through displayed probability, martingale, optional-stopping, boundary-decision, transport, replay, provenance, and finite-ledger induction rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Upcrossing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a general optional-stopping theorem, martingale convergence, almost-sure quotient equality, unbounded stopping, measure-theoretic completeness, or a standard bridge.

Upgrade path: A checked formal axis requires Lean coverage for the scoped finite martingale-window dependency route and its no-escape boundary.

Chapter 1630

A Concrete Naming Certificate for $\mathsf{DoobUpcrossing}^{\uparrow}$

Following Doob, the $\mathsf{DoobUpcrossing}^{\uparrow}$ packet names the finite upcrossing-inequality surface obtained from a displayed martingale window. It consumes the probability, random-variable, conditional-expectation, martingale, optional-stopping, and crossing-count certificates of chapter 184, chapter 185, chapter 188, chapter 190, chapter 383, and chapter 1629. The finite Doob-bound row consumes the crossing-count ledger of chapter 1629 and the bounded stopped-window rows of chapter 383 before any martingale-convergence consumer may read it. Its carrier is not a convergence theorem; it is the finite ledger that relates a displayed crossing count to the corresponding expectation-bound row.

Definition 1630.1 (Doob upcrossing carrier)**.** *A* $\mathsf{DoobUpcrossing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Omega, M, a, b, N, U, E, B, H, C, P, Q)$$

with the following visible rows:

1. Ω *is the displayed* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the probability context;*
2. M *is the consumed* $\mathsf{Martingale}^{\uparrow}$ *finite adapted-sequence packet over the displayed time spine* $0, \ldots, N$*;*
3. a *and* b *are displayed* $\mathsf{Real}^{\uparrow}$ *endpoints with a carried strict comparison row* $a <_R b$*;*
4. U *is the consumed* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count ledger for* M, a, b, N*;*
5. E *is the finite expectation row read through the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint rows and the* $\mathsf{CondExp}^{\uparrow}$ *faces of* M*;*
6. B *is the displayed Doob bound row comparing the scaled completed-count read* $(b-a) \cdot U_N(a, b)$ *with the final negative-part expectation read;*
7. H *records componentwise* hsame *transport for the probability row, martingale row, boundary endpoints, upcrossing ledger, expectation row, bound row, continuation row, provenance row, and local naming row;*
8. C *records the finite* Cont *routes from the martingale endpoint rows and bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *windows to the crossing-count and expectation-bound reads;*
9. P *is the* Pkg *provenance row naming exactly* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, *and the local Doob-bound rows;*

10. *Q is the local* $\mathsf{NameCert}_{\mathsf{DoobUpcrossing}^{\uparrow}}$ *row.*

The local classifier compares two carriers only through these displayed rows. In particular, it compares the bound row as a finite relation between the consumed upcrossing ledger and the displayed expectation read, not as an ambient theorem about all stochastic processes.

Lean4 ✓ `BEDC.Derived.DoobUpcrossingUp.DoobUpcrossingTasteGate single carrier alignment`

Theorem 1630.2 (Doob upcrossing NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DoobUpcrossing}^{\uparrow}}$ *surface consists of five obligations:*

1. *carrier: formation of the finite packet of Definition 1630.1;*
2. *classifier: componentwise transport of the probability row, martingale row, boundary endpoints, crossing-count ledger, expectation row, Doob-bound row,* hsame *rows,* Cont *routes,* Pkg *provenance, and local* NameCert *row;*
3. *upcrossing consumption: the completed-count coordinate is read only from the finite* $\mathsf{Upcrossing}^{\uparrow}$ *ledger of chapter 1629;*
4. *martingale-bound route: the expectation and stopped-window reads factor through the* $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, *and* $\mathsf{OptionalStopping}^{\uparrow}$ *rows named in the carrier;*
5. *ledger exactness: every row used by the inequality surface appears in the displayed carrier.*

Proof. Project the carrier tuple of Definition 1630.1. Carrier formation is exactly the finite package whose visible rows are Ω, M, a, b, N, U, E, B, H, C, P, and Q.

Classifier stability is componentwise. The probability, endpoint, martingale, upcrossing, expectation, and bound coordinates are compared by the displayed hsame rows, while the replay of the dependency route is confined to C and P.

The upcrossing-consumption obligation uses chapter 1629. Its finite ledger supplies the completed-count row, so the Doob packet does not construct a second crossing counter.

The martingale-bound route uses chapter 184, chapter 185, chapter 188, chapter 190, and chapter 383. These chapters provide the probability context, endpoint rows, conditional-expectation faces, finite martingale window, and bounded stopped-window reads consumed by E and B.

Ledger exactness follows because no coordinate outside D is named by the carrier or the local classifier. Every public inequality read therefore projects from one of the displayed rows. □

Theorem 1630.3 (Doob upcrossing martingale route)**.** *Every accepted* $\mathsf{DoobUpcrossing}^{\uparrow}$ *carrier scopes its finite inequality read through the displayed* $\mathsf{ProbSpace}^{\uparrow}$ *source, the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint rows, the* $\mathsf{CondExp}^{\uparrow}$ *martingale faces, the finite* $\mathsf{Martingale}^{\uparrow}$ *adapted-sequence packet, the bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *windows, and the consumed* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count ledger. The route contains no host stochastic process, no unbounded stopping theorem, no limiting event, and no martingale convergence principle.*

Proof. Start with the finite martingale packet M. Its public surface supplies only displayed endpoint rows, conditional-expectation faces, filtration visibility rows, and finite transport and provenance data as named by chapter 190.

The endpoint rows are interpreted inside the probability context through chapter 184, chapter 185, and chapter 188. The crossing-count coordinate is not recomputed here; it is the consumed $\mathsf{Upcrossing}^{\uparrow}$ row of chapter 1629.

The only stopped reads used to compare lower and upper visits with the final expectation row are bounded reads through chapter 383. Since the carrier fixes the horizon N and stores no unbounded index coordinate, the route cannot export an unbounded stopping theorem.

Thus the martingale-facing content of the packet is exhausted by the named finite dependency rows and the local Doob-bound row. No limiting event, almost-sure quotient, or convergence principle is present in the carrier. □

Theorem 1630.4 (Doob upcrossing no-escape boundary)**.** *The public boundary of* $\mathsf{DoobUpcrossing}^{\uparrow}$ *exports only the finite Doob upcrossing inequality row for a displayed martingale window, boundary pair* $a <_R b$*, consumed crossing-count ledger, and displayed expectation-bound read. It exports no martingale convergence theorem, no almost-sure quotient equality, no unbounded stopping principle, no measure completion, and no standard bridge beyond the rows explicitly carried by Definition 1630.1.*

Proof. Inspect the accepted carrier. Its time information is the finite horizon N, its stochastic information is the displayed probability and martingale dependency rows, and its crossing information is the consumed $\mathsf{Upcrossing}^{\uparrow}$ ledger.

Apply Definition 1630.2. The certificate surface reads the inequality only through the displayed carrier, classifier, upcrossing-consumption, martingale-bound-route, and ledger-exactness rows.

Apply Definition 1630.3. Every martingale-facing read factors through the finite adapted-sequence packet and every stopped-window read is bounded by the displayed finite horizon.

None of the carrier coordinates names a limiting event, a quotient of almost-sure equality classes, an unbounded stopping index, a completed measure space, or a standard bridge. Therefore none of those objects can be exported by the public boundary of $\mathsf{DoobUpcrossing}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{DoobUpcrossing}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DoobUpcrossing}^{\uparrow}$ packet is generated from a displayed probability row, a finite $\mathsf{Martingale}^{\uparrow}$ adapted-sequence packet, fixed lower and upper $\mathsf{Real}^{\uparrow}$ boundary endpoints, a consumed $\mathsf{Upcrossing}^{\uparrow}$ crossing-count ledger, endpoint expectation rows, a displayed Doob-bound comparison row, componentwise hsame transports, finite continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoobUpcrossing}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope names the finite carrier, the five-row naming-certificate obligation surface, the martingale dependency route, and the no-escape boundary for finite Doob upcrossing inequality rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoobUpcrossing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close martingale convergence, almost-sure quotient equality, unbounded stopping, measure completion, or a standard bridge.

Upgrade path: Obligation closure requires Lean targets for carrier transport, upcrossing consumption, martingale-bound routing, finite inequality-row exactness, and the no-escape boundary.

Chapter 1631

A Concrete Naming Certificate for $\mathsf{ModulusContinuity}^{\uparrow}$

Following Bishop and Bridges on constructive continuity with explicit moduli, the $\mathsf{ModulusContinuity}^{\uparrow}$ packet names the function-specific route by which a tolerance request is converted into a finite source-window budget before a Real or Completion consumer reads the target seal. It sits between the graph surface of chapter 130, the tolerance-to-window discipline of chapter 292, the finite source observations of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet records the local modulus-continuity boundary used by Real and Completion routes; it is not an open-cover compactness principle, a selected limit, a quotient stream equality, a host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1631.1 (Modulus-continuity carrier)**.** *A* $\mathsf{ModulusContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, S, K, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the named function, including the displayed source and target endpoints that every consumer must inspect before reading continuity data.*
2. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose entries supply the domain-side observations governed by the modulus.*
3. *K is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tolerance-to-window row, sending each positive dyadic target tolerance to the displayed finite source window read through S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the target tolerance, the source-window budget, and the dyadic comparison rows used by K.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the source and target windows inspected by the graph and modulus rows.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *target seal reached only after G, S, K, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the graph, source window, modulus row, dyadic ledger, regular readback, Real target seal, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a target tolerance request through D, then through the modulus row K, into the source window S, across the graph row G, through readback Q, and finally into the Real target seal R.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, S, K, D, Q, R, H, C, P, N$. It has no coordinate for open-cover compactness, selected limits, quotient stream equality, host real equality, a detached continuity oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.TasteGate.ModulusContinuityTasteGate single carrier alignment`

Theorem 1631.2 (Modulus-continuity NameCert obligations)**.** *For every accepted* $\mathsf{ModulusContinuity}^{\uparrow}$ *carrier $M = (G, S, K, D, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the continuous-map graph, source StreamName window, CauchyModulus tolerance-to-window row, dyadic tolerance ledger, RegSeqRat readback, Real target seal, transport, replay, provenance, and local naming row;*
2. *classifier transport, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the ordered route D, K, S, G, Q, R;*
3. *modulus-row stability, requiring every target tolerance read from D to select its source-window budget only through the displayed row K and never through an external continuity oracle;*
4. *continuity-window handoff, requiring every graph read in G and every regular readback in Q to consume the source window S selected by K before the target seal R is exposed;*
5. *ledger non-escape, requiring P and N to export no open-cover compactness, selected limit, quotient stream equality, host real equality, detached continuity oracle, or ambient Real completeness.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1631.1. The visible packet consists of the continuous-map graph G, the finite source-window row S, the Cauchy modulus row K, the dyadic ledger D, the readback row Q, the terminal Real seal R, and the structural rows H, C, P, N.

Classifier transport is structural. Componentwise hsame in H preserves each displayed coordinate, and displayed Cont replay in C repeats the same ordered route D, K, S, G, Q, R for every accepted tolerance request.

Modulus-row stability is forced by the placement of K. A target tolerance may be read from D, but the only row that converts it into a source-window budget is the displayed $\mathsf{CauchyModulus}^{\uparrow}$ row, so no detached continuity oracle can enter the carrier.

The continuity-window handoff follows next. The graph row G and the regular readback row Q are exposed only after the window S selected by K has been displayed, and the Real target seal R is reached only after those finite observations are replayed.

Finally, provenance is exhausted by P and N. Since the carrier has no coordinate for open-cover compactness, selected limits, quotient stream equality, host real equality, a detached continuity oracle, or ambient Real completeness, the local certificate cannot export any such object. □

Theorem 1631.3 (Modulus-continuity Real and Completion handoff)**.** *Every Real or Completion consumer of an accepted* ModulusContinuity$^{\uparrow}$ *carrier reads the function-specific modulus only through the displayed rows*

ContinuousMap$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg,

Consequently the consumer receives a finite tolerance-to-window route for the named function and no open-cover compactness, selected limit, quotient stream equality, host real equality, detached continuity oracle, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $M = (G, S, K, D, Q, R, H, C, P, N)$. Carrier projection gives a Real or Completion consumer access to the function-specific modulus only through those displayed rows.

The tolerance route starts in D. The target dyadic tolerance is converted into a finite source-window budget by K, and that budget identifies the source window S before any graph read is available.

The graph and readback route then passes through G and Q. These rows expose only the finite observations admitted by the selected window and the regular rational readback attached to it; the terminal Real target seal R is downstream of that replay.

The remaining rows do not add mathematical primitives. The BHist, hsame, Cont, Pkg, and NameCert rows transport, replay, source, and name the same finite route, so no excluded compactness, limit, quotient, host-equality, oracle, or completeness coordinate can be inserted. □

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityRealCompletion handoff`

Theorem 1631.4 (Modulus-continuity Cauchy route)**.** *For every accepted* ModulusContinuity$^{\uparrow}$ *carrier*

$$M = (G, S, K, D, Q, R, H, C, P, N),$$

every Cauchy, Real, or Completion tolerance request routed through M factors through the finite carrier path

$$D \to K \to S \to G \to Q \to R.$$

The rows H, C, P, N only transport, replay, source, and name that finite path. They do not add open-cover compactness, selected limits, quotient stream equality, host real equality, detached continuity oracles, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityCauchyRoute`

Proof. Project the accepted carrier into its displayed rows. By Definition 1631.2, carrier admission exposes only the graph row G, source-window row S, modulus row K, dyadic tolerance ledger D, regular readback row Q, Real target seal R, and the structural rows H, C, P, N.

The same obligation theorem fixes the order of use. Classifier transport preserves the displayed route, modulus-row stability forces each target tolerance read from D to pass through K, and continuity-window handoff sends the selected finite window through S before the graph and readback rows G and Q can reach the terminal seal R.

The structural coordinates cannot create an additional analytic source. Componentwise transport in H, displayed replay in C, provenance in P, and local naming in N only carry the already projected path $D \to K \to S \to G \to Q \to R$.

Finally apply Definition 1631.3. Any Cauchy, Real, or Completion consumer reads the function-specific modulus only through the displayed rows, so the excluded compactness, selected-limit,

quotient-stream, host-equality, detached-oracle, and ambient-completeness objects have no coordinate through which to enter the route. □

Theorem 1631.5 (Uniform Cauchy handoff for modulus continuity)**.** *Let*

$$M = (G, S, K, D, Q, R, H, C, P, N)$$

be an accepted $\mathsf{ModulusContinuity}^{\uparrow}$ *carrier over certified dyadic source windows. Suppose a family of source streams is presented through* $\mathsf{StreamName}^{\uparrow}$ *rows whose regular-rational readbacks are* $\mathsf{RegSeqRat}^{\uparrow}$ *streams and whose Cauchy witnesses share the same dyadic modulus row in* D*. Then the target streams obtained by routing each source stream through* M *are regular Cauchy target streams with the target modulus obtained by reindexing the shared dyadic budget through*

$$D \to K \to S \to G \to Q \to R.$$

The handoff uses only the chapter's non-escape and composition rows: it exports no selected limit, quotient stream equality, host real equality, detached continuity oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityUniformCauchyHandoff`

Proof. Project M through Definition 1631.1. The shared dyadic Cauchy modulus is read in D, and the carrier's modulus row K converts every target tolerance request into the same certified source-window budget.

Reindex the source streams along that budget. The $\mathsf{StreamName}^{\uparrow}$ row S selects the finite observations required by K, and the $\mathsf{RegSeqRat}^{\uparrow}$ row Q supplies the regular-rational readback for those windows. Since all source streams share the same dyadic modulus row, the reindexed windows are uniform across the family.

Route the selected windows through the graph row G and then to the target seal R. The Cauchy route of Definition 1631.4 fixes the order of this handoff, so every target tolerance is discharged by the finite path $D \to K \to S \to G \to Q \to R$.

Finally apply the composition and non-escape rows. The structural coordinates H, C, P, N transport and name the same finite route, while Definition 1631.9 prevents a selected limit, quotient equality, host equality, detached continuity oracle, or ambient completeness row from entering the exported regular Cauchy target stream. □

Theorem 1631.6 (Modulus-continuity composition route)**.** *Let*

$$M_f = (G_f, S_f, K_f, D_f, Q_f, R_f, H_f, C_f, P_f, N_f)$$

and

$$M_g = (G_g, S_g, K_g, D_g, Q_g, R_g, H_g, C_g, P_g, N_g)$$

be accepted $\mathsf{ModulusContinuity}^{\uparrow}$ *carriers. Suppose the target seal exposed by* M_f *is the source window and readback surface consumed by* M_g*. Then every target tolerance request for the composed Real or Completion consumer factors through the finite route*

$$D_g \to K_g \to S_g \to G_g \to Q_g \to D_f \to K_f \to S_f \to G_f \to Q_f \to R_f.$$

The composed route uses only the displayed $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the two carriers.*

Proof. Project the second carrier first. By Definition 1631.2, the request for the outer target tolerance starts in D_g, is converted by K_g into the finite window S_g, and reaches the graph and readback rows only through G_g and Q_g.

Use the stated seal match to hand the consumed source surface of M_g to the target surface of M_f. The handoff theorem Definition 1631.3 says that this surface is not a free Real or Completion oracle; it is read only through the displayed rows of M_f.

Project the first carrier along the same finite pattern. The matching request therefore passes through D_f, then K_f, then S_f, then G_f and Q_f, and only after those finite rows have been replayed does it reach the terminal Real seal R_f.

The structural rows add no new primitive. The BHist, hsame, Cont, Pkg, and NameCert coordinates in M_f and M_g transport and name the two projected routes, so their concatenation is still a finite tolerance-to-window route built from the displayed carrier rows alone. □

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityCompositionRoute`

Theorem 1631.7 (Modulus-continuity double-composition route)**.** *Let*

$$M_f = (G_f, S_f, K_f, D_f, Q_f, R_f, H_f, C_f, P_f, N_f),$$

$$M_g = (G_g, S_g, K_g, D_g, Q_g, R_g, H_g, C_g, P_g, N_g),$$

and

$$M_h = (G_h, S_h, K_h, D_h, Q_h, R_h, H_h, C_h, P_h, N_h)$$

be accepted ModulusContinuity$^{\uparrow}$ *carriers whose target and source surfaces match consecutively. Then every target tolerance request for the triple composed Real or Completion consumer factors through the finite concatenated route*

$$D_h \to K_h \to S_h \to G_h \to Q_h \to D_g \to K_g \to S_g \to G_g \to Q_g \to D_f \to K_f \to S_f \to G_f \to Q_f \to R_f.$$

The route uses only the displayed ContinuousMap$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of the three carriers.*

Proof. Apply Definition 1631.6 first to M_g and M_h. The outer tolerance request is routed through D_h, K_h, S_h, G_h, Q_h and then through the matched surface of M_g.

Apply the same composition route to the resulting matched surface and M_f. The second handoff extends the displayed route through D_g, K_g, S_g, G_g, Q_g and then through $D_f, K_f, S_f, G_f, Q_f, R_f$.

Use Definition 1631.3 at both matched surfaces. The handoff theorem prevents either match from becoming a detached continuity oracle, an ambient completeness row, or a selected Real limit; each match is read only through the displayed carrier rows.

The structural rows only transport and source the same finite route. Componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows concatenate the three packet routes without adding any object beyond the displayed modulus-continuity inventories. □

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityDoubleCompositionRoute`

Theorem 1631.8 (Modulus-continuity composition associativity route)**.** *For three accepted* ModulusContinuity$^{\uparrow}$ *carriers with matching consecutive source and target surfaces, applying the composition route as* $(h \circ g) \circ f$ *or as* $h \circ (g \circ f)$ *exposes the same finite tolerance-to-window route through the displayed* D, K, S, G, Q, R *rows of the three carriers and the same structural* H, C, P, N *rows. Neither parenthesization exports open-cover compactness, selected limits, quotient stream equality, host real equality, detached continuity oracles, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Apply Definition 1631.6 twice in the parenthesization $(h \circ g) \circ f$. The outer request reads through the rows of M_h, then the rows of M_g, and finally the rows of M_f before reaching the terminal Real seal.

Apply the same theorem twice in the parenthesization $h \circ (g \circ f)$. The intermediate grouping changes which composed route is named first, but the displayed tolerance-to-window reads still pass through the same D, K, S, G, Q, R rows in the same carrier order.

Compare both readings with the double-composition route of Definition 1631.7. It records the common finite concatenation, while the structural rows H, C, P, N only transport, replay, source, and name that concatenation.

Finally use Definition 1631.9. Since the composed consumer has no coordinate for compactness, selected limits, quotient stream equality, host real equality, detached continuity oracles, or ambient completeness, neither parenthesization can export one. □

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityCompositionAssociativityRoute`

Theorem 1631.9 (Modulus-continuity composition non-escape)**.** *Under the hypotheses of Definition 1631.6, the composed Real or Completion consumer exports no open-cover compactness, selected limit, quotient stream equality, host real equality, detached continuity oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every exported read is confined to the displayed rows of M_f and M_g and their concatenated finite tolerance-to-window route.*

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityCompositionNonescape`

Proof. Project both carriers through Definition 1631.1. The only rows available in each packet are the continuous-map graph, source window, modulus row, dyadic ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1631.3 to each leg. For M_g, the outer request reads its target tolerance through D_g, K_g, S_g, G_g, Q_g before it reaches the matched surface. For M_f, that matched surface is consumed only through $D_f, K_f, S_f, G_f, Q_f, R_f$.

Now concatenate the two displayed routes using Definition 1631.6. Concatenation adds no coordinate beyond the rows already projected from M_f and M_g; it only orders the finite tolerance-to-window reads into one longer route.

The excluded analytic principles are absent from both carrier inventories. Since transport, replay, provenance, and local naming preserve the displayed rows rather than adding open-cover compactness, selected limits, quotient stream equality, host real equality, detached continuity oracles, or ambient Real completeness, none of those objects can be exported by the composed consumer. □

Theorem 1631.10 (Modulus-continuity public consumer surface)**.** *Every public* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or Completion consumer of an accepted* $\mathsf{ModulusContinuity}^{\uparrow}$ *carrier must read the finite path*

$$D \to K \to S \to G \to Q \to R$$

together with the structural rows H, C, P, N. The exported public surface is exactly the displayed tolerance-to-window route, componentwise transport, continuation replay, provenance, and local naming; it contains no open-cover compactness, selected limit, quotient stream equality, host real equality, detached continuity oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusContinuityUp.ModulusContinuityPublicConsumerSurface`

Proof. Use the Real and Completion handoff of Definition 1631.3. It confines every Real or Completion read to the displayed graph, modulus, source-window, regular readback, dyadic tolerance, Real seal, and structural rows.

The Cauchy route of Definition 1631.4 fixes the order of those analytic rows as $D \to K \to S \to G \to Q \to R$. The uniform Cauchy handoff of Definition 1631.5 gives the same ordered read to public regular-rational consumers.

Composition does not enlarge the public surface. By Definition 1631.6, composed consumers concatenate displayed modulus-continuity routes without adding analytic coordinates, and Definition 1631.9 excludes open-cover compactness, selected limits, quotient stream equality, host real equality, detached continuity oracles, and ambient completeness from the exported route.

Thus the public consumer receives only the finite path and the structural rows H, C, P, N named in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusContinuity}^{\uparrow}$ packet is generated from a ContinuousMap graph row, a source StreamName window, a CauchyModulus tolerance-to-window row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real target seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ModulusContinuity}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1631.1, Definition 1631.2, Definition 1631.3, Definition 1631.4, Definition 1631.5, Definition 1631.6, Definition 1631.9, and Definition 1631.10 bind the public consumer surface as the bridge-facing route through ContinuousMap, CauchyModulus, StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ModulusContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: The mature paper-side treatment is complete for the displayed public consumer surface; formal and bridge verification remain separate verification-axis work.

Chapter 1632

A Concrete Naming Certificate for $\mathsf{CauchyContinuousExtension}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{CauchyContinuousExtension}^{\uparrow}$ packet records the finite handoff by which a Cauchy-continuous map on regular rational source data is read through the displayed completion route before it reaches a completed real-facing extension. It consumes the finite windows of chapter 126, the regular rational source rows of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the regular completion universal surface of chapter 1425, the extension and uniqueness interface of chapter 397, and the uniformly continuous extension route of chapter 769. The chapter names the Cauchy-continuous completion-extension boundary as finite BEDC data; it does not turn host completion, quotient representatives, or function equality into packet coordinates.

Definition 1632.1 (Cauchy-continuous extension carrier)**.** *A* $\mathsf{CauchyContinuousExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, W, D, F, U, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular-Cauchy row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *data and the regular source discipline of* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$*;*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule for source observations and comparison requests;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling Cauchy-continuous requests on those windows;*
4. *F is the Cauchy-continuous map row, recording that matching source windows inside the tolerance ledger produce matching target completion reads;*
5. *U is the completion-universal extension row, read through* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *and aligned with the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff when a uniform-modulus row is present;*
6. *L is the uniqueness ledger comparing two extension rows over the same regular source, finite windows, dyadic ledger, Cauchy-continuous map row, and completion-universal extension row;*
7. *H records componentwise* hsame *transport for S, W, D, F, U, L;*
8. *C records the displayed* Cont *replay route forcing every extension read through S, W, D, F, U, L in that order;*

9. *P is the* Pkg *provenance over* RegularCauchyCompletionUniversal$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, UniformContinuousExtension$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and local* NameCert *rows;*

10. *N is the local* NameCert$_{\text{CauchyContinuousExtension}^{\uparrow}}$ *row.*

The carrier stores no host function equality, quotient completion, selected limit, countable-choice schedule, or ambient completeness coordinate.

Theorem 1632.2 (CauchyContinuousExtension NameCert obligations)**.** *For the carrier of Definition 1632.1, the local* NameCert$_{\text{CauchyContinuousExtension}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet $E = (S, W, D, F, U, L, H, C, P, N)$;*

2. *regular source handoff, requiring each extension request to read S through the finite windows W and tolerance ledger D before any completion-facing row is available;*

3. *Cauchy-continuous map control, requiring the map row F to transport source Cauchy closeness into the target completion request consumed by U;*

4. *extension and uniqueness control, requiring the completion-universal row U and uniqueness ledger L to compare candidate extensions only over the same displayed source, window, tolerance, and map rows;*

5. *ledger non-escape, stating that H, C, P, N expose no host function equality, quotient completion, selected limit, countable choice, or ambient completeness principle.*

Proof. Project the packet in Definition 1632.1. Carrier admission is exactly the presence of the ten rows $S, W, D, F, U, L, H, C, P, N$ with a local naming row.

The source handoff reads the first three coordinates. The regular source S is visible only through the finite StreamName windows W and the dyadic tolerance ledger D, so a completion-facing request cannot bypass the regular rational source route.

The map and extension clauses then read F and U. The Cauchy-continuous map row F is the only route from source Cauchy closeness to a target completion request, and U is the only row that repacks that request through the completion-universal extension surface.

Finally the comparison and non-escape clauses inspect L, H, C, P, N. The uniqueness ledger L compares extensions over the same displayed coordinates, while H and C only transport and replay those coordinates. Since no excluded principle is a carrier coordinate, the five obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.CauchyContinuousExtensionNameCertObligations`

Theorem 1632.3 (CauchyContinuousExtension regular source handoff)**.** *Let $E = (S, W, D, F, U, L, H, C, P, N)$ be an accepted* CauchyContinuousExtension$^{\uparrow}$ *carrier. Every extension read exported by U factors through the regular-Cauchy source row S, the finite window schedule W, the dyadic tolerance ledger D, and the Cauchy-continuous map row F before it reaches the completion-universal extension surface.*

Proof. Start with the source coordinates. The rows S, W, D record the only regular-Cauchy observations available to the packet, so every admitted source read is a finite-window and tolerance-ledger read.

Apply the map row next. The row F consumes exactly those source reads and records the Cauchy-continuous target request; it is not accompanied by a separate host map or selected target limit.

The extension row U is therefore reached only after the route S, W, D, F has been replayed. The Cont row C preserves this order, and the provenance row P records the same sibling surfaces. Hence every exported extension factors through the regular source handoff before reading the completion-universal surface. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.TasteGate.CauchyContinuousExtensionRegularSourceHandof`

Theorem 1632.4 (CauchyContinuousExtension uniqueness ledger)**.** *Let $E = (S, W, D, F, U, L, H, C, P, N)$ and $E' = (S, W, D, F, U', L', H', C', P, N')$ be accepted* CauchyContinuousExtension$^{\uparrow}$ *carriers over the same regular source, finite windows, dyadic ledger, Cauchy-continuous map row, and provenance. Any comparison of the exported extension rows is exhausted by the displayed uniqueness ledgers L and L' together with componentwise* hsame *transport over S, W, D, F, U and U'. No host function equality, quotient completion, selected limit, countable choice, or ambient completeness row can contribute to the comparison.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.TasteGate.CauchyContinuousExtensionUniquenessLedger`

Proof. Read the shared coordinates S, W, D, F, P. They fix the regular source, window schedule, dyadic tolerance ledger, Cauchy-continuous map row, and provenance for both packets.

The only extension-specific coordinates are U, L, H, C, N and U', L', H', C', N'. The ledgers L and L' compare the two extension rows over the same shared source route, while H, H' provide only componentwise hsame transport and C, C' replay only the displayed coordinate order.

Because neither carrier contains host function equality, quotient completion, selected limits, countable-choice schedules, or ambient completeness witnesses, no external comparison principle is available. The uniqueness judgement is exactly the local ledger comparison over the displayed Cauchy-continuous extension route. □

Definition 1632.5 (Cauchy extension uniform-modulus sink)**.** *The uniform-modulus sink for a* CauchyContinuousExtension$^{\uparrow}$ *packet is the finite route*

$$S, W, D, F, U \longmapsto L, H, C, P, N$$

in which the StreamName$^{\uparrow}$ *windows W,* RegSeqRat$^{\uparrow}$ *regular source row S,* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, Cauchy-continuous map row F, and* UniformContinuousExtension$^{\uparrow}$ *modulus row recorded inside U are read before the completion-universal extension row can be consumed. The sink exports only the displayed completion-universal extension boundary and its uniqueness, transport, replay, provenance, and local naming rows; it exports no host function equality, quotient completion, selected limit, countable-choice schedule, or ambient completeness coordinate.*

Lean4 (definition) `BEDC.Derived.CauchyContinuousExtensionUp.CauchyExtensionUniformModulusSink`

Theorem 1632.6 (Cauchy extension regular-tail transport)**.** *Let $E = (S, W, D, F, U, L, H, C, P, N)$ be an accepted* CauchyContinuousExtension$^{\uparrow}$ *carrier. Componentwise* hsame *transport preserves the uniform-modulus sink of Definition 1632.5 only through the displayed rows $S, W, D, F, U, L, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.CauchyExtensionRegularTailTransport`

Proof. Project the accepted carrier. The sink begins with the regular source row S, finite windows W, dyadic tolerance ledger D, Cauchy-continuous map row F, and the extension/modulus handoff stored in U.

Componentwise hsame transport is recorded by H for exactly those rows and for the uniqueness ledger L. The replay row C then preserves the same order before provenance and local naming are read.

No other row is present in the carrier. Thus transport cannot use host function equality, quotient completion, selected limits, countable choice, or ambient completeness; it preserves the regular-tail sink precisely through $S, W, D, F, U, L, H, C, P, N$. □

Theorem 1632.7 (Cauchy extension completion consumer)**.** *Every* Real$^{\uparrow}$ *or* CompletionUniversalProperty$^{\uparrow}$ *consumer of an accepted* CauchyContinuousExtension$^{\uparrow}$ *packet reads the uniform-modulus sink of Definition 1632.5 before it can inspect the exported extension row.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.TasteGate.CauchyContinuousExtensionCarrier completion consumer`

Proof. Start with an accepted packet $E = (S, W, D, F, U, L, H, C, P, N)$. A real-facing or completion-universal consumer can reach the exported extension only through U, because the carrier contains no second extension coordinate.

The row U is available only after the source windows, regular source, dyadic tolerance ledger, Cauchy-continuous map row, and uniform-modulus handoff have been read. This is exactly the sink route named in Definition 1632.5.

The remaining rows L, H, C, P, N compare, transport, replay, source, and name the same route. Hence a Real$^{\uparrow}$ or CompletionUniversalProperty$^{\uparrow}$ consumer must read the uniform-modulus sink before inspecting the exported extension. □

Theorem 1632.8 (Cauchy-continuous extension choice-free density route)**.** *Every accepted* CauchyContinuousExten *extension read*

$$E = (S, W, D, F, U, L, H, C, P, N)$$

must expose the dense regular-Cauchy source row S, the finite StreamName$^{\uparrow}$ *windows W, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, and the Cauchy-continuous map row F before the extension row U is consumed. The displayed route reads through* RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RegularCauchyCompletionUniversal$^{\uparrow}$, *and* UniformContinuousExtension$^{\uparrow}$ *as finite packet data; it refuses selected representatives, host function equality, quotient completion, countable choice, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.CauchyContinuousExtensionCarrier choice free density route`

Proof. Project the carrier of Definition 1632.1. The rows $S, W, D, F, U, L, H, C, P, N$ are the only coordinates available to an accepted extension read.

Apply Definition 1632.3. It places the regular-Cauchy source row, finite windows, dyadic tolerance ledger, and Cauchy-continuous map row before the completion-universal extension surface can be read.

Use the sink of Definition 1632.5 and the consumer boundary of Definition 1632.7. Together they show that a Real$^{\uparrow}$ or completion-facing consumer reaches U only through the displayed finite-window route.

Thus density is carried by the visible regular-Cauchy source and its finite window ledger. Since no selected representative, host function equality, quotient completion, countable-choice schedule, or ambient completeness coordinate appears in the packet, the density route is choice-free BEDC data rather than an external selection principle. □

Theorem 1632.9 (Cauchy-continuous extension Real uniform handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyContinuousExtension}^{\uparrow}$ *packet that asks for a uniform entourage must first read the sink rows* S, W, D, F, U *of Definition 1632.5 and then the positive-radius and metric-entourage route of* $\mathsf{RealUniformStructure}^{\uparrow}$ *from chapter 1624. The handoff cannot inspect selected limits, quotient filters, countable choice, host function equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.CauchyContinuousExtensionCarrier real uniform handoff`

Proof. Start with the completion consumer theorem Definition 1632.7. A Real-facing consumer reaches the exported extension row only through the sink displayed by S, W, D, F, U.

Apply the choice-free density route of Definition 1632.8. It forces the same consumer to read the dense regular-Cauchy source, finite StreamName windows, dyadic tolerance ledger, and Cauchy-continuous map row before the extension row is consumed.

Now read the Real uniform-structure chapter. The metric-uniformity handoff and finite entourage-basis route of chapter 1624 expose uniform entourages only through Real endpoints, metric distance data, positive dyadic radii, generated entourage rows, finite windows, and regular rational readback.

Composing these routes gives the claimed handoff. The Cauchy-continuous extension packet supplies the sink rows, and the Real uniform-structure packet supplies the positive-radius entourage route; neither carrier contains selected limits, quotient filters, countable choice, host function equality, or ambient Real completeness. □

Theorem 1632.10 (Cauchy-continuous extension Hausdorff pullback route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyContinuousExtension}^{\uparrow}$ *packet that compares two exported extension rows through separated completion data must first read the sink rows* S, W, D, F, U *of Definition 1632.5, then the* $\mathsf{RealUniformStructure}^{\uparrow}$ *positive-radius route of chapter 1624, and then the* $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ *packet of chapter 8585. The comparison cannot inspect selected limits, quotient filters, countable choice, host function equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousExtensionUp.CauchyContinuousExtensionCarrier hausdorff pullback route`

Proof. Start with Definition 1632.7. A consumer reaches an exported extension row only through the completion sink, so the rows S, W, D, F, U must be displayed before any separated comparison can be requested.

Apply Definition 1632.8. It keeps the dense regular-Cauchy source, finite windows, dyadic tolerance ledger, and Cauchy-continuous map row on the public route, excluding selected representatives and countable-choice schedules.

Use Definition 1632.9. This routes the Real-facing read through the positive-radius and metric-entourage surface of $\mathsf{RealUniformStructure}^{\uparrow}$ before any Real comparison is consumed.

Finally project the carrier of Definition 8585.1. The rows $S, W, D, P_0, P_1, H_0, H_1, U, T, C, Q, N$ force the two exported extension rows through the Hausdorff separation witnesses before the pullback comparison becomes public, and no carrier coordinate remains for quotient filters, host equality, selected limits, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuousExtension}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyContinuousExtension}^{\uparrow}$ packet is generated from a regular-Cauchy source row, finite StreamName windows, a DyadicRatCore tolerance ledger, a Cauchy-continuous map row, a CompletionUniversalProperty

extension row, a uniqueness hsame ledger, displayed transport and replay rows, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyContinuousExtension}\uparrow}$, seed)

Scope closed: Definition 1632.1, Definition 1632.2, Definition 1632.3, and Definition 1632.4 seed the finite Cauchy-continuous extension route over the L10 Real and Completion spine.

Formal verification: FormalStatus(NameCert$_{\text{CauchyContinuousExtension}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyContinuousExtensionUp.TasteGate.CauchyContinuousExtensionTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not claim host function equality, quotient completion, selected limits, countable choice, ambient completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, regular-source handoff, Cauchy-continuous map control, completion-universal extension control, uniqueness-ledger exactness, and ledger non-escape for BEDC.Derived.CauchyContinuousExter

Chapter 1633

A Concrete Naming Certificate for $\mathsf{DyadicTailBall}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicTailBall}^{\uparrow}$ packet records the finite late-tail enclosure by which a regular Cauchy source enters a displayed dyadic ball before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads a seal. It binds the center-radius surface of chapter 311, the threshold and tolerance ledger of chapter 379, the late-tail route of chapter 1605, and the Real-specific Cauchy consumer of chapter 1590. The packet is a finite induction-friendly bridge from tail control to dyadic-ball containment; it is not a quotient stream, not a selected limit, not countable choice, not host real equality, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

The horizontal dependency route is substantive rather than decorative: chapter 379 supplies the late threshold and tolerance evidence, chapter 1605 turns that evidence into cofinite tail windows, chapter 311 records the resulting center-radius containment, and chapter 1590 is the downstream consumer that reads this finite late-tail containment bridge.

Definition 1633.1 (DyadicTailBall late-tail carrier)**.** *A* $\mathsf{DyadicTailBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, D, F, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{DyadicBall}^{\uparrow}$ *center-radius packet, carrying the dyadic center, positive radius, scheduled observation row, and containment ledger read from Definition 311.1.*
2. *D is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *threshold and tolerance ledger, recording the displayed late-tail threshold, dyadic tolerance budget, finite comparison rows, and seal-facing readback route.*
3. *F is the* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *route that exposes the cofinite late-tail neighbourhoods through the same threshold and tolerance rows before any downstream Cauchy consumer can inspect the packet.*
4. *R is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row, reading the late-tail windows, regular rational readback, dyadic tolerance ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal only after B, D, F have been displayed.*
5. *H records componentwise* hsame *transport for the dyadic ball row, tail-bound ledger, regular Cauchy tail-filter route, Real Cauchy criterion consumer, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a late-tail request through D, then through F, into the containment row of B, and finally into the consumer row R.*

7. *P is the* Pkg *provenance over* $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyTailFilter}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBall}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their componentwise hsame *transports, their displayed* Cont *routes, their* Pkg *provenance, and their local* NameCert *rows. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.TasteGate.DyadicTailBallTasteGate single carrier alignment`

Theorem 1633.2 (DyadicTailBall NameCert obligations)**.** *For every accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *carrier* $T = (B, D, F, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicTailBall}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic center-radius packet, dyadic tail-bound threshold and tolerance ledger, regular Cauchy tail-filter route, Real Cauchy criterion consumer, transport, replay, provenance, and local naming row;*

2. *tail-bound exactness, requiring the threshold and tolerance read by F and R to be the same displayed threshold and dyadic budget carried by D;*

3. *ball-containment exactness, requiring the late-tail observations admitted through F to enter the containment ledger of B before the consumer row R is exposed;*

4. *transport and replay stability, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the ordered route D, F, B, R;*

5. *provenance exhaustion, requiring P and N to name only the displayed rows and to export no quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1633.1. The visible packet consists of the dyadic ball row B, the tail-bound ledger D, the late-tail filter route F, the Real Cauchy criterion consumer R, and the structural rows H, C, P, N.

Tail-bound exactness is read from the order of D and F. The regular Cauchy tail-filter route may expose only the threshold and tolerance ledger already displayed by D, so no unrecorded tail selector or separate rational budget can enter the packet.

Ball-containment exactness is supplied by B. The late observations admitted through F are replayed through C into the center-radius containment ledger of the $\mathsf{DyadicBall}^{\uparrow}$ row before R can consume the packet.

Transport and replay are structural. Componentwise hsame in H preserves the four public rows D, F, B, R, and displayed Cont replay in C repeats the same route from late-tail request to dyadic-ball containment and then to the Real Cauchy criterion consumer.

Finally, provenance is exhausted by P and N. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness, the local certificate cannot export any such object. □

Theorem 1633.3 (DyadicTailBall regular Cauchy consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

Thus a consumer first reads the displayed late-tail threshold and dyadic tolerance ledger, then the regular Cauchy tail-filter route, then the dyadic center-radius containment packet, and only then the Real Cauchy criterion row with its terminal seal. The exported route contains no quotient stream, selected limit, countable-choice selector, host real equality, trichotomy, or ambient Real completeness assertion.

Proof. Start with an accepted packet $T = (B, D, F, R, H, C, P, N)$. Carrier projection exposes D as the only threshold and tolerance source available to the late-tail route.

Replay the continuation row C. The request first passes through D, then through F, so the regular Cauchy tail-filter reads the same finite threshold, tolerance, and comparison ledger rather than an external convergence predicate.

The next public row is the dyadic ball packet B. Its center-radius containment ledger receives the late-tail observations supplied by F, and its classifier reads only the displayed center, radius, schedule, observation, containment, transport, replay, provenance, and naming rows.

Only after this containment row has been replayed can the consumer inspect R. The Real Cauchy criterion row therefore receives a finite dyadic-ball late-tail packet rather than a quotient stream or a selected limit.

Transport through H and provenance through P, N preserve the same ordered route. The excluded quotient, choice, host-equality, trichotomy, and completeness objects are absent from the carrier inventory, so no consumer read can export them. □

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.TasteGate.DyadicTailBallCarrier regular cauchy consumer route`

Theorem 1633.4 (DyadicTailBall late-window stability)**.** *Let* $T = (B, D, F, R, H, C, P, N)$ *and* $T' = (B, D', F', R, H', C', P', N')$ *be accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packets sharing the same* $\mathsf{DyadicBall}^{\uparrow}$ *row* B *and the same* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row* R*. Suppose the second* $\mathsf{DyadicTailBound}^{\uparrow}$ *row* D' *refines the threshold and tolerance ledger of* D *through the* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *routes* F, F'*. Then every* $\mathsf{Real}^{\uparrow}$*-facing read available from* T *is available from* T' *through the same finite route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

The refinement exports no quotient stream, selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the two carriers. They share the dyadic ball row B and the Real Cauchy criterion consumer row R, so the only public late-tail change is the replacement of D, F by the refined pair D', F'.

Use the refinement hypothesis to replay every late-tail request through D' and F'. Because the refined threshold and tolerance ledger is served by the same regular Cauchy tail-filter route, each observation admitted by the first packet is still admitted before the shared containment ledger B is read.

The Real-facing consumer remains fixed. After B receives the refined late-tail observations, the same row R consumes the packet, so the public route has the same four stages as in Definition 1633.3.

Finally, replay H', C', P', N' componentwise. These rows transport, continue, source, and name the refined packet without adding any coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallWindowStability`

Theorem 1633.5 (DyadicTailBall monotone inclusion)**.** *Let $T = (B, D, F, R, H, C, P, N)$ and $T' = (B, D', F', R, H', C', P', N')$ be accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packets with the same* $\mathsf{DyadicBall}^{\uparrow}$ *row B and the same* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row R. Suppose D' refines the dyadic tail-bound ledger of D, and suppose the refined route preserves the same containment handoff from F' into B and the same Real Cauchy criterion handoff into R. Then every late-tail containment read accepted by T is accepted by T' through the same dyadic-ball containment row.*

Equivalently, tightening the displayed threshold or tolerance budget while preserving B and R gives a monotone inclusion of accepted containment reads. The inclusion exports no quotient stream, selected limit, countable-choice selector, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallMonotoneInclusion`

Proof. Project the two accepted carriers through Definition 1633.1. The public ball row B and Real Cauchy criterion row R are shared, so the containment target and terminal consumer boundary do not change.

Apply the regular Cauchy consumer route of Definition 1633.3. Every accepted containment read from T passes through the displayed order

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

The refinement hypothesis replaces D, F by D', F' without changing the ball containment row B or the consumer row R. Hence any late-tail observation already admitted through D, F is replayed through the refined threshold and tolerance ledger before it reaches the same containment row.

It remains to check that the refined packet exports only the same public route. This is exactly the late-window stability statement of Definition 1633.4: the refined rows H', C', P', N' transport, replay, source, and name the packet without adding quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness. □

Theorem 1633.6 (DyadicTailBall radius monotonicity)**.** *Let $T = (B, D, F, R, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packet. Suppose B' is obtained from the dyadic-ball row B by replacing the displayed radius row with a smaller displayed radius, while preserving the same center row, the same shared tail-bound ledger D, and the same* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row R. If the refined containment ledger still receives the late-tail observations admitted through F, then the refined packet factors through the same route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

Thus radius refinement is a finite containment-refinement read, not a new convergence principle, quotient stream, selected limit, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallRadiusMonotonicity`

Proof. Project the accepted packet. The only proposed change is the dyadic-ball radius coordinate inside B; the tail-bound ledger D, the regular late-tail route F, and the Real Cauchy criterion consumer R are shared.

Use the displayed radius refinement to form B'. Since the refined radius is smaller and the late-tail observations are assumed to enter the refined containment ledger, every containment read that reaches B' still arrives from the same D, F route.

Apply Definition 1633.5. It identifies the accepted containment reads after the radius replacement with reads through the same dyadic-ball containment row and the same downstream consumer boundary.

Finally, invoke late-window stability from Definition 1633.4. The structural rows transport, replay, source, and name the refined packet without adding quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness. □

Theorem 1633.7 (DyadicTailBall radius-monotone containment)**.** *Let $T = (B, D, F, R, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packet, and let $T' = (B', D, F', R, H', C', P', N')$ be an accepted refined packet with the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger D, the same* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *handoff shape, and the same* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row R. Suppose B' displays a smaller radius than B and the refined late-tail handoff still feeds the containment ledger of B' before R is read. Then every accepted refined containment read remains a read of the same finite* $\mathsf{DyadicTailBall}^{\uparrow}$ *route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

The containment refinement exports no quotient stream, selected limit, countable-choice selector, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with radius monotonicity from Definition 1633.6. The smaller displayed radius changes only the dyadic-ball radius coordinate, while the shared tail-bound ledger D and Real Cauchy criterion consumer R keep the public route fixed.

Apply monotone inclusion from Definition 1633.5. Since the refined handoff preserves the same dyadic tail-bound ledger and the same downstream consumer boundary, accepted containment reads for the refined packet are still reads through the displayed dyadic-ball containment row.

Use late-window stability from Definition 1633.4. The refined structural rows H', C', P', N' transport, replay, source, and name the same late-tail route without adding quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallRadiusMonotoneContainment`

Theorem 1633.8 (DyadicTailBall threshold refinement route)**.** *Let $T = (B, D, F, R, H, C, P, N)$ and $T' = (B, D', F', R, H', C', P', N')$ be accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packets with the same dyadic-ball row B, the same dyadic tolerance budget, the same regular Cauchy tail-filter handoff shape, and the same* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row R. Suppose D' tightens only the displayed threshold of D, and suppose the refined handoff still routes the admitted late-tail observations through F' before they enter B and R. Then every accepted containment read factors through the same finite route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

Thus threshold refinement is a late-window route refinement at fixed radius and fixed consumer boundary; it is not a quotient stream, selected limit, countable-choice selector, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the two accepted carriers. The dyadic-ball row B, the dyadic tolerance budget, and the Real Cauchy criterion row R are fixed, so the only public change is the displayed threshold inside D together with its regular Cauchy handoff F'.

Apply the regular Cauchy consumer route of Definition 1633.3. Both packets must read the same ordered route from tail-bound ledger to late-tail filter, then to dyadic-ball containment, and finally to the Real Cauchy criterion consumer.

Use late-window stability from Definition 1633.4. Tightening the threshold while keeping the tolerance budget and downstream rows fixed only delays the window at which the same containment evidence is replayed; it does not create a new radius, a new consumer row, or an external convergence predicate.

Finally apply monotone inclusion from Definition 1633.5. The refined threshold route preserves accepted containment reads through the same B and R, while H', C', P', N' transport, replay, source, and name only the displayed rows. Since quotient streams, selected limits, countable choice, trichotomy, host real equality, and ambient Real completeness are absent from the carrier inventory, the refined route cannot export them. □

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallThresholdRefinementRoute`

Theorem 1633.9 (Dyadic tail ball RealEquality consumer)**.** *Let $T = (B, D, F, R, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packet. Suppose the packet is presented as a monotone late-tail ball route in which the finite tail window accepted by the* $\mathsf{DyadicTailBall}^{\uparrow}$ *carrier is the same displayed* $\mathsf{StreamName}^{\uparrow}$ *window used by two regular-rational readbacks. Then T supplies exactly the dyadic tolerance ledger consumed by a* $\mathsf{RealEquality}^{\uparrow}$ *classifier row over those two readbacks.*

Equivalently, when both $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks are routed through the same displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the monotone tail-ball packet may be consumed as the tolerance side of the* $\mathsf{RealEquality}^{\uparrow}$ *classifier without adding quotient real equality, a selected limit, or any completeness datum.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallRealEqualityConsumer`

Proof. Start with the regular Cauchy consumer route of Definition 1633.3. It exposes the displayed order

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

Apply late-window stability from Definition 1633.4. Refining the late-tail window changes only the displayed threshold and tolerance ledger while preserving the same ball row and the same Real-facing consumer boundary.

Apply monotone inclusion from Definition 1633.5. The accepted containment reads of the original packet are still accepted after the refined route, so the dyadic ledger remains the public tolerance source for the shared window.

Finally route both regular-rational readbacks through the same displayed $\mathsf{StreamName}^{\uparrow}$ window and consume the classifier surface of chapter 1636. The $\mathsf{RealEquality}^{\uparrow}$ row receives the dyadic tolerance ledger already displayed by the $\mathsf{DyadicTailBall}^{\uparrow}$ packet; no quotient real equality, selected limit, or completeness datum is introduced. □

Theorem 1633.10 (Dyadic tail-ball RegSeqRat window consistency)**.** *Let $T_0 = (B_0, D, F_0, R, H_0, C_0, P_0, N_0)$ and $T_1 = (B_1, D, F_1, R, H_1, C_1, P_1, N_1)$ be accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packets feeding the same* $\mathsf{RegSeqRat}^{\uparrow}$ *late-tail consumer and sharing the displayed* $\mathsf{DyadicTailBound}^{\uparrow}$ *ledger D. If both packets route their*

ball-containment rows through the same displayed late-tail window before the Real-facing equality consumer is read, then the exposed tolerance route is the same finite route

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Thus the shared $\mathsf{RegSeqRat}^{\uparrow}$ *window is determined by the finite dyadic tail-bound and ball-containment rows, not by quotient streams, selected limits, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallRegSeqWindowConsistency`

Proof. Apply the regular Cauchy consumer route of Definition 1633.3. Both packets must first expose the same dyadic tail-bound ledger D before their late-tail filters and ball-containment rows can be consumed.

Use late-window stability from Definition 1633.4. Since the late-tail consumer is the same $\mathsf{RegSeqRat}^{\uparrow}$ read and the displayed tail-bound ledger is shared, both routes inspect the same finite window boundary before any Real-facing equality consumer appears.

Apply monotone inclusion from Definition 1633.5 and the threshold-refinement route of Definition 1633.8. These keep accepted containment reads fixed by the displayed dyadic tail-bound and ball-containment rows, even when the threshold presentation is refined.

Finally compare with Definition 1633.9. The Real-facing equality row can read only the already displayed tolerance ledger, so it cannot introduce quotient streams, selected limits, trichotomy, host real equality, or ambient completeness into the shared $\mathsf{RegSeqRat}^{\uparrow}$ window. □

Theorem 1633.11 (Dyadic tail-ball regular Cauchy apartness route)**.** *Let* $T_0 = (B_0, D, F_0, R, H_0, C_0, P_0, N_0)$ *and* $T_1 = (B_1, D, F_1, R, H_1, C_1, P_1, N_1)$ *be accepted* $\mathsf{DyadicTailBall}^{\uparrow}$ *packets sharing the displayed* $\mathsf{StreamName}^{\uparrow}$ *window used by two regular rational readbacks. Suppose the regular rational readbacks are separated by a displayed dyadic tolerance ledger carried through the shared tail-bound row* D*. Then every apartness-facing consumer of the pair factors through the finite route*

$$\mathsf{DyadicTailBound}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

before any $\mathsf{RealEquality}^{\uparrow}$ *consumer is read. The route exports only the displayed tail threshold, dyadic tolerance ledger, regular Cauchy tail-filter handoff, dyadic-ball containment rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks; it exports no quotient stream equality, selected limits, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicTailBallUp.DyadicTailBallRegularCauchyApartnessRoute`

Proof. Start with the regular Cauchy consumer route of Definition 1633.3. Each accepted packet exposes its late-tail read in the order from $\mathsf{DyadicTailBound}^{\uparrow}$ through $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ and $\mathsf{DyadicBall}^{\uparrow}$ before a Real-facing row can inspect the packet.

Use the RegSeqRat window consistency theorem, Definition 1633.10. Because the two packets share the displayed $\mathsf{StreamName}^{\uparrow}$ window and the same dyadic tolerance ledger D, the regular rational readbacks are compared inside the common finite route ending at $\mathsf{RegSeqRat}^{\uparrow}$.

The displayed separation ledger is therefore read as a dyadic-tail and ball-containment fact before the Real-facing equality row appears. The RealEquality consumer of Definition 1633.9 can only consume that already displayed tolerance surface; it cannot insert a quotient stream equality or a selected limit.

Finally inspect the carrier inventory. The accepted packets contain no coordinate for quotient stream equality, selected limits, trichotomy, or ambient Real completeness, and the apartness-facing read is only a route through the displayed dyadic ledger and regular rational window. □

The late-window $\mathsf{DyadicTailBall}^{\uparrow}$ carrier is consumed through the $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301 and the $\mathsf{RealEquality}^{\uparrow}$ route of chapter 1636. Tail-ball reads expose their dyadic tail-bound, regular Cauchy tail-filter, and dyadic-ball containment rows before those sibling consumers inspect them, so they do not bypass the regular-rational or Real-equality rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTailBall}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicTailBall}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1633.1, Definition 1633.2, and Definition 1633.3 seed the finite route from dyadic tail bounds through regular Cauchy late-tail filters into dyadic ball containment and the Real Cauchy criterion consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicTailBall}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, tail-bound exactness, ball-containment exactness, transport stability, replay stability, Real Cauchy consumer factorization, and provenance exhaustion for BEDC.Derived.DyadicTailBallUp.

Constructive story: A $\mathsf{DyadicTailBall}^{\uparrow}$ packet is generated from a DyadicBall center-radius packet, a DyadicTailBound threshold and tolerance ledger, a RegularCauchyTailFilter route, a RealCauchyCriterion consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1634

A Concrete Naming Certificate for $\mathsf{WeierstrassApproximation}^{\uparrow}$

Following Weierstrass' approximation theorem in the Bishop–Bridges constructive reading, the $\mathsf{WeierstrassApproximation}^{\uparrow}$ packet records a finite polynomial-approximation surface for a continuous real-valued map on a compact real interval. It consumes the real-name endpoint surface of chapter 38, the interval-window rows of chapter 1625, the compact-uniform-continuity route of chapter 388, the polynomial code surface of chapter 50, the endpoint handoff discipline of chapter 463, and the finite tagged-sum mesh rows of chapter 1615. The packet names the inspected approximation ledger only; it is not an open-cover compactness theorem, a Stone–Weierstrass algebra theorem, a quotient function-space construction, a host supremum norm, a selector for infinite data, or a completeness principle for ambient $\mathsf{Real}^{\uparrow}$.

As a sibling dependency, the finite approximation ledger is a consumer of chapter 388 and chapter 50 before it is exposed to chapter 463.

Definition 1634.1 (Weierstrass approximation carrier)**.** *A* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, F, \varepsilon, P, S, M, E, T, C, R, Q)$$

with the following displayed rows:

1. *I is the compact real interval row, read through* $\mathsf{Real}^{\uparrow}$ *endpoints and the* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *interval-window service.*
2. *F is the continuous-map row over the same interval source, exposing only finite real-name windows on inspected inputs.*
3. *ε is the requested positive rational error row.*
4. *P is the displayed* $\mathsf{Poly}^{\uparrow}$ *row whose coefficient ledger is finite and whose evaluation route is read through the same* $\mathsf{Real}^{\uparrow}$ *arithmetic surface as F.*
5. *S is the finite interval-enclosure sample family, recording the inspected subintervals, sample points, and real-name windows used to compare F with P.*
6. *M is the compact-uniform-modulus row obtained from the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *route for F on I.*
7. *E is the uniform-error ledger saying that every displayed sample comparison is bounded by ε after the modulus row has selected the required mesh scale.*

8. *T stores componentwise* hsame *transport for the interval row, continuous-map row, error row, polynomial row, sample family, compact-uniform-modulus row, and uniform-error ledger.*

9. *C stores the displayed* Cont *routes from interval enclosures to samples, from samples to function and polynomial evaluations, and from those evaluations to the uniform-error ledger.*

10. *R is the* Pkg *provenance over* $\mathsf{WeierstrassApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{CompactUniformContinuit}$ $\mathsf{Poly}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{WeierstrassApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their displayed transports, their continuation routes, provenance, and local naming row. It has no coordinate for open-cover compactness, Stone–Weierstrass generality, quotient equality of functions, a host supremum norm, selected infinite sample data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1634.2 (Weierstrass approximation NameCert obligations)**.** *For every accepted* WeierstrassApproximatio *carrier*

$$W = (I, F, \varepsilon, P, S, M, E, T, C, R, Q),$$

the local $\mathsf{NameCert}_{\mathsf{WeierstrassApproximation}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the interval, continuous-map, error, polynomial, sample, modulus, uniform-error, transport, continuation, provenance, and local naming rows;*

2. *compact interval source compatibility, requiring every sample and endpoint read to pass through the same* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *route attached to I;*

3. *polynomial-row admissibility, requiring P to be a displayed* $\mathsf{Poly}^{\uparrow}$ *code with finite coefficient and evaluation ledgers rather than a host function;*

4. *uniform-error exactness, requiring E to bind the sample comparisons to the requested rational error row ε after the compact-uniform-modulus row M has fixed the mesh scale;*

5. *transport stability, requiring T and C to replay the same interval, sample, evaluation, and error rows under componentwise* hsame *movement;*

6. *ledger refusal, excluding open-cover compactness, Stone–Weierstrass algebra closure, quotient function spaces, host supremum norms, selected infinite data, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and any standard bridge beyond the displayed rows.*

Lean4 ✓ `BEDC.Derived.WeierstrassApproximationUp.WeierstrassApproximationTasteGate single carrier alignment`

Proof. Carrier admission is the projection of Definition 1634.1. The accepted packet exposes exactly the compact interval, continuous map, rational error, polynomial code, sample family, modulus, uniform-error ledger, transport, continuation, provenance, and local name rows.

Source compatibility starts with the interval row I. Every sample in S is read from the same finite interval-enclosure service, so the function row F and the polynomial row P are evaluated on the same inspected real-name windows.

Polynomial admissibility is the row P. Its coefficient and evaluation ledgers are finite $\mathsf{Poly}^{\uparrow}$ data, and the carrier gives no second coordinate for a host function or a quotient of functions.

Uniform-error exactness is the route through M and E. The compact-uniform-modulus row fixes the displayed mesh scale for the requested rational error, and E records the finite comparisons between the inspected F values and the inspected polynomial values.

Transport stability is componentwise. The rows in T move the interval, map, error, polynomial, sample, modulus, and error ledgers, while C replays the same comparison route after transport.

The refusal clauses follow from the inventory. No coordinate names an open cover, a Stone–Weierstrass algebra, a quotient function space, a host norm, an infinite selected sample family, ambient completeness, or a standard bridge. □

Theorem 1634.3 (Weierstrass approximation polynomial handoff)**.** *Every downstream approximation consumer of an accepted* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *carrier factors through the displayed route*

$$I, F, \varepsilon \longmapsto S, M \longmapsto P, E \longmapsto T, C, R, Q.$$

Consequently the consumer reads only the $\mathsf{RealIntervalEnclosure}^{\uparrow}$*,* $\mathsf{CompactUniformContinuity}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{UniformLimit}^{\uparrow}$*,* $\mathsf{RiemannSum}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed by Definition 1634.1.*

Lean4 ✓ `BEDC.Derived.WeierstrassApproximationUp.WeierstrassApproximationPolynomialHandoff`

Proof. Begin with the accepted carrier $W = (I, F, \varepsilon, P, S, M, E, T, C, R, Q)$. The interval and map rows determine the inspected source windows, and the requested error row fixes the comparison threshold.

The sample family S is read through $\mathsf{RealIntervalEnclosure}^{\uparrow}$ and the compact-uniform-modulus row M is read through $\mathsf{CompactUniformContinuity}^{\uparrow}$. These rows determine the finite mesh on which the consumer may compare the continuous-map windows with the polynomial windows.

The polynomial row P supplies only the finite $\mathsf{Poly}^{\uparrow}$ coefficient and evaluation route. The error row E then records the comparison between those polynomial evaluations and the corresponding function evaluations, with $\mathsf{UniformLimit}^{\uparrow}$ and $\mathsf{RiemannSum}^{\uparrow}$ appearing only as downstream finite-window and mesh consumers named in the provenance row.

Finally T, C, R, Q transport, replay, source, and name the same route. Since the carrier has no other coordinate, every downstream approximation consumer factors through exactly these displayed BEDC rows and cannot read an open-cover proof, Stone–Weierstrass algebra closure, quotient function space, host supremum norm, selected infinite data, or ambient real completeness. □

Theorem 1634.4 (Weierstrass approximation UniformLimit consumer)**.** *Every* $\mathsf{UniformLimit}^{\uparrow}$*-facing read of an accepted* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *carrier first reads the compact interval row, continuous-map row, requested rational error, polynomial row, finite samples, compact-uniform modulus, and uniform-error ledger. The consumer boundary is therefore the route*

$$I, F, \varepsilon, P, S, M, E \longmapsto T, C, R, Q,$$

with $\mathsf{UniformLimit}^{\uparrow}$ *appearing only as the finite-window consumer named by the provenance row and by chapter 463.*

Lean4 ✓ `BEDC.Derived.WeierstrassApproximationUp.WeierstrassApproximationUniformLimitConsumer`

Proof. Start from the carrier of Definition 1634.1. Its rows $I, F, \varepsilon, P, S, M, E$ are the only interval, map, error, polynomial, sample, modulus, and uniform-error data exposed before structural replay.

Apply the polynomial handoff of Definition 1634.3. It forces every approximation consumer to pass through the same source-window, sample, modulus, polynomial, and error route before T, C, R, Q can transport, replay, source, and name the packet.

The $\mathsf{UniformLimit}^{\uparrow}$ consumer boundary is then exactly the sibling chapter chapter 463. Since the accepted carrier has no coordinate for a host supremum norm, quotient function space, selected infinite sample family, or ambient completeness principle, a uniform-limit-facing read receives only the displayed finite approximation ledger. □

Theorem 1634.5 (Weierstrass polynomial modulus ledger)**.** *Let $W = (I, F, \varepsilon, P, S, M, E, T, C, R, Q)$ be an accepted* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *packet. The packet exposes the polynomial approximation row P only after the compact-uniform-modulus row M fixes the finite mesh and the sample family S has been read through* $\mathsf{RealIntervalEnclosure}^{\uparrow}$*; the uniform-error ledger E then binds P to the requested rational error row ε.*

Lean4 ✓ `BEDC.Derived.WeierstrassApproximationUp.WeierstrassApproximationPolynomialModulusLedger`

Proof. Read the carrier of Definition 1634.1. The interval row I, continuous-map row F, requested error row ε, sample family S, compact-uniform-modulus row M, and error ledger E are all displayed coordinates of the accepted packet.

Apply the NameCert obligations of Definition 1634.2. Compact interval source compatibility forces S to be read through the same $\mathsf{RealIntervalEnclosure}^{\uparrow}$ service, while uniform-error exactness requires M to fix the finite mesh before E can compare the sampled function values with the polynomial row.

Finally use the polynomial handoff theorem Definition 1634.3. It places every downstream approximation read behind the route from I, F, ε through S, M and then through P, E. Thus E binds the displayed polynomial row P to the requested rational error, and no host supremum norm, quotient function space, selected infinite sample family, or ambient completeness row participates. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeierstrassApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{WeierstrassApproximation}^{\uparrow}$ packet is generated from a compact real interval row, continuous-map row, requested rational error row, displayed polynomial row, finite interval-enclosure samples, compact-uniform-modulus row, uniform-error ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeierstrassApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1634.1, Definition 1634.2, and Definition 1634.3 seed the finite polynomial-approximation surface over compact real intervals and routed continuous-map windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeierstrassApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, Stone–Weierstrass generality, quotient function spaces, host supremum norms, selected infinite data, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval source compatibility, polynomial-row admissibility, uniform-error exactness, transport stability, ledger refusal, and polynomial handoff proofs for BEDC.Derived.WeierstrassAppro

Chapter 1635

A Concrete Naming Certificate for $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$

Following Bishop–Bridges constructive completion together with Kelley/Bourbaki completion terminology, the $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ packet records the finite BEDC certificate for comparing two ways of flattening a triple Cauchy-completion route. It sits over the monadic transformer of chapter 378, the unit route of chapter 1527, the counit route of chapter 1539, the idempotence boundary of **??**, and the minimality ledger of chapter 1606. It also consumes the finite-window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a route-comparison certificate for repeated completion, not a quotient-completion equality, not a selected representative, not host equality of completed objects, not countable choice, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

The same finite flattening route is consumed by the Bishop regular Cauchy completion handoff of chapter 1639, where the shared StreamName, RegSeqRat, DyadicRatCore, and Real rows are read before any completion-facing consumer can ask for a terminal seal.

Definition 1635.1 (CauchyCompletionAssociativity carrier)**.** *A* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, U, V, I, L, S, R, D, E, F, G, H, C, P, N)$$

with the following visible rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-transformer ledger used by all three displayed completion layers.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row admitting the source-facing data into the first completion surface.*
3. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *row returning completion-facing reads to the displayed real-seal boundary.*
4. *I is the* $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$ *row flattening any adjacent pair of completion layers to the same finite route.*
5. *L is the* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *row recording that the flattened route is the least displayed completion service boundary consumed by downstream readers.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the two flattening orders.*

7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplied after the shared stream windows and tolerance ledger have been consumed.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every precision request in the triple-completion route.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by both displayed flattening orders.*
10. *F records the left-associated route that first flattens the outer two completion layers and then flattens the result with the remaining layer.*
11. *G records the right-associated route that first flattens the inner two completion layers and then flattens the result with the remaining layer.*
12. *H records componentwise* hsame *transport for $M, U, V, I, L, S, R, D, E, F, G$ and the structural rows.*
13. *C records displayed* Cont *replay from a triple-completion read through either F or G and then through the shared U, V, I, L, S, D, R, E ledger.*
14. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}$ $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAssociativity}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected Cauchy representatives, host equality of completed objects, countable-choice schedules, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 1635.2 (CauchyCompletionAssociativity NameCert obligations)**.** *For an accepted* CauchyCompletionAss *carrier $A = (M, U, V, I, L, S, R, D, E, F, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAssociativity}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the monad, unit, counit, idempotence, minimality, stream-window, regular-readback, dyadic-tolerance, real-seal, left-route, right-route, transport, replay, provenance, and local naming rows;*
2. *left-associated flattening, requiring the route F to apply the idempotence row I and then the counit/minimality ledger V, L before the shared S, D, R, E surface is exposed;*
3. *right-associated flattening, requiring the route G to apply the same I, V, L ledger in the other finite order before the shared S, D, R, E surface is exposed;*
4. *classifier stability, requiring transported packets with the same $M, U, V, I, L, S, D, R, E, F, G$ rows to be identified by the displayed* hsame *and* Cont *data;*
5. *ledger non-escape, stating that no quotient completion equality, selected representative, host equality, countable-choice schedule, open-cover compactness principle, ambient-completeness theorem, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported by the packet.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionAssociativityUp.CauchyCompletionAssociativityCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1635.1. The tuple lists exactly the completion transformer, unit, counit, idempotence, minimality, shared observation rows, the two association routes, transport, replay, provenance, and local name.

For the left-associated route, read F first. Its first replay flattens one adjacent pair of completion layers through I, then returns the resulting completion-facing read through V and the minimal service boundary L before the shared stream, dyadic, regular, and real-seal rows are consumed.

For the right-associated route, read G first. It uses the same idempotence, counit, and minimality rows in the other finite order, and the replay row C then sends the result to the same S, D, R, E surface.

Classifier stability is componentwise transport along H followed by replay through C. Since the carrier fields are exhausted by $M, U, V, I, L, S, R, D, E, F, G, H, C, P, N$, the excluded quotient, representative-selection, host-equality, choice, compactness, ambient-completeness, and real-completeness principles have no row from which a consumer could read them. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionAssociativityUp.TasteGate.CauchyCompletionAssociativityTasteGate single carrier alignment`

Theorem 1635.3 (CauchyCompletionAssociativity flattening route)**.** *Let $A = (M, U, V, I, L, S, R, D, E, F, G, H, C$ be an accepted* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ *carrier. The two finite routes from a triple completion to the single displayed completion factor through the same unit, counit, idempotence, and minimality ledger:*

$$F \longmapsto I \longmapsto V \longmapsto L \longmapsto S \longmapsto D \longmapsto R \longmapsto E,$$
$$G \longmapsto I \longmapsto V \longmapsto L \longmapsto S \longmapsto D \longmapsto R \longmapsto E.$$

Thus the visible associativity law is equality of the finite BEDC route through $M, U, V, I, L, S, D, R, E, H, C, P, N$, not equality of quotient completions, not host equality of completed metric objects, not a selected representative, and not countable choice or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionAssociativityUp.CauchyCompletionAssociativityFlatteningRoute`

Proof. Project the accepted carrier. The two route rows F and G are the only coordinates that distinguish the left-associated and right-associated flattening orders.

Read the ledger common to both routes. The idempotence row I supplies the adjacent-pair flattening step, the counit row V returns completion-facing reads to the displayed real-seal boundary, and the minimality row L records that downstream consumers receive the least displayed completion service boundary.

After that common ledger, both routes consume the same observation surface. The finite windows are named by S, each precision request is accounted for by D, the regular rational readback is R, and the terminal seal is E.

Finally M and U record the surrounding completion-transformer and source-admission rows, while H, C, P, N transport, replay, source, and name the same packet. No further coordinate remains for quotient equality, host equality, selected representatives, countable choice, or ambient completeness, so the two routes agree exactly on the displayed finite ledger. □

Theorem 1635.4 (CauchyCompletionAssociativity two-route coherence)**.** *Let $A = (M, U, V, I, L, S, R, D, E, F, G,$ and $A' = (M, U, V, I, L, S, R, D, E, F', G', H, C, P, N)$ be accepted* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ *carriers sharing the completion-transformer, unit, counit, idempotence, minimality, StreamName, RegSeqRat, DyadicRatCore, Real-seal, transport, replay, provenance, and local naming rows. Suppose the left and right route rows F, G, F', G' replay through the same displayed structural rows H, C, P, N. Then every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of either carrier receives the same finite ledger*

$$M, U, V, I, L, S, D, R, E, H, C, P, N$$

before any terminal seal is inspected.

Thus the comparison is a coherence statement about the displayed BEDC ledger. It is not quotient completion equality, not a selected representative comparison, not host equality of completed objects, not countable choice, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionAssociativityUp.CauchyCompletionAssociativityCarrier route coherence`

Proof. Project the two accepted carriers. By hypothesis, the non-route rows agree as displayed data: both packets expose the same $M, U, V, I, L, S, R, D, E, H, C, P, N$ rows before either association route is read.

Apply the NameCert obligations of Definition 1635.2. The obligations force carrier admission, left-associated flattening, right-associated flattening, classifier stability, and ledger non-escape to be read only from the displayed rows of each accepted packet.

Use the flattening-route theorem Definition 1635.3. It sends the left and right route rows through the same I, V, L, S, D, R, E ledger, while M, U, H, C, P, N supply the surrounding completion transformer, source admission, transport, replay, provenance, and local name.

Since F, G, F', G' replay through the same H, C, P, N rows, no Real-facing or Completion consumer can distinguish the carriers before the terminal seal by asking for quotient completion equality, a selected representative, host equality, countable choice, or ambient completeness. The only available comparison is the shared finite ledger in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionAssociativity}^{\uparrow}}$ ·

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAssociativity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1635.1, Definition 1635.2, and Definition 1635.3 seed the finite associativity certificate for flattening triple Cauchy-completion routes through the shared unit, counit, idempotence, minimality, StreamName, RegSeqRat, DyadicRatCore, and Real ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAssociativity}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyCompletionAssociativityUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host equality of completed metric objects, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, left- and right-associated flattening, classifier stability, and ledger non-escape for BEDC.Derived.CauchyCompletionAssociativityUp.

Constructive story: The construction starts with a triple-completion read, compares the left- and right-associated finite flattening rows, routes both through the same unit, counit, idempotence, and minimality ledger, and then exposes the shared StreamName, DyadicRatCore, RegSeqRat, and Real seal surface.

Chapter 1636

Real Equality Name Certificate

Following Bishop and Bridges, the $\mathsf{RealEquality}^{\uparrow}$ packet records equality of real names as regular-Cauchy closeness witnessed through finite tolerance requests, not as quotient equality of completed streams. It sits between the terminal real-name seal of chapter 38, the regular-rational source route of chapter 301, the finite-window discipline of chapter 126, the dyadic tolerance core of chapter 291, and the regular-Cauchy uniformity boundary of chapter 1628. The chapter gives downstream RealAlgOrder, metric, and completion-facing certificates a named equality boundary that remains inside displayed BEDC rows.

Definition 1636.1 (RealEquality carrier)**.** *A* $\mathsf{RealEquality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, S_X, S_Y, R_X, R_Y, W, D, U, C, H, K, P, N)$$

with the following displayed rows:

1. *X and Y are the two terminal* $\mathsf{Real}^{\uparrow}$ *seal rows whose equality boundary is being inspected.*
2. *S_X and S_Y are the two* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows admitted by those seals.*
3. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback rows exposed through S_X and S_Y.*
4. *W is the shared finite window of precision requests on which both regular names are compared.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, slack, and comparison budget for every request in W.*
6. *U is the* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *closeness row asserting that the two regular-rational readbacks meet the displayed dyadic tolerance schedule.*
7. *C records the classifier verdict obtained from W, D, U before either terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
8. *H stores componentwise* hsame *transport for the seals, windows, readbacks, tolerance ledger, uniformity row, classifier row, provenance, and local name.*
9. *K stores displayed* Cont *replay from X, Y through $S_X, S_Y, R_X, R_Y, W, D, U, C$ and back to the public equality boundary.*
10. *P records* Pkg *provenance over* $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$ *row.*

The packet has no coordinate for host real equality, quotient classes of streams, trichotomy, selected limits, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealEqualityUp.TasteGate.RealEqualityTasteGate single carrier alignment`

Theorem 1636.2 (RealEquality classifier stability)**.** *For every accepted* $\mathsf{RealEquality}^{\uparrow}$ *carrier* $E = (X, Y, S_X, S_Y, R_X, R_Y, W, D, U, C, H, K, P, N)$*, the classifier row* C *is stable under refinement of the displayed finite observation window whenever the refined window factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. The public equality read therefore depends only on the finite regular-Cauchy closeness route* W, D, U*, not on host equality of* X *and* Y*.*

Lean4 ✓ `BEDC.Derived.RealEqualityUp.RealEqualityCarrier classifier stability`

Proof. Proceed by induction over the finite observation window W. The empty window contributes no classifier read, so the verdict is carried only by the displayed structural rows H, K, P, N.

For a one-request extension, the new request is compared by first reading the two $\mathsf{RegSeqRat}^{\uparrow}$ rows through R_X and R_Y, then consulting the dyadic tolerance ledger D. The row U supplies the regular-Cauchy closeness witness at that dyadic radius, so the classifier verdict is determined before either terminal $\mathsf{Real}^{\uparrow}$ seal can be inspected.

The induction step appends this one-request argument to the previous finite window. Componentwise hsame transport in H and replay in K preserve the displayed rows, while P and N record the same source and local name. Thus every finite refinement that factors through the same readbacks and dyadic ledger yields the same public equality boundary. □

Theorem 1636.3 (RealEquality NameCert boundary)**.** *For every accepted* $\mathsf{RealEquality}^{\uparrow}$ *carrier, the local* $\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window classifier stability, dyadic tolerance ledger exactness, regular-Cauchy closeness replay, real-seal non-escape, and provenance-local-name transport. No NameCert obligation may replace these rows by* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, quotient equality, selected limits, countable choice, or host real equality.*

Lean4 ✓ `BEDC.Derived.RealEqualityUp.RealEqualityCarrier namecert boundary`

Proof. Carrier admission is projection from Definition 1636.1. The only visible coordinates are the two $\mathsf{Real}^{\uparrow}$ seals, their $\mathsf{StreamName}^{\uparrow}$ windows, their $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the shared finite observation window, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegularCauchyUniformity}^{\uparrow}$ closeness row, the classifier row, and the structural rows H, K, P, N.

Classifier stability is supplied by Definition 1636.2. Its induction over finite observation windows gives the finite-window part of the local certificate, and its dyadic ledger argument gives the exact tolerance route.

Regular-Cauchy closeness replay is the route through U after W and D have been displayed. The terminal seals X and Y are consumed only after that replay, so the public boundary cannot export host equality or quotient classes.

The provenance and local-name rows name the same packet and do not add analytic coordinates. Since the carrier contains no row for $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient equality, selected limits, countable choice, or host real equality, none of those principles can appear as a local $\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$ obligation. □

Theorem 1636.4 (RealEquality public boundary)**.** *Every downstream equality consumer of* $\mathsf{RealEquality}^{\uparrow}$ *receives exactly the finite route*

$$(X, Y, S_X, S_Y, R_X, R_Y, W, D, U, C, H, K, P, N)$$

and may use the public equality boundary only after the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *closeness row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row have been displayed.*

The boundary exports no host real equality, quotient class, selected limit, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealEqualityUp.RealEqualityCarrier public boundary`

Proof. Begin with classifier stability, Definition 1636.2. It fixes each public verdict by the finite observation window, the two regular readbacks, and the dyadic tolerance ledger rather than by host equality of the terminal seals.

Next apply the NameCert boundary of Definition 1636.3. That theorem exhausts the local certificate by the carrier admission, finite-window classifier stability, dyadic tolerance exactness, regular-Cauchy closeness replay, real-seal non-escape, provenance, and local-name transport rows.

Project the carrier of Definition 1636.1. It displays the two terminal Real seals only together with their finite StreamName windows, RegSeqRat readbacks, shared request window, dyadic tolerance ledger, uniformity row, classifier row, and structural rows. Thus every downstream public consumer receives the displayed BEDC boundary and no excluded analytic coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1636.1, Definition 1636.2, Definition 1636.3, and Definition 1636.4 bind the finite regular-Cauchy equality boundary for terminal RealUp names to one displayed carrier route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealEquality}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RealEqualityUp.RealEqualityCarrier\_namecert\_boundary`

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, trichotomy, quotient equality, selected limits, countable choice, host real equality, or bridge checking.

Upgrade path: Public closure requires a public equality surface for the same carrier, classifier stability, dyadic tolerance, RegSeqRat readback, Real seal, hsame, Cont, Pkg, and NameCert rows.

Constructive story: A $\mathsf{RealEquality}^{\uparrow}$ packet is generated from two terminal RealUp seals, finite StreamName windows, RegSeqRat readbacks, one finite observation window, a DyadicRatCore tolerance ledger, a RegularCauchyUniformity closeness row, a classifier verdict, componentwise transport, continuation replay, package provenance, and local naming.

Chapter 1637

A Concrete Naming Certificate for $\mathsf{RiemannStieltjes}^{\uparrow}$

Following Riemann and Stieltjes, the $\mathsf{RiemannStieltjes}^{\uparrow}$ packet records a finite tagged-sum integration surface in which a regulated integrand is read against a bounded-variation integrator. It sits over the variation ledger of chapter 398, the regulated-integral handoff of chapter 1557, the finite tagged-sum surface of chapter 1615, and the dyadic step approximation rows of chapter 428. The packet names only the displayed finite rows needed for a constructive Riemann–Stieltjes read; it does not introduce a measure space, a completed integrator, a host function quotient, or an ambient choice principle. As a downstream integration consumer, this packet also reads the calculus root package of chapter 3632: the tagged-sum row is an integration-facing use of the finite derivative/integral/limit substrate, not a separate host integration principle.

Definition 1637.1 (Riemann–Stieltjes carrier)**.** *A* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, A, T, S, I, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the regulated integrand row, exposing only the finitely requested approximation windows and endpoint reads.*
2. *A is the bounded-variation integrator row, carrying the displayed partition-variation ledger and transported endpoint jumps.*
3. *T is the tagged partition and* $\mathsf{RiemannSum}^{\uparrow}$ *row, with each tag contained in its displayed interval cell.*
4. *S is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation row used to replace the regulated integrand on the displayed refinement.*
5. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row reached after the step approximation, variation ledger, and tagged-sum rows are present.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal for the final accepted integral read.*
7. *H records componentwise* hsame *transport for the integrand, integrator, partition, step approximation, handoff, endpoint seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from partition cells to tag reads, from tag reads to step approximants, from variation jumps to finite sums, and from the handoff row to the* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *P is the* Pkg *provenance over* RiemannStieltjes$^{\uparrow}$, RegulatedIntegral$^{\uparrow}$, BoundedVariation$^{\uparrow}$, RiemannSum$^{\uparrow}$, DyadicStepFunction$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RiemannStieltjes}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, A, T, S, I, E, H, C, P, N$. It has no coordinate for Lebesgue integration, measure completion, selected limits, host real equality, a quotient of integrands or integrators, or a standard bridge.

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesTasteGate single carrier alignment`

Theorem 1637.2 (Riemann–Stieltjes NameCert obligations)**.** *For an accepted* RiemannStieltjes$^{\uparrow}$ *carrier $R = (F, A, T, S, I, E, H, C, P, N)$, the local* NameCert$_{\text{RiemannStieltjes}^{\uparrow}}$ *surface consists of exactly five rows:*

1. *carrier admission for the displayed tuple $F, A, T, S, I, E, H, C, P, N$;*
2. *partition-refinement stability for the tagged* RiemannSum$^{\uparrow}$ *row T and dyadic step row S;*
3. *bounded-variation ledger control for the integrator row A and its transported endpoint jumps;*
4. *regulated-integral handoff through I after the finite sum and variation rows have been displayed;*
5. *no-escape from host measure data, completion data, choice data, hidden function quotients, and ambient real equality.*

These rows are read through the finite route

$$F, A \longmapsto T \longmapsto S \longmapsto I \longmapsto E$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesNameCertObligations`

Proof. Carrier admission is the projection of Definition 1637.1. The rows F and A expose the regulated integrand and bounded-variation integrator before any tagged sum is accepted.

Partition-refinement stability is checked on the displayed row T. A common refinement transports tags and cell containment through the visible hsame rows, and the dyadic step row S reads the same refined cells without adding a host-level function comparison.

Bounded-variation ledger control is supplied by A. The integrator contributes only transported endpoint jumps and finite variation ledgers, so every summand is controlled by displayed bounded-variation data rather than by a measure or completed variation object.

The handoff row I is downstream of T and S. Continuation replay through C rebuilds the same path, while P and N record provenance and local naming. Since the excluded host objects do not occur among the carrier coordinates, the listed five rows exhaust the certificate obligations. □

Theorem 1637.3 (Riemann–Stieltjes regulated-integral handoff)**.** *Every accepted* RiemannStieltjes$^{\uparrow}$ *sum read factors through the displayed dyadic-step and regulated-integral rows before reaching the* Real$^{\uparrow}$ *seal. Concretely, a consumer of the endpoint row E must first read the regulated integrand row F, the bounded-variation integrator row A, the tagged sum row T, the dyadic step approximation row S, and the regulated-integral handoff row I.*

Proof. Project an accepted carrier as $R = (F, A, T, S, I, E, H, C, P, N)$. The rows F and A supply the only integrand and integrator data available to the packet, and T records the finite tagged partition on which those data are read.

The row S is the dyadic step approximation surface attached to that displayed partition. Thus a downstream read cannot pass directly from tags to a real endpoint seal; it must first consume the step row that makes the regulated integrand finite on the refinement.

The row I then packages the regulated-integral handoff from the step approximation and bounded-variation ledger. Only after this handoff is displayed does E expose a $\mathsf{Real}^{\uparrow}$ endpoint seal. Componentwise transport through H and replay through C preserve this order, and the package and local naming rows add no bypass coordinate. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier regulated integral handoff`

Theorem 1637.4 (Riemann–Stieltjes Darboux mesh refinement)**.** *Every accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier refines a finite Darboux mesh through the displayed* $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. For a carrier*

$$R = (F, A, T, S, I, E, H, C, P, N),$$

any downstream Darboux or tagged-sum consumer must read the refined mesh from T and S, the integrator control from A, the regulated-integral handoff from I, and the endpoint seal from E. The packet exports no selected limit, quotient of tagged sums, host integrand quotient, host integrator quotient, or ambient real equality beyond those displayed rows.

Proof. Project the accepted carrier as $R = (F, A, T, S, I, E, H, C, P, N)$. The only partition data available to the consumer is the finite tagged-sum row T, and the only step approximation data available on a refinement is the dyadic step row S.

Refine the displayed mesh by replaying the continuation row C. Each cell containment, tag read, and dyadic step replacement is transported componentwise through H, so the refinement is a BEDC row calculation rather than a host-level limit selection.

The bounded-variation row A controls the integrator contribution on the refined cells. Its endpoint jumps and variation ledger are finite rows, and the regulated-integral handoff row I can be read only after A, T, S have all been displayed.

Finally, P and N route the refined mesh through the local package and classifier. Since equality is mediated only by H and by the local $\mathsf{NameCert}_{\mathsf{RiemannStieltjes}^{\uparrow}}$ comparison, no quotient of tagged sums, selected limit, or ambient real equality is exported by the carrier. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesDarbouxMeshRefinement`

Theorem 1637.5 (Riemann–Stieltjes Darboux integral consumer route)**.** *Every* $\mathsf{DarbouxIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier*

$$R = (F, A, T, S, I, E, H, C, P, N)$$

must read the displayed bounded-variation row A, tagged-sum row T, dyadic-step row S, regulated-integral handoff I, Real seal E, and structural rows H, C, P, N before it treats the packet as a Darboux-facing integral route. The consumer receives a finite Stieltjes mesh with bounded-variation control and regulated handoff; it receives no selected limiting partition, host integrand quotient, host integrator quotient, measure completion, or ambient real equality.

Proof. Start from the NameCert obligations of Definition 1637.2. They expose carrier admission, tagged-sum refinement stability, bounded-variation ledger control, regulated-integral handoff, and local nonescape as the finite rows of the accepted packet.

Apply the regulated-integral handoff theorem, Definition 1637.3. The Darboux-facing consumer cannot reach the endpoint seal E directly; it must first read the integrand row F, the bounded-variation row A, the tagged-sum row T, the dyadic-step row S, and the handoff row I.

Apply Darboux mesh refinement, Definition 1637.4. The mesh part of the consumer is therefore the displayed T, S refinement with integrator control supplied by A and the regulated route supplied by I.

Finally, transport, replay, provenance, and local naming are exactly H, C, P, N. Since the carrier has no coordinate for selected limiting partitions, host quotients, measure completion, or ambient real equality, every $\mathsf{DarbouxIntegral}^{\uparrow}$ consumer remains on the displayed Riemann–Stieltjes route. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesDarbouxIntegralConsumerRoute`

Theorem 1637.6 (Riemann–Stieltjes bounded-variation jump boundary)**.** *Every accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier reads integrator jump data only through the displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *row before the tagged-sum and regulated-integral rows are consumed. For*

$$R = (F, A, T, S, I, E, H, C, P, N),$$

the order of every jump-facing read is

$$A \longrightarrow T, S \longrightarrow I \longrightarrow E.$$

The route cannot replace bounded-variation evidence by a measure space, selected limit, host function quotient, or ambient choice.

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier bounded variation jump boundary`

Proof. Project the carrier rows $F, A, T, S, I, E, H, C, P, N$ from Definition 1637.1. The integrator row A is the only displayed source of bounded-variation evidence and transported endpoint jumps.

Use Definition 1637.2. It places bounded-variation ledger control before the regulated-integral handoff, so a tagged-sum read cannot consume jump data except through A.

Apply Definition 1637.4. The finite mesh and dyadic step rows T, S are read after the bounded-variation row and before the handoff row I, and the endpoint seal E remains downstream of that handoff.

The structural rows H, C, P, N transport, replay, source, and name the same order. Since the packet has no coordinate for measure spaces, selected limits, host function quotients, or ambient choice, the displayed bounded-variation jump boundary cannot be replaced by any of them. □

Theorem 1637.7 (Riemann–Stieltjes refinement-window exhaustion)**.** *For every accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier*

$$R = (F, A, T, S, I, E, H, C, P, N),$$

every downstream refinement-window read is exhausted by the displayed rows $A, T, S, I, E, H, C, P, N$*. In particular, no consumer can bypass the* $\mathsf{RiemannSum}^{\uparrow}$ *row* T*, the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row* S*, the* $\mathsf{BoundedVariation}^{\uparrow}$ *row* A*, the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *row* I*, or the* $\mathsf{Real}^{\uparrow}$ *seal* E *when reading a refinement of the Riemann–Stieltjes packet.*

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier refinement window exhaustion`

Proof. Project the accepted carrier from Definition 1637.1. The only refinement-facing rows available to a consumer are the bounded-variation integrator row A, the tagged-sum row T, the dyadic step row S, the regulated-integral handoff row I, the endpoint seal E, and the structural rows H, C, P, N.

Apply Definition 1637.3. It forces every endpoint-facing read to pass through F, A, T, S, I before E is visible, so the endpoint seal cannot be used as a shortcut around the displayed finite rows.

Apply Definition 1637.4 and Definition 1637.6. The former confines mesh refinement to the tagged-sum and dyadic-step route, while the latter places every jump-facing integrator read behind the bounded-variation row A.

The rows H, C, P, N transport, replay, source, and name exactly this route. Since the carrier has no coordinate for a hidden refinement oracle, measure completion, selected limiting partition, host function quotient, or ambient real equality, the listed rows exhaust every downstream refinement-window read. □

Theorem 1637.8 (Riemann–Stieltjes regulated-integrator transport)**.** *Every* RiemannStieltjes$^{\uparrow}$ *read that is consumed as a regulated-integral handoff must pass through the bounded-variation integrator row A and the tagged-sum row T before the handoff row I is visible. For an accepted carrier*

$$R = (F, A, T, S, I, E, H, C, P, N),$$

the route to I is the displayed BEDC row route

$$F, A, T, S, H, C, P, N \longrightarrow I.$$

It cannot be replaced by a host measure integral, a quotient of integrators, a selected limiting partition, or an unrecorded real equality.

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier regulated integrator transport`

Proof. Project the carrier from Definition 1637.1. The regulated integrand row F and the bounded-variation integrator row A are the only sources from which the packet can read the two integration inputs.

Use the tagged-sum and step rows next. The row T displays the finite tagged partition, while S records the dyadic step approximation used by the regulated-integral handoff.

The handoff row I is therefore downstream of F, A, T, S. Componentwise transport through H and continuation replay through C preserve the same order, and P, N record provenance and local naming without adding any bypass coordinate.

Since the carrier has no coordinate for measure integration, integrator quotients, selected limiting partitions, or host real equality, every regulated-integrator transport consumed by the packet remains on this finite route. □

Theorem 1637.9 (Riemann–Stieltjes bounded-variation ledger)**.** *For every accepted* RiemannStieltjes$^{\uparrow}$ *carrier $R = (F, A, T, S, I, E, H, C, P, N)$, each integrator jump, variation read, and endpoint contribution used by the tagged sum is consumed as a visible* BHist *ledger row inside A before it is transported through H, C, P, N. The packet exports no hidden variation functional, measure-space control object, selected jump enumeration, or quotient of integrators.*

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier bounded variation ledger`

Proof. Read the bounded-variation component A from the carrier. By Definition 1637.6, jump-facing reads begin at A and cannot enter the tagged-sum route from any outside source.

The finite tagged-sum row T consumes only the displayed cells and tags, while the dyadic step row S supplies the corresponding finite integrand approximants. Thus every variation contribution used in the sum is already a visible row before the handoff row I is read.

Transport and replay do not create new variation data. The rows H and C move and replay the same ledger entries, while P and N identify the package and local NameCert surface. The excluded host objects have no coordinate in R, so the ledger is exactly the displayed bounded-variation row. □

Theorem 1637.10 (Riemann–Stieltjes mesh refinement stability)**.** *If an accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier is read along a mesh refinement, the refined packet preserves the same componentwise* hsame *transport, displayed* Cont *replay, and* Pkg *provenance route over* $F, A, T, S, I, E, H, C, P, N$*. Refinement may subdivide the visible tagged partition row, but it cannot introduce a new integrator, a new regulated-integral handoff, host function equality, selected limits, or a measure-space bridge.*

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier mesh refinement stability`

Proof. Start with the Darboux mesh-refinement theorem, Definition 1637.4. It confines every refinement-facing read to the displayed rows T, S, A, I, E together with the structural rows.

Refining the mesh changes only the visible tagged partition and the corresponding dyadic step rows. The bounded-variation ledger remains the row A, and the regulated-integral handoff remains the row I reached after the refined finite data are displayed.

The structural route is unchanged. Componentwise hsame transport is recorded by H, continuation replay by C, and provenance by P before the local naming row N accepts the refined packet. Because no host equality, selected limit, new integrator, or measure bridge occurs among the coordinates, refinement preserves the same finite BEDC route. □

Theorem 1637.11 (Riemann–Stieltjes bounded-variation partition coverage)**.** *For every accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier*

$$R = (F, A, T, S, I, E, H, C, P, N),$$

each cell of the finite BHist *partition row* T *is covered by a bounded-variation jump or oscillation row displayed inside* A *before the regulated-integral handoff* I *is public. The coverage is stable under componentwise* hsame *transport, replayed by* Cont *through* C*, sourced by the* Pkg *provenance row* P*, and named by the local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjes}^{\uparrow}}$ *row* N*.*

Proof. Project the carrier and read the finite partition row T. Its cells and tags are BHist entries, so coverage can be checked cell by cell rather than by a host partition object.

Induct over the displayed partition refinement rows. The base row is the original tagged partition, where Definition 1637.9 supplies the integrator jump and variation entries from A. In the refinement step, the subdivided cells inherit the same bounded-variation control by the mesh-refinement stability theorem and the bounded-variation jump boundary.

The structural rows preserve the coverage. Transport through H moves the displayed jump and oscillation rows componentwise, replay through C keeps the cell-to-jump route in the same order, and P, N record the package source and local certificate name. Thus I can only read a partition whose cells are already covered by the displayed bounded-variation rows. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier bounded variation partition coverage`

Theorem 1637.12 (Riemann–Stieltjes regulated-integral mesh handoff)**.** *Every mesh-facing read of an accepted* RiemannStieltjes$^{\uparrow}$ *carrier reaches the* RegulatedIntegral$^{\uparrow}$ *handoff row I only after the finite* BHist *partition row T, the bounded-variation jump and oscillation rows in A, and the dyadic step approximation row S have been displayed. The route is invariant under* hsame *transport, replayed by* Cont*, sourced by* Pkg *provenance, and accepted by the local* NameCert *row.*

Proof. Project $R = (F, A, T, S, I, E, H, C, P, N)$. The endpoint seal E is downstream of I, and the handoff theorem already places I after the integrand, integrator, tagged-sum, and dyadic-step rows.

Induct over the finite mesh refinement rows. At the base mesh, the partition row T and step row S are displayed directly, and the bounded-variation partition coverage theorem supplies the jump and oscillation rows from A. At a refinement step, Definition 1637.10 preserves the same A, T, S, I order while subdividing only the visible partition row.

Finally transport and replay do not change the route. The row H moves each displayed mesh, jump, oscillation, and step entry componentwise; C replays the handoff order; and P, N provide provenance and local naming. Hence a regulated-integral consumer cannot reach I without first reading the displayed finite mesh and bounded-variation control. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier regulated integral mesh handoff`

Theorem 1637.13 (Riemann–Stieltjes step-integrator exactness)**.** *For an accepted* RiemannStieltjes$^{\uparrow}$ *carrier $R = (F, A, T, S, I, E, H, C, P, N)$, each dyadic step contribution consumed by the handoff row I is exact with respect to the bounded-variation integrator row A: the value is computed from the displayed step value in S, the corresponding finite* BHist *partition cell in T, and the jump or oscillation ledger row in A. No hidden measure integral, selected limiting partition, host integrator quotient, or ambient real equality is used.*

Proof. Read the step row S together with the partition row T. Each step contribution names a displayed cell and a displayed step value, so the integrator contribution must be supplied by the bounded-variation ledger already present in A.

Proceed by induction over the displayed partition refinement rows. The base contribution is exact by direct projection from S, T, A: the step value is paired with the integrator jump or oscillation entry carried by the same cell. In the refinement step, the mesh-refinement stability theorem transports the subdivided step entries, while bounded-variation partition coverage supplies the matching integrator rows for every child cell.

The remaining structural rows only preserve this calculation. Componentwise hsame transport in H keeps step values, cells, and integrator ledger rows aligned; Cont replay through C repeats the same finite route; and P, N record provenance and local NameCert acceptance. The excluded host objects are absent from the carrier, so step-integrator exactness is a finite BEDC row calculation. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier step integrator exactness`

Theorem 1637.14 (Riemann–Stieltjes regulated-integrator variation exactness)**.** *For an accepted* RiemannStieltjes$^{\uparrow}$ *carrier $R = (F, A, T, S, I, E, H, C, P, N)$, every regulated-integrator variation contribution consumed by I is determined by the displayed bounded-variation row A, tagged partition row T, dyadic step row S, and structural rows H, C, P, N. No measure-space integral, selected limiting partition, host integrator quotient, or ambient real equality supplies variation data.*

Proof. Project the accepted carrier as $R = (F, A, T, S, I, E, H, C, P, N)$. The bounded-variation row A is the only component that carries integrator jumps, oscillation ledgers, and finite variation reads, while T and S identify the cells and step values on which those reads are consumed.

Use Definition 1637.9 and Definition 1637.11. They place every variation contribution inside A before the handoff row I can read the corresponding partition cell, and they keep each displayed cell of T covered by a visible bounded-variation ledger row.

Mesh-refinement stability then preserves the same rows under subdivision. Apply Definition 1637.10 to transport the refined cells through H and replay the finite route through C without adding a selected limiting partition.

Finally use Definition 1637.13. The step contribution is computed from the displayed rows S, T, A, and the remaining rows P, N only record provenance and local naming. Since the carrier has no coordinate for a measure-space integral, host quotient of integrators, or ambient real equality, the variation contribution is exact as a BEDC row calculation. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier regulated integrator variation exactness`

Theorem 1637.15 (Riemann–Stieltjes tagged-partition induction)**.** *For an accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier* $R = (F, A, T, S, I, E, H, C, P, N)$*, let a property of refinement-window reads be one that is evaluated only through the displayed rows* T, S, A, H, C, P, N*. If the property holds on the base tagged partition row* T*, and if it is preserved whenever one finite cell is subdivided through the same dyadic step row* S*, bounded-variation ledger* A*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*, then the property holds for every displayed finite refinement consumed by the handoff row* I*.*

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier tagged partition induction`

Proof. Induct over the finite BHist refinement ledger consumed by I. The base case is the displayed tagged partition row T: the tag containment, dyadic step data, and integrator control are read by projection from T, S, A.

For the refinement step, subdivide one visible cell. By Definition 1637.10, the refined read preserves the same componentwise transport, replay, and provenance route over $F, A, T, S, I, E, H, C, P, N$.

Use Definition 1637.11 to keep each child cell covered by the bounded-variation ledger in A. Then apply Definition 1637.13 to identify the step contribution on the subdivided cells through the displayed rows rather than through a hidden limit.

The induction hypothesis applies to the remaining cells, and the stated preservation clause applies to the subdivided cell. Since I consumes only finite refinements produced by this ledger, every displayed refinement-window read satisfies the property. □

Theorem 1637.16 (Riemann–Stieltjes scoped ledger)**.** *For every accepted* $\mathsf{RiemannStieltjes}^{\uparrow}$ *carrier* $R = (F, A, T, S, I, E, H, C, P, N)$*, every integral-facing consumer of the tagged-partition result factors through the concrete BEDC dependency ledger*

$$\mathsf{BoundedVariation}^{\uparrow}, \mathsf{DyadicStepFunction}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{RegulatedIntegral}^{\uparrow}, \mathsf{RiemannSum}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

before the endpoint seal E *is public. In particular, the carrier read cannot bypass the bounded-variation integrator row* A*, the dyadic step row* S*, the tagged* $\mathsf{RiemannSum}^{\uparrow}$ *row* T*, the regulated-integral handoff row* I*, componentwise transport* H*, replay* C*, provenance* P*, or the local naming row* N*.*

Proof. Begin with the regulated-integral handoff theorem. It places every endpoint-facing read behind the ordered rows F, A, T, S, I, so a consumer cannot reach E directly from a tagged partition or from an ambient real object.

Next use the Darboux mesh-refinement and bounded-variation ledger rows. Mesh refinement confines the partition read to T and S, while the ledger theorem forces every jump, variation read, and endpoint contribution used by the sum to be a visible row inside A before it is transported downstream.

The exactness rows keep the calculation local. Step-integrator exactness computes each dyadic step contribution from S, T, A, and regulated-integrator variation exactness determines the variation contribution through A, T, S, H, C, P, N rather than through a measure-space integral or selected limiting partition.

Finally apply tagged-partition induction over the finite BHist refinement ledger. The base row and each subdivision step preserve the same RiemannSum$^{\uparrow}$, DyadicStepFunction$^{\uparrow}$, BoundedVariation$^{\uparrow}$, RegulatedIntegral$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, and NameCert route, so every integral-facing consumer reads the tagged-partition result only through the stated dependency ledger. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier scope ledger`

Theorem 1637.17 (Riemann–Stieltjes public witness export)**.** *For every accepted* RiemannStieltjes$^{\uparrow}$ *carrier $R = (F, A, T, S, I, E, H, C, P, N)$, the regulated integrand row F, bounded-variation integrator row A, tagged partition and* RiemannSum$^{\uparrow}$ *row T, dyadic step approximation row S, regulated-integral handoff row I, and* Real$^{\uparrow}$ *endpoint seal E form the public finite witness packet consumed by downstream integration chapters. The exported packet is read only through H, C, P, N and contains no Lebesgue integral, measure completion, selected limiting partition, or host quotient of integrands or integrators.*

Proof. Start with the scoped ledger of Definition 1637.16. It already forces every integral-facing consumer to pass through the displayed dependency rows before the endpoint seal is visible.

The witness packet is the front face of that ledger. Rows F, A, T, S, I, E expose the regulated integrand, bounded-variation integrator, tagged Riemann sum, dyadic step approximation, handoff, and endpoint seal; rows H, C, P, N only transport, replay, source, and name the same finite data.

Because the carrier has no coordinate for measure completion, selected limiting partitions, or quotient equality of integrands and integrators, exporting these rows as public data does not add a stronger analytic claim. It only makes the finite Riemann–Stieltjes witness available to downstream integration chapters. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier public witness export`

Theorem 1637.18 (Riemann–Stieltjes regulated-integral public bridge)**.** *Any* RegulatedIntegral$^{\uparrow}$ *or* RiemannSum$^{\uparrow}$ *consumer of the public* RiemannStieltjes$^{\uparrow}$ *witness packet must pass through the rows*

$$F, A, T, S, I, E, H, C, P, N$$

before exporting an integration-facing read. The bridge exposes the regulated integrand, bounded-variation integrator, tagged partition, dyadic step approximation, regulated-integral handoff, Real endpoint seal, transport, replay, provenance, and local NameCert rows; it cannot substitute measure completion, selected limiting partitions, quotient integrand equality, quotient integrator equality, or a host limiting integral.

Proof. Start with the NameCert obligations of Definition 1637.2. They identify the accepted carrier as the finite row family $F, A, T, S, I, E, H, C, P, N$ and make the regulated integrand, bounded-variation integrator, tagged sum, dyadic step approximation, handoff, endpoint seal, transport, replay, provenance, and naming rows visible.

Apply the regulated-integral handoff of Definition 1637.3. It places each endpoint-facing read behind F, A, T, S, I, so a $\mathsf{RegulatedIntegral}^{\uparrow}$ consumer cannot bypass the displayed handoff row.

Use the Darboux mesh-refinement route, Definition 1637.4, together with the public witness export of Definition 1637.17. The former confines $\mathsf{RiemannSum}^{\uparrow}$ reads to the visible tagged partition and dyadic step rows, while the latter makes exactly F, A, T, S, I, E available as public witness data transported by H, C, P, N.

Since no carrier coordinate stores measure completion, a selected limiting partition, quotient equality of integrands or integrators, or a host limiting integral, the bridge remains a public finite-packet handoff and not a stronger integration theorem. □

Lean4 ✓ `BEDC.Derived.RiemannStieltjesUp.RiemannStieltjesCarrier regulated integral public bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannStieltjes}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannStieltjes}^{\uparrow}$ packet is generated from a regulated integrand row, bounded-variation integrator row, tagged partition and Riemann-sum row, dyadic step approximation row, regulated-integral handoff row, Real endpoint seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannStieltjes}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1637.1, Definition 1637.2, Definition 1637.3, Definition 1637.10, the bounded-variation jump boundary, Definition 1637.15, Definition 1637.17, and Definition 1637.18 bind the carrier, NameCert obligations, regulated-integral handoff, Darboux mesh refinement, bounded-variation control, refinement-window exhaustion, public finite witness export, and bridge-facing public handoff as the Riemann–Stieltjes route over $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannStieltjes}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lebesgue integration, measure completion, selected limits, host real equality, any quotient of integrands or integrators, Lean verification, or any standard bridge.

Upgrade path: No paper-side theory upgrade remains; bridgeCheckedV is the remaining formal-axis target for the public regulated-integral handoff.

Chapter 1638

A Concrete Naming Certificate for $\mathsf{RealMetric}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealMetric}^{\uparrow}$ packet names the standard metric on displayed regular real names by routing distance through finite absolute-value, stream-window, regular-rational, and dyadic-tolerance rows. It sits between the real-name seal of chapter 38, the absolute-value surface of chapter 1608, the generic metric obligations of chapter 57, the stream and regular-Cauchy readback interfaces of chapter 126 and chapter 301, and the dyadic tolerance ledger of chapter 291. When a distance consumer asks for completion-facing tail data, the packet consumes the regular-Cauchy completion route of chapter 1639 while retaining the local $\mathsf{RealAbs}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ rows. The chapter records the finite NameCert boundary for real distance; it does not identify quotient reals, select limits, invoke trichotomy, or assert completeness.

Definition 1638.1 (Real metric carrier)**.** *A* $\mathsf{RealMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathsf{Real}} = (X, Y, A, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two displayed* $\mathsf{Real}^{\uparrow}$ *seals whose distance is being named.*
2. *A is the* $\mathsf{RealAbs}^{\uparrow}$ *distance row for the displayed difference read from X and Y.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to present finite distance requests and triangle budgets.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened from the two real-name seals before the distance row is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the displayed stream windows and dyadic tolerances.*
6. *H records componentwise* hsame *transport for the two real seals, absolute-value distance row, dyadic tolerance row, stream windows, regular readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a distance request through X, Y, then through S, R, D, into the* $\mathsf{RealAbs}^{\uparrow}$ *row A, and finally into the generic* $\mathsf{Met}^{\uparrow}$ *laws consumed downstream.*
8. *P is the* Pkg *provenance over* $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RealMetric}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, Y, A, D, S, R, H, C, P, N$. The carrier has no coordinate for host real equality, quotient real representatives, selected limits, trichotomy, or completeness of $\mathsf{Real}^\uparrow$.

Theorem 1638.2 (Real metric NameCert obligations)**.** *For every accepted* $\mathsf{RealMetric}^\uparrow$ *carrier* $M_{\mathsf{Real}} = (X, Y, A, D, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealMetric}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed endpoint seals, absolute-value distance row, dyadic tolerance row, stream windows, regular readback, transport, replay, provenance, and local naming row;*
2. *distance-row exposure, requiring every public distance read to pass from the endpoint seals X, Y through the finite windows S, the regular readback R, and the dyadic tolerance row D before it reaches the* $\mathsf{RealAbs}^\uparrow$ *distance row A;*
3. *symmetry route, requiring the classifier for the reversed endpoint order to reuse the same* $\mathsf{RealAbs}^\uparrow$ *row after componentwise transport of the two endpoint seals and their readback rows;*
4. *zero-distance classifier handoff, requiring a zero-distance request to be handed to the displayed* $\mathsf{Real}^\uparrow$ *seal classifier through the same S, R, D, A route rather than through host equality;*
5. *triangle-budget handoff, requiring any triangle use to present the two endpoint distance rows and the composed dyadic tolerance budget before reading the corresponding* $\mathsf{Met}^\uparrow$ *triangle law;*
6. *refusal of host real equality, quotient reals, selected limits, trichotomy, and completeness as NameCert data.*

No NameCert obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.RealMetricUp.RealMetricCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1638.1. The only available distance data are the endpoint seals X, Y, the absolute-value distance row A, the dyadic tolerance row D, the stream windows S, the regular readback R, and the structural rows H, C, P, N.

Distance-row exposure is forced by the displayed route. A public distance request first opens finite windows on the two real names, reads the corresponding regular rational data, records the dyadic tolerance request, and only then reaches the $\mathsf{RealAbs}^\uparrow$ row naming the absolute value of the displayed difference.

Symmetry and zero-distance reads use the same classifier surface. Reversing the endpoints transports X and Y componentwise through H and replays the same windows and readback through C; a zero-distance request then returns to the displayed $\mathsf{Real}^\uparrow$ seal classifier through S, R, D, A rather than by comparing host reals.

Triangle use is downstream of the same finite route. The generic $\mathsf{Met}^\uparrow$ triangle law is readable only after the three endpoint pairs have exposed their $\mathsf{RealAbs}^\uparrow$ distance rows and after the dyadic tolerance budgets have been composed in D.

Finally, provenance is exhausted by P and N. Since host real equality, quotient representatives, selected limits, trichotomy, and completeness are not coordinates of M_{Real}, the local NameCert surface cannot export them. □

Theorem 1638.3 (Real metric absolute-value distance handoff)**.** *Every accepted* $\mathsf{RealMetric}^\uparrow$ *distance consumer factors through the* $\mathsf{RealAbs}^\uparrow$ *row for the displayed endpoint difference and through the* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*, and* $\mathsf{DyadicRatCore}^\uparrow$ *readback route before it may read any* $\mathsf{Met}^\uparrow$

law. In particular, symmetry, zero-distance, and triangle consumers receive only the displayed rows

$\mathsf{Real}^{\uparrow}, \mathsf{RealAbs}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$

The packet exports no host real equality, quotient real representative, selected limit, trichotomy, or completeness coordinate.

Lean4 ✓ `BEDC.Derived.RealMetricUp.RealMetricCarrier absolute value distance handoff`

Proof. Let a distance consumer read an accepted packet $M_{\mathsf{Real}} = (X, Y, A, D, S, R, H, C, P, N)$. Carrier admission gives the consumer access only to the displayed endpoint, distance, tolerance, window, readback, transport, replay, provenance, and local naming rows.

The distance value is therefore obtained through the absolute-value route. The endpoint seals X, Y provide the displayed difference source, S opens the finite windows, R supplies regular rational readback, D records the dyadic tolerance request, and A names the resulting $\mathsf{RealAbs}^{\uparrow}$ distance row.

Only after that route is displayed may the consumer invoke a generic $\mathsf{Met}^{\uparrow}$ law. Symmetry reuses A under endpoint transport, zero-distance returns through the displayed $\mathsf{Real}^{\uparrow}$ seal classifier, and triangle reads the composed dyadic budget before applying the metric triangle row.

The remaining coordinates are structural support. The BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows transport, replay, source, and name the same route, with no row from which host real equality, quotient representatives, selected limits, trichotomy, or completeness can be read. □

Theorem 1638.4 (Real metric located-distance handoff)**.** *Every located-distance or completion-facing consumer of an accepted* $\mathsf{RealMetric}^{\uparrow}$ *packet must pass through the endpoint seals* X, Y*, the stream windows* S*, the regular readback* R*, the dyadic tolerance row* D*, and the* $\mathsf{RealAbs}^{\uparrow}$ *row* A *before it reads any* $\mathsf{Met}^{\uparrow}$ *law. The located-distance route is therefore*

$$X, Y \longmapsto S, R, D \longmapsto A \longmapsto \mathsf{Met}^{\uparrow}$$

inside the structural rows H, C, P, N*. It exports no host real equality, quotient representative, selected limit, trichotomy, or completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RealMetricUp.RealMetricLocatedDistanceHandoff`

Proof. Project the accepted carrier $M_{\mathsf{Real}} = (X, Y, A, D, S, R, H, C, P, N)$ of Definition 1638.1. A located-distance request first receives only the displayed endpoint seals X, Y, so every downstream read is still tied to the two $\mathsf{Real}^{\uparrow}$ names carried by the packet.

The request then follows the same finite readback route as Definition 1638.3. The stream windows S expose the finite observations, the regular readback row R presents the $\mathsf{RegSeqRat}^{\uparrow}$ data over those windows, and the dyadic tolerance row D records the requested distance precision before the $\mathsf{RealAbs}^{\uparrow}$ distance row A is visible.

Only after A is exposed may a completion-facing consumer read a $\mathsf{Met}^{\uparrow}$ law. The rows H, C, P, N preserve this route under componentwise transport, replay, provenance, and local naming, while no carrier row names host equality, quotient representatives, selected limits, trichotomy, or completeness. □

Theorem 1638.5 (Real metric triangle-window stability)**.** *Every triangle request for accepted* $\mathsf{RealMetric}^{\uparrow}$ *packets factors through shared finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealAbs}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$ *rows before a triangle-inequality read is visible. For endpoint seals* X, Y, Z*, the three*

pairwise distance reads must first expose their stream windows, regular rational readbacks, dyadic tolerance budgets, and absolute-value distance rows inside the same BHist, hsame, Cont, Pkg, *and* NameCert *route.*

Lean4 ✓ `BEDC.Derived.RealMetricUp.RealMetricCarrier triangle window stability`

Proof. Inspect the carrier of Definition 1638.1. A distance row is never a raw host value; it is read from endpoint $\mathsf{Real}^{\uparrow}$ seals through S, R, D, A before it reaches the generic $\mathsf{Met}^{\uparrow}$ row.

A triangle request therefore opens three copies of the same finite window route, one for each endpoint pair. The stream windows are shared at the level of displayed $\mathsf{StreamName}^{\uparrow}$ observations, the regular readbacks land in $\mathsf{RegSeqRat}^{\uparrow}$, and the dyadic budgets are composed in $\mathsf{DyadicRatCore}^{\uparrow}$ before the absolute-value rows are compared.

Only after these finite rows are present can the consumer read a $\mathsf{Met}^{\uparrow}$ triangle law. The structural rows H, C, P, N keep the three pairwise routes attached to the accepted packets, so no selected limit, quotient representative, trichotomy, or ambient completeness principle enters the triangle read. □

Theorem 1638.6 (Real metric identity-of-indiscernibles window)**.** *Every zero-distance read from an accepted* $\mathsf{RealMetric}^{\uparrow}$ *packet hands off to the displayed* $\mathsf{Real}^{\uparrow}$ *classifier through the same finite windows used for distance:* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the* $\mathsf{RealAbs}^{\uparrow}$ *distance row, and the* $\mathsf{Met}^{\uparrow}$ *zero-distance law. The handoff identifies only the displayed real-name classifier data and does not use host equality, quotient representatives, selected limits, trichotomy, or completeness.*

Lean4 ✓ `BEDC.Derived.RealMetricUp.RealMetricCarrier identity of indiscernibles window`

Proof. Start with a zero-distance request for $M_{\mathsf{Real}} = (X, Y, A, D, S, R, H, C, P, N)$. The request first sees the endpoint seals X, Y, not host real representatives.

The distance route then exposes the finite windows S, readback R, tolerance row D, and absolute-value row A. These are the same rows used by located-distance and triangle consumers, so the zero-distance read has no separate equality channel.

The final handoff is to the displayed $\mathsf{Real}^{\uparrow}$ classifier, authenticated by H, C, P, N and then read through the generic $\mathsf{Met}^{\uparrow}$ zero-distance row. Since the carrier lacks host equality, quotient representatives, selected limits, trichotomy, and completeness coordinates, identity of indiscernibles is routed only through that finite window. □

Theorem 1638.7 (Real metric TasteGate scope)**.** *The accepted* $\mathsf{RealMetric}^{\uparrow}$ *carrier rows form a single-carrier* ChapterTasteGate *surface over endpoint* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{RealAbs}^{\uparrow}$ *absolute-value distance row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealMetric}^{\uparrow}}$ *row. The gate compares packets only through this displayed family and does not add host real equality, quotient representatives, selected limits, trichotomy, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RealMetricUp.taste gate`

Proof. Project the carrier of Definition 1638.1. Its displayed rows are exactly the endpoint seals X, Y, absolute-value distance row A, tolerance row D, windows S, readback R, and structural rows H, C, P, N.

Apply the NameCert obligations of Definition 1638.2. They force distance exposure, symmetry, zero-distance handoff, and triangle-budget handoff to read the same finite route before any $\mathsf{Met}^{\uparrow}$ law is visible.

Use the identity-of-indiscernibles window above. The zero-distance classifier also returns through the displayed $\mathsf{Real}^{\uparrow}$ seal and the same window/readback/tolerance/distance surface. Hence the TasteGate is a single-carrier surface over those rows, with no extra coordinate for the excluded host or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealMetric}^{\uparrow}}$.

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient real representatives, selected limits, trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires formal carrier admission, distance-row exposure, symmetry, zero-distance classifier handoff, triangle-budget handoff, and non-escape proofs for the same finite packet.

Constructive story: A $\mathsf{RealMetric}^{\uparrow}$ packet is generated from two displayed RealUp seals, a RealAbs distance row for their displayed difference, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1639

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges' constructive regular Cauchy completion, the $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ packet names the finite route by which dyadic tolerances, stream observations, regular rational sequences, and the terminal Real seal are assembled into a completion-facing object. It sits on the L10 spine supplied by the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational sequence route of chapter 301, and the displayed real-name seal of chapter 38. The packet records a regular Cauchy completion boundary for Real and Completion consumers; it does not assert completeness of $\mathsf{Real}^{\uparrow}$, identify quotient streams, select limits, invoke countable choice, or compare host real values.

Definition 1639.1 (Bishop regular Cauchy completion carrier)**.** *A* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, S, R, D, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, containing the dyadic source endpoints and tolerance comparisons used by the regular Cauchy reading.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation family opened from the named stream before any completion-facing consumer reads a tail claim.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording the regular rational sequence data exposed by the stream windows and dyadic endpoint ledger.*
4. *D is the dyadic tail modulus row, assigning each displayed dyadic tolerance a finite tail index and the dyadic comparison budget used at that tail.*
5. *W is the common-tail window row, recording the shared finite window in which two accepted regular readings may be compared without quotienting their streams.*
6. *H records componentwise* hsame *transport for endpoints, observations, regularity, tail modulus, common-tail windows, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion tolerance request through D, then through W, S, R, E, and finally into the displayed* $\mathsf{Real}^{\uparrow}$ *seal.*

8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, S, R, D, W, H, C, P, N$. The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionTasteGate single carrier alignment`

Theorem 1639.2 (Bishop regular Cauchy completion regularity envelope)**.** *For every accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier $B = (E, S, R, D, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyComplet}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic endpoint row, finite stream observations, regular rational sequence row, dyadic tail modulus, common-tail window, transport, replay, provenance, and local naming row;*

2. *classifier transport, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the ordered route D, W, S, R, E;*

3. *regularity envelope, requiring every regular Cauchy read to pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the dyadic endpoint ledger E before reaching the* $\mathsf{Real}^{\uparrow}$ *seal;*

4. *common-tail modulus stability, requiring any comparison of two accepted readings to expose the same displayed tail budget in D and the same common-tail window in W;*

5. *Real-seal handoff, requiring any Real consumer to read the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after S, R, E, D, W have been displayed;*

6. *ledger non-escape, requiring P and N to export no quotient stream equality, host real equality, selected limit, countable choice, or ambient Real completeness.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionRegularityEnvelope`

Proof. Carrier admission is projection from Definition 1639.1. The visible packet consists of the endpoint ledger E, finite observations S, regularity row R, dyadic tail modulus D, common-tail window W, and the structural rows H, C, P, N.

Classifier transport is structural. Componentwise hsame in H preserves each displayed coordinate, and displayed Cont replay in C repeats the same ordered route D, W, S, R, E for every accepted tolerance request.

The regularity envelope is forced by the placement of R and E. A consumer cannot read the completion boundary until the finite stream windows have exposed regular rational data and the dyadic ledger has supplied the corresponding endpoint and tolerance comparisons.

Common-tail stability is the row W governed by the tail modulus D. Two accepted readings are compared only inside the displayed shared window and under the same dyadic budget, so the packet never identifies their underlying streams by quotient equality.

Finally, the Real-seal handoff and ledger boundary are exhausted by C, P, N. Since no excluded quotient, host-equality, selected-limit, choice, or Real-completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1639.3 (Bishop regular Cauchy completion seal stability)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier reads only the displayed regular Cauchy completion rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Consequently the consumer receives finite endpoint, observation, regularity, tail-modulus, common-tail, transport, replay, provenance, and naming data, and receives no quotient stream equality, host real equality, selected limit, countable-choice schedule, or ambient Real completeness theorem.

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier seal stability`

Proof. Let a $\mathsf{Real}^{\uparrow}$ consumer read an accepted packet $B = (E, S, R, D, W, H, C, P, N)$. Carrier projection gives access only to the displayed rows of Definition 1639.1.

The Real-facing route starts with the tolerance request. The dyadic tail modulus D fixes the tail budget, W identifies the common window, S supplies finite observations, R records regular rational readback, and E supplies the dyadic endpoint comparisons before the terminal $\mathsf{Real}^{\uparrow}$ seal is reached.

The remaining rows transport and replay the same route. The BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates preserve the finite packet boundary and add no quotient, host-equality, selected-limit, choice, or completeness object. □

Theorem 1639.4 (Bishop regular Cauchy completion classifier transport)**.** *Let* $B = (E, S, R, D, W, H, C, P, N)$ *and* $B' = (E', S', R', D', W', H', C', P', N')$ *be accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carriers. If* H *records componentwise* hsame *transport from each row of* B *to the corresponding row of* B'*, and if* C *displays* Cont *replay of the route* D, W, S, R, E *into the terminal* $\mathsf{Real}^{\uparrow}$ *seal, then the local classifier transports acceptance from* B *to* B' *only through the displayed rows*

$$E, S, R, D, W, H, C, P, N.$$

In particular, the transport step may replace endpoint, observation, regularity, tail-modulus, common-window, replay, provenance, and local naming rows by their displayed hsame *companions, but it cannot introduce quotient stream equality, host real equality, a selected limit, countable choice, or ambient Real completeness.*

Proof. The classifier for Definition 1639.1 is row-local. Its admissible inputs are precisely the coordinates $E, S, R, D, W, H, C, P, N$, so a transported packet must be read by projecting these coordinates and comparing them with their displayed companions.

The componentwise hsame row H supplies the only equality-like transport available to the classifier. It moves endpoints, finite observations, regularity witnesses, dyadic tail budgets, common-tail windows, replay rows, provenance, and local naming rows without changing the ordered completion route.

The Cont row C then replays the same tolerance request through D, W, S, R, E before the $\mathsf{Real}^{\uparrow}$ seal is exposed. Since no excluded coordinate is present in either carrier, classifier transport has no path to quotient equality, host equality, selected limits, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier classifier transport`

Theorem 1639.5 (Bishop regular Cauchy completion cofinal-tail refinement)**.** *If an accepted* BishopRegularCauchyCompletion$^{\uparrow}$ *packet receives a* CauchyFilter$^{\uparrow}$ *row whose displayed base refines the packet's common-tail window, then every* Real$^{\uparrow}$*-facing completion read can be replayed through a* RegSeqRat$^{\uparrow}$ *tail window with the same* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* StreamName$^{\uparrow}$ *finite observations,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The replay exports no quotient filters, selected limits, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet from Definition 1639.1. Its comparison route exposes the dyadic tail modulus D, common-tail window W, StreamName observations S, RegSeqRat readback R, endpoint ledger E, and the structural rows H, C, P, N.

Read the incoming CauchyFilter$^{\uparrow}$ row only through its displayed cofinal-base refinement. By hypothesis that base refines the common-tail window W, so the filter request selects the finite window already named by the Bishop packet rather than introducing a quotient of filters.

Inside that window, replay the existing carrier route. The finite observations are read through S, the regular tail data through R, and the tolerance budget through D before the terminal Real$^{\uparrow}$ seal is available.

The rows H and C transport and replay the same route componentwise, while P and N keep the provenance and local naming attached to the displayed carrier. Since the packet contains no coordinate for quotient filters, selected limits, countable choice, host real equality, or ambient Real completeness, the cofinal-tail refinement adds no such data to the completion read. □

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCofinalTailRefinement`

Theorem 1639.6 (Bishop regular Cauchy completion common-tail modulus stability)**.** *For every accepted* BishopRegularCauchyCompletion$^{\uparrow}$ *carrier* $B = (E, S, R, D, W, H, C, P, N)$*, any comparison of two completion-facing regular readings must first expose the same displayed dyadic tail budget in* D *and the same displayed common-tail window in* W*. The comparison may then read finite observations from* S*, regularity data from* R*, and endpoint comparisons from* E*, but the terminal* Real$^{\uparrow}$ *seal is reached only after the shared* D *and* W *rows have been fixed.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier common tail modulus stability`

Proof. A completion-facing comparison begins with a dyadic tolerance request. The carrier has only one displayed tail-modulus row D, so both readings must use the same finite tail index and dyadic comparison budget attached to that request.

Once D is fixed, the common-tail row W supplies the shared finite window in which the two readings may be compared. The stream observations S, regularity data R, and endpoint ledger E are read inside that window, not by identifying the underlying streams.

The Real seal is therefore downstream of the displayed common-tail route. The packet cannot bypass D or W through quotient stream equality, selected limits, countable choice, or an ambient completeness theorem for Real$^{\uparrow}$. □

Theorem 1639.7 (Bishop regular Cauchy completion tail-diameter control)**.** *For every accepted* BishopRegularCauchyCompletion$^{\uparrow}$ *carrier* $B = (E, S, R, D, W, H, C, P, N)$*, a displayed dyadic tail budget* D *together with the common-tail window* W *determines a finite* CauchyTailDiameter$^{\uparrow}$ *row controlling any two* RegSeqRat$^{\uparrow}$ *readbacks visible to the completion comparison before the terminal* Real$^{\uparrow}$ *seal is inspected. The control row is obtained from the displayed* $D, W, S, R, E, H, C, P, N$

route and exports no quotient stream equality, selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionTailDiameterControl`

Proof. Begin with common-tail modulus stability, Definition 1639.6. It forces every comparison of two completion-facing regular reads to expose the same dyadic budget D and the same common-tail window W before the Real seal can be reached.

Next use diagonal-window stability, Definition 1639.8. Inside the fixed D, W window, both $\mathsf{RegSeqRat}^{\uparrow}$ readbacks are read through the finite StreamName observations and endpoint ledger rows, so their diameter claim is a row of the same displayed packet rather than an equality of underlying streams.

The row named by $\mathsf{CauchyTailDiameter}^{\uparrow}$ is therefore the finite tail-diameter ledger extracted from D, W, S, R, E and transported through H with replay through C. Provenance and local naming remain in P, N.

Finally apply nonescape exactness, Definition 1639.15. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness, the tail-diameter control closes before any terminal $\mathsf{Real}^{\uparrow}$ seal is inspected. □

Theorem 1639.8 (Bishop regular Cauchy completion diagonal-window stability)**.** *Let* $B = (E, S, R, D, W, H, C, P,$ *and* $B' = (E', S', R', D, W, H', C', P', N')$ *be accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packets sharing the same displayed dyadic tail modulus* D *and common-tail window* W*. Any diagonal comparison between the two packets must first read* D*, then* W*, then the* $\mathsf{StreamName}^{\uparrow}$ *windows* S, S' *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R, R'*, before either terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *or* E' *is available.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier diagonal window stability`

Proof. Project the carrier definition Definition 1639.1. The only comparison rows available to the diagonal read are the displayed tail modulus, common window, stream observations, regular readbacks, terminal seals, transport, replay, provenance, and naming rows.

Apply common-tail modulus stability from Definition 1639.6. It forces the comparison to expose the shared dyadic budget D and the shared finite window W before any Real seal can be inspected.

Use classifier transport from Definition 1639.4. Componentwise hsame and displayed Cont replay move only the visible S, S', R, R' rows along the already fixed D, W route.

Finally apply seal stability from Definition 1639.3. The Real seals are downstream of the displayed regular Cauchy route, so the diagonal comparison cannot bypass the ordered read through quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness. □

Theorem 1639.9 (Bishop regular Cauchy completion window induction)**.** *Every accepted completion-facing comparison over a* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier*

$$B = (E, S, R, D, W, H, C, P, N)$$

is obtained by induction on the displayed finite window row W*. The base case reads the first finite observation through* S, R, E *under the dyadic tail budget exposed by* D*. The step extends the same dyadic budget through* D, W *before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible, and then replays the enlarged window through* S, R, E, H, C, P, N*. The induction exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionWindowInduction

Proof. Start with the carrier definition Definition 1639.1. The only finite growth coordinate available to a completion-facing comparison is the common-tail window row W, and every read of that row is tied to the dyadic tail modulus D.

The base case is the first displayed observation. By common-tail modulus stability, Definition 1639.6, the comparison must expose the dyadic budget in D before it can read the finite observation row S, the regular readback row R, or the endpoint seal row E.

For the step, extend the same finite window rather than choosing a new stream representative. Diagonal-window stability, Definition 1639.8, keeps the comparison inside the already fixed D, W route as the next StreamName and RegSeqRat observations are displayed.

Finally apply seal stability and nonescape exactness, Definition 1639.3 and Definition 1639.15. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of the finite window recursion, while quotient stream equality, selected limits, countable choice, host equality, and ambient Real completeness have no carrier coordinate from which they could be read. □

Theorem 1639.10 (Bishop regular Cauchy completion finite-window induction)**.** *Every accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet consumes its finite observation windows by induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *sections. At each step the read preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The induction exports no selected limit, quotient representative, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionFiniteWindowInduction

Proof. Project the carrier $B = (E, S, R, D, W, H, C, P, N)$ from Definition 1639.1. The finite observation ledger is the $\mathsf{StreamName}^{\uparrow}$ row S, with regular readback in R, dyadic tolerance control in E, D, common-tail scope in W, and terminal sealing in E through the Real-facing route.

Run induction over the displayed window ledger. The base window reads the first finite StreamName section, then exposes the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ row and dyadic tolerance rows before any $\mathsf{Real}^{\uparrow}$ seal can be inspected.

For the step, extend only the displayed StreamName section. Common-tail modulus stability and diagonal-window stability keep the enlarged window inside the same D, W, S, R, E route, so the regular readback and dyadic tolerance rows are preserved rather than replaced by a chosen representative.

Finally replay the enlarged route through H, C, P, N and then through the Real seal discipline. Since the carrier has no coordinate for a selected limit, quotient representative, countable-choice schedule, or ambient Real completeness, the induction cannot export any of those objects. □

Theorem 1639.11 (Bishop regular Cauchy completion finite-stage induction)**.** *Every accepted finite-stage completion read of a* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet factors through the displayed sequence of rows*

$$D, W, S, R, E, H, C, P, N.$$

The stage induction first fixes the dyadic tail budget D and common-tail window W, then reads the finite $\mathsf{StreamName}^{\uparrow}$ *observation row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N. No induction step may replace the finite-stage route by quotient stream equality, a selected limit, a countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionFiniteStageInduction`

Proof. Induct on the finite stage named by the window row W. The base stage is the first displayed StreamName window, so Definition 1639.10 already forces the read through D, W, S, R, E before any terminal seal is visible.

For the successor stage, extend the displayed window while keeping the same dyadic budget. Common-tail modulus stability from Definition 1639.6 keeps the enlarged stage inside the fixed D, W route.

The regular readback and seal rows then follow the existing finite-window induction. Componentwise transport, replay, provenance, and naming are carried by H, C, P, N rather than by an external representative of the Cauchy stream.

Finally use diagonal-window stability from Definition 1639.8. It blocks any comparison that skips the displayed stage rows, so the induction cannot export quotient stream equality, a selected limit, countable choice, host real equality, or ambient Real completeness. □

Theorem 1639.12 (Bishop regular Cauchy completion universal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet factors through the single displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the packet's BHist*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The handoff is obtained by combining the common-tail, finite-window, diagonal-window, tail-diameter, seal-stability, and nonescape rows already displayed in this chapter; it exports no selected limit, quotient stream representative, host real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionUniversalHandoff`

Proof. Start with finite-window induction from Definition 1639.10. It forces the consumer to read $\mathsf{StreamName}^{\uparrow}$ windows by finite induction while preserving the $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, transport, replay, provenance, and terminal Real seal.

Next apply common-tail modulus stability and diagonal-window stability from Definition 1639.6 and Definition 1639.8. These rows fix the shared dyadic budget and common window before the stream, regularity, and Real-seal rows can be consumed.

Use tail-diameter control to keep the two regular readbacks inside the same finite completion comparison. Then apply seal stability and the abstract bridge route, Definition 1639.3 and Definition 1639.23, to send the same displayed packet to either a $\mathsf{Real}^{\uparrow}$ consumer or a $\mathsf{Completion}^{\uparrow}$-facing consumer.

Finally apply nonescape exactness from Definition 1639.15. Since the carrier contains only the displayed BHist, hsame, Cont, Pkg, and NameCert rows over the dyadic-stream-regular-Real route, no excluded host-level or choice-level object can be exported by the universal handoff. □

Theorem 1639.13 (Bishop regular Cauchy completion tail equivalence is quotient-free)**.** *Let* $B = (E, S, R, D, W, H, C, P, N)$ *and* $B' = (E', S', R', D, W, H', C', P', N')$ *be accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packets sharing the same dyadic tail modulus* D *and the same common-tail window* W*. Then their completion-facing comparison is carried only by the displayed rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

In particular, the comparison reads the common dyadic budget, the shared StreamName window, the two RegSeqRat readbacks, the Real seal boundaries, componentwise transport, replay, provenance,

and local naming data; it exports no quotient-stream equality, selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier tail equivalence quotient free`

Proof. Begin with common-tail modulus stability from Definition 1639.6. The shared rows D and W must be exposed before either packet can reach its Real seal boundary.

Transport the classifier by Definition 1639.4. Componentwise hsame and displayed Cont replay compare only the listed endpoint, observation, regularity, tail-modulus, common-window, provenance, and naming rows.

Use seal stability from Definition 1639.3. The terminal $\mathsf{Real}^{\uparrow}$ boundaries are downstream of the displayed regular Cauchy route, so the comparison cannot be replaced by a selected limit or host real equality.

Finally apply nonescape exactness from Definition 1639.15. Since no quotient-stream equality, selected-limit, choice, host-equality, or Real-completeness coordinate is present in either carrier, the shared-tail comparison is quotient-free. □

Theorem 1639.14 (Bishop regular Cauchy completion tail determinacy)**.** *Let* $B = (E, S, R, D, W, H, C, P, N)$ *and* $B' = (E', S', R', D, W, H', C, P', N')$ *be accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packets sharing the same displayed dyadic tail modulus* D*, the same common-tail window* W*, componentwise transport through* H, H'*, and the same displayed* Cont *replay* C*. Then every completion-facing consumer reads the two packets through the same displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

before reaching the terminal Real-seal boundary. The determinacy is a rowwise read-route claim: it exports no quotient stream equality, no selected limit, no host real equality, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionTailDeterminacy`

Proof. Begin with common-tail modulus stability from Definition 1639.6. The shared rows D and W force both completion-facing reads to expose the same dyadic tail budget and the same finite comparison window before either Real seal can be inspected.

Next use classifier transport from Definition 1639.4. Componentwise hsame transport moves only the displayed endpoint, observation, regularity, tail-modulus, common-window, provenance, and naming rows, while the shared Cont replay C preserves the same ordered route.

Apply seal stability from Definition 1639.3. The terminal Real-facing boundary is downstream of the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint ledger, $\mathsf{StreamName}^{\uparrow}$ finite observations, and $\mathsf{RegSeqRat}^{\uparrow}$ readback, so the two reads reach their seals through the same visible dependency route.

Finally apply nonescape exactness from Definition 1639.15. Since neither carrier has a coordinate for quotient stream equality, selected limits, host real equality, countable choice, or ambient Real completeness, no such object can distinguish the completion-facing read route. □

Theorem 1639.15 (Bishop regular Cauchy completion nonescape exactness)**.** *Every completion-facing read of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier* $B = (E, S, R, D, W, H, C, P, N)$ *is exhausted by the rows* $E, S, R, D, W, H, C, P, N$*. Thus the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}$ *boundary exports only dyadic endpoints, finite stream observations, regular rational sequence data, dyadic tail moduli, common-tail windows, componentwise* hsame *transport, displayed* Cont *replay,*

Pkg *provenance, and local naming data, and exports no quotient stream equality, host real equality, selected limit, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionNonescapeExactness`

Proof. Carrier projection is exhaustive: the tuple $B = (E, S, R, D, W, H, C, P, N)$ lists every coordinate admitted by the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}$ surface. A completion-facing consumer can therefore read only those displayed rows.

The structural rows do not enlarge the carrier. The hsame row transports already displayed coordinates, the Cont row replays the displayed route, P records provenance for the named packet, and N records the local NameCert row.

The excluded objects are absent from the tuple and absent from the replay route. Since there is no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient Real completeness, no completion-facing read can escape the displayed carrier boundary. □

Theorem 1639.16 (Bishop regular Cauchy completion Real seal consumer)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier* $B = (E, S, R, D, W, H, C, P, N)$ *must pass through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto W \longmapsto H, C, P, N \longmapsto E.$$

In particular, the consumer first reads StreamName windows, then the RegSeqRat readback, dyadic tolerance budget, common-tail modulus, classifier transport, and seal stability route before the terminal $\mathsf{Real}^{\uparrow}$ *seal is exposed. The read exports no quotient stream equality, selected limit, countable choice, host real equality, or ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier real seal consumer`

Proof. Begin with the regularity envelope. By Definition 1639.2, a completion-facing read must pass through the displayed finite stream observations S and regular rational sequence data R before it can be treated as a completion route.

Next fix the tolerance and tail data. The common-tail modulus stability theorem Definition 1639.6 forces the dyadic budget D and common-tail window W to be read before the Real seal is inspected.

Transport is then confined by Definition 1639.4. The componentwise hsame row and displayed Cont replay preserve the same route through S, R, D, W and do not introduce an outside real-equality coordinate.

Finally apply seal stability and nonescape exactness. The theorem Definition 1639.3 places the terminal seal E downstream of the displayed route, while Definition 1639.15 removes quotient equality, selected limits, countable choice, host equality, and ambient Real completeness from the accepted consumer boundary. □

Theorem 1639.17 (Bishop regular Cauchy completion density handoff)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer, and every countable-density consumer, of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet must first read the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows supplied by that completion packet before it may consume any dense embedding or countable dense surface. The handoff is the finite route*

$$\mathsf{BishopRegularCauchyCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RealSeparability}^{\uparrow},$$

where the first arrow is the quotient-free Real-seal route of this chapter and the second arrow is the RealSeparability hub route through regular rational readback and completion-facing dense embeddings. It exports no host dense subset, selected approximant, quotient real equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionCarrier density handoff`

Proof. Begin with the Real-seal consumer theorem Definition 1639.16. It forces every Real-facing read of the Bishop regular Cauchy completion packet through the finite StreamName window, RegSeqRat readback, dyadic tolerance, common-tail, transport, replay, provenance, and local naming rows before the terminal $\mathsf{Real}^{\uparrow}$ seal is visible.

Next apply the universal handoff of Definition 1639.12. The same displayed route serves either a $\mathsf{Real}^{\uparrow}$ consumer or a completion-facing consumer, so a density consumer cannot bypass the packet by reading a quotient representative, selected limit, host equality coordinate, or choice schedule.

Finally use the $\mathsf{RealSeparability}^{\uparrow}$ hub route of chapter 1809, in particular the RegSeqRat forward route Definition 1810.35. That route admits completion-facing density only after the regular rational readback and the dense-embedding boundary have been exposed. Composing the two routes gives the stated density handoff and leaves no coordinate for host dense subsets, selected approximants, quotient real equality, countable choice, or ambient Real completeness. □

Theorem 1639.18 (Bishop regular Cauchy completion obligation package)**.** *The carrier definition together with the regularity-envelope, seal-stability, classifier-transport, common-tail-modulus-stability, nonescape-exactness, and Real-seal-consumer theorems form the obligation-closed* BishopRegularCauchyCo *packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. Its visible obligation surface consists exactly of carrier admission, the regularity envelope, Real-seal handoff, classifier transport, shared tail budget, ledger non-escape, and terminal Real consumer routing.*

Consequently no quotient stream equality, selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row remains as an unlisted local NameCert obligation for this packet.*

Proof. Project the carrier tuple from Definition 1639.1. Its coordinates are precisely the dyadic endpoint row, finite stream observations, regular rational sequence row, dyadic tail modulus, common-tail window, componentwise transport, replay, provenance, and local naming row, so carrier admission is already displayed by the definition.

The regularity and Real-facing rows are supplied by Definition 1639.2 and Definition 1639.3. These rows force every completion-facing read through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the finite stream observations before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed.

Classifier and tail-budget transport are supplied by Definition 1639.4 and Definition 1639.6. The former restricts transport to the displayed hsame and Cont rows, while the latter fixes the shared dyadic tail budget and common-tail window before any comparison reaches the Real seal.

Finally, Definition 1639.15 and Definition 1639.16 close the ledger boundary. Since the carrier tuple contains no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}$ obligations and the terminal Real consumer surface. □

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionObligationClosurePack`

Theorem 1639.19 (Bishop regular Cauchy completion scoped kernel route)**.** *Every accepted carrier read, classifier transport, common-tail comparison, and Real-seal handoff in the* BishopRegularCauchyCompletion *packet factors through exactly the displayed rows*

$$E, S, R, D, W, H, C, P, N.$$

Here E is grounded in $\mathsf{DyadicRatCore}^{\uparrow}$*, S in* $\mathsf{StreamName}^{\uparrow}$*, R in* $\mathsf{RegSeqRat}^{\uparrow}$*, the terminal handoff in* $\mathsf{Real}^{\uparrow}$*, and the structural support in* BHist, hsame, Cont, Pkg, *and* NameCert*. No accepted route factors through quotient stream equality, host real equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionScopedKernelRoute`

Proof. Carrier reads are forced by Definition 1639.1. The tuple exposes only $E, S, R, D, W, H, C, P, N$, with the endpoint, observation, regularity, terminal seal, history, transport, replay, provenance, and local naming roles named there.

The regularity and Real-facing passages are supplied by Definition 1639.2 and Definition 1639.3. They route every completion-facing request through the regular sequence row, dyadic endpoint ledger, finite observation family, tail budget, and terminal $\mathsf{Real}^{\uparrow}$ seal.

Classifier and comparison steps are supplied by Definition 1639.4 and Definition 1639.6. The classifier reads componentwise hsame transport and displayed Cont replay, while the comparison first fixes the shared dyadic tail budget and common-tail window before reaching S, R, E.

The remaining boundary is Definition 1639.15 together with Definition 1639.16, and the rows are packaged by Definition 1639.18. Since those results exhaust the local NameCert obligations and identify no additional coordinate, the displayed kernel rows are exactly the dependency surface for the accepted routes. □

Theorem 1639.20 (Bishop regular Cauchy completion public Real-seal export)**.** *For every accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet, the public export available to* $\mathsf{Real}^{\uparrow}$ *and completion-facing consumers is exactly the quotient-free Real-seal handoff through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The export consists of the displayed dyadic endpoint ledger, finite stream observations, regular rational readback, dyadic tail modulus, common-tail window, seal-stability route, componentwise classifier transport, replay, package provenance, and local NameCert rows. It does not assert $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient stream equality, countable choice, host real equality, or any detached equality of Real names.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionPublicRealSeal`

Proof. Begin with the obligation package of Definition 1639.18. It identifies the carrier admission, regularity envelope, classifier transport, common-tail modulus, Real-seal handoff, nonescape boundary, and terminal Real consumer rows as the complete local obligation surface.

Next apply the scoped kernel route of Definition 1639.19. That theorem restricts every accepted carrier read, classifier transport, common-tail comparison, and Real-seal handoff to the displayed rows $E, S, R, D, W, H, C, P, N$ over the named DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert dependencies.

Seal stability supplies the public endpoint discipline. By Definition 1639.3, the terminal Real consumer reads finite endpoint, observation, regularity, tail-modulus, common-tail, transport, replay, provenance, and naming data before the $\mathsf{Real}^{\uparrow}$ seal is exposed.

The excluded objects are absent from all three ingredients. Since none of the carrier, obligation package, scoped route, or seal-stability row contains Real completeness, selected limits, quotient stream equality, countable choice, host real equality, or detached equality of Real names, the public export is exactly the quotient-free Real-seal handoff stated above. □

Theorem 1639.21 (Bishop regular Cauchy completion filter-Real handoff)**.** *A* BishopRegularCauchyCompletion$^{\uparrow}$ *packet receiving a* CauchyFilter$^{\uparrow}$ *basis reaches the terminal* Real$^{\uparrow}$ *seal only through the displayed CauchyFilter finite base,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *regular readback,* DyadicRatCore$^{\uparrow}$ *endpoint ledger, common-tail modulus, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. This handoff exports no* Real$^{\uparrow}$ *completeness, quotient stream equality, selected limits, host equality, or countable choice.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionFilterRealHandoff`

Proof. Start from the CauchyFilter Real-RegSeq handoff non-escape theorem Definition 333.8. It confines the incoming basis to displayed filter-base rows, stream schedules, regular readbacks, dyadic neighbourhood rows, real-ball bounds, refinement rows, modulus rows, ledger evidence, and provenance.

Apply the regularity envelope of Definition 1639.2. The accepted Bishop completion packet reads the incoming basis only as finite StreamName windows, RegSeqRat regularity data, dyadic endpoint ledgers, and the same local naming route.

Use common-tail modulus stability and seal stability from Definition 1639.6 and Definition 1639.3. These theorems force the terminal Real seal to remain over the displayed endpoint, tail modulus, common-tail window, transport, replay, provenance, and local NameCert rows.

Finally apply the public Real-seal export of Definition 1639.20. The export is already quotient-free, so the CauchyFilter-to-Real route cannot acquire Real completeness, quotient stream equality, selected limits, host equality, or countable choice. □

Theorem 1639.22 (Bishop regular Cauchy completion consumer exactness)**.** *Every* Completion$^{\uparrow}$*-facing consumer of an accepted* BishopRegularCauchyCompletion$^{\uparrow}$ *packet is exhausted by the displayed dyadic endpoint ledger,* StreamName$^{\uparrow}$ *finite observations,* RegSeqRat$^{\uparrow}$ *readback, dyadic tail budget, classifier transport, terminal* Real$^{\uparrow}$ *seal handoff, and local* NameCert *rows. Equivalently, the consumer-facing route is*

$$E, S, R, D, W, H, C, P, N \longmapsto \mathsf{Completion}^{\uparrow},$$

where the left side is the concrete regular Cauchy completion packet over DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The route exports no ambient* Real$^{\uparrow}$ *completeness, quotient stream equality, selected limit, countable-choice schedule, host real equality, or detached equality of Real names.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionConsumerExactness`

Proof. First apply seal stability from Definition 1639.3. It forces any terminal Real read to pass through the finite endpoint, stream-window, regular readback, tail budget, common-tail, transport, replay, provenance, and local naming rows.

Next use the universal handoff and nonescape exactness supplied by Definition 1639.16 and Definition 1639.15. These theorems keep completion-facing reads inside the displayed packet $E, S, R, D, W, H, C, P, N$ and leave no coordinate for quotient streams, selected limits, countable choice, host equality, or detached Real-name equality.

Then apply the public Real-seal export of Definition 1639.20. The public export is already the quotient-free handoff over DyadicRatCore endpoints, StreamName windows, RegSeqRat readback, the terminal Real seal, and the structural rows.

Finally use the filter-Real handoff of Definition 1639.21. It shows that even a CauchyFilter-facing basis reaches the terminal Real seal only through the same displayed route. Therefore every Completion-facing consumer sees exactly that finite regular Cauchy completion surface, and not an ambient completeness principle. □

Theorem 1639.23 (Bishop regular Cauchy completion abstract bridge route)**.** *Every abstract* $\mathsf{Completion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet must pass through the displayed carrier admission, classifier transport, regularity-envelope, common-tail modulus stability, Real-seal handoff, and nonescape rows before reading the abstract completion interface. The bridge-facing route is*

$$E, S, R, D, W, H, C, P, N \longmapsto \mathsf{Completion}^{\uparrow},$$

where the left side is the concrete DyadicRatCore, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local NameCert packet. It exports no quotient stream equality, selected limit, host real equality, countable-choice schedule, or detached equality of Real names.

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionAbstractBridgeRoute`

Proof. Start with carrier admission from Definition 1639.1. The concrete packet exposes exactly the rows $E, S, R, D, W, H, C, P, N$, so any abstract completion-facing consumer must begin from those displayed coordinates.

Use the regularity envelope and common-tail modulus stability from Definition 1639.2 and Definition 1639.6. They force the StreamName observations, RegSeqRat regularity row, dyadic tail budget, and common-tail window to be read before the route can behave as a completion-facing object.

Apply classifier transport and the Real-seal handoff from Definition 1639.4 and Definition 1639.16. These rows keep the abstract-facing read tied to componentwise hsame transport, displayed Cont replay, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use nonescape exactness, the obligation package, and the public Real-seal export from Definition 1639.15, Definition 1639.18, and Definition 1639.20. They identify the concrete rows as the whole local NameCert surface and exclude quotient streams, selected limits, countable choice, host equality, and detached Real-name equality from the bridge-facing route. □

Theorem 1639.24 (Bishop regular Cauchy completion mature route)**.** *Every mature completion-facing read of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet factors, in order, through the obligation package, the scoped kernel route, the public Real-seal export, and the abstract bridge route. The resulting consumer boundary is over*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

It exports the finite regular Cauchy completion route to $\mathsf{Completion}^{\uparrow}$*-facing consumers without exporting* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, countable choice, host real equality, or detached equality of Real names.*

Proof. First apply the obligation package of Definition 1639.18. It exhausts the local rows by carrier admission, regularity envelope, Real-seal handoff, classifier transport, shared tail budget, ledger nonescape, and terminal Real consumer routing.

Next use the scoped kernel route of Definition 1639.19. It fixes the displayed dependency surface as the rows $E, S, R, D, W, H, C, P, N$ over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Then apply the public Real-seal export of Definition 1639.20. This makes the terminal Real read public only as a quotient-free seal over the same dyadic endpoint, stream-window, regular readback, tail, transport, replay, provenance, and local naming rows.

Finally apply the abstract bridge route of Definition 1639.23. It sends the same concrete packet toward $\mathsf{Completion}^{\uparrow}$ and adds no coordinate for Real completeness, quotient stream equality, selected limits, countable choice, host real equality, or detached equality of Real names. □

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionMatureRoute`

Theorem 1639.25 (Bishop regular Cauchy completion limit-witness route)**.** *Any* $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet must factor through dyadic tail modulus,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows before reading a limit witness. The witness-facing route exports the mature regular Cauchy completion surface; it does not export quotient stream equality, selected limits outside the displayed packet, countable choice, host Real equality, detached Real-name equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionLimitWitnessRoute`

Proof. Start with the mature route of Definition 1639.24. It already factors every mature completion-facing read through the obligation package, scoped kernel route, public Real-seal export, and abstract bridge route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Apply the public Real-seal export of Definition 1639.20. The limit-witness consumer sees the terminal Real read only as a quotient-free seal after dyadic endpoints, stream windows, regular readback, tail data, transport, replay, provenance, and local naming have been displayed.

Next use the filter-Real handoff of Definition 1639.21. It keeps even filter-facing basis reads on the same displayed route before the terminal Real seal can be used, so a $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ consumer cannot bypass the finite tail and readback rows.

Finally apply nonescape exactness from Definition 1639.15. Since the carrier has no coordinate for quotient stream equality, selected limits outside the displayed packet, countable choice, host Real equality, detached Real-name equality, or ambient Real completeness, the witness-facing read remains exactly the finite regular Cauchy completion route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}, \mathsf{maturePackageClosed})$
