Scope closed: Definition 1639.1, Definition 1639.2, Definition 1639.3, Definition 1639.4, Definition 1639.6, Definition 1639.14, Definition 1639.15, Definition 1639.16, Definition 1639.18, Definition 1639.19, Definition 1639.20, Definition 1639.23, and Definition 1639.24 close the finite regular Cauchy completion dependency surface, public Real-seal export, mature consumer boundary, and bridge-facing route to the abstract completion interface over displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCompletion}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.BishopRegularCauchyCompletionUp.BishopRegularCauchyCompletionMatureRoute`

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host real equality, selected limits, countable choice, or standard bridge checking.

Upgrade path: The next formal upgrade is a standard bridge theorem for the mature route over the same displayed BEDC primitives.

Constructive story: A BishopRegularCauchyCompletion$^{\uparrow}$ packet is generated from DyadicRatCore endpoints, StreamName finite observations, RegSeqRat regularity, a dyadic tail modulus, a common-tail window, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1640

A Concrete Naming Certificate for $\mathsf{UpperSemicontinuous}^{\uparrow}$

Following Bishop–Bridges constructive analysis, upper semicontinuity is read through upper-bound and sublevel windows rather than through a host topology. The $\mathsf{UpperSemicontinuous}^{\uparrow}$ packet is the upper-side companion of chapter 1536: it reads finite stream windows from chapter 126, regular rational readbacks from chapter 301, upper-real comparison rows from chapter 1447, located endpoint rows from **??**, and the terminal seal of chapter 38. The chapter therefore supplies the missing constructive dual interface for the L10 real-and-completion boundary without identifying it with the lower epigraph certificate.

Definition 1640.1 (UpperSemicontinuous carrier)**.** *An* $\mathsf{UpperSemicontinuous}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, F, S, W, R, O, H, C, P, N)$$

with the following visible rows:

1. *X is the source carrier row whose accepted points are read through displayed* BHist *histories and classifier transport;*
2. *F is the function graph or displayed value row whose finite reads are inspected only after a source window has been selected;*
3. *S is the sublevel ledger, consisting of finite rows (x, q) saying that the inspected value is bounded above by the rational threshold q at the displayed window;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite source, value, and threshold windows used by each sublevel inspection;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row giving the regular rational value windows and threshold witnesses consumed by S;*
6. *O is the* $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *comparison ledger used to read upper windows, located endpoint checks, terminal real seals, and the finite contrast with lower-side reads;*
7. *H records componentwise* hsame *transport for source histories, graph rows, sublevel rows, schedules, regular readbacks, comparison ledgers, provenance rows, and local naming rows;*
8. *C records displayed* Cont *replay from source admission through schedule selection, regular rational readback, sublevel inspection, located readback, and real-seal handoff;*

9. *P is the* Pkg *provenance over* UpperSemicontinuous$^{\uparrow}$, LowerSemicontinuous$^{\uparrow}$, UpperReal$^{\uparrow}$, LocatedReal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{UpperSemicontinuous}^{\uparrow}}$ *row.*

The classifier relates two accepted packets exactly when their source rows, finite sublevel windows, regular rational readbacks, upper-real comparisons, located readbacks, terminal Real$^{\uparrow}$ *seal rows, and provenance rows transport componentwise along H and replay through the same displayed routes in C. No host topology, quotient real equality, selected limit, trichotomy, countable choice, or* Real$^{\uparrow}$ *completeness principle is a carrier coordinate.*

Lean4 ✓ `BEDC.Derived.UpperSemicontinuousUp.UpperSemicontinuousTasteGate single carrier alignment`

Theorem 1640.2 (UpperSemicontinuous lower-dual boundary)**.** *The accepted* UpperSemicontinuous$^{\uparrow}$ *carrier is constructively dual to the* LowerSemicontinuous$^{\uparrow}$ *epigraph surface of chapter 1536: lower semicontinuity records finite lower-bound rows, while upper semicontinuity records finite upper-bound and sublevel rows over the same kind of stream schedule, regular rational readback, located endpoint check, transport, replay, provenance, and local naming route. This duality compares the two finite certificate surfaces and does not identify their carriers, classifiers, or exported* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.UpperSemicontinuousUp.UpperSemicontinuousLowerDualBoundary`
↪ variant `BEDC.Derived.UpperSemicontinuousUp.UpperSemicontinuousCarrier lower dual boundary`

Proof. Read the lower-side packet through Definition 1536.1. Its distinguishing ledger is the finite epigraph row of lower rational bounds. Read the upper-side packet through Definition 1640.1. Its distinguishing ledger is the finite sublevel row of upper rational bounds.

The common route consists of displayed source histories, stream schedules, regular rational readbacks, located endpoint checks, Real$^{\uparrow}$ seal rows, componentwise hsame transport, Cont replay, package provenance, and a local name. These coordinates support a boundary comparison because every inspection on either side is finite and routed through named sibling certificates.

The two packets remain separate certificates. The lower carrier exports epigraph-facing rows; the upper carrier exports sublevel-facing rows. Since their local NameCert rows are different coordinates and neither carrier contains a quotient real equality or selected limit coordinate, the duality is a constructive boundary relation rather than an identification. □

Theorem 1640.3 (UpperSemicontinuous finite-window stability)**.** *Every upper-bound read from an accepted* UpperSemicontinuous$^{\uparrow}$ *carrier $U = (X, F, S, W, R, O, H, C, P, N)$ factors through the finite seal route*

$$W, R, O, H, C, P, N$$

where W is the StreamName$^{\uparrow}$ *schedule, R is the* RegSeqRat$^{\uparrow}$ *readback, O is the* UpperReal$^{\uparrow}$, LocatedReal$^{\uparrow}$, *and* Real$^{\uparrow}$ *comparison ledger, and H, C, P, N are the transport, replay, provenance, and local naming rows. No consumer can read an upper bound by bypassing that finite route through host topology, quotient real equality, a selected limit, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with an upper-bound inspection of U. The source and value rows are not read directly: the schedule W first selects the finite source, value, and threshold windows that the inspection may observe.

The readback row R supplies the regular rational data attached to those windows. The sublevel ledger S records the upper-bound row (x, q) for that same inspection, and the comparison ledger O checks the row against the $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ surfaces.

Transport and replay are exhausted by H and C. They move the source, graph, sublevel, readback, comparison, and seal rows together, so the same finite route remains visible after classifier transport.

Finally, P and N expose exactly this route to downstream consumers. Since the carrier has no coordinate for host topology, quotient equality, selected limits, trichotomy, countable choice, or real completeness, those principles cannot be obtained from an upper-bound read. □

Lean4 ✓ `BEDC.Derived.UpperSemicontinuousUp.UpperSemicontinuousFiniteWindowStability`

Closure status for $\mathsf{NameCert}_{\mathsf{UpperSemicontinuous}^{\uparrow}}$.

Constructive story: A $\mathsf{UpperSemicontinuous}^{\uparrow}$ packet is generated from displayed source histories, finite sublevel rows, StreamName schedules, RegSeqRat readbacks, UpperReal and LocatedReal comparison ledgers, RealUp seal rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperSemicontinuous}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1640.1, Definition 1640.2, and Definition 1640.3 seed the finite upper-bound certificate over sublevel windows, stream schedules, regular rational readbacks, upper-real and located comparison rows, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpperSemicontinuous}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close host topology, quotient real equality, selected limits, trichotomy, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, sublevel-window exactness, upper-real classifier stability, located readback compatibility, transport replay, provenance, and real-seal non-escape for BEDC.Derived.UpperSemicontinuousUp.

Chapter 1641

A Concrete Naming Certificate for $\mathsf{SequentialCompactness}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{SequentialCompactness}^{\uparrow}$ packet records only explicit finite subsequence-selector and convergence-window data for compact-metric sequence consumers. It sits over the compact metric source of chapter 129, the sequence-window interface of chapter 126, the regular rational handoff of chapter 301, the terminal real-name seal of chapter 38, and the displayed selector route of chapter 1408. The chapter names the finite boundary that compactness consumers may inspect; it is not unrestricted sequential compactness and does not import choice-like subsequence selection.

Definition 1641.1 (Sequential compactness carrier)**.** *A* $\mathsf{SequentialCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, S, B, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite covering and metric inspection data bound the sequence consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *sequence-window row, recording the inspected source indices, target windows, and finite request schedule opened by the consumer.*
3. *B is the displayed* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *subsequence window, including the selected index row and the finite evidence that the selected windows stay inside the compact-metric source.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *convergence handoff row attached to the selected subsequence windows and rational tail budgets.*
5. *H is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed limit read after the regular rational handoff has been accepted.*
6. *C records componentwise* hsame *transports for K, S, B, R, H and displayed* Cont *replays from compact-metric source reads to sequence windows, selected subsequence windows, regular rational tail reads, and the terminal real seal.*
7. *P is the* Pkg *provenance over* $\mathsf{SequentialCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BolzanoWeierstrassSelecto}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through K, S, B, R, H, C, P, N. It has no coordinate for host sequential compactness, countable choice, quotient equality of streams, a subsequence selected outside B, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessTasteGate single carrier alignment`

Theorem 1641.2 (Sequential compactness NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompactness}^{\uparrow}$ *carrier*

$$Q = (K, S, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompactness}^{\uparrow}}$ *surface consists of the following finite obligation rows:*

1. *carrier admission for the compact-metric source row, sequence-window row, displayed selector window, regular rational convergence handoff, real seal, transports, provenance, and local naming row;*
2. *finite-window classifier exposure, requiring every sequence read to pass through S and every compactness read to pass through K before a selector row is inspected;*
3. *selector stability, requiring selected indices and selected windows to be exactly the rows displayed in B and stable under the componentwise transports in C;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exactness, requiring convergence reads to enter R only from the selected windows in B and the rational tail budgets displayed by the packet;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the terminal limit read to pass through H after R and forbidding any ambient completeness or quotient stream equality coordinate.*

No accepted packet carries a further obligation row for host sequential compactness, countable choice, external subsequence selection, quotient streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1641.1. The packet exposes exactly the compact source, sequence window, selector window, convergence handoff, real seal, transport, provenance, and local naming rows.

Finite-window classifier exposure follows from the route through K and S. A consumer first reads the compact metric source and the finite sequence windows; only then can it inspect the displayed selector window B.

Selector stability is internal to B and C. The selected indices and selected windows are the rows stored in B, and C transports those rows componentwise without adding a second selection principle.

The convergence handoff is the row R. It accepts only the selected windows displayed by B together with the rational tail budgets stored in the carrier, so the handoff cannot be replaced by host convergence of an unspecified subsequence.

Finally, the limit read is sealed by H. Since the carrier has no coordinate for host sequential compactness, countable choice, quotient stream equality, external selected subsequences, or ambient real completeness, none of those data can be exported by the local NameCert surface. □

Theorem 1641.3 (Sequential compactness selector refusal)**.** *No accepted* $\mathsf{SequentialCompactness}^{\uparrow}$ *consumer may replace the displayed selector rows by host sequential compactness, countable choice,*

quotient stream equality, a selected subsequence outside B, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. Every accepted consumer factors through the displayed route*

$$K, S \longmapsto B \longmapsto R \longmapsto H, C, P, N.$$

Proof. Let a consumer read an accepted carrier $Q = (K, S, B, R, H, C, P, N)$. The only compactness source is K, and the only sequence access route is the finite window row S.

The only subsequence data are stored in B. Thus selected indices, selected windows, and the boundary evidence that they remain inside the compact-metric source must be read from B itself.

The only convergence route is then R, followed by the real seal H. The structural rows C, P, N transport, source, and name this same route; they do not add host sequential compactness, choice, quotient stream equality, an external subsequence, or ambient completeness.

Therefore every accepted consumer factors through K, S, B, R, H, C, P, N, and every attempted replacement by the listed external data lies outside the $\mathsf{SequentialCompactness}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessCarrier selector refusal`

Theorem 1641.4 (Sequential compactness compact-metric route)**.** *Every accepted* $\mathsf{SequentialCompactness}^{\uparrow}$ *packet*

$$Q = (K, S, B, R, H, C, P, N)$$

reads its compact source K through $\mathsf{CompactMetric}^{\uparrow}$*, then reads the finite sequence windows S, then reads the* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *row B, and only then reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R and the* $\mathsf{Real}^{\uparrow}$ *seal H. No host sequential compactness theorem, choice-selected subsequence, quotient stream equality, or ambient completeness row can bypass the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source.*

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessCompactMetricRoute`

Proof. Project the carrier of Definition 1641.1. The first row K is the compact-metric source, and the sequence-window row S is the only route by which a consumer can inspect source indices and target windows.

Apply Definition 1641.2. Its finite-window classifier clause requires every sequence read to pass through S and every compactness read to pass through K before the selector row is inspected.

Now apply Definition 1641.3. It blocks host sequential compactness, countable choice, quotient stream equality, externally selected subsequences, and ambient real completeness. Therefore the only route to R and H is the displayed K, S, B, R, H, C, P, N route, with $\mathsf{CompactMetric}^{\uparrow}$ as the compact source. □

Theorem 1641.5 (Sequential compactness Bolzano-Weierstrass window)**.** *Every accepted* $\mathsf{SequentialCompactness}^{\uparrow}$ *packet consumed by a Bolzano-Weierstrass-facing route must factor through the finite window*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{BoundedRealSequence}^{\uparrow}, \quad \mathsf{RealSequenceClusterPoint}^{\uparrow}.$$

The route reads compact-metric finite nets, sequence windows, regular rational readback, RealUp seal rows, and the sibling surfaces of chapter 1415 and chapter 1580. It exports no unrestricted subsequence selector, countable choice, open-cover compactness theorem, quotient stream equality, or ambient Real completeness row.

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessBolzanoWeierstrassWindow`

Proof. Project the carrier of Definition 1641.1. The compact source K, sequence windows S, displayed selector row B, regular rational handoff R, and terminal Real seal H are the only rows available to a consumer.

Apply Definition 1641.4. It forces every route to R and H through the compact-metric source and the displayed sequence windows before the selector row can be inspected.

The bounded-real-sequence sibling supplies the finite bounded-window source surface, and the real-sequence-cluster-point sibling supplies the cluster-seal handoff. Reading those siblings through K, S, B, R, H, C, P, N gives the displayed Bolzano-Weierstrass-facing route while preserving the refusal of unrestricted selection, countable choice, open-cover compactness, quotient stream equality, and ambient Real completeness. □

Theorem 1641.6 (Sequential compactness finite-window exhaustion)**.** *Every subsequence-facing claim exported by an accepted* $\mathsf{SequentialCompactness}^{\uparrow}$ *carrier*

$$Q = (K, S, B, R, H, C, P, N)$$

must factor through the compact metric source K, the $\mathsf{StreamName}^{\uparrow}$ *windows S, the displayed selector window B, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal H before any structural row C, P, N is consumed. The export is exhausted by the finite route*

$$K, S \longmapsto B \longmapsto R \longmapsto H \longmapsto C, P, N.$$

It supplies no host sequential compactness theorem, no selector outside B, no quotient stream equality, no countable-choice schedule, no open-cover compactness theorem, and no ambient Real completeness row.

Lean4 ✓ `BEDC.Derived.SequentialCompactnessUp.SequentialCompactnessCarrier finite window exhaustion`

Proof. Project the carrier of Definition 1641.1. The only compact source row is K, the only source-window row is S, the only selector data are stored in B, and the only convergence and limit rows are R and H.

Use the NameCert obligations of Definition 1641.2. They force every sequence read through S, every compactness read through K, every selector read through the displayed window B, and every convergence read through the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R before the $\mathsf{Real}^{\uparrow}$ seal H is available.

Apply the selector refusal theorem Definition 1641.3 and the compact-metric route theorem Definition 1641.4. Together they block replacement by host sequential compactness, choice, quotient streams, externally selected subsequences, and ambient completeness, while keeping $\mathsf{CompactMetric}^{\uparrow}$ as the source of the route.

Finally apply the Bolzano-Weierstrass window theorem Definition 1641.5. It identifies the downstream bounded-real-sequence and cluster-point reads as consumers of the same finite window. Thus every subsequence-facing export is exhausted by K, S, B, R, H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompactness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1641.1, Definition 1641.2, and Definition 1641.3 seed the finite selector-boundary surface for compact-metric sequence consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly refuses unrestricted sequential compactness, host subsequence selection, countable choice, quotient stream equality, selected subsequences outside the displayed selector row, ambient Real completeness, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window classifier exposure, selector stability, RegSeqRat handoff exactness, RealUp seal nonescape, and selector-refusal proofs for BEDC.Derived.SequentialCompactnessUp.

Constructive story: A SequentialCompactness$^{\uparrow}$ packet is generated from a CompactMetric source row, StreamName sequence-window row, displayed BolzanoWeierstrassSelector subsequence window, RegSeqRat convergence handoff, Real seal row, componentwise transport and replay rows, provenance, and a local NameCert row.

Chapter 1642

A Concrete Naming Certificate for $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$

Following Bishop and Bridges, Cauchy continuity is read here as preservation of regular Cauchy names through explicit moduli. The $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ packet sits on the finite observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational source route of chapter 301, the pointwise modulus schedule of chapter 1486, the uniform compatibility boundary of chapter 391, the target tail-estimate route of chapter 1487, and the terminal real-name seal of chapter 38. It names the theorem surface that a modulus-controlled map sends displayed regular Cauchy source names to displayed regular Cauchy target names before any Real seal is consumed.

Definition 1642.1 (Cauchy continuity principle carrier)**.** *A* $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, D, M, U, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row naming the regular rational Cauchy source data.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family through which source and target observations are inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested target tolerances, source-window budgets, and comparison rows.*
4. *M is the* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *data that converts each target tolerance into the source-window read used by the map.*
5. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *compatibility row, requiring the pointwise Cauchy-modulus route to agree with the available uniform read whenever a uniform packet is supplied.*
6. *T is the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *target handoff, recording the target tail estimate obtained after S, W, D, M, U have been replayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the target* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff carried by T is displayed.*
8. *H records componentwise* hsame *transport for S, W, D, M, U, T, E and for the replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a target tolerance request through D, then M, then the source row S and finite windows W, then U, then the target tail estimate T, and finally the seal row E.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuityPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, M, U, T, E, H, C, P, N$. It has no coordinate for host function equality, quotient completion, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or equality of completed real values.*

Theorem 1642.2 (Cauchy continuity principle NameCert obligations)**.** *For every accepted* CauchyContinuityPrincip *carrier $Q = (S, W, D, M, U, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuityPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source regular Cauchy row, finite windows, dyadic tolerance ledger, Cauchy-continuity modulus, uniform compatibility row, target tail estimate, Real seal, transport, replay, provenance, and local naming row;*

2. *classifier transport, requiring H and C to preserve the ordered route D, M, S, W, U, T, E componentwise;*

3. *modulus exactness, requiring every target tolerance to reach its source-window budget only through the displayed row M and the dyadic ledger D;*

4. *regular-target handoff, requiring the target Cauchy read to pass through T before the Real seal E is exposed;*

5. *ledger non-escape, requiring P and N to export no host function equality, quotient completion, countable choice, selected limit, ambient Real completeness, or equality of completed real values.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1642.1. The projection exposes exactly the regular source row S, finite windows W, dyadic ledger D, modulus data M, uniform compatibility row U, target tail estimate T, Real seal E, and the structural rows H, C, P, N.

Classifier transport is componentwise. The transport row H moves the displayed coordinates to a common finite surface, and the replay row C repeats the same dependency order D, M, S, W, U, T, E for every accepted tolerance request.

Modulus exactness is exhausted by M and D. A target tolerance first reads the dyadic ledger, then the Cauchy-continuity modulus row, and only then obtains the source-window budget used to inspect S through W.

The regular-target handoff is the row T. It records the finite target tail estimate produced after the source row, windows, ledger, modulus, and compatibility row have been replayed, so the Real seal E is downstream of the regular target data.

Finally inspect P and N. Since the carrier contains no host function equality, quotient completion, countable-choice source, selected limit, ambient completeness witness, or equality of completed real values, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CauchyContinuityPrincipleUp.TasteGate.CauchyContinuityPrincipleTasteGate single carrier alignment`

Theorem 1642.3 (Cauchy continuity principle RegSeqRat handoff)**.** *Let* $Q = (S, W, D, M, U, T, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ *carrier. Every target* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by the packet factors through the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *row* M*, the* $\mathsf{UniformContinuity}^{\uparrow}$ *compatibility row* U*, and the target* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *row* T*.*

Lean4 ✓ `BEDC.Derived.CauchyContinuityPrincipleUp.CauchyContinuityPrincipleCarrier regseqrat handoff`

Proof. Start with the source side. Carrier admission gives the source regular rational Cauchy row S and the finite window family W, so source observations are available only as displayed finite-window reads.

Next read the tolerance side. The dyadic ledger D supplies the requested target tolerance and comparison budget, and the modulus row M converts that request into the source-window budget used on S and W.

The compatibility row U does not add an external modulus. It records that the same finite route agrees with the available uniform-continuity packet whenever that packet is present.

The target handoff is then forced through T. This row records the regular Cauchy target tail estimate produced from the replayed route, and H, C, P, N transport, replay, source, and name only those displayed coordinates. Hence every target $\mathsf{RegSeqRat}^{\uparrow}$ read factors through the stated route and cannot be obtained from host function equality, quotient completion, countable choice, selected limits, or ambient Real completeness. □

Theorem 1642.4 (Cauchy continuity principle modulus-composition handoff)**.** *Let*

$$Q_1 = (S_1, W_1, D_1, M_1, U_1, T_1, E_1, H_1, C_1, P_1, N_1)$$

and

$$Q_2 = (S_2, W_2, D_2, M_2, U_2, T_2, E_2, H_2, C_2, P_2, N_2)$$

be accepted $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ *carriers. Suppose the target* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff displayed by* T_1 *is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S_2 *read by the second packet. Then every composite target* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by* Q_2 *factors through the finite route* $D_2, M_2, S_2, W_2, U_2, T_2$*, with the displayed occurrence of* S_2 *supplied by the first packet route* $D_1, M_1, S_1, W_1, U_1, T_1$*. The terminal* $\mathsf{Real}^{\uparrow}$ *seal is exposed only after both finite routes have been replayed.*

Lean4 ✓ `BEDC.Derived.CauchyContinuityPrincipleUp.CauchyContinuityPrincipleCarrier modulus composition handoff`

Proof. Apply Definition 1642.2 to Q_1 and Q_2. Carrier admission gives the two displayed rows $S_i, W_i, D_i, M_i, U_i, T_i, E_i, H_i, C_i, P_i, N_i$, while classifier transport and replay preserve the order $D_i, M_i, S_i, W_i, U_i, T_i,$ in each packet.

Apply Definition 1642.3 to Q_2. Its exported target $\mathsf{RegSeqRat}^{\uparrow}$ read must pass through $D_2, M_2, S_2, W_2, U_2, T_2$, so the only source regular Cauchy row available to that read is the displayed row S_2.

Use the assumed handoff identification. The row S_2 is not an ambient equality of completed values; it is the target $\mathsf{RegSeqRat}^{\uparrow}$ handoff displayed by T_1. Applying Definition 1642.3 to Q_1 therefore replaces that source read by the finite route $D_1, M_1, S_1, W_1, U_1, T_1$.

Finally replay the seal order from the two obligation surfaces. Since E_2 is downstream of T_2, and T_2 has already consumed the displayed S_2 supplied by T_1, the terminal $\mathsf{Real}^{\uparrow}$ seal is visible

only after the second route and the first route have both been displayed. The carrier coordinates contain no host function equality, quotient completion, countable choice, selected limit, ambient Real completeness, or completed-real equality, so there is no additional route for the composite read. □

Theorem 1642.5 (Cauchy continuity principle Real seal boundary)**.** *For every accepted* $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ *carrier* $Q = (S, W, D, M, U, T, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *consumer of the seal row* E *first reads the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CauchyModulusOfContinuity}^{\uparrow},\ \mathsf{UniformContinuity}^{\uparrow},\ \mathsf{RegularCauchyTail}$$

Consequently the consumer receives a finite source-name, tolerance, modulus, compatibility, target-tail, and seal route, and receives no host function equality, quotient completion, countable-choice selector, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or completed-real equality principle.*

Lean4 ✓ `BEDC.Derived.CauchyContinuityPrincipleUp.CauchyContinuityPrincipleCarrier real seal boundary`

Proof. Read the seal coordinate in Definition 1642.1. The row E is listed only as the terminal $\mathsf{Real}^{\uparrow}$ seal reached after the target tail estimate T is displayed.

Use Definition 1642.3. The target regular Cauchy read has already passed through S, W, D, M, U, T before a real-facing consumer can inspect the seal.

Replay the structural rows. The continuation row C preserves the dependency order, the transport row H preserves the same finite coordinates, and the provenance and naming rows P, N record no additional source.

Thus the Real consumer receives exactly the displayed finite route through the sibling surfaces. Because none of the excluded principles is present as a carrier coordinate, no consumer can bypass the route by reading host function equality, quotient completion, countable choice, a selected limit, ambient Real completeness, or equality of completed real values. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuityPrinciple}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyContinuityPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1642.1, Definition 1642.2, Definition 1642.3, Definition 1642.4, and Definition 1642.5 seed the finite theorem surface connecting modulus-controlled maps to preservation of displayed regular Cauchy names before Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyContinuityPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient completion, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, completed-real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier admission and handoff proofs for BEDC.Derived.CauchyContinuityPrincipleUp over the same $S, W, D, M, U, T, E, H, C, P, N$ rows.

Constructive story: A $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$ packet is generated from a source RegSeqRat row, finite StreamName windows, a DyadicRatCore tolerance ledger, CauchyModulusOfContinuity data, UniformContinuity compatibility, RegularCauchyTailEstimate target handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1643

A Concrete Naming Certificate for $\mathsf{RieszRepresentation}^{\uparrow}$

Following Riesz, the Riesz representation packet treats a bounded scalar-valued functional as data that can be read against a representing vector or representing measure only after the relevant Banach, Hilbert, norm, and measure surfaces have already supplied their carriers and classifiers. It depends on $\mathsf{NameCert}_{\mathsf{Banach}^{\uparrow}}$ (chapter 90), $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$ (chapter 91), $\mathsf{NameCert}_{\mathsf{FunctionalAnalysis}^{\uparrow}}$ (chapter 94), $\mathsf{NameCert}_{\mathsf{Norm}^{\uparrow}}$ (chapter 89), and $\mathsf{NameCert}_{\mathsf{Measure}^{\uparrow}}$ (chapter 92). The packet is a cross-chapter representation surface: it names the carrier and obligations needed by later spectral and measure-representation chapters without asserting every classical representation theorem at once.

1643.1 Carrier definition

Definition 1643.1 (RieszRepresentation carrier)**.** *A* $\mathsf{RieszRepresentation}^{\uparrow}$ *carrier is a representation row*

$$\mathsf{RieszRep}(S, T, \lambda, r, \Lambda)$$

whose source S is either a Hilbert row or a locally measured Banach-function row supplied by the dependency certificates named above. The target T is the scalar $\mathsf{Real}^{\uparrow}$ *face used by the bounded-functional row of* $\mathsf{FunctionalAnalysis}^{\uparrow}$*, λ is the bounded scalar-valued functional row, r is the proposed representing datum, and Λ is the visible ledger binding the functional row to the representing datum.*

In the Hilbert branch, r is a carried Hilbert endpoint and the ledger records the row

$$\lambda(x) \sim_{\mathsf{Real}^{\uparrow}} \langle x, r \rangle$$

for every carried Hilbert endpoint x, using the inner-product and norm rows of $\mathsf{Hilbert}^{\uparrow}$*. In the measure branch, r is a finite signed or positive measure row over the displayed measurable carrier, and the ledger records scalar integration rows against bounded test endpoints. The classifier compares two representation rows only by inherited transport of the functional endpoint, representing datum, scalar value rows, and ledger entries; it does not identify host-level functions, host-level vectors, or host-level measures.*

1643.2 Certificate obligations

Theorem 1643.2 (RieszRepresentation NameCert obligation surface)**.** *The* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet exposes exactly the following NameCert obligation surface:*

1. *a source row from* $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, *and* $\mathsf{Measure}^{\uparrow}$ *identifying the carried functional domain;*
2. *a bounded scalar-valued functional row inherited from* $\mathsf{FunctionalAnalysis}^{\uparrow}$*;*
3. *a representing datum row, either a Hilbert endpoint or a measure endpoint, with its own carrier and classifier;*
4. *a scalar evaluation ledger comparing the functional value with the inner-product or integration value on every carried test endpoint;*
5. *a boundary row saying which representation branch is present and which branch is outside the current certificate.*

The classifier preserves the packet precisely when these five rows are transported by their inherited classifiers.

Proof. Read the bounded functional through the dual-space face of $\mathsf{FunctionalAnalysis}^{\uparrow}$. That face already fixes the source carrier, scalar target, pointwise classifier, norm-bound row, and visible ledger, so the representation packet begins with a stable functional endpoint rather than a host-level functional equality.

For the Hilbert branch, use the carrier-sharing rows of $\mathsf{Hilbert}^{\uparrow}$. The representing datum is a carried Hilbert endpoint, and the displayed scalar comparison is an inner-product value row transported by the same Hilbert classifier that transports the functional source endpoint.

For the measure branch, use the event and value rows of $\mathsf{Measure}^{\uparrow}$. The representing datum is a measure endpoint, and the displayed scalar comparison is an integration ledger over the carried test endpoints. Transport preserves the test endpoint, measure endpoint, scalar output, and evidence row componentwise.

These two branches share only the bounded-functional and scalar-output faces. The boundary row records which branch is active, so the certificate does not collapse vector representation and measure representation into one host-level equality. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationNameCertObligations`

Theorem 1643.3 (RieszRepresentation Hilbert functional bridge)**.** *For a Hilbert source already accepted by* $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$*, a* $\mathsf{RieszRepresentation}^{\uparrow}$ *Hilbert branch row packages a bounded scalar-valued functional* λ *together with a representing endpoint* r *and the scalar ledger*

$$\lambda(x) \sim_{\mathsf{Real}^{\uparrow}} \langle x, r \rangle$$

on every carried endpoint x*. If the functional row, Hilbert endpoint row, or representing endpoint row is transported by the inherited classifiers, then the displayed scalar ledger transports to the new row and exposes the same* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *dual-space face.*

Proof. Start from the $\mathsf{Hilbert}^{\uparrow}$ dependency. It supplies a Banach surface, an inner-product surface, the norm-induced compatibility ledger, and classifier transport for carried endpoints.

Next read λ through the $\mathsf{FunctionalAnalysis}^{\uparrow}$ dual-space face. Its pointwise classifier compares scalar outputs on carried Hilbert inputs, so it is already stated in the form needed by the displayed ledger.

Finally transport the representing endpoint through the Hilbert classifier. Inner-product stability moves $\langle x, r\rangle$ along the transported endpoint rows, and the scalar $\mathsf{Real}^{\uparrow}$ classifier moves the value comparison. The repacked row is therefore the same dual-space face plus a transported representing endpoint ledger. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationHilbertFunctionalBridge`

Theorem 1643.4 (Riesz representation dual functional route)**.** *Every* $\mathsf{RieszRepresentation}^{\uparrow}$ *bounded-functional branch must read its source through the displayed* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *dual-space row, the* $\mathsf{Norm}^{\uparrow}$ *bound row, and the* $\mathsf{Banach}^{\uparrow}$ *carrier row before a representing datum is consumed. The route exposes the functional endpoint, scalar* $\mathsf{Real}^{\uparrow}$ *target, bound ledger, source carrier, and branch boundary as finite rows; it does not assert arbitrary dual identification, nonconstructive Hahn–Banach extension, uniqueness of representing data, or host-level equality of linear maps.*

Proof. Start with the source row of Definition 1643.2. It already requires the Banach, FunctionalAnalysis, and Norm certificates to be visible before a bounded scalar-valued functional row is read.

Next use the Hilbert bridge of Definition 1643.3 only for the branch in which the source is Hilbert. The same bounded-functional face remains the entry point, but the representing datum is then a carried Hilbert endpoint rather than an arbitrary dual object.

For the non-Hilbert branch, keep the boundary row active. Since no row supplies arbitrary dual identification, Hahn–Banach extension, representing uniqueness, or host-level linear-map equality, the route is exactly the finite dual-functional surface named in the theorem. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationDualFunctionalRoute`

Theorem 1643.5 (Riesz representation measure handoff)**.** *The measure branch of a* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet hands a bounded functional row to* $\mathsf{Measure}^{\uparrow}$ *only after the source carrier, scalar target, boundedness ledger, measurable endpoint, and test-endpoint integration ledger have been displayed. The handoff records a finite measure-facing representation surface; it does not claim uniqueness of representing measures, full measure representation, Radon regularity, countable choice, or ambient completeness of the scalar target.*

Proof. Read the bounded functional through Definition 1643.4. This fixes the source carrier, scalar target, and norm-bound ledger before the measure endpoint is inspected.

Now project the measure branch listed in Definition 1643.1. The representing datum is a measure endpoint, and the scalar comparison is an integration ledger over carried bounded test endpoints.

The branch boundary records that this is a handoff to $\mathsf{Measure}^{\uparrow}$, not a full representation theorem. Because the packet has no coordinate for uniqueness, Radon regularity, countable choice, or ambient scalar completeness, the handoff cannot export those endpoints. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationMeasureHandoff`

Theorem 1643.6 (Riesz representation Banach-Hilbert scope)**.** *The exact scope of the* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet is the finite family of rows supplied by* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{FunctionalAnalysis}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{Measure}^{\uparrow}$*: a source carrier, bounded scalar-valued functional, norm-bound ledger, optional Hilbert representing endpoint, optional measure endpoint, scalar comparison ledger, branch boundary, and inherited classifier transport. No accepted packet extends this scope to arbitrary nonconstructive duality, spectral representation, selected representing datum, quotient equality of functions, or uniqueness of representing measures.*

Proof. Combine the obligation surface of Definition 1643.2 with the Hilbert bridge of Definition 1643.3. These two rows display the source carrier, bounded functional, Hilbert representing endpoint when present, scalar comparison ledger, and branch boundary.

Add the dual-functional route and measure handoff above. They force the Banach, FunctionalAnalysis, Norm, and Measure rows to remain visible before either a Hilbert or measure representation read is consumed.

The classifier of Definition 1643.1 compares packets only through the inherited rows and ledger entries. Therefore the scope is exactly the five named dependency certificates and their branch rows, with the excluded representation theorems left outside the packet. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationBanachHilbertScope`

Theorem 1643.7 (Riesz representation branch-boundary nonescape)**.** *Every accepted* RieszRepresentation$^{\uparrow}$ *packet keeps the Hilbert representing-endpoint row and the measure representing-endpoint row separated by the branch boundary of Definition 1643.1. A consumer may project one branch only after reading the shared* FunctionalAnalysis$^{\uparrow}$ *bounded-functional row and the active branch row. It cannot infer representing uniqueness, Radon regularity, Hahn–Banach extension, spectral representation, or host-level equality from the inactive branch.*

Proof. Use the NameCert obligation surface of Definition 1643.2. Its boundary row is part of every accepted packet, so a consumer cannot read either representing endpoint before the active branch has been displayed.

For the Hilbert side, apply the Hilbert functional bridge of Definition 1643.3. It identifies the representing datum only as a carried Hilbert endpoint tied to the shared bounded-functional row and scalar comparison ledger.

For the measure side, apply the dual-functional route of Definition 1643.4 and the measure handoff of Definition 1643.5. These rows keep the bounded-functional face visible while exposing only the measure endpoint and its test-endpoint integration ledger.

Finally project the boundary coordinate from the carrier definition. Since the classifier compares packets through the active branch rows and the shared bounded-functional row, no inactive branch coordinate can export uniqueness, Radon regularity, Hahn–Banach extension, spectral representation, or host-level equality. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationBranchBoundaryNonescape`

Theorem 1643.8 (RieszRepresentation public export)**.** *The public export surface of a* RieszRepresentation$^{\uparrow}$ *packet is the finite certificate obtained by composing the obligation surface of Definition 1643.2, the Hilbert functional bridge of Definition 1643.3, the dual-functional route of Definition 1643.4, the measure handoff of Definition 1643.5, the Banach-Hilbert scope of Definition 1643.6, and the branch-boundary nonescape theorem of Definition 1643.7. A public consumer may read only the source carrier, bounded scalar-valued functional row, active representing datum row, scalar comparison ledger, inherited classifier transports, and branch boundary displayed by these certificates; it receives no Hahn–Banach extension, representing uniqueness, Radon regularity, spectral representation, selected representative, or host-level equality of functional rows.*

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationPublicExport`

Proof. Start with the obligation surface. It supplies the source row, bounded scalar-valued functional row, representing datum row, scalar evaluation ledger, and branch boundary as the local NameCert inventory.

For the Hilbert branch, use the Hilbert functional bridge to expose only a carried Hilbert endpoint and its inner-product scalar ledger. For the shared bounded-functional entry, use the dual-functional route so that every public read still passes through the displayed $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, and $\mathsf{Banach}^{\uparrow}$ rows.

For the measure branch, use the measure handoff to expose only the representing measure endpoint and the integration ledger over carried test endpoints. Then apply the Banach-Hilbert scope and branch-boundary nonescape theorems: together they keep the active branch public while preventing the inactive branch or any unlisted representation theorem from escaping the packet. □

Theorem 1643.9 (Riesz representation obligation closure package)**.** *The carrier, obligation surface, Hilbert bridge, dual-functional route, measure handoff, Banach-Hilbert scope, and branch-boundary nonescape of this chapter assemble the full obligationClosure surface for* $\mathsf{RieszRepresentation}^{\uparrow}$ *over* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{FunctionalAnalysis}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{Measure}^{\uparrow}$*. The package closes exactly the displayed finite representation obligations and does not claim a full representation theorem, nonconstructive duality, Hahn–Banach extension, selected representative, or uniqueness of representing data.*

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationObligationClosure`

Proof. Start with the carrier of Definition 1643.1 and the obligation surface of Definition 1643.2. Together they identify the source row, bounded scalar-valued functional row, representing datum row, scalar evaluation ledger, and branch boundary as the only public rows of the packet.

Apply the Hilbert bridge Definition 1643.3 and the dual-functional route Definition 1643.4. These results force every Hilbert-facing or bounded-functional read through the displayed $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, and $\mathsf{Banach}^{\uparrow}$ rows before a representing datum is consumed.

Use the measure handoff Definition 1643.5 for the measure branch, then combine the Banach-Hilbert scope theorem Definition 1643.6 with branch-boundary nonescape Definition 1643.7. The resulting package is exactly the finite obligation surface over the five named dependencies, while full representation, nonconstructive duality, Hahn–Banach extension, selected representatives, and uniqueness remain outside the carrier. □

Theorem 1643.10 (Riesz representation scope binding)**.** *Every accepted* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet scopes the bounded-functional route through* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{FunctionalAnalysis}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{Measure}^{\uparrow}$ *before either branch is projected. The branch-boundary rows keep Hilbert representing endpoints and measure endpoints separate, so a Hilbert projection cannot export a measure endpoint and a measure projection cannot export a Hilbert representing vector. The scoped packet exposes only the shared bounded-functional face, the active representing row, scalar comparison ledgers, inherited classifier transport, and the branch boundary.*

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationScopeBinding`

Proof. Start with the obligation surface of Definition 1643.2. It requires the source row, bounded scalar-valued functional row, representing datum row, scalar ledger, and branch boundary to be displayed as the local NameCert surface.

For the Hilbert branch, apply the Hilbert bridge Definition 1643.3. For the shared bounded-functional entry, use the dual-functional route Definition 1643.4. These bind the $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, and $\mathsf{Banach}^{\uparrow}$ rows before a representing endpoint is consumed.

For the measure branch, apply the measure handoff Definition 1643.5. Then combine Banach-Hilbert scope Definition 1643.6 with branch-boundary nonescape Definition 1643.7. The boundary

coordinate keeps the Hilbert and measure endpoints disjoint while preserving the shared bounded-functional face, so the accepted packet has exactly the scoped route stated above. □

Theorem 1643.11 (Riesz representation functional-carrier obligation)**.** *Every accepted* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet must display the functional-analysis, Banach, Hilbert, Norm, and Real rows that make the bounded scalar-valued functional readable before any representing datum is projected. The obligation is the finite row*

$$(F, A, H, N, R, B)$$

where F *is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *bounded-functional face,* A *is the* $\mathsf{Banach}^{\uparrow}$ *source carrier,* H *is the optional* $\mathsf{Hilbert}^{\uparrow}$ *branch source,* N *is the* $\mathsf{Norm}^{\uparrow}$ *bound ledger,* R *is the scalar* $\mathsf{Real}^{\uparrow}$ *seal, and* B *is the branch boundary. The row exports carrier admission and classifier transport only; it does not assert a host representation theorem, a selected representing vector, or equality of host linear maps.*

Proof. Read the carrier of Definition 1643.1. Its source and bounded-functional coordinates already require the Banach, Hilbert, FunctionalAnalysis, Norm, and Real faces before a representing datum can be consumed.

Apply the dual-functional route of Definition 1643.4. It keeps the bounded scalar-valued functional row visible as a finite NameCert coordinate rather than as a host-level function equality.

Finally use the branch-boundary nonescape theorem. Since B is part of the displayed row, the functional-carrier obligation cannot select a representing datum or identify host linear maps outside the active branch. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationFunctionalCarrierObligation`

Theorem 1643.12 (Riesz representation measure-row obligation)**.** *In the measure branch, every accepted* $\mathsf{RieszRepresentation}^{\uparrow}$ *packet must display the Measure and Real rows*

$$(M, T, I, R, L, B)$$

before a measure-facing representation read is exported. Here M *is the* $\mathsf{Measure}^{\uparrow}$ *representing endpoint,* T *is the finite test-endpoint schedule,* I *is the integration ledger over those tests,* R *is the scalar* $\mathsf{Real}^{\uparrow}$ *seal,* L *is the inherited bounded-functional ledger, and* B *records that the measure branch is active. This obligation exports only finite NameCert rows for the measure handoff; it does not choose a representing measure, prove uniqueness, assert Radon regularity, or close a host measure-representation theorem.*

Proof. Start from the measure branch in Definition 1643.1. The representing datum is a carried measure endpoint, and the scalar comparison is an integration ledger over displayed test endpoints.

Use the measure handoff theorem Definition 1643.5. It forces the source carrier, scalar target, boundedness ledger, measure endpoint, and test-endpoint integration ledger to be visible before the handoff is consumed.

The branch boundary then blocks the extra conclusions. Because no row carries a selected measure, uniqueness proof, Radon regularity theorem, or host-level representation theorem, the measure obligation remains a finite packet row. □

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationMeasureRowObligation`

Theorem 1643.13 (Riesz representation Real-seal obligation)**.** *Every scalar comparison exported by* $\mathsf{RieszRepresentation}^{\uparrow}$ *must pass through the terminal* $\mathsf{Real}^{\uparrow}$ *seal row shared by the Hilbert and measure branches. In the Hilbert branch the sealed comparison is the inner-product value ledger; in the measure branch it is the integration value ledger. The seal exports only scalar value rows and their inherited classifier transport, not Real completeness, selected representatives, equality of host functions, or a full representation theorem.*

Lean4 ✓ `BEDC.Derived.RieszRepresentationUp.RieszRepresentationRealSealObligation`

Proof. For the Hilbert branch, apply Definition 1643.3. The comparison row is a scalar ledger between the functional value and an inner-product value, both read through the same Real classifier.

For the measure branch, apply Definition 1643.5. The comparison row is an integration value ledger over displayed tests, again sealed by the scalar Real row.

Combine these branches with Definition 1643.6. The common Real seal is the only scalar export coordinate, so ambient Real completeness, selected representatives, host function equality, and full representation theorems remain outside the packet. □

Theorem 1643.14 (Riesz representation scoped-closure handoff)**.** *The scoped closure surface for* $\mathsf{RieszRepresentation}^{\uparrow}$ *is exactly the composition of the carrier of Definition 1643.1, the obligation surface of Definition 1643.2, the Hilbert functional bridge of Definition 1643.3, the dual-functional route of Definition 1643.4, the measure handoff of Definition 1643.5, the Banach-Hilbert scope of Definition 1643.6, the branch-boundary nonescape theorem of Definition 1643.7, the functional-carrier obligation of Definition 1643.11, the measure-row obligation of Definition 1643.12, and the Real-seal obligation of Definition 1643.13. Every consumer must display the* $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before projecting either the Hilbert branch or the measure branch.*

Proof. Begin with the carrier and NameCert obligation surface. They provide the source row, bounded functional row, representing datum row, scalar comparison ledger, inherited transport, and branch boundary as the only rows available to a consumer.

For the Hilbert branch, apply the Hilbert functional bridge together with the Banach-Hilbert scope. These force the $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, and $\mathsf{Norm}^{\uparrow}$ rows to remain visible before a representing endpoint is projected.

For the measure branch, apply the dual-functional route, the measure handoff, and the measure-row obligation. These bind the $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before a measure-facing representation read is exported.

Finally use branch-boundary nonescape, the functional-carrier obligation, and the Real-seal obligation. The branch boundary keeps the Hilbert and measure projections separate, while the Real seal is the only scalar export coordinate. Therefore scoped closure is exactly the displayed composition and not a full representation theorem, selected representative, uniqueness theorem, or host-level equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszRepresentation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RieszRepresentation}^{\uparrow}$ packet is generated from an inherited bounded scalar-valued functional row, a source row from the Banach, Hilbert, FunctionalAnalysis, Norm, and Measure certificates, a representing Hilbert endpoint or measure endpoint, scalar comparison ledgers for inner-product or integration values, componentwise classifier transport, and a branch-boundary row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszRepresentation}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1643.1, Definition 1643.2, Definition 1643.3, Definition 1643.5, Definition 1643.6, and Definition 1643.14 bind the carrier, NameCert obligation surface, Hilbert functional bridge, measure handoff, Banach-Hilbert scope, and scoped-closure handoff over the existing Banach, Hilbert, FunctionalAnalysis, Norm, Measure, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RieszRepresentation}\uparrow}$, auditClean)

Lean target: `BEDC.Derived.RieszRepresentationUp.RieszRepresentationNameCertObligations`

Bridge status: none

Not claimed: It does not claim full measure-representation, arbitrary nonconstructive duality, spectral representation, uniqueness of representing measures, Lean verification, or a standard bridge.

Upgrade path: Public closure requires a public export package that packages the scoped rows for downstream consumers without adding full representation, selected representatives, uniqueness, or bridge checking.

Chapter 1644

A Concrete Naming Certificate for $\mathsf{BoundedLinearOperator}^{\uparrow}$

Following Kreyszig and Conway, the $\mathsf{BoundedLinearOperator}^{\uparrow}$ packet records the standard bounded linear map surface as finite NameCert data over displayed Banach candidates. It is read from the Banach carrier of chapter 90, the linear-map obligations of chapter 48, the normed real-line rows of chapter 1500, the limit-witness interface of chapter 128, the stream window interface of chapter 126, and the regular rational handoff of chapter 301. The chapter exposes the public operator object already carried by the Banach bounded-linear-operator rows: endpoint action, linearity, norm bound, composition, identity and zero units, and transport of regular Cauchy and complete-metric limit witnesses.

Definition 1644.1 (Bounded linear operator carrier)**.** *For displayed* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D*, a* $\mathsf{BoundedLinearOperator}^{\uparrow}(C, D)$ *carrier is the public packaging of a Banach bounded-linear-operator row*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

from Definition 90.49. Its visible coordinates are the endpoint map T*, the RealUp norm-bound endpoint* K*, and the ledger* Λ *recording source and target endpoint rows, source and target norm rows, scalar rows, additive and homogeneous compatibility rows, classifier-respect rows, and bound-witness rows.*

The classifier compares two accepted representatives only by componentwise hsame *transport of their endpoint actions on carried source endpoints, RealUp transport of their bound endpoints, and componentwise transport of the displayed ledgers. It has no coordinate for host function extensionality, quotient equality of operators, selected limits, ambient completion data, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorTasteGate single carrier alignment`

Theorem 1644.2 (Bounded linear operator NameCert obligations)**.** *For displayed* $\mathsf{Banach}^{\uparrow}$ *candidates* C, D*, the carrier of Definition 1644.1 carries the public* $\mathsf{NameCert}_{\mathsf{BoundedLinearOperator}^{\uparrow}}$ *surface with the following obligation rows:*

1. *carrier admission for* $\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$*;*
2. *classifier stability under source and target Banach endpoint classifiers;*
3. *linearity exactness for additive and homogeneous endpoint action;*

4. *norm-bound exactness through the RealUp endpoint K;*
5. *Lipschitz and regular-Cauchy transport through the norm-induced metric rows;*
6. *zero, sum, scalar, identity, and composition rows when the corresponding Banach ledgers are displayed;*
7. *refusal of host function extensionality, operator quotients, selected limits, hidden Banach completeness, and bridge data.*

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorCarrier namecert obligations`

Proof. Carrier admission and classifier stability are projections of Definition 90.49. That definition already records the endpoint map, bound endpoint, and visible ledger, and it compares representatives only through displayed endpoint, bound, and ledger transports.

Linearity exactness is the conjunction of the additive and homogeneous compatibility rows in the same carrier. The rows are stated over carried Banach endpoints and carried RealUp scalars, so they are public operator data rather than host-level equations between functions.

The metric obligations are supplied by the Banach bounded-linear-operator surface. Apply Definition 90.50 for the displayed Lipschitz estimate, and apply Definition 90.51 for transport of regular Cauchy $\mathsf{StreamName}^{\uparrow}$ streams.

The algebraic operator rows are inherited from the Banach child files. The zero, pointwise sum, scalar, identity, and composition rows are accepted only when their visible Banach ledgers are present, and the public packet stores those rows as operator coordinates rather than as an ambient operator space quotient.

The refusal row follows from the carrier coordinates. Since the packet contains only T, K, Λ and their componentwise transports, there is no field from which host function extensionality, quotient operator equality, selected limits, hidden completeness, or a bridge can be read. □

Theorem 1644.3 (Bounded linear operator composition closure)**.** *Let C, D, E be displayed* $\mathsf{Banach}^{\uparrow}$ *candidates. If*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

and

$$\mathsf{BanachBLOp}(D, E, S, L, \Gamma)$$

are accepted $\mathsf{BoundedLinearOperator}^{\uparrow}$ *carrier rows, then their endpoint composite is accepted as*

$$\mathsf{BanachBLOp}(C, E, S \circ T, L \cdot K, \Gamma \star \Lambda).$$

The public composition ledger records exactly the two input operator ledgers together with the RealUp multiplication, monotonicity, associativity, and non-negativity rows needed for the product bound.

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorUpTasteGate single carrier alignment`

Proof. Read the two input rows through Definition 1644.1. They are precisely the Banach bounded-linear-operator rows required by Definition 90.64.

Apply that Banach composition theorem. It constructs the composite endpoint map $S \circ T$, the product bound $L \cdot K$, and the concatenated ledger $\Gamma \star \Lambda$, with classifier, additive, homogeneous, and norm-bound rows transported through the middle Banach carrier.

Repack the result as a $\mathsf{BoundedLinearOperator}^{\uparrow}(C, E)$ carrier. No further equality principle is used: endpoint comparison is pointwise over carried source endpoints, bound comparison is RealUp transport, and ledger comparison is the displayed concatenation row. □

Theorem 1644.4 (Bounded linear operator limit transport)**.** *Let C, D be displayed* $\mathsf{Banach}^{\uparrow}$ *candidates and let*

$$\mathsf{BanachBLOp}(C, D, T, K, \Lambda)$$

be an accepted $\mathsf{BoundedLinearOperator}^{\uparrow}(C, D)$ *carrier row. If a regular Cauchy* $\mathsf{StreamName}^{\uparrow}$ *stream over the norm-induced metric of C carries a* $\mathsf{CompleteMetric}^{\uparrow}$ *limit witness with limit endpoint ℓ, then the pointwise target stream carries a* $\mathsf{CompleteMetric}^{\uparrow}$ *limit witness over D with displayed limit endpoint $T(\ell)$.*

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorCarrier limit transport`

Proof. Read the accepted operator row as a Banach bounded-linear-operator carrier. The source limit witness is a complete-metric witness over the norm-induced metric attached to the source Banach candidate.

Apply Definition 90.75. Its construction first uses regular-Cauchy transport for the pointwise target stream and then applies the Lipschitz bound to late-distance estimates between stream observations and the source limit endpoint.

The resulting target witness has displayed limit endpoint $T(\ell)$ and its ledger is exactly the operator ledger together with the source and target complete-metric rows. Repacking that witness gives the public $\mathsf{BoundedLinearOperator}^{\uparrow}$ limit-transport surface. □

Theorem 1644.5 (Bounded linear operator nonescape boundary)**.** *Every accepted* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *consumer factors through the displayed route*

$$\mathsf{Banach}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

In particular, the packet cannot export host function extensionality, quotient operator equality, selected limits, ambient Banach completeness beyond the displayed input rows, or bridge checking data.

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorCarrier nonescape boundary`

Proof. Let a consumer read an accepted carrier. By Definition 1644.1, the only operator coordinates are the endpoint map T, the RealUp bound endpoint K, and the visible ledger Λ.

The linear-map data are the additive and homogeneous rows inside Λ, the norm-bound data are the RealUp and NormUp rows inside Λ, and the metric data are obtained by the Lipschitz and regular-Cauchy transport rows cited in Definition 1644.2.

Composition and limit transport do not add hidden coordinates. Composition concatenates two displayed ledgers as in Definition 1644.3, and limit transport reuses the source complete-metric witness and target Banach rows as in Definition 1644.4.

Thus any public read factors through the displayed Banach, linear, norm, real, complete-metric, stream, regular-rational, history, transport, continuation, provenance, and naming rows. The excluded host and quotient objects are absent from the carrier and from the two transport constructions, so they cannot be exported by the packet. □

Theorem 1644.6 (Bounded linear operator scoped dependency route)**.** *Every accepted* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *packet reads its carrier, linearity row, norm-bound row, composition row, limit-transport row, and nonescape boundary only through*

$$\mathsf{Banach}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The route therefore binds the paper-side scope of the packet to displayed Banach, linear, norm, real, complete-metric, stream, regular-rational, history, transport, replay, provenance, and naming data.

Lean4 ✓ `BEDC.Derived.BoundedLinearOperatorUp.BoundedLinearOperatorCarrier scoped dependency route`

Proof. Read the accepted carrier through Definition 1644.1 and the local obligations in Definition 1644.2. These rows expose the endpoint action, linearity ledger, norm-bound endpoint, classifier transport, provenance, and local NameCert data.

Composition remains inside the same route by Definition 1644.3. The composite ledger is built from displayed source and target Banach rows, RealUp multiplication rows, and the two visible operator ledgers.

Limit transport remains inside the complete-metric and regular-rational route by Definition 1644.4. The proof consumes the source complete-metric witness, StreamName and RegSeqRat data, and the target Banach rows without adding a selected limit or hidden completeness coordinate.

Finally apply Definition 1644.5. Since that boundary excludes host function extensionality, quotient operator equality, selected limits, ambient Banach completeness beyond the displayed rows, and bridge checking, the listed dependencies are exactly the scoped route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearOperator}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearOperator}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1644.1, Definition 1644.2, Definition 1644.3, Definition 1644.4, Definition 1644.5, and Definition 1644.6 bind carrier admission, classifier stability, linearity and bound exactness, composition closure, limit transport, algebraic operator rows, nonescape, and the scoped dependency route over displayed Banach carriers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly excludes host function extensionality, quotient operator equality, selected limits, ambient Banach completeness beyond the input rows, and bridge checking.

Upgrade path: The theory axis has no higher closure grade; audit-clean and bridge-checked verification remain independent formal-axis obligations for BEDC.Derived.BoundedLinearOperatorUp.

Constructive story: A $\mathsf{BoundedLinearOperator}^{\uparrow}$ packet is generated from displayed source and target Banach candidates, an endpoint action, a RealUp norm-bound endpoint, visible linearity and bound ledgers, regular-Cauchy and complete-metric transport rows, componentwise transport, provenance, and a local NameCert row.

Chapter 1645

A Concrete Naming Certificate for $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ packet names the finite interval-operation surface obtained when both endpoints are displayed $\mathsf{DyadicRatCore}^{\uparrow}$ rows and every enclosure claim is routed through rational and real interval packets already present in the BEDC library. It sits after the dyadic endpoint core of chapter 291, the rational interval carrier of chapter 354, the metric-ball observation surface of chapter 1450, the located interval boundary of chapter 394, and the real interval enclosure route of chapter 1625. The packet records addition, multiplication, refinement, and containment comparison as finite endpoint ledgers; it is not a quotient interval type, a selected real representative, a trichotomy service, a countable-choice construction, an open-cover compactness argument, or an appeal to Real completeness.

Definition 1645.1 (Dyadic interval arithmetic carrier)**.** *A* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, U, O, +_{\Delta}, \cdot_{\Delta}, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are lower and upper endpoint rows accepted by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *O is the endpoint-order ledger, recording that the lower endpoint row is below the upper endpoint row through the same dyadic comparison surface.*
3. *$+_{\Delta}$ is the addition-operation row, whose lower and upper outputs are computed from the displayed dyadic endpoint additions with outward endpoint witnesses.*
4. *$\cdot_{\Delta}$ is the multiplication-operation row, whose four endpoint products and selected lower and upper dyadic bounds are displayed as finite rows.*
5. *R is the refinement row, recording that a later dyadic endpoint pair tightens the current pair through endpoint comparisons over the same scale ledger.*
6. *E is the enclosure-comparison row, relating the dyadic endpoint pair to the* $\mathsf{RationalInterval}^{\uparrow}$ *and* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *containment rows consumed by downstream readers.*
7. *H records componentwise* hsame *transport for the endpoint, order, operation, refinement, enclosure, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the endpoint rows through the operation and enclosure rows.*

9. *P is the* Pkg *provenance over* DyadicIntervalArithmetic$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RationalInterval$^{\uparrow}$, MetricBall$^{\uparrow}$, LocatedInterval$^{\uparrow}$, RealIntervalEnclosure$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalArithmetic}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite dyadic endpoint interval-operation packet. It has no coordinate for quotient intervals, host real endpoints, selected real representatives, trichotomy, countable choice, open-cover compactness, or Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicIntervalArithmeticUp.DyadicIntervalArithmeticTasteGate single carrier alignment`

Theorem 1645.2 (Dyadic interval arithmetic NameCert obligations)**.** *For every accepted* DyadicIntervalArithmetic$^{\uparrow}$ *carrier $A = (L, U, O, +_{\Delta}, \cdot_{\Delta}, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalArithmetic}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two endpoint rows, endpoint-order ledger, addition row, multiplication row, refinement row, enclosure-comparison row, componentwise transport, continuation replay, provenance, and local naming row;*
2. *endpoint order stability, requiring O to transport along the displayed* hsame *and* Cont *rows without replacing the dyadic comparison by host order on reals;*
3. *operation enclosure soundness, requiring $+_{\Delta}$ and $\cdot_{\Delta}$ to compute their exported lower and upper endpoint rows from the displayed dyadic endpoint rows and outward comparison witnesses;*
4. *refinement monotonicity, requiring R to preserve containment when lower endpoints move upward and upper endpoints move downward through named dyadic comparison rows;*
5. *classifier transport, requiring every accepted operation and refinement row to remain accepted after componentwise* hsame *transport and displayed* Cont *replay;*
6. *ledger non-escape, excluding quotient intervals, selected real representatives, trichotomy, countable choice, open-cover compactness, Real completeness, and hidden host endpoint arithmetic.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.DyadicIntervalArithmeticUp.DyadicIntervalArithmeticCarrier namecert obligations`

Proof. Project the carrier of Definition 1645.1. The projection exposes exactly the two dyadic endpoint rows, endpoint-order ledger, operation rows, refinement row, enclosure-comparison row, and structural rows H, C, P, N.

Endpoint order stability is the row O transported by H and replayed by C. Since O is a dyadic comparison row, transport can only move the displayed endpoint histories and cannot insert an external order relation.

Operation enclosure soundness is read from $+_{\Delta}$ and $\cdot_{\Delta}$. The addition row uses the two endpoint additions with outward witnesses, while the multiplication row displays the four dyadic endpoint products and the selected lower and upper dyadic bounds. Each output endpoint is therefore read from the visible dyadic arithmetic ledger.

Refinement monotonicity is the row R. It records the tightening comparisons between the old and later endpoint rows, so containment can only be weakened along the displayed dyadic order witnesses.

Classifier transport follows by applying H and C componentwise to the same finite rows. The exclusions are immediate from the carrier inventory: there is no coordinate for quotient

intervals, selected real representatives, trichotomy, countable choice, open-cover compactness, Real completeness, or hidden host endpoint arithmetic. □

Theorem 1645.3 (Dyadic interval arithmetic endpoint-order transport)**.** *Let $A = (L, U, O, +_\Delta, \cdot_\Delta, R, E, H, C, P, N$ be an accepted* DyadicIntervalArithmetic$^\uparrow$ *carrier. If O is the displayed endpoint-order ledger and H, C are the componentwise* hsame *transport and displayed* Cont *replay rows, then lower-before-upper order is preserved for every transported dyadic interval packet read from A. The transport is a rowwise dyadic endpoint claim; it uses no host real order, trichotomy, selected representatives, quotient intervals, or* Real$^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 1645.1. The lower endpoint row L, upper endpoint row U, endpoint-order ledger O, structural transport row H, and replay row C are all visible before any downstream interval consumer is reached.

Read O as the finite dyadic comparison ledger asserting that the displayed lower endpoint precedes the displayed upper endpoint. This row is part of the carrier inventory, not a derived host-order statement about real endpoints.

Apply H rowwise to transport the endpoint histories and the order ledger together. Then apply C to replay the transported endpoint route through the same finite dyadic interval packet.

The carrier contains no coordinate for host real order, trichotomy, selected representatives, quotient intervals, or Real completeness. Thus lower-before-upper order is preserved exactly by the displayed O, H, C rows and cannot escape to an ambient interval principle. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalArithmeticUp.DyadicIntervalArithmeticCarrier endpoint order transport`

Theorem 1645.4 (Dyadic interval arithmetic enclosure soundness)**.** *Every exported operation of an accepted* DyadicIntervalArithmetic$^\uparrow$ *carrier factors through the displayed dyadic endpoint rows and preserves the containment interfaces of* RationalInterval$^\uparrow$ *and* RealIntervalEnclosure$^\uparrow$*. More precisely, if an accepted packet exports an addition, multiplication, or refinement result, then every downstream* RationalInterval$^\uparrow$*,* MetricBall$^\uparrow$*,* LocatedInterval$^\uparrow$*, or* RealIntervalEnclosure$^\uparrow$ *consumer reaches that result through the finite route*

$$L, U, O \longmapsto +_\Delta, \cdot_\Delta, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a dyadic endpoint enclosure whose rational and real containment rows are the displayed rows in E, with no quotient interval, selected real representative, trichotomy, countable-choice row, open-cover compactness row, or Real$^\uparrow$ *completeness witness inserted into the route.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalArithmeticUp.DyadicIntervalArithmeticCarrier enclosure soundness`

Proof. Start with an accepted carrier $A = (L, U, O, +_\Delta, \cdot_\Delta, R, E, H, C, P, N)$. The only endpoint coordinates are the two DyadicRatCore$^\uparrow$ rows L and U, and the only order coordinate between them is O.

For addition, project $+_\Delta$. Its output lower and upper endpoint rows are formed from the displayed dyadic endpoint additions and outward comparison witnesses. For multiplication, project $\cdot_\Delta$. Its output bounds are chosen from the four displayed dyadic endpoint products by the finite comparison ledger. For refinement, project R, which names the tightening comparisons between endpoint pairs.

The enclosure-comparison row E is the sole handoff to $\mathsf{RationalInterval}^{\uparrow}$ and $\mathsf{RealIntervalEnclosure}^{\uparrow}$. A $\mathsf{MetricBall}^{\uparrow}$ or $\mathsf{LocatedInterval}^{\uparrow}$ reader can consume the same handoff only after the dyadic endpoints and operation rows have been displayed.

Finally H, C, P, N package the route. Componentwise transport and continuation replay preserve the same endpoint and enclosure rows, while provenance records the dependency anchors. Since every exported operation is reached through this route, there is no remaining coordinate from which a quotient interval, selected real representative, trichotomy, countable-choice row, open-cover compactness row, or $\mathsf{Real}^{\uparrow}$ completeness witness could be read. □

Theorem 1645.5 (Dyadic interval arithmetic refinement monotonicity)**.** *Let $A = (L, U, O, +_{\Delta}, \cdot_{\Delta}, R, E, H, C, P, N$ be an accepted* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *carrier. If the refinement row R displays a later lower endpoint above L and a later upper endpoint below U through named* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison rows, then every* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*, or* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *consumer reads a narrower or equal enclosure through the same endpoint arithmetic ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalArithmeticUp.DyadicIntervalArithmeticCarrier refinement monotonicity`

Proof. Project the carrier of Definition 1645.1. The endpoint rows L and U, the endpoint-order ledger O, the operation rows, the refinement row R, and the enclosure row E are all visible before any downstream interval consumer is reached.

Apply Definition 1645.4. Every downstream $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, or $\mathsf{RealIntervalEnclosure}^{\uparrow}$ read already factors through the displayed endpoint route

$$L, U, O \longmapsto +_{\Delta}, \cdot_{\Delta}, R \longmapsto E \longmapsto H, C, P, N.$$

The refinement row only strengthens the containment data. Moving the lower endpoint upward and the upper endpoint downward through displayed dyadic comparison rows leaves the old enclosure as an outer bound and presents the later pair as a narrower or equal bound.

Componentwise hsame transport and displayed Cont replay preserve the same endpoint arithmetic ledger and refinement comparisons. Therefore every listed consumer reads the refined enclosure through the original finite packet, with no quotient interval, selected real representative, trichotomy, countable choice, open-cover compactness, or Real completeness claim inserted. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ packet is generated from lower and upper $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, an endpoint-order ledger, displayed addition and multiplication rows, a refinement row, an enclosure-comparison row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1645.1, Definition 1645.2, and Definition 1645.4 seed the finite dyadic endpoint interval-operation surface over DyadicRatCore, RationalInterval, MetricBall, LocatedInterval, and RealIntervalEnclosure consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalArithmetic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient interval semantics, selected real representatives, trichotomy, countable choice, open-cover compactness, Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint order stability, operation enclosure soundness, refinement monotonicity, classifier transport, and ledger non-escape proofs for BEDC.Derived.DyadicIntervalArithmeticUp.

Chapter 1646

A Concrete Naming Certificate for $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ packet names the finite tolerance bracket in which real metric distance, locatedness requests, and real equality boundaries are read from the same displayed route. It sits between the metric distance packet of chapter 1638, the locatedness request surface of chapter 1627, the equality boundary of chapter 1636, the finite-window and regular-readback rows of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The bracket gives downstream Real and Completion consumers one displayed route for tolerance-sensitive reads; it does not identify quotient streams, select limits, invoke trichotomy, use countable choice, or assert ambient Real completeness.

Definition 1646.1 (Real metric locatedness bracket carrier)**.** *A* $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, L, E, S, R, D, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *distance row whose public read supplies the displayed distance boundary.*
2. *L is the* $\mathsf{LocatednessModulus}^{\uparrow}$ *tolerance-request row that records the finite locatedness budget attached to the distance read.*
3. *E is the* $\mathsf{RealEquality}^{\uparrow}$ *boundary row that records when the same tolerance bracket is read as an equality boundary.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened from the real-name seals before M, L, or E is consumed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the windows in S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, slack, comparison, and refinement rows used by the three sibling packets.*
7. *H records componentwise* hsame *transport for the metric row, locatedness row, equality row, stream windows, regular readback, dyadic ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through S, R, D, then through M, L, E as the consumer asks for distance, locatedness, or equality data.*

9. *P is the* Pkg *provenance over* $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealMetricLocatednessBracket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, E, S, R, D, H, C, P, N$. The carrier has no coordinate for host real equality, quotient streams, selected limits, trichotomy, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealMetricLocatednessBracketUp.RealMetricLocatednessBracketTasteGate single carrier alignment`

Theorem 1646.2 (Real metric locatedness bracket NameCert obligations)**.** *For every accepted* $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ *carrier $B = (M, L, E, S, R, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealMetricLocatednessBracke}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real metric row, locatedness request row, real equality boundary row, stream windows, regular readback, dyadic tolerance ledger, transport, replay, provenance, and local naming row;*
2. *distance-to-tolerance compatibility, requiring every* $\mathsf{RealMetric}^{\uparrow}$ *read from M to expose the same S, R, D route before a locatedness request in L is consumed;*
3. *tolerance-to-equality compatibility, requiring every equality-boundary read in E to use the displayed dyadic budget already carried by L and D;*
4. *window transport, requiring H and C to preserve the same finite bracket under componentwise transport of the metric, locatedness, equality, stream, readback, and dyadic rows;*
5. *non-escape, excluding host real equality, quotient streams, selected limits, trichotomy, countable choice, and ambient Real completeness from the exported certificate.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealMetricLocatednessBracketUp.RealMetricLocatednessBracketCarrier non escape`

Proof. Carrier admission is projection from Definition 1646.1. The only visible rows are $M, L, E, S, R, D, H, C, P, N$ so every obligation must be read through the same finite packet.

Distance-to-tolerance compatibility follows by applying the real-metric route of Definition 1638.3. A public distance read from M already factors through stream windows, regular readback, and the dyadic tolerance ledger, which are precisely the rows S, R, D carried by the bracket before L is consumed.

Tolerance-to-equality compatibility uses Definition 1627.3 and Definition 1636.2. The locatedness request keeps the tolerance budget attached to the same finite windows and readbacks, and the equality classifier remains stable under refinements that factor through the same regular-rational and dyadic rows.

Window transport is then supplied by H and C. Componentwise hsame transport moves M, L, E, S, R, D together, while displayed replay records that distance, locatedness, and equality consumers read the same bracket route rather than three unrelated certificates.

The exclusions follow from the carrier inventory. Since B contains no row for host real equality, quotient streams, selected limits, trichotomy, countable choice, or ambient Real completeness, none of those principles can be exported by the local $\mathsf{NameCert}_{\mathsf{RealMetricLocatednessBracket}^{\uparrow}}$ surface. □

Theorem 1646.3 (Real metric locatedness bracket window transport)**.** *Every finite consumer of an accepted* RealMetricLocatednessBracket$^{\uparrow}$ *carrier transports distance, locatedness, and equality reads through the common route*

$$S, R, D \longmapsto M, L, E \longmapsto H, C, P, N.$$

Consequently a Real, metric, equality, or completion-facing consumer receives one displayed tolerance bracket, not separate host comparisons of completed real values.

Lean4 ✓ `BEDC.Derived.RealMetricLocatednessBracketUp.RealMetricLocatednessBracketCarrier window transport`

Proof. Let $B = (M, L, E, S, R, D, H, C, P, N)$ be accepted. The stream row S, regular readback R, and dyadic ledger D are the only window and tolerance coordinates in the carrier.

The metric read is therefore transported through S, R, D before M is consumed. This is the same finite route used by the RealMetric$^{\uparrow}$ distance handoff.

The locatedness read is transported through the same rows because the LocatednessModulus$^{\uparrow}$ request has no second tolerance coordinate inside B. Its request is replayed through the displayed finite windows and dyadic refinements already present in the bracket.

The equality read is transported through the same route because E may read only the regular-rational and dyadic classifier rows exposed in the carrier. The structural rows H, C, P, N package this common route, so the consumer cannot split it into unrelated host comparisons. □

Theorem 1646.4 (Real metric locatedness bracket non-escape)**.** *For every accepted* RealMetricLocatednessBracket$^{\uparrow}$ *carrier* $B = (M, L, E, S, R, D, H, C, P, N)$*, every Real-facing read factors through the displayed metric, locatedness, equality, stream-window, regular-readback, dyadic-tolerance, transport, replay, provenance, and local naming rows. It cannot export host real equality, quotient streams, selected limits, trichotomy, countable choice, or ambient Real completeness.*

Proof. Read the Real-facing part of Definition 1646.1. The only analytic rows are the metric distance row M, the locatedness request row L, the equality boundary row E, the finite windows S, the regular readback R, and the dyadic tolerance ledger D.

Transport and replay do not add another analytic source. The rows H and C move the same listed data through componentwise equality and displayed continuation, while P and N record package provenance and local naming.

It remains to rule out non-displayed Real data. The carrier has no field for host real equality, quotient streams, selected limits, trichotomy, countable choice, or ambient Real completeness; every Real-facing read is therefore a projection from B. □

Lean4 ✓ `BEDC.Derived.RealMetricLocatednessBracketUp.RealMetricLocatednessBracketNonEscape`

Closure status for NameCert$_{\text{RealMetricLocatednessBracket}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RealMetricLocatednessBracket}^{\uparrow}}$, seed)

Scope closed: Definition 1646.1, Definition 1646.2, Definition 1646.3, and Definition 1646.4 seed the finite bracket joining real metric distance, locatedness requests, and real equality boundaries.

Formal verification: FormalStatus(NameCert$_{\text{RealMetricLocatednessBracket}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient streams, selected limits, trichotomy, countable choice, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, distance-to-tolerance compatibility, tolerance-to-equality compatibility, window transport, and non-escape proofs for BEDC.Derived.RealMetricLocatednessBracketUp.

Constructive story: A RealMetricLocatednessBracket$^{\uparrow}$ packet is generated from a RealMetric$^{\uparrow}$ distance row, a LocatednessModulus$^{\uparrow}$ tolerance request, a RealEquality$^{\uparrow}$ boundary, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, a DyadicRatCore$^{\uparrow}$ tolerance ledger, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 1647

A Concrete Naming Certificate for $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ packet records the finite parity-tail criterion by which two regular rational subsequence rows are fused into a single Real-facing Cauchy route. It sits between the regular rational carrier of chapter 301, the finite schedule discipline of chapter 126, the Real-specific Cauchy consumer of chapter 1590, and the parity-selector interleaving surface of chapter 414. The packet is a parity-subsequence Cauchy certificate; it is not a Real completeness principle, quotient stream equality, selected limit, host real equality, trichotomy, or countable-choice source.

Definition 1647.1 (EvenOddCauchyCriterion carrier)**.** *An* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, one for the even subsequence and one for the odd subsequence.*
2. *S_A and S_B are the two* $\mathsf{StreamName}^{\uparrow}$ *schedules exposing the finite observation windows for the even and odd rows.*
3. *ϵ is the even–odd selector row recording which schedule is inspected at each displayed parity step.*
4. *M is the shared* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger, carrying the common precision request, the two side budgets, and the late-tail threshold used by both parity rows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the rational radii, dyadic comparisons, and triangle-budget cells used to compare same-parity and cross-parity late windows.*
6. *F is the cross-parity tail-fusion row, tying every accepted even late window to an accepted odd late window under the same M, D budget.*
7. *R is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *handoff row, exposed only after $A, B, S_A, S_B, \epsilon, M, D, F$ have been displayed.*
8. *H records componentwise* hsame *transport for the two regular rows, two schedules, selector, shared modulus ledger, dyadic tolerance ledger, fusion row, Real Cauchy handoff, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from a precision request through the selector, the selected schedule, the selected regular row, the shared modulus ledger, the dyadic tolerance ledger, the cross-parity fusion row, and the Real Cauchy handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EvenOddCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionTasteGate single carrier alignment`

Theorem 1647.2 (EvenOddCauchyCriterion NameCert obligations)**.** *For an accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *carrier $K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EvenOddCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two regular rational rows, two stream schedules, parity selector, shared CauchyModulus ledger, DyadicRatCore tolerance ledger, cross-parity fusion row, Real Cauchy handoff, transport, replay, provenance, and local naming row;*
2. *parity schedule compatibility, requiring each even read to use A, S_A and each odd read to use B, S_B under the selector row ϵ;*
3. *shared modulus exactness, requiring both parity sides and every cross-parity late comparison to consume the same displayed M budget;*
4. *dyadic tolerance exactness, requiring same-parity and cross-parity tail comparisons to be recorded in D before the fusion row F can be exposed;*
5. *transport and replay stability, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the ordered route through ϵ, M, D, F, R;*
6. *provenance exhaustion, requiring P and N to name only this displayed route and to export no quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1647.1. The visible packet contains exactly the two regular rows, two schedules, selector, shared modulus ledger, dyadic tolerance ledger, fusion row, Real Cauchy handoff, and the structural rows H, C, P, N.

Parity schedule compatibility is read from ϵ, S_A, S_B. Even requests are routed through A, S_A, while odd requests are routed through B, S_B; the packet has no third schedule or unscheduled subsequence row.

Shared modulus and dyadic tolerance exactness are the roles of M and D. The same M budget is consumed on both parity sides, and D stores the dyadic comparisons needed before F may identify the cross-parity late-tail route.

Transport and replay are structural. Componentwise hsame in H preserves the displayed rows, and Cont replay in C repeats the precision-request route through the selector, selected schedule, shared budget, tolerance ledger, fusion row, and Real Cauchy handoff.

Finally, provenance is exhausted by P and N. Since the carrier has no row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness, the local certificate cannot export any such object. □

Theorem 1647.3 (EvenOddCauchyCriterion parity-tail fusion)**.** *Every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *carrier factors each late-tail comparison through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RealCauchyCriterion}^{\uparrow}.$$

The even side uses A, S_A and the odd side uses B, S_B, while the cross-parity row F records that both sides consume the same M, D budget before the handoff to R. Thus the packet fuses the parity tails without introducing quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionCarrier parity tail fusion`

Proof. Start with an accepted carrier K. The projection of Definition 1647.1 exposes the two regular rows and their two schedules before any tolerance comparison is available.

Use the selector row ϵ to split the finite read. The even case reads through A, S_A, and the odd case reads through B, S_B.

Both cases then pass through the same shared modulus row M. The dyadic tolerance ledger D records the corresponding same-parity and cross-parity comparison cells under that common budget.

The fusion row F is downstream of M, D. It can therefore identify the even and odd late-tail routes only after the shared budget and dyadic comparisons have been displayed.

Finally, the Real Cauchy handoff R receives the fused parity-tail route. The excluded quotient, choice, host-equality, trichotomy, and completeness objects are absent from the carrier inventory, so the fusion cannot export them. □

Theorem 1647.4 (EvenOddCauchyCriterion Real seal route)**.** *For every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N),$$

any Real-facing consumer of the packet must pass through the two $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the two* $\mathsf{StreamName}^{\uparrow}$ *schedules, the even–odd selector, the shared* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the cross-parity fusion row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before it can consume the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *handoff R.*

Proof. Project the carrier rows of K. The handoff row R is not an independent Real seal; it is placed after the two regular rows, two schedules, selector, shared modulus, dyadic tolerance ledger, and cross-parity fusion row.

Definition 1647.2 supplies the certificate surface controlling carrier admission, schedule compatibility, shared modulus exactness, dyadic tolerance exactness, transport, replay, and provenance exhaustion.

Definition 1647.3 supplies the parity-tail route. Combining that route with the carrier projection shows that any Real-facing use of R first passes through the displayed even and odd windows and the common M, D comparison ledger.

The rows H, C, P, N preserve and name the same route. Since no quotient stream, selected limit, countable-choice selector, host real equality, trichotomy, or ambient completeness row appears in the carrier, no consumer can bypass the displayed $\mathsf{RealCauchyCriterion}^{\uparrow}$ handoff boundary. □

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionCarrier real seal route`

Theorem 1647.5 (EvenOddCauchyCriterion shared modulus transport)**.** *For every accepted* EvenOddCauchyCriter *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N),$$

the shared M budget and the D tolerance ledger are transported componentwise through the hsame *row H and replayed through the* Cont *row C before either the cross-parity fusion row F or the Real Cauchy handoff row R can be exposed. In particular, no accepted consumer can replace M by separate parity budgets or replace D by an undisplayed tolerance ledger while still reaching F or R.*

Proof. Begin with the carrier inventory of Definition 1647.1. The rows M and D are displayed before F, R, H, C, P, N, and the classifier compares packets only through the listed coordinates.

Definition 1647.2 identifies shared modulus exactness, dyadic tolerance exactness, transport stability, and replay stability as local NameCert obligations. Therefore H must preserve the same M, D cells on the even and odd sides rather than admitting parity-specific substitutes.

Next apply the replay row C. Its route starts from a precision request and passes through the selector, selected schedule, selected regular row, shared modulus ledger, dyadic tolerance ledger, fusion row, and Real Cauchy handoff. Thus replay cannot expose F or R until the transported M, D ledger has already been displayed.

Finally combine the parity-tail factorization of Definition 1647.3 with the Real seal boundary of Definition 1647.4. The only late-tail route reaching F or R is the one carrying the same shared budget and dyadic tolerance ledger through H and C. □

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionCarrier shared modulus transport`

Theorem 1647.6 (EvenOddCauchyCriterion cross-parity handoff non-escape)**.** *For every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N),$$

the cross-parity fusion row F and the Real Cauchy handoff row R can be consumed only after the packet has displayed the two $\mathsf{RegSeqRat}^{\uparrow}$ *rows A, B, the two* $\mathsf{StreamName}^{\uparrow}$ *schedules S_A, S_B, the selector ϵ, the shared modulus ledger M, the dyadic tolerance ledger D, componentwise transport H, displayed replay C, provenance P, and the local* NameCert *row N.*

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionCrossParityHandoffNonEscape`

Proof. The carrier definition Definition 1647.1 places F and R in a finite packet whose earlier coordinates name both regular rows, both schedules, the selector, the common budget, and the tolerance ledger. There is no independent coordinate from which a consumer could obtain a fusion row or a Real handoff.

Definition 1647.2 then fixes the admission and stability surface. Carrier admission accounts for $A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N$, while transport, replay, and provenance exhaustion require the later rows to preserve and name that same displayed route.

The factorization in Definition 1647.3 supplies the cross-parity ordering: F is downstream of the two parity tails under the shared M, D budget. Hence F cannot be consumed before the two regular rows, two schedules, selector, shared modulus, and dyadic ledger have been displayed.

The Real seal route in Definition 1647.4 adds the handoff boundary. Since R is downstream of F and is preserved only through H, C, P, N, a Real-facing consumer reaches R only through the complete displayed NameCert route, and no quotient stream, selected limit, countable-choice selector, host real equality, trichotomy, or ambient completeness object can provide an escape path. □

Theorem 1647.7 (EvenOddCauchyCriterion induction lock)**.** *For every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N),$$

finite induction over the displayed parity schedule ϵ routes every accepted read through exactly one of the two parity rows A, S_A or B, S_B, and then through the same shared ledger cells M, D. Thus an accepted finite read has no route to F or R that bypasses the selected parity schedule, the common $\mathsf{CauchyModulus}^{\uparrow}$ *ledger, or the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyInductionLock`

Proof. The base read is determined by the first displayed selector cell of ϵ. By Definition 1647.1, an even selector exposes A, S_A, and an odd selector exposes B, S_B; no third row is present in the carrier.

For the successor step, assume the accepted prefix has already been routed through the selected parity row and the shared M, D ledger. The next selector cell again chooses either A, S_A or B, S_B, and Definition 1647.2 requires parity schedule compatibility, shared modulus exactness, and dyadic tolerance exactness for that cell.

The induction therefore preserves the invariant that each accepted read first uses one parity schedule and then the common ledger. Definition 1647.3 and Definition 1647.5 place F and R downstream of the same M, D cells, so the completed finite schedule has no escaping handoff route. □

Theorem 1647.8 (EvenOddCauchyCriterion tail merge)**.** *For every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *packet K, once the late even tail and the late odd tail have both displayed the shared M, D cells, the cross-parity fusion row F merges the two parity tails into one BEDC route. The merge uses the same finite NameCert obligations as the carrier surface and does not introduce a quotient stream, selected limit, countable-choice selector, host real equality, trichotomy, or ambient Real completeness row.*

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyCriterionTailMerge`

Proof. Start from the two late tails exposed by Definition 1647.7. Each accepted read has already passed through either A, S_A or B, S_B and then through the shared modulus and tolerance cells.

Definition 1647.2 identifies those common cells as certificate obligations rather than auxiliary choices. Hence the two tails meet at displayed data: the same precision budget in M and the same dyadic comparison ledger in D.

Now apply Definition 1647.3. The row F is exactly the downstream fusion row for those displayed parity tails, and Definition 1647.6 prevents a consumer from reaching F through any undisplayed object. The late even and odd tails therefore merge through F as one finite route. □

Theorem 1647.9 (EvenOddCauchyCriterion single modulus)**.** *For every accepted* $\mathsf{EvenOddCauchyCriterion}^{\uparrow}$ *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N),$$

the RealCauchyCriterion$^{\uparrow}$ *handoff row R consumes one shared modulus route. It cannot split into separate even and odd Cauchy budgets after F has displayed the common M, D ledger.*

Proof. The carrier definition displays only one CauchyModulus$^{\uparrow}$ ledger M and one DyadicRatCore$^{\uparrow}$ tolerance ledger D. The classifier of Definition 1647.1 has no coordinate for parity-specific replacement budgets.

Definition 1647.7 routes each finite parity read through that same ledger, and Definition 1647.8 merges the late tails through F once the shared cells have been displayed.

Finally use the Real seal boundary of Definition 1647.4 together with the transport statement of Definition 1647.5. The handoff row R sits downstream of the fused parity route and of componentwise hsame and Cont replay, so it receives the single shared M, D route rather than two independent parity budgets. □

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchySingleModulus`

Theorem 1647.10 (EvenOddCauchyCriterion Real handoff exhaustion)**.** *Every* RealCauchyCriterion$^{\uparrow}$*-facing handoff from an accepted* EvenOddCauchyCriterion$^{\uparrow}$ *packet*

$$K = (A, B, S_A, S_B, \epsilon, M, D, F, R, H, C, P, N)$$

factors through exactly the displayed route consisting of the selector row ϵ, the selected parity RegSeqRat$^{\uparrow}$ *and* StreamName$^{\uparrow}$ *rows, the shared* CauchyModulus$^{\uparrow}$ *ledger M, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, the cross-parity fusion row F, and then the handoff row R. The route is preserved by H, C, P, N and exposes no second RealCauchyCriterion surface, no parity-specific completion datum, no quotient stream equality, no selected limit, no trichotomy, and no countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.EvenOddCauchyCriterionUp.EvenOddCauchyRealHandoffExhaustion`

Proof. First use the induction lock of Definition 1647.7. Every finite read of the parity schedule chooses exactly one displayed side: either A, S_A or B, S_B. The same induction keeps the chosen side tied to the shared M, D cells.

Next apply the tail merge theorem Definition 1647.8. Once both late parity tails have displayed the common modulus and dyadic tolerance rows, the cross-parity fusion row F is the unique downstream merge point available in the packet.

The single-modulus theorem Definition 1647.9 then prevents the handoff row R from splitting the route into separate even and odd Cauchy budgets. The Real seal route of Definition 1647.4 places R after the selector, selected parity row, shared ledger, dyadic tolerance ledger, and fusion row.

Finally the non-escape theorem Definition 1647.6 and the structural rows H, C, P, N show that no other packet coordinate can serve as a RealCauchyCriterion handoff. Thus the displayed route exhausts every Real-facing handoff surface. □

Closure status for NameCert$_{\text{EvenOddCauchyCriterion}^{\uparrow}}$**.**

Constructive story: An EvenOddCauchyCriterion$^{\uparrow}$ packet is generated from two RegSeqRat rows, two StreamName schedules, an even–odd selector, a shared CauchyModulus ledger, a DyadicRatCore tolerance ledger, a cross-parity fusion row, a RealCauchyCriterion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{EvenOddCauchyCriterion}^{\uparrow}}$, obligation)

Scope closed: Definition 1647.1, Definition 1647.2, Definition 1647.3, Definition 1647.4, Definition 1647.5, Definition 1647.6, Definition 1647.7, Definition 1647.8, and Definition 1647.9 seed the parity-tail criterion route through RegSeqRat, StreamName, CauchyModulus, DyadicRatCore, RealCauchyCriterion, and RegularCauchyInterleaving faces.

Formal verification: FormalStatus(NameCert$_{\mathsf{EvenOddCauchyCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient streams, selected limits, host real equality, trichotomy, countable choice, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, parity schedule compatibility, shared modulus exactness, dyadic tolerance exactness, tail-fusion factorization, Real Cauchy handoff factorization, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.EvenOddCauchyCriterionUp.

Chapter 1648

A Concrete Naming Certificate for $\mathsf{FractionalPart}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FractionalPart}^{\uparrow}$ packet names the finite integer-part and residual-real interface used before decimal-prefix and comparison consumers may inspect a real name. It sits after the terminal real-name seal of chapter 38, the integer carrier of chapter 31, the public Archimedean bound surface of chapter 430, the integer-part bracket packet of chapter 1479, the decimal-prefix route of chapter 1417, the finite stream windows of chapter 126, the regular-rational readback surface of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet records the residual route as finite BEDC data; it is not a host fractional-part operation, a floor selector, a trichotomy service, a quotient-real equality witness, a selected representative, or an appeal to ambient Real completeness.

Definition 1648.1 (FractionalPart carrier)**.** *A* $\mathsf{FractionalPart}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, I, F, B, D, S, G, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *name row for the source real, exposed through the real-name seal and the regular-Cauchy readback route before any integer-part read is consumed.*
2. *I is the* $\mathsf{Int}^{\uparrow}$ *integer-part row, read through the* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket packet and its displayed integer candidate.*
3. *F is the residual fractional* $\mathsf{Real}^{\uparrow}$ *row, recording the real-name route for the residual obtained from the source row and integer row.*
4. *B is the Archimedean bound and bracket row, binding the source real, the integer candidate, and the residual interval confinement to the same public* $\mathsf{ArchimedeanReal}^{\uparrow}$ *and* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *comparison data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii, slack comparisons, and refinements used to observe both the source row and residual row.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for decimal-prefix and comparison reads of the residual.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that reads the windows in S as regular rational data before the residual reaches a decimal-prefix consumer.*

8. *H records componentwise* hsame *transport for the source real, integer row, residual row, Archimedean bracket, dyadic tolerance ledger, stream windows, regular readback, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision or decimal-prefix request through R, I, F, B, D, S, G, without inserting another integer search or host arithmetic operation.*

10. *P is the* Pkg *provenance over* $\mathsf{FractionalPart}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FractionalPart}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite residual certificate. It has no coordinate for host floor, trichotomy over arbitrary real names, quotient real equality, selected representatives, countable choice, hidden Archimedean search, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FractionalPartUp.FractionalPartTasteGate single carrier alignment`

Theorem 1648.2 (FractionalPart NameCert obligations)**.** *For every accepted* $\mathsf{FractionalPart}^{\uparrow}$ *carrier $K = (R, I, F, B, D, S, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FractionalPart}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real row, integer-part row, residual real row, Archimedean bracket row, dyadic tolerance row, stream-window row, regular-rational handoff row, componentwise transport, continuation replay, provenance, and local naming row;*

2. *componentwise classifier transport, requiring the accepted status of R, I, F, B, D, S, G to remain stable under the* hsame *transports in H and the displayed* Cont *replay in C;*

3. *residual interval confinement, requiring the residual row F to stay within the displayed unit-bracket route supplied by B and observed through the tolerance ledger D;*

4. *decimal-prefix readback, requiring every decimal-prefix consumer to reach F only through the finite-window row S and the regular-rational handoff row G;*

5. *ledger exhaustion, excluding host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, and ambient Real completeness from the exported certificate.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FractionalPartUp.FractionalPartCarrier namecert obligations`

Proof. Project the accepted packet $K = (R, I, F, B, D, S, G, H, C, P, N)$. The projection exposes exactly the source real row, integer-part row, residual row, Archimedean bracket, dyadic tolerance ledger, stream windows, regular readback, transport row, continuation replay, provenance, and local naming row.

Componentwise classifier transport is read from H and C. The transports move the rows R, I, F, B, D, S, G together, and replay sends each precision request back through the same displayed route rather than through a detached host operation.

Residual interval confinement is the content of the bracket row B together with the tolerance row D. The bracket binds the source real, integer candidate, and residual to the same Archimedean comparison data, while the dyadic ledger records the finite tolerances under which the residual is observed.

Decimal-prefix readback is supplied by S and G. A decimal consumer first opens a finite $\mathsf{StreamName}^{\uparrow}$ window and then reads it through the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, so the residual is never presented as an untracked completed real value.

The exclusions follow from the carrier inventory. Since no row stores host floor, trichotomy, quotient equality, selected representatives, countable choice, hidden Archimedean search, or ambient Real completeness, none of those principles can be exported by the local certificate. □

Theorem 1648.3 (FractionalPart Real-Int handoff)**.** *Every consumer of the fractional residual in an accepted* $\mathsf{FractionalPart}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{ArchimedeanReal}^{\uparrow} \longmapsto \mathsf{Int}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Concretely, the consumer receives the displayed source real row R, Archimedean bracket row B, integer-part row I, dyadic tolerance row D, stream-window row S, and regular-rational handoff row G before reading the residual row F. It receives no host floor function, trichotomy service, quotient real, selected representative, or $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.FractionalPartUp.FractionalPartCarrier real int handoff`

Proof. Let a downstream consumer request the fractional residual from an accepted carrier. The source real row R is the first analytic coordinate, so the route begins at the displayed $\mathsf{Real}^{\uparrow}$ name rather than at a host real value.

The Archimedean and integer-part data are then forced by B and I. The bracket row exposes the public Archimedean bound and comparison route, and the integer row is read through the displayed $\mathsf{Int}^{\uparrow}$ candidate supplied by the integer-part packet.

The residual can be inspected only through the dyadic and window rows. The tolerance ledger D records the finite dyadic observations of the residual, S opens the finite stream windows requested by a decimal or comparison consumer, and G converts those windows into the regular-rational readback surface.

Finally H, C, P, N package and name the same route. They transport, replay, source, and certify the displayed rows without adding a floor function, trichotomy service, quotient real, selected representative, or $\mathsf{Real}^{\uparrow}$ completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FractionalPart}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FractionalPart}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1648.1, Definition 1648.2, and Definition 1648.3 seed the finite integer-part and residual-real interface for decimal-prefix and Real-comparison consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FractionalPart}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completeness, host floor, trichotomy, quotient equality, selected representatives, hidden Archimedean search, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, componentwise classifier transport, residual interval confinement, decimal-prefix readback, Real-Int handoff, and ledger-exhaustion proofs for BEDC.Derived.FractionalPartUp.

Constructive story: A $\mathsf{FractionalPart}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ source row, an $\mathsf{Int}^{\uparrow}$ integer-part row, a residual $\mathsf{Real}^{\uparrow}$ row, an Archimedean bracket row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1649

A Concrete Naming Certificate for $\mathsf{StableManifold}^{\uparrow}$

Hadamard–Perron stable manifold theory identifies the local invariant surface through a hyperbolic equilibrium by combining a local flow, a charted phase space, and a contraction estimate on the stable direction. The $\mathsf{StableManifold}^{\uparrow}$ packet records only the finite BEDC certificate needed by that local reading: an equilibrium row, a $\mathsf{DynSystem}^{\uparrow}$ flow row, an $\mathsf{Ode}^{\uparrow}$ local-flow row, a $\mathsf{Manifold}^{\uparrow}$ chart row, a $\mathsf{LipschitzMap}^{\uparrow}$ contraction ledger, a stable tangent cone row, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. It does not import the full analytic theorem as a primitive.

Definition 1649.1 (StableManifold carrier)**.** *A* $\mathsf{StableManifold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, D, O, M, L, T, H, C, P, N)$$

with the following visible coordinates:

1. *E is the equilibrium point row on the phase carrier;*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *local flow packet whose source and endpoint rows are read in the same phase carrier;*
3. *O is the* $\mathsf{Ode}^{\uparrow}$ *local-flow row used by D as its generator-facing dependency;*
4. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart row naming the local coordinate domain;*
5. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *contraction ledger on the stable chart coordinate;*
6. *T is a stable tangent cone row, recording the finite direction labels whose chart coordinates are governed by L;*
7. *H records componentwise* hsame *transports for equilibrium, flow, ODE, chart, contraction, tangent-cone, and endpoint rows;*
8. *C records the* Cont *routes by which local flow endpoints remain readable inside the charted stable packet;*
9. *P records* Pkg *provenance for* $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *dependency rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StableManifold}^{\uparrow}}$ *provenance row.*

The carrier accepts exactly those packets whose flow row fixes the displayed equilibrium, whose chart row admits the tangent-cone labels, and whose contraction ledger is read on the stable coordinate rows named by T.

Lean4 ✓ `BEDC.Derived.StableManifoldUp.StableManifoldTasteGate single carrier alignment`

Theorem 1649.2 (StableManifold NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{StableManifold}^\uparrow}$ *seed surface consists of six finite obligations:*

1. *carrier: the packet of Definition 1649.1;*
2. *classifier: componentwise comparison of the equilibrium, flow, ODE, chart, contraction, tangent-cone, transport, continuation, provenance, and local certificate rows;*
3. *equilibrium stability: the* $\mathsf{DynSystem}^\uparrow$ *flow row classifies the displayed equilibrium with its zero-time endpoint;*
4. *chart compatibility: the* $\mathsf{Manifold}^\uparrow$ *chart row carries every stable tangent-cone coordinate used by the packet;*
5. *contraction ledger: the* $\mathsf{LipschitzMap}^\uparrow$ *row supplies the finite contracting bound on stable chart coordinates;*
6. *ledger policy:* Pkg *and* NameCert *expose only the listed dynamical, ODE, manifold, Lipschitz, transport, continuation, and tangent-cone rows.*

Lean4 ✓ `BEDC.Derived.StableManifoldUp.StableManifoldCarrier namecert obligations`

Proof. Read the carrier coordinates of Definition 1649.1. The flow row is already a finite $\mathsf{DynSystem}^\uparrow$ packet, and chapter 195 identifies its public surface as a phase row, elapsed-time row, endpoint row, ODE dependency row, and displayed Cont ledger.

Read the generator dependency through chapter 193. It supplies the local-flow row and keeps vector-field evaluation, Picard data, and endpoint transport inside the ODE certificate surface.

Read chart and contraction data through chapter 96 and chapter 410. The chart row names the local coordinate domain, while the Lipschitz row supplies the finite bound ledger on the stable coordinate rows. Repacking these displayed rows with componentwise hsame, Cont, Pkg, and the local naming row gives the six advertised obligations. □

Theorem 1649.3 (StableManifold flow invariance)**.** *Let* $S = (E, D, O, M, L, T, H, C, P, N)$ *be an accepted* $\mathsf{StableManifold}^\uparrow$ *carrier. Suppose a local* $\mathsf{DynSystem}^\uparrow$ *flow segment in D starts at a point classified with the stable tangent-cone chart rows T and remains inside the chart domain named by M for the displayed time row. Then its endpoint is again classified with the same* $\mathsf{StableManifold}^\uparrow$ *carrier after transporting the equilibrium, flow, ODE, chart, contraction, and tangent-cone coordinates by the stored* hsame *and* Cont *rows.*

Proof. Project the local flow segment from D. By chapter 195, its endpoint is exposed by a displayed Cont route over the same $\mathsf{Manifold}^\uparrow$ phase row and $\mathsf{Ode}^\uparrow$ source row.

Use the $\mathsf{Manifold}^\uparrow$ chart row M to keep the source and endpoint chart coordinates in the same local coordinate surface. The stable tangent-cone row T is finite, so transport of its coordinate labels is componentwise through the stored hsame entries rather than through host equality of tangent spaces.

Finally read the $\mathsf{LipschitzMap}^\uparrow$ ledger L on those transported stable coordinates. The contraction bound is part of the same packet, so the endpoint coordinate repacks with the original

equilibrium, flow, ODE, chart, tangent, provenance, and local naming rows. This is exactly the classifier of Definition 1649.1. □

Lean4 ✓ `BEDC.Derived.StableManifoldUp.StableManifoldFlowInvariance`

Theorem 1649.4 (StableManifold local attraction)**.** *For an accepted* $\mathsf{StableManifold}^{\uparrow}$ *carrier* $S = (E, D, O, M, L, T, H, C, P, N)$*, any finite local orbit segment whose source row is classified with the stable tangent-cone coordinates* T *has every displayed successor endpoint read through the contraction ledger* L *and the same chart row* M*. Consequently the segment's endpoint-distance rows form a finite contraction ledger toward the equilibrium row* E *inside the local* $\mathsf{NameCert}_{\mathsf{StableManifold}^{\uparrow}}$ *surface.*

This is a local attraction certificate: it records the finite BEDC rows that make attraction readable, not a selected infinite trajectory or a global basin classification.

Lean4 ✓ `BEDC.Derived.StableManifoldUp.StableManifoldLocalAttraction`

Proof. Proceed along the finite orbit ledger. Each successor row is a $\mathsf{DynSystem}^{\uparrow}$ flow segment, so chapter 195 exposes its endpoint through the same phase carrier and displayed continuation route.

At each step, use the $\mathsf{Ode}^{\uparrow}$ local-flow source of chapter 193 to keep the generator-facing Picard and endpoint rows on the same local-flow surface. The ManifoldUp chart row then reads the source and endpoint coordinates in the chart named by M.

The $\mathsf{LipschitzMap}^{\uparrow}$ contraction row L supplies the finite comparison between the previous stable coordinate distance and the next one. Because the orbit segment is finite, iterating this ledger only concatenates the displayed comparison rows and their Cont routes. The endpoint-distance rows therefore remain a local contraction ledger toward E inside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StableManifold}^{\uparrow}}$**.**

Constructive story: A stable-manifold packet is generated from an equilibrium row, a DynSystemUp local-flow row, an OdeUp generator-facing local-flow row, a ManifoldUp chart row, a LipschitzMapUp contraction ledger, a finite stable tangent-cone row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StableManifold}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed surface names the local finite carrier rows for equilibrium, charted flow, ODE source, stable tangent cone, contraction ledger, transport, continuation, provenance, and local naming, but it does not close the paper axis beyond this carrier presentation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StableManifold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global stable-manifold theorem, smooth foliation, spectral hyperbolicity proof, selected global solutions, or bridge verification.

Upgrade path: Scoped closure requires checked carrier admission, classifier laws, local flow invariance, contraction-ledger exactness, and endpoint attraction for the named stable-manifold packet.

Chapter 1650

A Concrete Naming Certificate for $\mathsf{RegularCauchySeparation}^{\uparrow}$

Following Bishop and Bridges-style regular Cauchy equality, the $\mathsf{RegularCauchySeparation}^{\uparrow}$ packet records how two regular rational names can be read as separated, or not yet separated at a displayed tolerance, before any $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the regular rational rows of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance rows of chapter 291, the modulus surface of chapter 292, and the terminal real-name boundary of chapter 38. The certificate keeps separation evidence as finite NameCert data, not as quotient real equality, host real equality, trichotomy, or ambient completeness.

Definition 1650.1 (Regular Cauchy separation carrier)**.** *A* $\mathsf{RegularCauchySeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, W, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
2. *R is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger naming the left and right observation windows inspected by the separation read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and rational comparison rows used at those windows.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *separation-modulus evidence, stating which finite windows in W must be displayed before the tolerance rows in D may be read as equality or separation evidence.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after L, R, W, D, M have been displayed.*
7. *H records componentwise* hsame *transport for the two regular names, finite windows, dyadic tolerance rows, separation modulus evidence, Real seal boundary, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from every equality or separation read through $L, R, W, D, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySeparation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySeparation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, host real equality, trichotomy, selected limits, countable choice, ambient Real completeness, or a standard bridge.

Lean4 ✓ `BEDC.Derived.RegularCauchySeparationUp.RegularCauchySeparationTasteGate single carrier alignment`

Theorem 1650.2 (Regular Cauchy separation NameCert obligations)**.** *For an accepted carrier $K = (L, R, W, D, M, E, H, C, P, N)$ of Definition 1650.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySeparation}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows L, R, the* $\mathsf{StreamName}^{\uparrow}$ *window ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{CauchyModulus}^{\uparrow}$ *separation-modulus row M, the* $\mathsf{Real}^{\uparrow}$ *boundary row E, and the structural rows H, C, P, N;*
2. *classifier exposure, stating that every equality or separation read of the packet is classified through the displayed route L, R, W, D, M before it can reach E;*
3. *finite-window stability, stating that transport through H and replay through C preserve the same left and right windows named by W;*
4. *dyadic tolerance exactness, stating that the rational comparison rows read from D are the only tolerance rows admitted for the displayed separation read;*
5. *modulus boundary, stating that M is the only row allowed to turn a requested equality or separation tolerance into finite windows of W;*
6. *Real seal non-escape, stating that E is a boundary row consumed only after $L, R, W, D, M, H, C, P, N$ have been retained;*
7. *package provenance and local naming, stating that P names exactly the listed sibling certificates and N names the same finite packet as a local* $\mathsf{NameCert}_{\mathsf{RegularCauchySeparation}^{\uparrow}}$.

Lean4 ✓ `BEDC.Derived.RegularCauchySeparationUp.RegularCauchySeparationCarrier namecert obligations`

Proof. Project the accepted carrier. The rows L, R, W, D, M, E are the analytic coordinates, while H, C, P, N transport, replay, source, and name the same finite packet.

Read the classifier in dependency order. A separation or equality request first reads the two regular rational names L and R, then the finite observation windows W, then the dyadic tolerance ledger D, and then the modulus row M that binds the requested tolerance to those windows.

The Real-facing row is downstream of that route. Since E is stored only after L, R, W, D, M, a consumer that bypasses one of those rows has not obtained a read of the packet's Real seal boundary.

The structural rows add no hidden equality principle. Transport through H, replay through C, provenance through P, and local naming through N preserve the displayed route, so the listed rows exhaust the seed NameCert surface. □

Theorem 1650.3 (Regular Cauchy separation modulus boundary)**.** *For every accepted* $\mathsf{RegularCauchySeparation}^{\uparrow}$ *packet $K = (L, R, W, D, M, E, H, C, P, N)$, every equality or separation read factors through the finite route*

$$(L, R) \longmapsto W \longmapsto D \longmapsto M$$

before reaching the $\mathsf{Real}^{\uparrow}$ *seal boundary E. Thus the packet exports no equality or separation evidence whose source is a detached Real value, a host equality relation, trichotomy, a selected limit, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchySeparationUp.RegularCauchySeparationCarrier modulus boundary`

Proof. Start from Definition 1650.2. The classifier exposure places every accepted equality or separation read on the displayed left and right regular names, their finite window ledger, the dyadic tolerance ledger, and the separation-modulus row.

The modulus row is the last analytic gate before the seal boundary. It converts the requested tolerance into the finite windows already named by W and the dyadic comparison rows already named by D; it does not select a completed real or import host equality.

Finally read E as a boundary row. The package reaches $\mathsf{Real}^{\uparrow}$ only after the finite route through L, R, W, D, M has been displayed, and the transport, continuation, provenance, and local naming rows preserve that route. Therefore every equality or separation read factors through W, D, M before reaching the Real seal boundary. □

Theorem 1650.4 (Regular Cauchy separation zero-distance reflection)**.** *Let $K = (L, R, W, D, M, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySeparation}^{\uparrow}$ *packet. Suppose the separation read uses the same displayed* $\mathsf{StreamName}^{\uparrow}$ *windows for L and R, and suppose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger collapses through the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M to the zero-distance boundary. Then the* $\mathsf{Real}^{\uparrow}$ *seal receives equality evidence only through the finite route*

$$(L, R) \longmapsto W \longmapsto D \longmapsto M \longmapsto E.$$

The packet exports no quotient real equality, host real equality, trichotomy, selected limit, countable choice, or ambient completeness assertion.

Lean4 ✓ `BEDC.Derived.RegularCauchySeparationUp.RegularCauchySeparationCarrier zero distance reflection`

Proof. Project the carrier from Definition 1650.1. The equality-facing read has access only to the two regular rational names L, R, the finite window ledger W, the dyadic tolerance ledger D, the modulus row M, the Real seal boundary E, and the structural rows H, C, P, N.

Use the NameCert obligations of Definition 1650.2. Classifier exposure forces the two displayed StreamName windows to be read before the dyadic tolerance ledger can be interpreted as equality evidence.

Apply the modulus boundary theorem Definition 1650.3. When the tolerance ledger collapses through M to the zero-distance boundary, the collapse is still routed through W, D, M before any Real seal read occurs.

The conclusion is therefore a finite route statement. The carrier has no quotient-real coordinate, no trichotomy coordinate, no selected-limit coordinate, and no ambient-completeness coordinate, while H, C, P, N preserve only the displayed rows. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchySeparation}^{\uparrow}$ consumer that reaches an equality or separation read without the displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{CauchyModulus}^{\uparrow}$ separation-modulus row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, cauchymodulus, real: no listed sibling supplies the whole ten-row packet $K = (L, R, W, D, M, E, H, C, P, N)$, because each sibling contributes only regular-name rows, finite windows, dyadic tolerances, modulus evidence, or a Real seal boundary while this chapter binds the separation route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySeparation}^{\uparrow}}$.

Constructive story: A RegularCauchySeparation$^{\uparrow}$ packet is generated from left and right RegSeqRat$^{\uparrow}$ rows, a StreamName$^{\uparrow}$ finite-window ledger, a DyadicRatCore$^{\uparrow}$ tolerance ledger, a CauchyModulus$^{\uparrow}$ separation-modulus row, a Real$^{\uparrow}$ seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchySeparation}^{\uparrow}}$, seed)

Scope closed: Definition 1650.1, Definition 1650.2, and Definition 1650.3 seed the certified separation boundary for regular Cauchy names over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyModulus$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchySeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, host real equality, trichotomy, selected limits, countable choice, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, finite-window stability, dyadic tolerance exactness, modulus boundary, Real seal non-escape, package provenance, and local naming for the displayed separation packet.

Chapter 1651

A Concrete Naming Certificate for $\mathsf{DenseUniformEmbedding}^{\uparrow}$

Following the Bourbaki and Kelley treatment of uniform completions, and the Bishop–Bridges constructive use of dense uniform embeddings, the $\mathsf{DenseUniformEmbedding}^{\uparrow}$ packet records the finite interface by which a source uniform or metric object enters a separated completion as a dense uniformly controlled subobject. It binds the dense embedding surface of chapter 1512, the completion target of chapter 1473, the modulus route of chapter 391, the extension consumer of chapter 769, and the separated target boundary of chapter 1612. The packet is a NameCert carrier for the L10 completion route; it is not a quotient completion, a representative selector, or an assertion of ambient completeness.

Definition 1651.1 (DenseUniformEmbedding carrier)**.** *A* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, T, I, Q, M, E, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source uniform or metric data row whose point histories, entourages, and metric observations supply the dense domain.*
2. *T is the target separated completion data row, read through the* $\mathsf{UniformCompletion}^{\uparrow}$ *and* $\mathsf{SeparatedCompletion}^{\uparrow}$ *surfaces before any consumer treats target reads as separated completion reads.*
3. *I is the dense image witness row, recording that every displayed target tolerance window has a source-side image window.*
4. *Q is the uniform-continuity modulus row, read through* $\mathsf{UniformContinuity}^{\uparrow}$*, that transports source closeness to target closeness along the displayed image route.*
5. *M is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *handoff row by which source observations enter the completion-facing target route.*
6. *E is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *consumer row naming the downstream extension interface that may read the dense source and target separated completion together.*
7. *U is the local compatibility row stating that I, Q, M, E are read over the same source row S and target row T.*
8. *H records componentwise* hsame *transport for S, T, I, Q, M, E, U and for the structural rows.*

9. *C records displayed* Cont *replay from source histories through dense image, uniform modulus, completion embedding handoff, extension consumer, and separated completion target.*

10. *P is the* Pkg *provenance over* $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseUniformEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completions, selected representatives, host equality, countable choice, ambient completeness, or a detached target-completion object.

Lean4 ✓ `BEDC.Derived.DenseUniformEmbeddingUp.DenseUniformEmbeddingTasteGate single carrier alignment`

Theorem 1651.2 (DenseUniformEmbedding NameCert obligations)**.** *For every accepted* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *carrier $D = (S, T, I, Q, M, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseUniformEmbedding}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the source uniform or metric row, target separated completion row, dense image witness, uniform-continuity modulus, completion embedding handoff, extension consumer, compatibility row, hsame transport, Cont replay, package provenance, and local naming;*

2. *dense image coverage, requiring each target tolerance request in T to route through the source image witness I before any separated completion read is exported;*

3. *uniform-modulus stability, requiring every source closeness read consumed by the dense route to pass through Q before it reaches the target side;*

4. *completion-embedding compatibility, requiring the handoff row M to be the only route from source observations into the completion-facing target;*

5. *extension-consumer compatibility, requiring every* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *consumer to read the same S, T, I, Q, M route before using E;*

6. *transport and replay preservation, requiring H and C to preserve the ordered route under componentwise* hsame *transport and displayed* Cont *replay;*

7. *ledger non-escape, excluding quotient completions, selected representatives, host equality, countable choice, ambient completeness, and detached target-completion data.*

Lean4 ✓ `BEDC.Derived.DenseUniformEmbeddingUp.DenseUniformEmbeddingNameCertObligations`

Proof. Carrier admission is projection from Definition 1651.1. The tuple lists the source row, target separated completion row, dense image witness, modulus, completion handoff, extension consumer, compatibility row, transport, replay, provenance, and local naming.

Dense image coverage is read from I over the same target row T. A target tolerance request cannot be consumed until the packet has displayed a source-side image window for that request.

Uniform-modulus stability is the row Q. It is the only route by which source closeness is transported to target closeness, so every completion-facing dense read must pass through Q before reaching the target side.

The completion and extension boundaries are the rows M and E. The handoff row M admits source observations into the completion-facing route, and the extension row E is read only after S, T, I, Q, M have been fixed by U.

Finally, H, C, P, N record transport, replay, provenance, and local naming for exactly those rows. Since the carrier contains no quotient, selected representative, host equality, choice, ambient-completeness, or detached-completion coordinate, the listed obligations exhaust the NameCert surface. □

Theorem 1651.3 (DenseUniformEmbedding completion consumer route)**.** *Every completion or extension consumer of an accepted* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto I \longmapsto Q \longmapsto M \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a dense uniformly controlled source image inside the separated completion target, not a quotient-completion point, selected representative, host equality witness, countable-choice schedule, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.DenseUniformEmbeddingUp.DenseUniformEmbeddingCarrier completion consumer route`

Proof. Begin with the source row S. The consumer may read only the displayed source uniform or metric histories supplied by the packet.

The dense image row I and uniform-modulus row Q are the next route components. They turn a target tolerance request into a source image window and transport source closeness to target closeness.

The completion embedding handoff M then sends the controlled source observations into the completion-facing boundary. The target row T is reached only after this dense uniform route has been recorded.

Finally the extension consumer row E may read the same route, while H, C, P, N preserve and name it. No excluded quotient, representative, host equality, choice, or ambient completeness object has a coordinate in the carrier, so no consumer can escape the displayed route. □

Theorem 1651.4 (DenseUniformEmbedding ledger non-escape)**.** *For every accepted* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *carrier* $D = (S, T, I, Q, M, E, U, H, C, P, N)$*, every exported read remains inside the rows*

$$S, T, I, Q, M, E, U, H, C, P, N$$

of Definition 1651.1. The packet exports no quotient completion, selected representative, host equality, countable-choice selector, ambient completeness witness, or detached completion object.

Lean4 ✓ `BEDC.Derived.DenseUniformEmbeddingUp.DenseUniformEmbeddingCarrier ledger nonescape`

Proof. The NameCert obligations of Definition 1651.2 enumerate every admissible carrier, coverage, modulus, handoff, extension, transport, replay, provenance, and naming row.

The completion consumer route of Definition 1651.3 covers each downstream read by forcing it through $S, I, Q, M, T, E, H, C, P, N$. The compatibility row U states that these route components are read over the same source and target rows.

There is no remaining carrier coordinate from which a consumer could project a quotient class, selected representative, host equality judgement, choice schedule, ambient-completeness theorem, or detached completion object. Therefore every exported read stays within the displayed finite ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{DenseUniformEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseUniformEmbedding}^{\uparrow}$ packet is generated from a source uniform or metric row, a target UniformCompletion and SeparatedCompletion row, a dense image witness, a UniformContinuity modulus, a CompletionEmbedding handoff, a UniformContinuousExtension consumer row, route compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseUniformEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1651.1, Definition 1651.2, Definition 1651.3, and Definition 1651.4 seed the dense uniform embedding interface for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseUniformEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DenseUniformEmbeddingUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host equality, countable choice, ambient completeness, or detached target-completion objects.

Upgrade path: Obligation closure requires checked carrier admission, dense image coverage, uniform-modulus stability, completion-embedding compatibility, extension-consumer compatibility, transport replay, and ledger non-escape for BEDC.Derived.DenseUniformEmbeddingUp.

Chapter 1652

A Concrete Naming Certificate for $\mathsf{UniformEmbedding}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges on constructive completion, the $\mathsf{UniformEmbedding}^{\uparrow}$ packet names the standard finite interface by which a uniformly controlled injective source enters a completion-facing target. It sits between the uniform-completion surface of chapter 1473, the metric-completion surface of chapter 1506, the source-to-completion handoff of chapter 1512, and the dense specialization of chapter 1651. The packet records the non-dense embedding route used by completion consumers; it is not quotient completion equality, a selected representative, host function equality, countable choice, or ambient completeness.

Definition 1652.1 (Uniform embedding carrier)**.** *A* $\mathsf{UniformEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, T, I, U, J, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source uniform or metric row whose point histories and finite entourage observations are admitted into the embedding route.*
2. *T is the target completion row, read through the* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *surface before any completion-facing consumer inspects target data.*
3. *I is the injective classifier row, recording that two displayed source histories are identified only when the target embedding route identifies their finite observations.*
4. *U is the uniform-modulus row that transports source closeness into target closeness and reflects the target-controlled closeness needed by the embedding interface.*
5. *J is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *handoff row by which source observations enter the completion-facing target route.*
6. *R is the local route-compatibility row stating that I, U, J are read over the same source row S and target completion row T.*
7. *H records componentwise* hsame *transport for S, T, I, U, J, R and for the structural rows.*
8. *C records displayed* Cont *replay from source histories through the injective classifier, uniform modulus, completion-embedding handoff, and target completion row.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, host function equality, countable-choice schedules, ambient completeness, or a detached completed target object.

Lean4 ✓ `BEDC.Derived.UniformEmbeddingUp.UniformEmbeddingTasteGate single carrier alignment`

Theorem 1652.2 (Uniform embedding NameCert obligations)**.** *For every accepted* $\mathsf{UniformEmbedding}^{\uparrow}$ *carrier* $E = (S, T, I, U, J, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source row, target completion row, injective classifier, uniform-modulus row, completion-embedding handoff, route-compatibility row, hsame transport, Cont replay, package provenance, and local naming;*
2. *classifier transport, requiring I to be read through the same S, T route under componentwise* hsame *transport and displayed* Cont *replay;*
3. *uniform-modulus stability, requiring every source-to-target closeness read and every reflected embedding-control read to pass through U before target completion data are available;*
4. *embedding injectivity, requiring source identifications exported by the packet to be justified by the displayed injective classifier rather than by host function equality;*
5. *completion-handoff compatibility, requiring the row J to be the only route from source observations into the completion-facing target row T;*
6. *ledger non-escape, excluding quotient completion equality, selected representatives, countable choice, host function equality, ambient completeness, and detached completed target objects.*

Proof. Carrier admission is projection from Definition 1652.1. The tuple lists the source, target completion, injective classifier, uniform modulus, completion handoff, route compatibility, transport, replay, provenance, and local naming rows.

Classifier transport is read from I, H, C. The classifier is not a host equality predicate; it is transported componentwise along the displayed packet and replayed only through the same S, T route.

Uniform-modulus stability is the row U. Every target-facing closeness assertion used by the embedding route passes through this row before the completion handoff is available.

Embedding injectivity and completion compatibility use I and J together. The injective classifier supplies the finite source-identification test, and the handoff row J is the only route from source observations into the target completion row T.

Finally P and N record provenance and local naming for exactly those rows. Since no carrier coordinate stores quotient equality, selected representatives, host function equality, choice, ambient completeness, or detached target objects, the listed obligations exhaust the NameCert surface. □

Theorem 1652.3 (Uniform embedding completion handoff)**.** *Let* $E = (S, T, I, U, J, R, H, C, P, N)$ *be an accepted* $\mathsf{UniformEmbedding}^{\uparrow}$ *carrier. Every completion-facing consumer of E factors through the finite route*

$$S \longmapsto I, U \longmapsto J \longmapsto T \longmapsto R, H, C, P, N.$$

Consequently the consumer can use only the displayed uniform-control and completion-embedding rows. It cannot use quotient completion equality, selected representatives, countable choice, host function equality, or ambient completeness.

Proof. Start with a completion-facing consumer. Projection gives the source row S, but the packet exposes no completed point or representative selector at this stage.

The consumer must next read the classifier I and the uniform-modulus row U. These rows provide the finite injectivity and uniform-control surface needed before target completion data are public.

The completion-embedding handoff J then carries the controlled source observations into the target row T. The compatibility row R states that the classifier, modulus, and handoff are all read over the same S, T boundary.

Transport, replay, provenance, and local naming are exactly H, C, P, N. They preserve the displayed route and add no quotient equality, selected representative, host function equality, countable-choice schedule, or ambient-completeness witness, so every completion-facing consumer factors through the stated handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1652.1, Definition 1652.2, and Definition 1652.3 seed the non-dense uniform embedding interface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host function equality, countable choice, ambient completeness, dense image coverage, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, uniform-modulus stability, embedding injectivity, completion-handoff compatibility, and ledger non-escape for the same packet.

Constructive story: A $\mathsf{UniformEmbedding}^{\uparrow}$ packet is generated from a source uniform or metric row, a target UniformCompletion or MetricCompletion row, an injective classifier, a uniform-modulus row, a CompletionEmbedding handoff, route compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1653

A Concrete Naming Certificate for $\mathsf{DyadicSupremum}^{\uparrow}$

Following Bishop and Bridges-style constructive least-upper-bound reasoning, the $\mathsf{DyadicSupremum}^{\uparrow}$ packet records only the finite dyadic upper-bound and lower-approximation ledgers needed before a located supremum or Real-facing consumer reads the boundary. It sits over the dyadic endpoint core of chapter 291, the interval comparison surface of chapter 306, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, the Real seal boundary of chapter 38, and the located-supremum packet of chapter 1427. The certificate is a finite boundary for dyadic supremum reads; it is not an arbitrary least-upper-bound principle, a quotient-cut construction, a selected supremum, trichotomy, host Real equality, countable choice, or Real completeness.

Definition 1653.1 (DyadicSupremum carrier)**.** *A* $\mathsf{DyadicSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, A, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded dyadic family row, recording the displayed family entries and the finite upper-bound ledger through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{DyadicInterval}^{\uparrow}$ *comparison rows.*
2. *A is the lower-approximation ledger, recording finite dyadic witnesses that every demanded lower approximation is met by an inspected family entry.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly the finite family windows inspected by the upper-bound and lower-approximation ledgers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic scales at which the bound and approximation comparisons are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, translating the displayed dyadic ledgers into regular rational approximation data without selecting a completed real.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after B, A, W, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the bounded family, lower-approximation ledger, StreamName window, DyadicRatCore tolerance, RegSeqRat handoff, Real seal, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from every dyadic supremum read through $B, A, W, D, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicSupremum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary least-upper-bound completeness, quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, or Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicSupremumUp.TasteGate.DyadicSupremumTasteGate single carrier alignment`

Theorem 1653.2 (DyadicSupremum NameCert obligations)**.** *For an accepted carrier $S = (B, A, W, D, R, E, H, C,$ of Definition 1653.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the bounded dyadic family row B, lower-approximation ledger A,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R,* $\mathsf{Real}^{\uparrow}$ *seal boundary E, and the structural rows H, C, P, N;*
2. *upper-bound exposure, stating that every exported upper-bound read of the packet is classified through the displayed dyadic family ledger B and tolerance row D before it reaches the Real seal boundary;*
3. *lower-approximation exposure, stating that every exported lower read factors through a displayed witness in A inside one of the windows named by W;*
4. *finite-window stability, stating that transport through H and replay through C preserve the same inspected windows, dyadic scales, upper-bound rows, and lower-approximation witnesses;*
5. *dyadic tolerance exactness, stating that all supremum comparisons use only the dyadic scales and comparison rows displayed in D;*
6. *regular rational handoff, stating that R is the only row allowed to translate the dyadic ledgers into regular rational approximation data for downstream Real-facing consumers;*
7. *Real seal non-escape, stating that E is a boundary row consumed only after $B, A, W, D, R, H, C, P, N$ have been retained;*
8. *package provenance and local naming, stating that P names exactly the listed sibling certificates and N names the same finite packet as a local* $\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}$.

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.DyadicSupremumUp.DyadicSupremumNameCertObligations`

Proof. Project the accepted carrier. The rows B, A, W, D, R, E are the analytic coordinates, while H, C, P, N transport, replay, source, and name the same finite packet.

Read the classifier in dependency order. An upper-bound request first reads the bounded dyadic family row B and the dyadic tolerance ledger D. A lower-approximation request first reads the witness ledger A, the finite windows W, and the same dyadic tolerance row D.

The regular rational handoff is downstream of those finite ledgers. The row R can only translate the displayed dyadic comparisons into regular rational approximation data; it does not select a completed supremum or import an order-completeness principle.

The Real-facing row is the final boundary. Since E is stored only after B, A, W, D, R, a consumer that bypasses one of those rows has not obtained a read of the packet's Real seal boundary.

The structural rows add no hidden supremum principle. Transport through H, replay through C, provenance through P, and local naming through N preserve the displayed route, so the listed rows exhaust the seed NameCert surface. □

Theorem 1653.3 (DyadicSupremum located-supremum handoff)**.** *For every accepted* $\mathsf{DyadicSupremum}^{\uparrow}$ *packet* $S = (B, A, W, D, R, E, H, C, P, N)$*, every located-supremum or Real-facing read factors through the finite route*

$$B, A \longmapsto W, D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently any consumer from chapter 291, chapter 306, chapter 126, chapter 301, chapter 38, or chapter 1427 receives only the displayed dyadic upper-bound and lower-approximation ledgers, with no arbitrary least-upper-bound completeness, quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, or Real completeness inserted into the route.

Proof. Start with an accepted carrier $S = (B, A, W, D, R, E, H, C, P, N)$. The only family coordinate is B, the only lower-approximation coordinate is A, and the only inspected windows and comparison scales are W and D.

For an upper-bound read, project B and D. The exported bound is read from the displayed dyadic family ledger and the dyadic comparison rows at the named scales. For a lower-approximation read, project A, W, D. The witness is one of the inspected family entries named by W and compared at a displayed dyadic scale in D.

The row R is the sole handoff to $\mathsf{RegSeqRat}^{\uparrow}$ approximation data, and E is the sole boundary row for $\mathsf{Real}^{\uparrow}$ consumers. A $\mathsf{LocatedSupremum}^{\uparrow}$ reader can consume the same handoff only after the dyadic upper-bound and lower-approximation rows have been displayed.

Finally H, C, P, N package the route. Componentwise transport and continuation replay preserve the same finite ledgers, while provenance records the dependency anchors. Since every exported read is reached through this route, there is no remaining coordinate from which arbitrary least-upper-bound completeness, quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, or Real completeness could be read. □

Lean4 ✓ `BEDC.Derived.DyadicSupremumUp.DyadicSupremumLocatedCutHandoff`

Theorem 1653.4 (DyadicSupremum finite-window exhaustion)**.** *Every accepted* $\mathsf{DyadicSupremum}^{\uparrow}$ *consumer read of the lower-approximation ledger factors through a finite list of dyadic upper-bound and lower-approximation rows before any* $\mathsf{LocatedSupremum}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer sees the handoff.*

Proof. Project the accepted carrier of Definition 1653.1. The only rows available to a lower-approximation read are the bounded dyadic family row B, the lower-approximation ledger A, the finite window row W, and the dyadic tolerance row D.

Use Definition 1653.2. Its obligation surface exposes upper-bound rows through B, D, lower-approximation witnesses through A, W, D, finite-window stability through H, C, dyadic tolerance exactness through D, regular rational handoff through R, Real seal non-escape through E, provenance through P, and local naming through N.

Apply Definition 1653.3. The handoff to $\mathsf{LocatedSupremum}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ appears only after the finite dyadic ledgers have been displayed and routed through R and E.

Thus the consumer read is exhausted by the finite window named in W together with the dyadic rows displayed in B, A, D. The packet introduces no arbitrary least-upper-bound completeness, quotient cut, selected supremum, trichotomy, host Real equality, countable choice, or Real completeness coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicSupremumUp.DyadicSupremumFiniteWindowExhaustion`

Falsifiable prediction: An accepted $\mathsf{DyadicSupremum}^{\uparrow}$ consumer that reaches a located-supremum or Real-facing read without the displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: dyadicratcore, dyadicinterval, streamname, regseqrat, real, located-supremum: no listed sibling supplies the whole ten-row packet $S = (B, A, W, D, R, E, H, C, P, N)$, because each sibling contributes dyadic comparison rows, interval rows, finite windows, regular rational handoff data, a Real seal boundary, or a located-supremum consumer while this chapter binds the dyadic upper-bound and lower-approximation route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicSupremum}^{\uparrow}$ packet is generated from a bounded dyadic family row, a lower-approximation ledger, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff row, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1653.1, Definition 1653.2, and Definition 1653.3 seed the finite dyadic supremum boundary over DyadicRatCore, DyadicInterval, StreamName, RegSeqRat, Real, and LocatedSupremum consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicSupremum}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DyadicSupremumUp.DyadicSupremumLocatedCutHandoff`

Bridge status: none

Not claimed: This chapter does not claim arbitrary least-upper-bound completeness, quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, upper-bound exposure, lower-approximation exposure, finite-window stability, dyadic tolerance exactness, regular rational handoff, Real seal non-escape, package provenance, and local naming for the displayed dyadic supremum packet.

Chapter 1654

A Concrete Naming Certificate for $\mathsf{RegularCauchyMetric}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMetric}^{\uparrow}$ packet names the metric-facing dyadic closeness route for two displayed regular rational Cauchy names before the completed $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the dyadic arithmetic core of chapter 291, the common finite windows of chapter 126, the regular rational readback rows of chapter 301, the terminal real-name seal of chapter 38, and the real metric consumer surface of chapter 1638. The packet exposes a finite distance route for regular Cauchy names; it does not identify quotient reals, assert host real equality, choose limits, use trichotomy, or claim completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1654.1 (Regular Cauchy metric carrier)**.** *A* $\mathsf{RegularCauchyMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{rc}} = (R_0, R_1, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
2. R_1 *is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
3. W *is the common* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger naming the paired observation windows inspected from* R_0 *and* R_1*.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius and the rational comparison budget for the two observed windows.*
5. Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *distance row naming the displayed dyadic distance bound extracted from the same windows and tolerance ledger.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the regular rows, common windows, dyadic tolerance row, and dyadic distance row have been displayed.*
7. H *records componentwise* hsame *transport for the two regular names, common windows, dyadic tolerance row, dyadic distance row, Real seal row, replay row, provenance row, and local naming row.*
8. C *records displayed* Cont *replay from every metric-facing read through* $R_0, R_1, W, D, Q, E, H, P, N$*.*
9. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, W, D, Q, E, H, C, P, N$. The carrier has no coordinate for quotient real equality, host real equality, selected limits, trichotomy, ambient Real completeness, or a detached completed-real distance.

Lean4 ✓ `BEDC.Derived.RegularCauchyMetricUp.RegularCauchyMetricTasteGate single carrier alignment`

Theorem 1654.2 (Regular Cauchy metric NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMetric}^{\uparrow}$ *carrier $M_{\mathrm{rc}} = (R_0, R_1, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMetric}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows R_0, R_1, the common* $\mathsf{StreamName}^{\uparrow}$ *window ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *distance row Q, the* $\mathsf{Real}^{\uparrow}$ *seal boundary E, and the structural rows H, C, P, N;*
2. *common-window exposure, requiring every metric-facing read to inspect the paired windows named by W before any dyadic comparison row is read;*
3. *dyadic tolerance exactness, requiring D to supply the requested radius and comparison budget before the distance bound Q is exposed;*
4. *dyadic distance handoff, requiring Q to be the only displayed distance row handed to the downstream* $\mathsf{RealMetric}^{\uparrow}$ *consumer;*
5. *Real seal boundary, requiring E to be consumed only after the route through R_0, R_1, W, D, Q has been displayed;*
6. *transport and replay stability, requiring H and C to preserve the same two regular names, common windows, dyadic tolerance row, dyadic distance row, Real seal boundary, provenance, and local naming row;*
7. *package provenance and local naming, requiring P and N to name exactly the listed sibling certificates and the same finite packet;*
8. *refusal of quotient real equality, host real equality, selected limits, trichotomy, and Real completeness as NameCert data.*

No NameCert obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyMetricUp.RegularCauchyMetricCarrier namecert obligations`

Proof. Project the accepted carrier. The analytic coordinates are the two regular rational names R_0, R_1, the common window ledger W, the dyadic tolerance row D, the dyadic distance row Q, and the Real seal boundary E; the remaining rows transport, replay, source, and name the same packet.

Read the metric-facing route in dependency order. A distance request first opens the paired finite windows named by W from the two $\mathsf{RegSeqRat}^{\uparrow}$ rows, then reads the dyadic radius and comparison budget in D, and only then exposes the dyadic distance row Q.

The downstream Real-facing boundary is therefore ordered. The row E is reached after the regular names and dyadic rows have been displayed, and the $\mathsf{RealMetric}^{\uparrow}$ consumer receives Q as a finite distance row rather than a host completed-real distance.

Finally apply componentwise transport and replay. The rows H and C preserve the same displayed route, while P and N name exactly the sibling certificate dependencies. Since no carrier coordinate stores quotient equality, host equality, selected limits, trichotomy, or Real completeness, none of those principles can be exported by the local NameCert surface. □

Theorem 1654.3 (Regular Cauchy metric dyadic closeness route)**.** *Every accepted* $\mathsf{RegularCauchyMetric}^{\uparrow}$ *consumer factors a metric-facing closeness read through the finite route*

$$(R_0, R_1) \longmapsto W \longmapsto D \longmapsto Q \longmapsto E$$

before it may hand the read to a $\mathsf{RealMetric}^{\uparrow}$ *surface. Thus the consumer receives regular rational readback, common finite windows, dyadic tolerance data, a dyadic distance bound, and a Real seal boundary; it receives no quotient real equality, host real equality, selected limit, trichotomy, or Real completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMetricUp.RegularCauchyMetricCarrier dyadic closeness route`

Proof. Start with an accepted carrier $M_{\mathrm{rc}} = (R_0, R_1, W, D, Q, E, H, C, P, N)$. The only source rows for the closeness read are the two regular rational names R_0 and R_1, and the only observation route attached to them is the common finite window ledger W.

The dyadic request then passes through D and Q. The tolerance row D names the radius and comparison budget, while the distance row Q names the bound extracted from the same displayed windows; no second distance row is present.

Replay the route through C and transport it through H. The replay reaches the Real seal boundary E only after the regular rows, windows, tolerance row, and distance row have been displayed.

The provenance row P points to the sibling surfaces of chapter 291, chapter 126, chapter 301, chapter 38, and chapter 1638. Together with N, it packages the same finite route and adds no coordinate for quotient equality, host equality, selected limits, trichotomy, or completeness. □

Theorem 1654.4 (Regular Cauchy metric scoped kernel route)**.** *Every accepted* $\mathsf{RegularCauchyMetric}^{\uparrow}$ *read factors through* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and distance rows, the* $\mathsf{Real}^{\uparrow}$ *seal boundary,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *before any metric consumer inspects zero-distance or triangle-style data. The scoped kernel route exposes only the displayed regular Cauchy metric packet and no quotient real equality, host real equality, selected limit, trichotomy, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMetricUp.RegularCauchyMetricScopedKernelRoute`

Proof. Project the NameCert obligations of Definition 1654.2. They expose the two $\mathsf{RegSeqRat}^{\uparrow}$ rows, common $\mathsf{StreamName}^{\uparrow}$ windows, dyadic tolerance row, dyadic distance row, Real seal boundary, transport, replay, provenance, and local naming as the whole local surface.

Apply the dyadic closeness route of Definition 1654.3. It forces every metric-facing closeness read through $(R_0, R_1) \longmapsto W \longmapsto D \longmapsto Q \longmapsto E$ before any $\mathsf{RealMetric}^{\uparrow}$ surface is available.

The structural rows H, C, P, N preserve that same route for zero-distance and triangle-style consumers. Since the carrier contains no quotient equality, host equality, selected limit, trichotomy, or completeness coordinate, the scoped kernel route is exactly the displayed finite metric packet. □

Theorem 1654.5 (Regular Cauchy metric separated-zero route)**.** *Let*

$$M_{\mathrm{rc}} = (R_0, R_1, W, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMetric}^{\uparrow}$ *packet. If the dyadic distance row* Q *is routed through the zero-distance comparison at every displayed finite window, then every* $\mathsf{RealMetric}^{\uparrow}$ *zero-distance consumer still factors through* $R_0, R_1, W, D, Q, E, H, C, P, N$*. The consumer obtains classifier-compatible regular Cauchy equality only through those displayed rows, not through quotient real equality, host equality, a selected limit, trichotomy, or ambient Real completeness.*

Proof. Begin with Definition 1654.2. The local surface contains only the two regular rational names, the common finite window, the dyadic tolerance row, the dyadic distance row, the Real seal boundary, and the structural transport, replay, provenance, and naming rows.

Apply Definition 1654.3. It forces the zero-distance comparison to read Q only after R_0, R_1, W, D have been displayed and before the Real-facing seal boundary E is exposed.

Finally use Definition 1654.4. The zero-distance consumer is a metric-facing read of the same scoped kernel, so H, C, P, N preserve and name exactly the displayed packet. The resulting regular Cauchy equality is therefore classifier-compatible along the packet rows and is not quotient real equality or host equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMetric}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyMetric}^{\uparrow}}$, seed)

Scope closed: Definition 1654.1, Definition 1654.2, and Definition 1654.3 seed the metric-facing finite dyadic closeness surface for two $\mathsf{RegSeqRat}^{\uparrow}$ rows over common $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and distance rows, $\mathsf{Real}^{\uparrow}$ seal data, and $\mathsf{RealMetric}^{\uparrow}$ consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality, host real equality, selected limits, trichotomy, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, common-window exposure, dyadic tolerance exactness, dyadic distance handoff, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMetricU

Constructive story: A $\mathsf{RegularCauchyMetric}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ rows, common $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and distance rows, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1655

A Concrete Naming Certificate for $\mathsf{MetricTopology}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{MetricTopology}^{\uparrow}$ packet names the metric-generated topology obtained from center-radius ball rows. It sits between the metric carrier of chapter 57, the center-radius ball surface of chapter 1450, the indexed-open topology carrier of chapter 88, and the radius ledgers of chapter 38 and chapter 37. The packet records the public bridge from metric data to topology data as finite NameCert rows; it does not select opens from a host powerset and does not quotient generated opens by ambient equality.

Definition 1655.1 (Metric topology carrier)**.** *A* $\mathsf{MetricTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G_{\mathsf{mtop}} = (M, B, T, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the certified* $\mathsf{Met}^{\uparrow}$ *carrier with its point classifier, distance witness, and displayed metric-law rows.*
2. *B is the finite* $\mathsf{MetricBall}^{\uparrow}$ *basis ledger whose singleton rows are center-radius ball data compatible with the metric carrier M.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open carrier $\mathcal{T}_{d,\mathsf{ball}}$ generated from the finite ball indices of Definition 88.10.*
4. *R records the* $\mathsf{Real}^{\uparrow}$ *strict-comparison and positive-radius ledgers used by membership tests of the form $d(c, x) <_{\mathsf{R}} r$.*
5. *Q records the* $\mathsf{Rat}^{\uparrow}$ *radius ledger and its transport into the displayed positive* $\mathsf{Real}^{\uparrow}$ *radius rows.*
6. *H records componentwise* hsame *transport for metric points, ball centers, radius ledgers, singleton-ball predicates, finite ball lists, indexed-open witnesses, replay rows, provenance, and the local certificate.*
7. *C records displayed* Cont *replay from a public open request through the metric carrier M, the ball ledger B, the real and rational radius ledgers R, Q, and the indexed topology carrier T.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, T, R, Q, H, C, P, N$. The carrier has no coordinate for an ambient powerset of M, quotient equality of opens, hidden open selectors, selected centers outside B, or radius data outside R, Q.

Lean4 (definition) `BEDC.Derived.MetricTopologyUp.TasteGate.MetricTopologyUp`
Lean4 ✓ `BEDC.Derived.MetricTopologyUp.TasteGate.MetricTopologyTasteGate single carrier alignment`

Theorem 1655.2 (Metric topology NameCert obligations)**.** *For every accepted* $\mathsf{MetricTopology}^{\uparrow}$ *carrier* $G_{\mathsf{mtop}} = (M, B, T, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricTopology}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed metric carrier, ball basis ledger, indexed topology carrier, real and rational radius ledgers, transport, replay, provenance, and local naming row;*
2. *classifier transport for metric-basic opens, requiring each singleton ball predicate to move along the point classifier of M through the displayed comparison and radius ledgers;*
3. *singleton-ball coverage, requiring every public singleton metric-ball open of T to be read through a row of B before it is admitted as an indexed open;*
4. *finite intersection closure by ball-list concatenation, requiring the intersection of two finite ball-list opens to use the concatenated finite-list index named by the metric-generated topology source;*
5. *arbitrary-union ledger admission, requiring every union row to present an indexed family of already carried generated opens together with the supplied union witness of T;*
6. *boundary rows for the empty and whole opens, requiring the distinguished boundary indices of T and their visible* BHist *ledger rows;*
7. *ledger non-escape, requiring public topology consumers to read only $M, B, T, R, Q, H, C, P, N$ and never an ambient powerset, quotient-open representative, hidden open selector, or radius row outside the displayed ledgers.*

No NameCert obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.MetricTopologyUp.MetricTopologyCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1655.1. The only available public rows are the metric carrier M, the ball basis ledger B, the indexed topology carrier T, the radius ledgers R, Q, and the structural rows H, C, P, N.

Classifier transport and singleton coverage are the displayed route from $\mathsf{MetricBall}^{\uparrow}$ into $\mathsf{Topology}^{\uparrow}$. The singleton data are the ball rows of B, and Definition 88.11 supplies the indexed-open carrier and its membership transport along the point classifier of M.

Finite intersections are read through finite-list concatenation. The source of Definition 88.12 uses finite lists of ball data as indices, and Definition 88.17 identifies the concatenated list with the carried intersection predicate.

Arbitrary unions and boundary opens are the remaining displayed topology rows. The union witness and the empty and whole indices are part of T, so every public open admitted by the packet has a visible constructor ledger row.

Finally, provenance is exhausted by P and N. Since ambient powersets, quotient-open representatives, hidden open selectors, and detached radius rows are not coordinates of G_{mtop}, no local NameCert obligation can export them. □

Theorem 1655.3 (Metric topology ball-basis scope)**.** *Every public* $\mathsf{MetricTopology}^{\uparrow}$ *open carried by an accepted packet* $G_{\mathsf{mtop}} = (M, B, T, R, Q, H, C, P, N)$ *is read through the displayed* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{Topology}^{\uparrow}$ *rows. More precisely, each public open is witnessed by one of the constructor rows of the metric-generated topology source: a singleton metric ball from* B*, a finite-list intersection of such balls, a binary generated-open meet, an indexed arbitrary union of already carried generated opens, the empty open, or the whole open. Thus every downstream consumer of the metric topology receives only the route*

$$\mathsf{Met}^{\uparrow}, \mathsf{MetricBall}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Rat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The packet exports no host powerset of metric points, quotient open, hidden open selector, or radius datum outside the displayed ledgers.

Lean4 ✓ `BEDC.Derived.MetricTopologyUp.MetricTopologyCarrier ball basis scope`

Proof. Let a public open be carried by G_{mtop}. By Definition 1655.1, the open can be read only through the indexed topology row T generated from the ball basis ledger B.

The constructor analysis is the metric-generated exactness surface of Definition 88.12. Singleton rows come from B; finite intersections are finite-list rows; binary meets, arbitrary unions, and boundary opens are the corresponding constructor rows of T.

Each constructor row preserves the same public route. The metric carrier M supplies points and distance witnesses, the ledgers R, Q supply positive-radius comparison data, H and C transport and replay the route, and P, N record provenance and local naming.

No other coordinate is present in the packet. Therefore a consumer cannot recover a host powerset, quotient open, hidden selector, or detached radius datum from a public $\mathsf{MetricTopology}^{\uparrow}$ open. □

Theorem 1655.4 (Metric topology ball-prebasis route)**.** *Every public* $\mathsf{MetricTopology}^{\uparrow}$ *open read from an accepted carrier* $G_{\mathsf{mtop}} = (M, B, T, R, Q, H, C, P, N)$ *factors first through* $\mathsf{MetricBall}^{\uparrow}$ *center-radius rows, then through finite-meet and indexed-union rows of* $\mathsf{Topology}^{\uparrow}$*, and then through the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *radius ledgers and structural* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The route exports no host powerset of metric points, quotient-open representative, hidden open selector, detached radius datum, completeness theorem, or compactness theorem.*

Lean4 ✓ `BEDC.Derived.MetricTopologyUp.MetricTopologyBallPrebasisRoute`

Proof. Project the carrier. The only basic-open data available to a public read are the metric carrier M and the center-radius ball ledger B.

Apply Definition 1655.3. Singleton ball rows, finite-list intersections, binary meets, indexed unions, and boundary opens are exactly the constructor rows by which T admits public opens.

The radius rows are read with the ball data. The $\mathsf{Real}^{\uparrow}$ ledger R supplies strict comparison and positive-radius rows, while the $\mathsf{Rat}^{\uparrow}$ ledger Q supplies rational radius data and its transport into the displayed real-radius rows.

Finally H, C, P, N transport, replay, source, and name the same route. Since the packet has no ambient powerset, quotient-open representative, hidden selector, detached radius datum, completeness row, or compactness row, every public open factors through the displayed ball-prebasis route. □

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricTopology}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host powersets of metric points, quotient opens, hidden open selectors, completeness, compactness, or continuity theorems.

Upgrade path: Obligation closure requires formal carrier admission, singleton-ball coverage, classifier transport, finite-intersection concatenation, arbitrary-union admission, boundary rows, and ledger non-escape for the same finite packet.

Constructive story: A $\mathsf{MetricTopology}^{\uparrow}$ packet is generated from a MetricSpace carrier row, a MetricBall basis ledger, a Topology indexed-open carrier, RealUp and RatUp radius ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1656

A Concrete Naming Certificate for $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$

Bishop–Bridges constructive analysis treats a real name as usable only when the comparison route from fast modulus data to regular Cauchy readback is visible. The $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ packet records that route as finite BEDC data between the fast dyadic-modulus carrier of chapter 1589, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the completion-facing boundary of chapter 360. The packet is a two-way readback bridge; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1656.1 (Fast regular Cauchy equivalence carrier)**.** *A* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FastCauchyReal}^{\uparrow}$ *fast dyadic-modulus real-name row, including the visible precision schedule that every outgoing read must use.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose displayed observations are exactly the observations read by both the fast route and the regular route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, rounded comparison rows, and endpoint arithmetic for the shared stream windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from S and D without adding a quotient stream or a chosen limit.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the shared route through F, S, D, Q has been displayed.*
6. *H records componentwise* hsame *transport for the fast name, stream windows, dyadic ledger, regular readback, real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from every finite precision request through F, S, D, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$, $\mathsf{FastCauchyReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FastRegularCauchyEquivalence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.FastRegularCauchyEquivalenceUp.TasteGate.FastRegularCauchyEquivalenceTasteGate single carrier alignment`

Theorem 1656.2 (Fast regular Cauchy equivalence NameCert obligations)**.** *For every accepted* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ *carrier* $K = (F, S, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FastRegularCauchyEquivalence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the fast dyadic-modulus row F, shared stream-window row S, dyadic tolerance ledger D, regular rational readback Q, real-seal row E, and structural rows H, C, P, N;*
2. *fast-to-regular handoff, requiring each finite precision read of F to pass through the displayed S, D rows before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q may be consumed;*
3. *regular-to-fast schedule extraction, requiring every regular Cauchy readback request on Q to recover a finite fast schedule in F from the same S, D rows;*
4. $\mathsf{Real}^{\uparrow}$*-seal nonescape, requiring E to remain terminal with respect to F, S, D, Q and forbidding any detached completion read;*
5. *ledger refusal, forbidding quotient stream equality, selected limits, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and any read not routed through the displayed carrier rows.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FastRegularCauchyEquivalenceUp.FastRegularCauchyEquivalenceNameCert obligations`

Proof. Carrier admission is projection from Definition 1656.1. The tuple displays exactly the fast name, shared stream windows, dyadic tolerance ledger, regular readback, real seal, transport, replay, provenance, and local name.

For the fast-to-regular handoff, read a precision request in F. The request names a finite window in S and a dyadic tolerance row in D; those two rows are then repacked as the regular rational readback Q.

For the regular-to-fast schedule extraction, start with a finite regular Cauchy request on Q. Because Q is stored only as the readback of the same S, D route, the request recovers the stream windows and dyadic budget already admitted by F.

The real seal and refusal clauses follow by inspection of the carrier. The row E appears only after F, S, D, Q, while quotient streams, selected limits, countable choice, host real equality, ambient completeness, and detached completion reads are not coordinates of K. □

Theorem 1656.3 (Fast regular Cauchy two-way route)**.** *Every accepted* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ *carrier* $K = (F, S, D, Q, E, H, C, P, N)$ *proves both finite readback directions:*

1. *the fast dyadic-modulus row F yields the regular rational row Q by reading the shared* $\mathsf{StreamName}^{\uparrow}$ *row S and* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
2. *the regular rational row Q yields the fast schedule of F by reading the same S, D rows and the displayed* hsame *and* Cont *routes.*

Both directions reach the $\mathsf{Real}^{\uparrow}$ *seal only through E and the completion-facing provenance of* $\mathsf{RealCauchyCompletion}^{\uparrow}$*. The route constructs no quotient streams, selected limits, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden completion object.*

Lean4 ✓ `BEDC.Derived.FastRegularCauchyEquivalenceUp.FastRegularCauchyEquivalenceTwoWayRoute`

Proof. The forward direction begins with the fast row F. Its precision schedule selects finite observations in S and dyadic tolerance rows in D; the regular readback row Q is precisely the repackaging of those displayed rows.

The reverse direction begins with the regular row Q. Since the carrier stores Q only downstream of S, D, every finite regular request traces back to the same stream windows and dyadic tolerances, and these rows determine the fast schedule already named by F.

Transport and replay do not change the route. The rows H and C preserve the componentwise reads through F, S, D, Q, E, while P records the source certificates and N binds the packet locally.

Finally, the $\mathsf{Real}^{\uparrow}$ seal is terminal. A completion-facing consumer may cite the $\mathsf{RealCauchyCompletion}^{\uparrow}$ provenance but receives only the displayed route through E, so no quotient stream, selected limit, countable choice, host real equality, or ambient completeness principle is exported. □

Theorem 1656.4 (Fast regular Cauchy schedule lock)**.** *Every accepted* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ *carrier* $K = (F, S, D, Q, E, H, C, P, N)$ *that serves either a* $\mathsf{FastCauchyReal}^{\uparrow}$ *consumer or a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer must read the same displayed* S, D *rows before* Q *or* E *may be consumed. Thus no consumer may substitute a detached fast schedule, quotient stream, selected limit, or hidden completion representative for the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carried by* K*.*

Lean4 ✓ `BEDC.Derived.FastRegularCauchyEquivalenceUp.FastRegularCauchyEquivalenceRegularScheduleLock`

Proof. Project the carrier of Definition 1656.1. The schedule row S and dyadic ledger D are the only rows connecting the fast dyadic-modulus name F to the regular readback Q.

Use the obligation surface of Definition 1656.2. Its fast-to-regular and regular-to-fast clauses both require reads to pass through the displayed S, D rows before the regular readback or real seal is available.

Apply the two-way route of Definition 1656.3. Since both directions recover their schedules from the same S, D rows and the carrier has no quotient stream, selected limit, detached fast schedule, or hidden completion coordinate, every accepted consumer is locked to the displayed schedule. □

Theorem 1656.5 (Fast regular Cauchy tail-window cofinality)**.** *Every accepted* $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ *carrier* $K = (F, S, D, Q, E, H, C, P, N)$ *serving a completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing tail request must read a cofinal family of displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows whose* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is the same* Q *used by the fast schedule. No detached tail selector, quotient stream, selected limit, or hidden completion representative can replace that cofinal family.*

Lean4 ✓ `BEDC.Derived.FastRegularCauchyEquivalenceUp.FastRegularCauchyEquivalenceTailWindowCofinality`

Proof. Project the rows $F, S, D, Q, E, H, C, P, N$ from Definition 1656.1. A completion-facing or $\mathsf{Real}^{\uparrow}$-facing tail request can reach the seal E only through the displayed fast row, stream windows, dyadic ledger, and regular readback.

Use the fast-to-regular and regular-to-fast obligations in Definition 1656.2. The forward direction forces every fast precision read to pass through S, D before Q is consumed, while the reverse direction recovers the fast schedule from the same S, D rows when the request starts from Q.

Apply the two-way route of Definition 1656.3 together with the schedule lock of Definition 1656.4. Both tail-facing directions therefore identify their finite requests with the same displayed S, D windows, and the readback remains the same row Q used by the fast schedule.

Finally, the structural rows H, C, P, N transport, replay, source, and name only this carrier. Since K has no coordinate for a detached tail selector, quotient stream, selected limit, or hidden completion representative, none can replace the cofinal displayed family. □

Falsifiable prediction: An accepted $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ consumer that obtains a $\mathsf{RegSeqRat}^{\uparrow}$ readback from $\mathsf{FastCauchyReal}^{\uparrow}$ data without the displayed $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows refutes the carrier surface.

Independence witness: fastcauchyreal, regseqrat, streamname, dyadicratcore, real, real-cauchy-completion: no listed sibling supplies the whole nine-row packet $K = (F, S, D, Q, E, H, C, P, N)$, because each sibling contributes only a fast name, regular readback, finite window, dyadic ledger, seal, or completion-facing boundary while this chapter binds both readback directions with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FastRegularCauchyEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$ packet is generated from a $\mathsf{FastCauchyReal}^{\uparrow}$ fast dyadic-modulus row, a shared $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ regular readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastRegularCauchyEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1656.1, Definition 1656.2, Definition 1656.3, Definition 1656.4, and Definition 1656.5 seed the finite two-way readback bridge between fast dyadic-modulus real names and regular Cauchy rational names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastRegularCauchyEquivalence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FastRegularCauchyEquivalenceUp.TasteGate.FastRegularCauchyEquivalenceTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fast-to-regular handoff, regular-to-fast schedule extraction, real-seal nonescape, ledger refusal, transport, replay, provenance, and local naming for the same displayed packet.

Chapter 1657

A Concrete Naming Certificate for $\mathsf{CauchyUniformNet}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Moore–Smith nets, the $\mathsf{CauchyUniformNet}^{\uparrow}$ packet records uniform Cauchy-net evidence as finite BEDC rows before any $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the uniform entourage surface of chapter 339, the directed Cauchy-net boundary of chapter 589, the Cauchy-filter surface of chapter 333, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite uniform-net completion route; it is not a quotient of nets, not a selected limit, not countable choice, not host equality, and not ambient completeness.

Definition 1657.1 (Cauchy uniform net carrier)**.** *A* $\mathsf{CauchyUniformNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, F, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the directed index row, recording the finite preorder and upper-tail witnesses used by the net.*
2. *F is the Cauchy-filter-base trace row, naming the finite tail filters generated from the displayed directed windows.*
3. *U is the uniform entourage and tolerance row, carrying the selected entourage, its symmetric or composed tolerance cells, and the finite request budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the windows of the net that have been requested through I, F, U.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows and tolerances.*
6. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary, reachable only after I, F, U, W, R have been consumed.*
7. *H records componentwise* hsame *transport for the directed index row, filter-base trace, uniform tolerance row, finite windows, rational readbacks, seal boundary, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite entourage request through the directed tail, then through F, U, W, R, and finally to the seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient net equality, selected limits, countable-choice subnet selection, host equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyUniformNetUp.CauchyUniformNetTasteGate single carrier alignment`

Theorem 1657.2 (Cauchy uniform net NameCert obligations)**.** *For every accepted* $\mathsf{CauchyUniformNet}^{\uparrow}$ *carrier* $Q = (I, F, U, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformNet}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the directed index row, filter-base trace, uniform tolerance row, finite windows, regular rational readbacks,* $\mathsf{Real}^{\uparrow}$ *seal boundary, transport, continuation, provenance, and local naming row;*
2. *directed-tail stability, requiring every later-window request to pass through the displayed upper-tail witness in I before it can read F;*
3. *uniform tolerance exactness, requiring the requested entourage and its tolerance cells to be read from U before any window, readback, or seal handoff is exported;*
4. *finite-window transport, requiring H and C to preserve the route through I, F, U, W, R, E under componentwise* hsame *and displayed replay;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring every seal-facing read to pass through F, U, W, R before it reaches E;*
6. *provenance and name exhaustion, requiring P and N to name only this displayed finite route and to export no quotient nets, selected limits, countable choice, host equality, or ambient completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1657.1. The displayed packet contains exactly the directed row, filter-base trace, uniform tolerance row, finite windows, regular rational readbacks, seal boundary, and the structural rows H, C, P, N.

For directed-tail stability, replay a finite request through C. The request first consumes the displayed directed upper-tail witness in I, then reads the filter-base trace F attached to that tail. A finite-window induction over the requested window list shows that every inspected window is still downstream of the same I, F route.

Uniform tolerance exactness is read from U. Each induction step carries the same selected entourage and tolerance cells from U into the next requested window W, and then into the regular rational readback R.

Transport is componentwise. The row H identifies corresponding directed, filter, uniform, window, readback, seal, provenance, and local-name coordinates, while C repeats the same ordered route after transport.

Finally, the seal boundary E appears only after F, U, W, R. Since the carrier has no row for quotient net equality, selected limits, countable-choice subnet selection, host equality, or ambient completeness, the local certificate is exhausted by the listed finite rows. □

Lean4 ✓ `BEDC.Derived.CauchyUniformNetUp.CauchyUniformNetNameCertObligations`

Theorem 1657.3 (Cauchy uniform net filter-real route)**.** *Let $Q = (I, F, U, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyUniformNet}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read of Q factors through the finite route*

$$I, F, U, W, R \longmapsto E \longmapsto H, C, P, N.$$

In particular, the read consumes the Cauchy-filter-base trace F, the uniform entourage and tolerance row U, the finite-window row W, and the regular rational readback row R before it reaches E. The packet exports no quotient net, selected limit, countable-choice selector, host equality, or ambient completeness principle.

Proof. Begin with an accepted carrier Q. Projection from Definition 1657.1 exposes the seal row E only in the same packet as $I, F, U, W, R, H, C, P, N$.

Apply the NameCert obligations of Definition 1657.2. Directed-tail stability forces the request through I and F, while uniform tolerance exactness forces the entourage budget through U before any window or readback is available.

The finite-window transport clause then carries the request through W and R under H and C. Thus the seal-facing read reaches E only after the filter-base trace, uniform tolerance row, finite windows, and regular rational readbacks have all been consumed.

The provenance and name rows P, N name only that route. Since no excluded quotient, selected limit, countable-choice, host-equality, or completeness row appears in the carrier, no $\mathsf{Real}^{\uparrow}$ consumer can bypass F, U, W, R or replace the finite route by an ambient limit principle. □

Lean4 ✓ `BEDC.Derived.CauchyUniformNetUp.CauchyUniformNetCarrier filter real route`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyUniformNet}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyUniformNet}^{\uparrow}$ packet is generated from a directed index row, Cauchy-filter-base trace, uniform entourage and tolerance row, StreamName finite windows, RegSeqRat readbacks, Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyUniformNet}^{\uparrow}}$, seed)

Scope closed: Definition 1657.1, Definition 1657.2, and Definition 1657.3 seed the finite uniform Cauchy-net route through directed tails, filter-base traces, uniform tolerance rows, StreamName windows, RegSeqRat readbacks, and the downstream Real seal boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyUniformNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient net equality, host limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail stability, uniform tolerance exactness, finite-window transport, Real-seal non-escape, and provenance/name exhaustion for BEDC.Derived.CauchyUniformNetUp.

Chapter 1658

A Concrete Naming Certificate for $\mathsf{Dyadic}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{Dyadic}^{\uparrow}$ interface records the finite dyadic naming surface used by constructive real-name and completion routes. It is the direct handoff object between $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal: every consumer receives displayed finite tolerance, stream-window, regular-sequence, transport, replay, provenance, and naming rows, rather than host real equality, selected binary expansions, trichotomy, or completed quotient data.

Definition 1658.1 (DyadicUp carrier)**.** *A* $\mathsf{Dyadic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, carrying the dyadic rational numerator, denominator, tolerance budget, and arithmetic ledger read by dyadic consumers.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which requested precision windows are opened.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row attached to the same window surface.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the displayed real-name boundary reached after Q, S, R have been read.*
5. *H records componentwise* hsame *transport for the dyadic core, stream window, regular sequence, real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a precision request through Q, S, R and then to the real seal E.*
7. *P is the* Pkg *provenance over* $\mathsf{Dyadic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$ *row.*

The carrier contains no coordinate for selected binary expansions, host real equality, countable choice, trichotomy, quotient-stream representatives, or ambient completeness.

Lean4 (definition) `BEDC.Derived.DyadicUp.DyadicUp`

Theorem 1658.2 (DyadicUp NameCert obligations)**.** *For every accepted* $\mathsf{Dyadic}^{\uparrow}$ *carrier*

$$D = (Q, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic core, stream window, regular sequence, real seal, transport, replay, provenance, and local naming rows;*
2. *dyadic core admission, requiring every tolerance and arithmetic read to pass through* Q*;*
3. *stream and regular-sequence admission, requiring the precision window* S *and regular rational row* R *to be displayed before any real-name consumer reads the dyadic packet;*
4. *real-seal handoff, requiring* E *to expose only the* $\mathsf{Real}^{\uparrow}$ *boundary reached from* Q, S, R*;*
5. *transport and replay stability, requiring* H *and* C *to preserve the same dyadic core, stream, regular sequence, and real-seal rows componentwise;*
6. *nonescape from selected binary expansions, host real equality, countable choice, trichotomy, quotient-stream representatives, and ambient completeness.*

No $\mathsf{Dyadic}^{\uparrow}$ *naming obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 1658.1. The accepted packet displays exactly the dyadic rational core Q, finite stream window S, regular rational row R, real seal E, and the structural rows H, C, P, N.

Dyadic core, stream, and regular-sequence admission follow from the displayed route order. A precision request first reads the dyadic tolerance ledger Q, opens the finite window S, and then reads the regular rational row R attached to that window.

The real-seal handoff is then forced through E. Since E is the only Real-facing coordinate of the carrier, a downstream Real or Completion consumer cannot replace the displayed handoff by host equality, a selected binary expansion, or a quotient-stream representative.

Transport and replay are componentwise. The hsame row H preserves each displayed coordinate, while the Cont row C repeats the same finite path from precision request to real seal.

Finally inspect P and N. Provenance and local naming mention only Q, S, R, E, H, C, so the excluded choice, trichotomy, quotient, host-equality, and completeness data have no projection from the packet. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicNameCertObligations`

Theorem 1658.3 (DyadicUp obligation-closure route)**.** *For every accepted* $\mathsf{Dyadic}^{\uparrow}$ *carrier* $D = (Q, S, R, E, H, C, P, N)$*, the rows* Q, S, R, E, H, C, P, N *listed in Definition 1658.1 and certified by Definition 1658.2 are sufficient to witness the* obligation *surface consumed by downstream* $\mathsf{Dyadic}^{\uparrow}$ *readers. The route binds* Q *to* $\mathsf{DyadicRatCore}^{\uparrow}$*,* S *to* $\mathsf{StreamName}^{\uparrow}$*,* R *to* $\mathsf{RegSeqRat}^{\uparrow}$*,* E *to* $\mathsf{Real}^{\uparrow}$*, and* H, C, P, N *to* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *before any Real-facing or Completion-facing read can inspect the dyadic packet.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUp obligation closure route`

Proof. Start from the carrier and NameCert obligations. The carrier displays exactly the dyadic core, stream window, regular rational readback, Real seal, transport, replay, provenance, and local naming rows, while the obligation theorem states that no local naming obligation is stored outside those rows.

Read the mathematical rows first. The dyadic tolerance ledger Q, the finite stream window S, the regular rational row R, and the terminal Real seal E appear before any Real-facing or Completion-facing consumer can use the packet.

The structural rows H, C, P, N then preserve, replay, source, and name the same route over BHist, hsame, Cont, Pkg, and NameCert. Since every obligation row is displayed before the consumer-facing reads and no excluded analytic or quotient object is a carrier coordinate, the displayed rows witness the obligation-closure surface for $\mathsf{Dyadic}^{\uparrow}$ consumers. □

Theorem 1658.4 (DyadicUp obligation-closure dependency surface)**.** *For every accepted* $\mathsf{Dyadic}^{\uparrow}$ *obligation read, the dependency surface factors through exactly the displayed rows*

$$Q, S, R, E, H, C, P, N.$$

Here Q is read from $\mathsf{DyadicRatCore}^{\uparrow}$*, S from* $\mathsf{StreamName}^{\uparrow}$*, R from* $\mathsf{RegSeqRat}^{\uparrow}$*, and E from* $\mathsf{Real}^{\uparrow}$ *before any Real or Completion consumer can use the dyadic packet. The rows H, C, P, N then transport, replay, source, and locally name that same route. No selected binary expansion, quotient stream, trichotomy, countable choice, host equality, or ambient completeness row is admitted by the dependency surface.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUp obligation closure dependency surface`

Proof. Start with Definition 1658.2. Its finite obligation list admits only the dyadic core, stream window, regular rational sequence, real seal, transport, replay, provenance, and local naming rows of the carrier.

Next apply Definition 1658.6. It forces every Real-facing read to expose Q, then S, then R before the terminal row E becomes visible.

Finally use Definition 1658.5. Since Real and Completion consumers can reach the packet only through that terminal factorization, the remaining rows H, C, P, N merely preserve and name the same finite route, and the excluded binary-expansion, quotient-stream, trichotomy, choice, host-equality, and completeness data have no coordinate from which they can be read. □

Theorem 1658.5 (DyadicUp real-seal factorization)**.** *Let $D = (Q, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{Dyadic}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of D must read the displayed dyadic core Q, the finite stream window S, the regular rational row R, and the terminal real seal E in that order before it can export a Real-facing name.*

Consequently a downstream Real or Completion route cannot introduce selected binary expansions, quotient stream representatives, trichotomy, host real equality, countable choice, or ambient completeness while still claiming to consume the same $\mathsf{Dyadic}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUpRealSealFactorization`

Proof. Project the carrier of Definition 1658.1. The only Real-facing coordinate is E, and it is displayed after the dyadic rational core Q, finite window row S, and regular rational row R.

Apply Definition 1658.2. Its dyadic core, stream, regular-sequence, and real-seal obligations force each precision request through Q, S, R, E before any local name can be read by a downstream Real consumer.

The structural rows H, C, P, N only preserve, replay, account for, and name that same displayed route. Since the excluded analytic and quotient objects are absent from the carrier, they cannot be inserted by a Real-facing consumer without leaving the accepted $\mathsf{Dyadic}^{\uparrow}$ NameCert surface. □

Theorem 1658.6 (DyadicUp StreamName RegSeqRat route)**.** *Let $D = (Q, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{Dyadic}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing* $\mathsf{Dyadic}^{\uparrow}$ *read first opens the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Q, then the* $\mathsf{StreamName}^{\uparrow}$ *finite window S, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is visible. Thus the dyadic route depends on the sibling chapters chapter 291, chapter 126, and chapter 301 as finite packet rows, not as ambient host-real completeness data.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUp streamname regseqrat route`

Proof. Project the carrier of Definition 1658.1. The displayed coordinates place Q, S, and R before the only terminal seal coordinate E.

Apply Definition 1658.5. A Real-facing consumer cannot reach E until the dyadic core, stream window, and regular rational row have all been read in the carrier order.

The sibling chapters provide exactly those finite rows: the tolerance ledger from chapter 291, the finite-window classifier from chapter 126, and the regular rational readback from chapter 301. The structural rows H, C, P, N preserve and name that route, so no selected binary expansion, quotient stream, trichotomy, host real equality, countable choice, or ambient completeness principle is exposed by the handoff. □

Theorem 1658.7 (Dyadic exponent-shift composition)**.** *Two displayed* $\mathsf{Dyadic}^{\uparrow}$ *exponent-shift tolerance ledgers compose only by common precision refinement. Any* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of the composed tolerance row must first read the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, refine them to a common finite precision window, expose the corresponding* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, and only then consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicExponentShiftComposition`

Proof. Start with the NameCert obligations of Definition 1658.2. Each exponent-shift read is a displayed dyadic core row together with its stream window, regular sequence row, Real seal boundary, transport, replay, provenance, and local naming.

Use Definition 1658.5 for both ledgers. A Real-facing read of either ledger is unavailable until the dyadic core, finite stream window, and regular rational row have all been displayed.

Now compare the two exponent-shift windows by common precision refinement. The refinement is finite because it is formed from the two displayed $\mathsf{StreamName}^{\uparrow}$ windows and the two displayed dyadic tolerance rows; no quotient stream or selected limit is introduced.

Finally apply Definition 1658.6. The composed tolerance row reaches $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers only through the refined finite route, so it exposes no host quotient, selected limit, trichotomy, countable choice, or ambient Real completeness. □

Theorem 1658.8 (DyadicUp common-exponent normalization)**.** *Let $D_0 = (Q_0, S_0, R_0, E_0, H_0, C_0, P_0, N_0)$ and $D_1 = (Q_1, S_1, R_1, E_1, H_1, C_1, P_1, N_1)$ be accepted* $\mathsf{Dyadic}^{\uparrow}$ *carriers whose dyadic tolerance ledgers are read by a common* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer. Then the two accepted reads admit a finite common exponent window before the consumer inspects either terminal row.*

Concretely, the consumer first projects the dyadic core rows Q_0, Q_1, refines the displayed stream windows S_0, S_1 to one finite precision request, transports the regular rational readbacks R_0, R_1 across the componentwise hsame *rows, and only then exposes E_0, E_1 to the terminal* $\mathsf{Real}^{\uparrow}$ *handoff. The normalization exports the shared finite exponent window; it does not add a selected binary expansion, quotient stream, host equality, trichotomy, countable choice, or ambient Real-completeness witness.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUpCommonExponentNormalization`

Proof. Project the two carriers of Definition 1658.1. Each accepted read exposes its dyadic core row, finite stream window, regular rational readback, terminal real seal, and the structural rows that transport and replay that route.

Apply Definition 1658.7 to the two dyadic core ledgers. The common exponent is obtained by finite precision refinement of the two displayed windows, so the construction remains inside the BHist rows already present in D_0 and D_1.

Use Definition 1658.6 after the refinement. Both regular rational readbacks are attached to the common window before the consumer reaches either $\mathsf{Real}^{\uparrow}$ seal.

Finally apply Definition 1658.5. Since the terminal rows are visible only after the refined finite route, the normalized handoff cannot read any quotient, choice, trichotomy, host-equality, selected-expansion, or ambient-completeness data outside the accepted packets. □

Theorem 1658.9 (Dyadic common-exponent totality for shared finite consumers)**.** *For any two accepted* $\mathsf{Dyadic}^{\uparrow}$ *carriers read by the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer, the displayed finite windows determine a common exponent and tolerance window before either terminal* $\mathsf{Real}^{\uparrow}$ *seal is exposed. The total common window is read from the two dyadic core rows, the two finite stream windows, the two regular rational readbacks, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$ *rows.*

The route excludes selected binary expansions, quotient streams, trichotomy, choice, host equality, and ambient Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCommonExponentTotality`

Proof. Project the two accepted carriers through Definition 1658.1. The only rows available to the shared consumer are the two dyadic core ledgers, finite stream windows, regular rational readbacks, terminal seals, transport, replay, provenance, and local naming rows.

Apply dyadic exponent-shift composition from Definition 1658.7. The two displayed exponent-shift ledgers compose by finite precision refinement, so a common exponent and tolerance window is determined before any terminal seal can be read.

Use common-exponent normalization, Definition 1658.8. It places both $\mathsf{StreamName}^{\uparrow}$ windows and both $\mathsf{RegSeqRat}^{\uparrow}$ readbacks over the common finite window and keeps the route inside componentwise hsame transport and displayed Cont replay.

Finally apply the StreamName-RegSeqRat route of Definition 1658.6 and the real-seal factorization of Definition 1658.5. The shared consumer reaches the terminal Real seals only after the finite common window is visible, and no carrier row supplies a selected binary expansion, quotient stream, trichotomy, choice principle, host equality, or ambient Real-completeness witness. □

Theorem 1658.10 (DyadicUp common-window tail envelope)**.** *Let* $D_0 = (Q_0, S_0, R_0, E_0, H_0, C_0, P_0, N_0)$ *and* $D_1 = (Q_1, S_1, R_1, E_1, H_1, C_1, P_1, N_1)$ *be accepted* $\mathsf{Dyadic}^{\uparrow}$ *carriers read by one* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer. Then the two reads determine a shared finite tail-envelope window before either terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible.*

The envelope is read from the two dyadic core ledgers Q_0, Q_1*, the shared finite StreamName window refined from* S_0, S_1*, the two regular rational readbacks* R_0, R_1*, componentwise transport, displayed replay, provenance, and the two local* $\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$ *rows. It exposes no selected binary expansion, quotient stream, trichotomy branch, countable-choice selector, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUpCommonWindowTailEnvelope`

Proof. Project the two carriers through Definition 1658.1. The only rows available to the shared consumer are the two dyadic core ledgers, stream windows, regular rational readbacks, terminal seals, and structural rows.

Apply Definition 1658.7. The two dyadic ledgers compose by common finite precision refinement, so the consumer obtains a single candidate window before any terminal seal can be read.

Use Definition 1658.8. It places both StreamName windows and both RegSeqRat readbacks over the refined common exponent window, which is exactly the tail-envelope window seen by the shared consumer.

Finally apply Definition 1658.6. The terminal Real seals E_0, E_1 become visible only after the finite window and readback rows are displayed, and the excluded binary-expansion, quotient, trichotomy, choice, host-equality, and completeness data have no coordinate in either accepted carrier. □

Theorem 1658.11 (DyadicUp Real-RegSeqRat common-window readback)**.** *Any two accepted* $\mathsf{Dyadic}^{\uparrow}$ *packets consumed by the same* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *route expose their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers through one finite* $\mathsf{StreamName}^{\uparrow}$ *window before either* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal is available.*

The readback route first projects the two dyadic core rows, refines their displayed StreamName windows to the common finite window, attaches the two regular rational readback rows to that window, and only then exposes the terminal Real seals. It exports no selected binary expansion, quotient stream, trichotomy branch, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Apply Definition 1658.6 to each accepted packet. A shared $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer must read the dyadic core row, then the StreamName window, then the regular rational readback row before any terminal Real seal can be used.

Use Definition 1658.8. The two dyadic core tolerance ledgers are refined to a common finite exponent window, and the two StreamName rows are transported into that same displayed window.

Now apply Definition 1658.10. It identifies the shared tail-envelope window as the finite route seen by the common consumer before either terminal row is visible.

Thus the RegSeqRat readbacks and Real seals are downstream of one finite StreamName window over the two DyadicRatCore ledgers. Since every step is a displayed carrier projection or finite refinement, no selected binary expansion, quotient stream, trichotomy, countable choice, host equality, or ambient Real completeness data is exposed. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUpRealRegSeqRatCommonWindowReadback`

Theorem 1658.12 (DyadicUp terminal Real-seal boundary)**.** *Let*

$$D = (Q, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{Dyadic}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of* D *factors through exactly the rows* Q, S, R, E, H, C, P, N*, with* Q *read from* $\mathsf{DyadicRatCore}^{\uparrow}$*,* S *from* $\mathsf{StreamName}^{\uparrow}$*,* R *from* $\mathsf{RegSeqRat}^{\uparrow}$*, and* E *from* $\mathsf{Real}^{\uparrow}$*. No selected binary expansion, quotient stream, host equality, trichotomy, countable choice, or ambient Real-completeness row is readable from the terminal handoff.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicUpTerminalRealSealBoundary`

Proof. Project the carrier of Definition 1658.1. It displays the mathematical route rows Q, S, R, E and the structural rows H, C, P, N, and it contains no additional Real-facing or Completion-facing coordinate.

Apply Definition 1658.2. The accepted NameCert surface forces dyadic core admission through Q, stream-window admission through S, regular-sequence admission through R, and real-seal admission through E.

Now use Definition 1658.5 and Definition 1658.6. Together they exhaust the route from the dyadic tolerance ledger through finite windows and regular rational readback before the terminal seal can be read.

The remaining rows H, C, P, N only transport, replay, source, and name that route. Since the excluded binary, quotient, host-equality, trichotomy, choice, and completeness data are absent from every displayed coordinate, no terminal consumer can read them while staying inside the accepted $\mathsf{Dyadic}^{\uparrow}$ packet. □

The $\mathsf{Dyadic}^{\uparrow}$ terminal route consumes the finite dyadic tolerance ledger of chapter 291, the finite window classifier of chapter 126, the regular-rational readback of chapter 301, and the terminal seal of chapter 38. These siblings are the displayed L10 dependency route for the dyadic packet, not external host-real infrastructure.

The dyadic Cauchy interface packets collect finite approximation and tail-envelope certificates for displayed real-name routes before Real and Completion consumers can read them. This interface consumes the DyadicRatCore tolerance ledger of chapter 291, the RegSeqRat regular-sequence handoff of chapter 301, and the RealUp terminal seal of chapter 38.

Chapter 1659

A Concrete Naming Certificate for $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ packet records the finite tail-envelope boundary that lets a regular rational Cauchy name expose dyadic tolerance data before the terminal real seal is read. It sits between the finite stream windows of chapter 126, the regular rational name surface of chapter 301, the dyadic tolerance core of chapter 291, the reindexing discipline of chapter 1568, and the real-name boundary of chapter 38. The packet is a finite envelope around displayed tails; it is not a quotient stream, a selected limit, countable choice, trichotomy, host real equality, or Real completeness.

Definition 1659.1 (DyadicCauchyTailEnvelope carrier)**.** *A* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, D, T, I, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected tail coordinates of the underlying sequence.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic precision budget for the tail comparison.*
4. *T is the tail-envelope ledger, recording the displayed assertion that all inspected post-bound rows of R remain inside the dyadic budget named by D.*
5. *I is the* $\mathsf{CauchyReindexing}^{\uparrow}$ *route row, recording the finite reindexing data used to move from one requested precision window to the tail window named by S.*
6. *H records componentwise* hsame *transport for the stream window, regular rational readback, dyadic tolerance, tail-envelope ledger, reindexing route, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through I, S, R, D, T.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicCauchyTailEnvelopeUp.TasteGate.DyadicCauchyTailEnvelopeTasteGate single carrier alignment`

Theorem 1659.2 (DyadicCauchyTailEnvelope NameCert obligations)**.** *For every accepted* DyadicCauchyTailEnvelo *carrier* $E = (S, R, D, T, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, tail-envelope ledger,* $\mathsf{CauchyReindexing}^{\uparrow}$ *route, transport, replay, provenance, and local naming rows;*
2. *window admission, requiring every tail-envelope read to open the finite stream window* S *before reading regular rational rows;*
3. *tolerance admission, requiring the dyadic budget* D *to be displayed before the tail ledger* T *is consumed;*
4. *reindexing admission, requiring the row* I *to witness the finite precision-to-tail route used by the read;*
5. *tail containment, requiring* T *to compare the displayed rows of* R *inside the dyadic budget named by* D *after the route* I *has been fixed;*
6. *transport and replay stability, requiring* H *and* C *to preserve the same window, readback, tolerance, route, and ledger rows componentwise;*
7. *ledger nonescape from quotient streams, selected limits, countable choice, trichotomy, host real equality, and Real completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1659.1. The accepted packet displays exactly the finite stream window S, regular rational readback R, dyadic tolerance row D, tail ledger T, reindexing route I, and the structural rows H, C, P, N.

Window, tolerance, and reindexing admission follow from the route order. A precision request first fixes the finite reindexing row I, opens the stream window S, reads the regular rational row R, and displays the dyadic budget D before the tail-envelope ledger T can be consumed.

Tail containment is exactly the role of T. It compares only the displayed post-bound rows of R inside the dyadic budget named by D, so the envelope does not introduce a completed quotient stream or a selected limit.

Transport and replay are structural. The hsame row H moves each displayed coordinate componentwise, and the Cont row C repeats the same finite route for later consumers.

The nonescape clause follows because none of the excluded objects is a coordinate of the carrier. The local $\mathsf{NameCert}$ row N can therefore export only the displayed tail-envelope surface. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeNameCertObligations`

Theorem 1659.3 (DyadicCauchyTailEnvelope RegSeqRat Real route)**.** *Every accepted* DyadicCauchyTailEnvelope$^{\uparrow}$ *carrier* $E = (S, R, D, T, I, H, C, P, N)$ *exposes a finite route*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$$

from a precision request to the tail-envelope boundary used by $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers. Any downstream Real or Completion reader receives only the displayed reindexing, finite-window, regular-readback, dyadic-tolerance, and tail-ledger rows, with transport, replay, provenance, and local naming data attached.*

Proof. Start with an accepted carrier $E = (S, R, D, T, I, H, C, P, N)$. Projection gives the finite reindexing route I from the requested precision to the tail window, and then the stream window S opened along that route.

The regular rational row R is read only through this opened window. The dyadic tolerance row D supplies the comparison budget, and the tail-envelope ledger T records the displayed post-bound containment at that budget.

Thus the Real-facing consumer reaches the envelope only through I, S, R, D, T. The remaining rows H, C, P, N transport, replay, source, and name the same finite route, so no quotient stream, selected limit, countable-choice selector, trichotomy datum, host real equality, or Real-completeness principle is inserted into the handoff. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeRegSeqRatRealRoute`

Theorem 1659.4 (DyadicCauchyTailEnvelope common refinement)**.** *Let* $E = (S, R, D, T, I, H, C, P, N)$ *and* $E' = (S', R', D', T', I', H', C', P', N')$ *be accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *carriers serving the same displayed precision request. If the reindexing rows* I *and* I' *are transported through the same displayed* hsame *and* Cont *route, then there are a single finite tail window* S^* *and a single dyadic tolerance row* D^* *through which both* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks factor before either* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Equivalently, the paired read has one finite common route

$$I^* \longrightarrow S^* \longrightarrow R, R' \longrightarrow D^* \longrightarrow T, T'$$

whose rows are all displayed in BHist *and named by the two local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}$ *surfaces. The common route exports no quotient stream, selected limit, countable choice, trichotomy, host real equality, or Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeCommonRefinement`

Proof. Inspect the carrier rows of E and E'. The two accepted packets expose only their finite stream windows, regular rational readbacks, dyadic tolerance rows, tail ledgers, reindexing routes, componentwise transports, replay rows, provenance rows, and local naming rows.

Use the displayed Cont replay to compose the two reindexing routes over the common precision request. Since I and I' are transported through the same hsame route, their comparison is a finite reindexing comparison rather than a choice of a completed stream.

Take S^* to be the common displayed tail window reached by that composed route, and take D^* to be the displayed dyadic tolerance row read after the shared window has been opened. Transport both regular readbacks through the shared hsame rows, so R and R' are read only as rows over S^*.

Finally repack the data as the finite route

$$I^* \longrightarrow S^* \longrightarrow R, R' \longrightarrow D^* \longrightarrow T, T'.$$

Both tail ledgers are consumed before either $\mathsf{Real}^{\uparrow}$ seal boundary is inspected. Because the repacked object uses only carrier coordinates already listed in Definition 1659.1, it cannot expose quotient streams, selected limits, countable-choice selectors, trichotomy data, host real equality, or a Real-completeness principle. □

Theorem 1659.5 (DyadicCauchyTailEnvelope window handoff)**.** *Every accepted* DyadicCauchyTailEnvelope$^{\uparrow}$ *packet* $E = (S, R, D, T, I, H, C, P, N)$ *hands a precision request to any* Real$^{\uparrow}$ *or completion-facing consumer through the ordered route*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T.$$

The row I *is the* CauchyReindexing$^{\uparrow}$ *handoff,* S *is the opened* StreamName$^{\uparrow}$ *window,* R *is the* RegSeqRat$^{\uparrow}$ *readback on that window,* D *is the* DyadicRatCore$^{\uparrow}$ *tolerance row, and* T *is the displayed tail-envelope ledger consumed before the* Real$^{\uparrow}$ *seal is read.*

Proof. Project the carrier of Definition 1659.1. The precision request can reach a tail-envelope consumer only through the displayed rows I, S, R, D, T and the structural rows H, C, P, N.

Apply Definition 1659.3. It orders the Real-facing read from the reindexing row to the stream window, regular rational readback, dyadic tolerance, and tail ledger.

Apply Definition 1659.4 for paired consumers. The same ordering survives common refinement, so the window handoff remains a finite route through CauchyReindexing$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeWindowHandoff`

Theorem 1659.6 (DyadicCauchyTailEnvelope nonescape)**.** *Any* Real$^{\uparrow}$ *or* CauchyLimitSeal$^{\uparrow}$ *consumer of an accepted* DyadicCauchyTailEnvelope$^{\uparrow}$ *packet receives no quotient stream, selected limit, countable choice, trichotomy, host real equality, or Real completeness row. It receives only the displayed* CauchyReindexing$^{\uparrow}$ *route,* StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance, tail-envelope ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows.*

Proof. Project the accepted carrier. The packet has coordinates only for $S, R, D, T, I, H, C, P, N$, and none of the excluded objects is a coordinate of Definition 1659.1.

Apply Definition 1659.3. A Real-facing consumer receives the finite route through the reindexing row, stream window, regular readback, dyadic tolerance, and tail ledger, with no additional row inserted before the seal.

For paired reads, apply Definition 1659.4. The common route still uses only displayed carrier coordinates, so no quotient stream, selected limit, countable-choice schedule, trichotomy datum, host real equality, or Real-completeness row can escape to a Real$^{\uparrow}$ or CauchyLimitSeal$^{\uparrow}$ consumer. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeNonescape`

Theorem 1659.7 (DyadicCauchyTailEnvelope regular-seal handoff)**.** *Every accepted* DyadicCauchyTailEnvelope$^{\uparrow}$ *packet* $E = (S, R, D, T, I, H, C, P, N)$ *reaches any* Real$^{\uparrow}$ *or* CauchyLimitSeal$^{\uparrow}$ *consumer only through the ordered finite route*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$$

before the seal row is read. The route presents the reindexing request, finite stream window, regular rational readback, dyadic tolerance row, and tail-envelope ledger through the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows, and it exposes no quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 1659.1. The accepted packet exposes only $S, R, D, T, I, H, C, P, N$, so a Real or Completion consumer has no route except the displayed envelope rows.

Apply Definition 1659.3. It orders the consumer-facing read as the finite path from the precision request through I, then S, then R, then D, and finally T before any Real-facing seal is consumed.

For paired tail reads, use Definition 1659.4. The common refinement supplies a shared finite route for the two reads, so neither branch can replace the displayed stream window, regular readback, dyadic budget, or tail ledger by a quotient stream, selected limit, countable-choice selector, trichotomy datum, host real equality, or ambient completeness proof. □

Theorem 1659.8 (DyadicCauchyTailEnvelope budget exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet* $E = (S, R, D, T, I, H, C, P, N)$ *must consume all budget rows* $I, S, R, D, T, H, C, P, N$*. There is no partial route that reads the Real seal after only* S, R, D *or only* I, S, R*; the seal is available only after the reindexing row, stream window, regular rational readback, dyadic budget, tail ledger, transport, replay, provenance, and local naming rows have all been displayed.*

Proof. Project the carrier of Definition 1659.1. Its budget surface is exactly $I, S, R, D, T, H, C, P, N$, with I routing the precision request, S opening the finite window, R reading regular rational data, D naming the dyadic tolerance, and T recording the tail containment ledger.

Apply the RegSeqRat Real route, window handoff, common refinement, and regular-seal handoff. These results force every consumer path to pass through $I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$ before any Real-facing or CauchyLimitSeal-facing boundary is read.

Finally use nonescape and the structural rows H, C, P, N. They transport, replay, source, and locally name the same finite route, so a consumer that stops at S, R, D or at I, S, R has not exhausted the carrier coordinates and has not reached the seal. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeBudgetExhaustion`

Theorem 1659.9 (DyadicCauchyTailEnvelope obligation completeness)**.** *For every accepted* DyadicCauchyTailEnve *packet* $E = (S, R, D, T, I, H, C, P, N)$*, the displayed rows*

$$I,\ S,\ R,\ D,\ T,\ H,\ C,\ P,\ N$$

exhaust carrier admission, window admission, tolerance admission, reindexing admission, tail containment, transport and replay stability, provenance, local naming, and nonescape. Thus every $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of the envelope reads the same finite obligation surface before a seal row is available, and no quotient stream, selected limit, countable-choice schedule, trichotomy row, host real equality, or ambient Real-completeness row remains outside the listed packet.*

Proof. Project the carrier of Definition 1659.1. It lists exactly the stream window, regular rational readback, dyadic tolerance, tail ledger, reindexing route, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations of Definition 1659.2. They assign those rows to carrier admission, window admission, tolerance admission, reindexing admission, tail containment, transport and replay stability, and ledger nonescape.

Use the RegSeqRat Real route and common refinement theorems, Definition 1659.3 and Definition 1659.4. They force the consumer path and paired refinements through the same ordered route $I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$.

Finally apply nonescape and budget exhaustion, Definition 1659.6 and Definition 1659.8. Nonescape excludes every row outside the displayed packet, while budget exhaustion requires the structural

rows H, C, P, N as well as I, S, R, D, T before any Real-facing or CauchyLimitSeal-facing boundary is read. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCauchyTailEnvelopeObligationCompleteness`

Theorem 1659.10 (DyadicCauchyTailEnvelope scoped dependency package)**.** *For every accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet* $E = (S, R, D, T, I, H, C, P, N)$*, the obligation surface displayed in this chapter closes exactly over*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$.

Every $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer must pass through those dependencies, in the order*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T,$$

before it reads the seal. The seal is therefore scoped by the listed dependencies and by no quotient stream, selected limit, countable-choice schedule, trichotomy row, host real equality, or ambient Real-completeness row.

Proof. Start with carrier projection and the NameCert obligations of Definition 1659.1 and Definition 1659.2. They expose exactly the stream window, regular rational readback, dyadic tolerance, tail ledger, reindexing route, transport, replay, provenance, and local naming rows.

Apply the RegSeqRat Real route, common refinement, and window handoff of Definition 1659.3, Definition 1659.4, and Definition 1659.5. These results force each consumer read to pass from the reindexing row through the finite stream window, regular rational row, dyadic budget, and tail ledger before any Real-facing boundary is available.

Finally use nonescape and the regular-seal handoff, Definition 1659.6 and Definition 1659.7. They exclude every row outside the listed dependency package, so a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer can inspect the seal only after the displayed BEDC dependencies have already been read. □

Theorem 1659.11 (DyadicCauchyTailEnvelope obligation scope)**.** *Every accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *tail-containment read is scoped by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row before any Real-facing consumer can inspect the tail. Thus the only exported obligation route is the finite path*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T,$$

with structural rows H, C, P, N *attached. The route excludes quotient streams, selected limits, countable choice, trichotomy rows, host real equality, and ambient Real completeness.*

Proof. Start from the common refinement and window handoff, Definition 1659.4 and Definition 1659.5. They force each tail-containment read to open a finite $\mathsf{StreamName}^{\uparrow}$ window and read the $\mathsf{RegSeqRat}^{\uparrow}$ row before the dyadic budget can be consumed.

Next apply the regular-seal handoff of Definition 1659.7. It keeps the $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary behind the ordered route $I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$, so the seal is not available before the tolerance row and tail ledger have both been displayed.

Finally use nonescape and the scoped dependency package, Definition 1659.6 and Definition 1659.10. These results attach the hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows to the same route and exclude quotient streams, selected limits, countable choice, trichotomy rows, host real equality, and ambient Real completeness from the obligation scope. □

Theorem 1659.12 (DyadicCauchyTailEnvelope obligation closure)**.** *Every accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet* $E = (S, R, D, T, I, H, C, P, N)$ *carries all rows required for obligation closure: the* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{CauchyReindexing}^{\uparrow}$ *route,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise transport, displayed replay,* Pkg *provenance, local* $\mathsf{NameCert}$ *row, nonescape from excluded principles, and budget exhaustion before any Real-facing or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer can inspect the seal.*

Proof. Carrier projection and the NameCert obligations, Definition 1659.1 and Definition 1659.2, list the finite window, readback, tolerance, reindexing, transport, replay, provenance, and local naming rows.

Obligation completeness and the scoped dependency package, Definition 1659.9 and Definition 1659.10, identify those rows as the whole dependency surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Finally apply nonescape and budget exhaustion, Definition 1659.6 and Definition 1659.8. Nonescape excludes quotient streams, selected limits, countable choice, trichotomy rows, host real equality, and ambient Real completeness, while budget exhaustion forces every consumer to display $I, S, R, D, T, H, C, P, N$ before any seal read. These clauses give precisely the obligation-closure surface for the accepted envelope. □

Theorem 1659.13 (DyadicCauchyTailEnvelope obligation route)**.** *Every accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet exposes its obligation route in the order*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad T,\quad \mathsf{CauchyReindexing}^{\uparrow},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Equivalently, a consumer first opens the finite stream window, reads the regular rational row, displays the dyadic tolerance, records the tail-envelope ledger, fixes the common reindexing route, and only then consumes transport, replay, provenance, and local naming. The route contains no quotient stream, selected limit, countable-choice schedule, trichotomy row, host real equality, or ambient Real-completeness row.

Proof. Project the carrier and the NameCert obligations. The carrier exposes only $S, R, D, T, I, H, C, P, N$, and the obligation list assigns these rows to window admission, tolerance admission, reindexing admission, tail containment, transport, replay, provenance, and local naming.

Use common refinement and nonescape. Common refinement keeps paired tail reads on one displayed finite route, while nonescape excludes every row outside the carrier inventory.

Finally apply budget exhaustion and the scoped dependency package. They force the structural rows H, C, P, N to be consumed with I, S, R, D, T, so the displayed route exhausts the obligation surface before any Real-facing seal can be read. □

Theorem 1659.14 (DyadicCauchyTailEnvelope public boundary)**.** *The public reader of an accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet receives exactly the finite path*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$$

with structural rows H, C, P, N*, before any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary is available. Thus the public surface is the reindexing route, finite stream window, regular rational readback, dyadic tolerance, tail ledger, transport, replay, provenance, and local naming, and it excludes quotient streams, selected limits, countable-choice schedules, trichotomy rows, host real equality, and ambient Real completeness.*

Proof. Begin with the RegSeqRat Real route and common refinement, Definition 1659.3 and Definition 1659.4. They order each public read through the reindexing row, finite window, and regular rational readback before the dyadic budget is consumed.

Next apply nonescape and budget exhaustion, Definition 1659.6 and Definition 1659.8. These results keep every visible read inside the rows I, S, R, D, T and attach no extra quotient, selected-limit, choice, trichotomy, host-equality, or completeness coordinate.

Finally use Definition 1659.13. It attaches H, C, P, N to the same route and exhausts the public obligation surface before a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer can inspect a terminal seal. □

Theorem 1659.15 (DyadicCauchyTailEnvelope radius stability)**.** *Let $E = (S, R, D, T, I, H, C, P, N)$ be an accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet. If a displayed tail refinement replaces the stream window S by a later finite window along the same reindexing route I, then the dyadic radius row D remains the controlling tolerance for the refined tail ledger. The refined read still factors through*

$$I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$$

with structural rows H, C, P, N, and no new radius, quotient stream, selected limit, or Real-completeness row is introduced.

Proof. Start with the common refinement theorem. It supplies a single finite tail window and a single dyadic tolerance row for paired reads serving the same displayed precision request.

Apply the window handoff and regular-seal handoff. They keep every refined consumer path behind the ordered route $I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$, so the tolerance row is read before the tail ledger and remains the only dyadic budget available.

Use nonescape and budget exhaustion. Since the carrier has no coordinate for an additional radius row or completed stream object, displayed tail refinement preserves the original dyadic radius control. □

Theorem 1659.16 (DyadicCauchyTailEnvelope Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet reads the terminal seal only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *row and the dyadic tail rows have been displayed. In carrier notation, the consumer path must pass through R, D, T after the finite window and reindexing rows, then through H, C, P, N, before a Real-facing seal is available.*

Proof. Read the RegSeqRat Real route. It orders the consumer path from the reindexing row to the stream window, regular rational readback, dyadic tolerance, and tail ledger.

Apply the regular-seal handoff. The seal is reached only after the route $I \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow T$ has been displayed.

Finally use obligation completeness and the scoped dependency package. They attach transport, replay, provenance, and local naming to the same route, so a $\mathsf{Real}^{\uparrow}$ consumer cannot inspect the terminal seal before the RegSeqRat and dyadic tail rows have already been read. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a tail-envelope ledger, a $\mathsf{CauchyReindexing}^{\uparrow}$ route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1659.1, Definition 1659.2, Definition 1659.3, Definition 1659.4, Definition 1659.5, Definition 1659.6, Definition 1659.7, Definition 1659.8, Definition 1659.9, Definition 1659.10, Definition 1659.11, Definition 1659.13, Definition 1659.15, and Definition 1659.16 bind the cauchy-tail envelope obligation surface to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert through carrier admission, window admission, tolerance admission, reindexing admission, tail containment, common-tail refinement, RegSeqRat-to-Real handoff,

window handoff, transport and replay stability, nonescape, obligation completeness, regular-seal handoff, obligation route, radius stability, Real-seal handoff, and obligation scope.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, countable choice, trichotomy, host real equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: The next grade requires Lean verification and bridge checking for the displayed carrier admission, window admission, tolerance admission, reindexing admission, tail containment, common-tail refinement, RegSeqRat-to-Real handoff, window handoff, transport and replay stability, nonescape, and regular-seal handoff rows.

Theorem 1659.17 (Dyadic core sibling route)**.** *Every dyadic hub route serving a* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *packet factors through the displayed sibling chain in the following order: chapter 1659, chapter 291, chapter 126, chapter 301, and chapter 38. The exported surface is only the finite tail-envelope read, dyadic tolerance ledger, finite stream window, regular rational readback, and terminal real-name seal, with transport, replay, provenance, and local naming rows attached. It exports no quotient stream, selected host limit, trichotomy, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with the hub input chapter 1659. Its carrier exposes the finite stream window, regular rational readback, dyadic tolerance row, tail-envelope ledger, reindexing route, transport, replay, provenance, and local naming rows of an accepted $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ packet.

Next read the sibling sources named by that packet. The $\mathsf{DyadicRatCore}^{\uparrow}$ chapter supplies the tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ supplies the finite window, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies the terminal seal consumed by downstream Real and Completion readers.

The route is therefore exhausted by the five displayed chapter surfaces and the structural rows already present in the packet. Since neither the hub nor the tail-envelope carrier contains a quotient stream, selected host limit, trichotomy row, host real equality row, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, none of those objects can be exported by the dyadic hub route. □

Lean4 ✓ `BEDC.Derived.DyadicUp.DyadicCoreSiblingRoute`

Theorem 1659.18 (Dyadic Cauchy real-route sibling dependency)**.** *Every* $\mathsf{Dyadic}^{\uparrow}$ *Cauchy interface read consumed by Real and Completion routes factors through the dyadic-tail envelope before it reaches the sibling rows named by chapter 301, chapter 38, and chapter 291. The route exposes only the finite tail-envelope packet, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming rows.*

Proof. Start with a dyadic Cauchy read at the hub. The hub enters the route through the dyadic-tail envelope, so the first public packet is the finite tail envelope rather than a host Cauchy stream or a selected limit.

The envelope then reads the dyadic tolerance ledger from chapter 291. That ledger supplies the rational tolerance rows used by the regular readback without exporting quotient stream equality or ambient completeness.

Next the route passes through chapter 301 and then chapter 38. These sibling rows provide the regular rational schedule and terminal real-name seal consumed by downstream Real and Completion readers.

Transport, replay, provenance, and naming preserve exactly that ordered route. Since no coordinate of the carrier stores host real equality, a selected completed limit, trichotomy, or an external completion operator, none of those objects can be read from the dyadic Cauchy interface. □

Theorem 1659.19 (DyadicUp obligation-closure scope)**.** *Every accepted* $\mathsf{Dyadic}^{\uparrow}$ *obligation read is exhausted by the dyadic core ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *route,* $\mathsf{DyadicRatCore}^{\uparrow}$ *sibling route, Real-route sibling dependency, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows. It exports no selected binary expansion, quotient stream, trichotomy, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1658.2. The local NameCert surface already restricts the dyadic packet to the dyadic core, stream window, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Use Definition 1659.12, Definition 1659.17, and Definition 1659.18. These sibling routes add the Cauchy tail-envelope obligation, DyadicRatCore dependency, and Real-facing handoff surface without introducing a second carrier coordinate.

The remaining rows are exactly componentwise hsame, displayed Cont, Pkg, and local NameCert data. Since none of the cited routes contains selected binary expansions, quotient streams, trichotomy, countable choice, host equality, or ambient completeness, the accepted obligation read is closed at the displayed obligation surface. □

Theorem 1659.20 (DyadicUp public consumer boundary)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *or Completion-facing* $\mathsf{Dyadic}^{\uparrow}$ *consumer must read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Q*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, the* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *sibling route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *sibling route, the Real-route sibling dependency, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows before exporting a dyadic public name. The boundary exports no selected binary expansion, quotient stream, trichotomy, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the real-seal factorization of Definition 1658.5. A Real-facing consumer cannot reach the terminal row E without first reading the dyadic core row Q, the finite window S, and the regular rational readback row R.

Next apply the StreamName-RegSeqRat route of Definition 1658.6. It identifies the visible route from Q through S and R as the only finite real-name path available to the consumer.

Use the terminal Real-seal boundary of Definition 1658.12. This pins every $\mathsf{Real}^{\uparrow}$ or Completion-facing read to the rows Q, S, R, E, H, C, P, N and excludes the selected binary, quotient, choice, trichotomy, host-equality, and ambient-completeness data.

Finally apply Definition 1659.19. The Cauchy tail-envelope route, DyadicRatCore sibling route, Real-route sibling dependency, componentwise hsame, displayed Cont, Pkg, and local NameCert rows are already part of the closed obligation surface, so the public consumer receives exactly that displayed package before it may export a dyadic public name. □

Closure status for $\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Dyadic}^{\uparrow}$ packet is generated from a DyadicRatCore ledger, a finite StreamName window, a RegSeqRat readback row, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1658.1, Definition 1658.2, Definition 1658.5, and Definition 1659.19 exhaust the finite dyadic obligation surface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dyadic}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.DyadicUp.DyadicNameCertObligations`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected binary expansions, trichotomy, host real equality, ambient Real completeness, or a completed bridge.

Upgrade path: Scoped closure requires a public consumer boundary over the same dyadic core, stream window, regular readback, Real seal, sibling routes, transport, replay, provenance, and local naming rows.

The $\mathsf{Hyperspace}^{\uparrow}$ packet reads compact-subset and Hausdorff-distance requests through chapter 129 before any Vietoris or finite-net consumer can inspect the local hyperspace rows.

Every $\mathsf{Hyperspace}^{\uparrow}$ Hausdorff-distance or Vietoris consumer first reads the compact-metric finite-net source of chapter 129 and the metric witness route before inspecting the hyperspace rows.

Hausdorff-distance and Vietoris consumers read $\mathsf{Hyperspace}^{\uparrow}$ through chapter 2086 and chapter 5944 before completion-facing routes consume compact-subset data.

Chapter 1660

A Concrete Naming Certificate for $\mathsf{Hyperspace}^{\uparrow}$

Following Vietoris and Kelley on compact hyperspaces, the $\mathsf{Hyperspace}^{\uparrow}$ packet names the finite BEDC surface for nonempty compact subsets of a displayed compact metric source. It sits over the metric source of chapter 57, the compact finite-net row of chapter 129, the total-boundedness schedule of chapter 127, the completeness boundary of chapter 128, the diameter ledger of chapter 1503, the directed convergence row of chapter 1667, and the uniform Cauchy-net route of chapter 1657. The packet is a finite Hausdorff-distance ledger for compact-subset presentations; it is not a host powerset, not a quotient compactum, not a selected limit object, not open-cover compactness, and not a choice-selected representative.

Definition 1660.1 (Hyperspace carrier)**.** *A* $\mathsf{Hyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$$

with the following displayed rows:

1. *X is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, including its* $\mathsf{Met}^{\uparrow}$ *distance witnesses, finite-net schedules, total-boundedness row, and completeness boundary.*
2. *K_0 and K_1 are compact-subset presentations over X, each given by finite net schedules whose centers and radii are readable only through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *rows.*
3. *N_0 and N_1 are the requested net-resolution ledgers for K_0 and K_1, recording the finite witness lists used to inspect each subset presentation.*
4. *D_0 is the directed Hausdorff-distance coverage ledger from K_0 to K_1: every displayed center of K_0 is matched to a displayed K_1 center within the current tolerance after routing through the source metric row.*
5. *D_1 is the directed Hausdorff-distance coverage ledger from K_1 to K_0 with the same source row, tolerance budget, and finite-read discipline.*
6. *R is the dyadic and* $\mathsf{Real}^{\uparrow}$ *tolerance readback for the two directed ledgers, including the comparison cells that package the maximum of D_0 and D_1 as the finite Hausdorff-distance request.*
7. *H_s records componentwise* hsame *transport for the compact source, the two subset presentations, the two net ledgers, the two directed coverage ledgers, the tolerance readback, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a compact-subset request through $X, K_0, K_1, N_0, N_1, D_0, D_1, R$ and then to the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CauchyUniformNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *M is the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

The carrier has no coordinate for host powersets, quotient compacta, selected limits, open-cover compactness, or choice-selected representatives.

Lean4 (definition) `BEDC.Derived.HyperspaceUp.HyperspaceCarrier`

Theorem 1660.2 (Hausdorff-distance ledger stability)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$, classifier transport preserves the two-sided finite Hausdorff-distance ledger. More precisely, any componentwise* hsame *transport of the displayed source, subset presentations, net ledgers, directed coverage ledgers, and tolerance readback carries the finite route through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, *and* $\mathsf{CauchyUniformNet}^{\uparrow}$ *to a carrier with the same directed K_0-to-K_1 and K_1-to-K_0 coverage obligations.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace hausdorff distance stability`

Proof. Project the accepted carrier of Definition 1660.1. The source row X fixes the compact metric surface, while K_0, K_1, N_0, N_1 identify the finite subset-net data that any Hausdorff-distance read can inspect.

The two directed ledgers are then transported componentwise. The row H_s compares the source, subset presentations, net schedules, directed coverage rows, and tolerance readback, and the replay row C repeats the same route after transport.

The compact-source part of the route remains inside $\mathsf{CompactMetric}^{\uparrow}$. Diameter and tolerance comparisons are read through $\mathsf{MetricDiameter}^{\uparrow}$ and R, and the finite convergence and uniform-net inspections are routed through $\mathsf{NetConvergence}^{\uparrow}$ and $\mathsf{CauchyUniformNet}^{\uparrow}$.

Thus each transported center match in D_0 and D_1 still cites the same kind of displayed source-distance witness and the same finite tolerance readback. Since the packet contains no host powerset, quotient compactum, selected limit, open-cover compactness, or choice-selected representative, no external coordinate can alter the two-sided ledger. □

Theorem 1660.3 (Hyperspace NameCert obligations)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *compact-source admission for the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source row X and its* $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *and* $\mathsf{CompleteMetric}^{\uparrow}$ *support;*

2. *finite subset-net admission for K_0, K_1, N_0, N_1, requiring every subset presentation and net resolution to be read through the displayed compact-source schedules;*

3. *bidirectional distance coverage, requiring both directed ledgers D_0 and D_1 to be present before the Hausdorff-distance tolerance readback R is public;*

4. *classifier and transport stability through H_s and C, preserving the source, subset-net, coverage, and readback rows under componentwise* hsame *and displayed replay;*

5. *provenance and name exhaustion through P and M, excluding host powersets, quotient compacta, selected limits, open-cover compactness, and choice-selected representatives.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1660.1. The packet exposes a compact metric source X and only the displayed finite rows attached to X.

Finite subset-net admission follows from the same projection. The rows K_0, K_1, N_0, N_1 are the only subset-presentation and resolution coordinates, so every compact-subset inspection passes through them.

Bidirectional coverage is exactly the pair D_0, D_1. A Hausdorff-distance read is not public until both directed ledgers have been consumed and the dyadic or $\mathsf{Real}^{\uparrow}$ tolerance readback R has compared them.

Transport is componentwise through H_s and replayed through C. These rows preserve the compact source, subset nets, directed coverage witnesses, and tolerance readbacks without adding a second classifier surface.

Finally, P and M name precisely the displayed packet. Because the carrier contains no row for host powersets, quotient compacta, selected limits, open-cover compactness, or choice-selected representatives, the five listed rows exhaust the local naming obligations. □

Theorem 1660.4 (Hyperspace Hausdorff-obligation surface)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, any public Hausdorff-distance obligation must expose compact-source admission through* X*, finite subset-net schedules through* K_0, K_1, N_0, N_1*, both directed ledgers* D_0, D_1*, tolerance readback through* R*, componentwise* hsame *transport through* H_s*, displayed* Cont *replay through* C*, provenance through* P*, and the local name through* M *before a consumer reads a symmetric distance.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHausdorffObligationSurface`

Proof. Start with the carrier projection in Definition 1660.1. It lists exactly the compact source, the two subset presentations, the two finite net schedules, the directed cover rows, the tolerance readback, transport, replay, provenance, and local naming rows.

Use Definition 1660.3. Its carrier-admission, finite subset-net, bidirectional coverage, transport-stability, and provenance clauses order the public obligation surface before any Hausdorff-distance consumer can read the symmetric value.

Now apply Definition 1660.6 and Definition 1660.7. They force each displayed hit through the compact source and finite schedules, and they require both directed ledgers D_0 and D_1 before the symmetric readback R is public.

The excluded objects are absent from the carrier. Host powersets, quotient compacta, selected limits, open-cover compactness, and choice-selected representatives therefore cannot supply a missing Hausdorff obligation or replace any of $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$. □

Theorem 1660.5 (Hyperspace carrier obligations)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier*

$$H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M),$$

carrier projection exposes exactly compact-source admission through X*, subset-net schedules through* K_0, K_1, N_0, N_1*, directed-coverage ledgers through* D_0, D_1*, tolerance readback through* R*, componentwise transport through* H_s*, displayed replay through* C*, provenance through* P*, and local* $\mathsf{NameCert}$ *rows through* M*. No root consumer receives any carrier row outside this list.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCarrierObligations`

Proof. Project the displayed carrier of Definition 1660.1. Its coordinates are precisely $X, K_0, K_1, N_0, N_1, D_0, D_1, R,$

Use Definition 1660.3. The compact-source, finite subset-net, bidirectional coverage, transport, replay, provenance, and local-name clauses account for each coordinate in the carrier.

The tolerance readback is R, and the directed-coverage ledgers are D_0, D_1. Since the excluded host powerset, quotient compactum, selected-limit, open-cover, and choice-selected coordinates are absent, no root consumer can read beyond the listed rows. □

Theorem 1660.6 (Hyperspace finite-net hit)**.** *Every directed Hausdorff hit exposed by an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must first pass through the* $\mathsf{CompactMetric}^{\uparrow}$ *source row* X *and the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules carried by* K_0, K_1, N_0, N_1 *before the tolerance readback row* R *can be consumed. Thus a hit in* D_0 *or* D_1 *is a scheduled finite-net comparison over the displayed compact source, not a host point-selection event.*

Proof. Read Definition 1660.5. A directed hit is public only inside D_0 or D_1, and those rows occur after the compact-source and subset-net schedules have been exposed.

The schedules K_0, K_1, N_0, N_1 are attached to the same source row X. They carry the finite centers and resolution ledgers that a Hausdorff comparison may inspect.

Only after those rows are present can R compare the directed ledgers at the requested tolerance. Therefore every hit is routed through $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{TotallyBounded}^{\uparrow}$ finite-net data before tolerance readback, with no selected host point added to the carrier. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteNetHit`

Theorem 1660.7 (Hyperspace finite hit directed cover)**.** *Every finite Hausdorff hit accepted by a* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must expose both directed cover rows* D_0 *and* D_1 *before any symmetric Hausdorff-distance read is public. A consumer may read a hit from* K_0 *toward* K_1 *only as part of* D_0*, and a hit from* K_1 *toward* K_0 *only as part of* D_1*; neither direction can be replaced by a host compact-subset choice, quotient compactum, selected nearest point, or one-sided coverage oracle.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteHitDirectedCover`

Proof. Project the carrier of Definition 1660.1. The only directed coverage coordinates are D_0 and D_1, and both are listed before the tolerance readback row R.

Apply Definition 1660.6. Each displayed hit is already a finite-net comparison over the compact source and its total-bounded schedules.

Use Definition 1660.3. The bidirectional distance clause requires both directed ledgers before the public Hausdorff read is admitted, so no one-sided host selection can stand in for the missing direction. □

Theorem 1660.8 (Hyperspace tolerance readback exhaustion)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, the tolerance visible to a finite Hausdorff-distance consumer is exhausted by the readback row* R*. Once the compact source, subset-net schedules, and directed ledgers* D_0, D_1 *have been displayed, no downstream consumer may read an additional tolerance comparison from* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{MetricDiameter}^{\uparrow}$*,* $\mathsf{NetConvergence}^{\uparrow}$*,* $\mathsf{CauchyUniformNet}^{\uparrow}$*, a selected limit, or a host real completeness coordinate.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceToleranceReadbackExhaustion`

Proof. Begin with Definition 1660.7. The symmetric Hausdorff read is not public until both directed cover rows D_0 and D_1 have been shown.

The carrier definition names R as the dyadic and $\mathsf{Real}^{\uparrow}$ tolerance readback for those two directed ledgers. Thus every comparison between the two directions passes through the same displayed row.

Finally apply Definition 1660.10. Completeness, diameter, convergence, and uniform-net rows support the finite route, but they do not export selected limits or an ambient tolerance object outside R. □

Theorem 1660.9 (Hyperspace compact source scope)**.** *Every compact-subset read of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet is scoped to the displayed rows*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CauchyUniformN}$

The read may inspect compact source admission, finite-net schedules, completion boundary, diameter or tolerance comparisons, net-convergence replay, and uniform Cauchy-net replay only through those rows and the carrier coordinates $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$*. It exports no host powerset of compact subsets, open-cover compactness coordinate, quotient compactum, selected limit, or choice-selected representative.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace compact source scope`

Proof. Read the source row X in Definition 1660.1. It already contains the compact metric source, total-bounded finite schedules, and complete metric boundary available to the packet.

Use Definition 1660.11. The public Hausdorff route passes through the diameter, directed convergence, and uniform Cauchy-net rows only as displayed support for D_0, D_1, R and replay C.

Apply Definition 1660.8. Since tolerance is exhausted by R and every directed hit is finite, the listed compact-source rows are the whole compact-subset scope. □

Theorem 1660.10 (Hyperspace CompleteMetric nonescape)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier, the* $\mathsf{CompleteMetric}^{\uparrow}$ *support carried by the source row* X *supplies only the displayed completion boundary needed by the finite compact-metric route. It cannot export selected limits, quotient compacta, open-cover compactness, choice-selected representatives, or an ambient hyperspace completion outside*

$$X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M.$$

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace complete metric nonescape`

Proof. Begin with Definition 1660.11. Completeness enters the route through the compact metric source row X before subset-net schedules, directed ledgers, and tolerance readback are public.

Apply Definition 1660.6. Any Hausdorff hit must pass through the finite-net schedules before it reaches R, so completeness cannot be read as an independent selected limit for a compact subset.

Finally use Definition 1660.5. The only remaining rows are transport, replay, provenance, and local naming. None is a quotient compactum, open-cover compactness proof, choice-selected representative, or ambient hyperspace completion, so the CompleteMetric support cannot escape the displayed boundary. □

Theorem 1660.11 (Hyperspace compact Hausdorff-distance route)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, the public Hausdorff-distance route is exactly the finite route through the* $\mathsf{CompactMetric}^{\uparrow}$ *source admission row* X*, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules in* K_0, K_1, N_0, N_1*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit boundary carried by* X*, the* $\mathsf{MetricDiameter}^{\uparrow}$ *tolerance readback in* R*, and the* $\mathsf{NetConvergence}^{\uparrow}$ *and* $\mathsf{CauchyUniformNet}^{\uparrow}$ *replay named by the directed ledgers* D_0, D_1 *and the replay row* C*. No downstream compact-subset consumer receives a host powerset, open-cover compactness coordinate, quotient compactum, or selected limit object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompactHausdorffDistanceRoute`

Proof. Project the carrier in Definition 1660.1. The coordinate X is the only compact metric source row, and it already contains the displayed metric witnesses, total-boundedness support, and completeness boundary.

The subset coordinates K_0, K_1, N_0, N_1 provide the finite net schedules. Thus every center inspected by a Hausdorff-distance request is read through the same $\mathsf{TotallyBounded}^{\uparrow}$ schedule attached to the compact source rather than through an ambient compact-subset universe.

The directed ledgers D_0 and D_1 supply the two coverage directions. The tolerance row R packages their dyadic and $\mathsf{Real}^{\uparrow}$ readback, so the distance request can only compare the two directed ledgers through the displayed $\mathsf{MetricDiameter}^{\uparrow}$ boundary.

Apply Definition 1660.2 to transport the directed coverage rows and apply Definition 1660.3 to exhaust the local naming surface. The replay row C keeps every convergence read inside the displayed $\mathsf{NetConvergence}^{\uparrow}$ and $\mathsf{CauchyUniformNet}^{\uparrow}$ route.

Finally, P and M certify that no further coordinates are public. The packet therefore exports the compact Hausdorff-distance route only through $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$. □

Theorem 1660.12 (Hyperspace finite Hausdorff carrier)**.** *Every public Hausdorff-distance read of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier is exactly the pair of directed finite ledgers* D_0, D_1 *together with the tolerance readback row* R*, over the displayed source and net rows*

$$X, K_0, K_1, N_0, N_1.$$

The read exposes no host powerset of compact subsets, quotient compactum, selected limit object, open-cover compactness coordinate, or choice-selected representative.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteHausdorffCarrier`

Proof. Project the carrier of Definition 1660.1. The compact source row X and the finite subset-net rows K_0, K_1, N_0, N_1 are the only rows that can be inspected before a Hausdorff-distance request.

Apply Definition 1660.11. The public distance route consumes both directed ledgers D_0, D_1 and then reads R as the dyadic and $\mathsf{Real}^{\uparrow}$ tolerance comparison.

Use Definition 1660.3 to exhaust the local naming surface. Since the forbidden host powerset, quotient, selected-limit, open-cover, and choice-selected coordinates are absent from the carrier, the finite directed-ledger read is the whole public Hausdorff surface. □

Theorem 1660.13 (Hyperspace complete-metric handoff)**.** *Completeness in an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet enters only through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source row* X *and its* $\mathsf{CompleteMetric}^{\uparrow}$ *support. It cannot be replaced by host compactness, selected limit data, open-cover compactness, or an ambient compact-subset universe outside* $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$.

Proof. Read the source coordinate X in Definition 1660.1. It is the only row that carries the compact metric source together with the displayed metric witnesses, finite-net schedules, total-boundedness row, and completeness boundary.

Apply Definition 1660.12. The subset and distance rows use X through finite net ledgers and directed coverage rows, so a Hausdorff read never asks for a host compact-subset universe or a selected limit.

Finally apply Definition 1660.2. Transport preserves the same source row and directed ledgers, while H_s, C, P, M add only structural comparison, replay, provenance, and local naming. Thus completeness is read only through the displayed CompactMetric and CompleteMetric source support. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompleteMetricHandoff`

Definition 1660.14 (Hyperspace finite-window carrier)**.** *The finite-window surface of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier is the same displayed packet*

$$H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$$

read with X *as the* $\mathsf{CompactMetric}^{\uparrow}$ *source,* K_0, K_1, N_0, N_1 *as finite subset-net schedules over* X*,* D_0, D_1 *as the two directed Hausdorff ledgers,* R *as the dyadic and* $\mathsf{Real}^{\uparrow}$ *readback row,* H_s *as componentwise* hsame *transport,* C *as displayed* Cont *replay,* P *as* Pkg *provenance, and* M *as the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. A finite-window read has no coordinate for a host hyperspace, selected compact subset, open-cover compactness proof, quotient compactum, or ambient completeness witness outside* X*.*

Lean4 (definition) `BEDC.Derived.HyperspaceUp.HyperspaceFiniteWindowCarrier`

Theorem 1660.15 (Hyperspace obligation surface)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, the root-unblock obligation surface consists exactly of the* $\mathsf{CompactMetric}^{\uparrow}$ *source admission in* X*, the finite subset-net schedules* K_0, K_1, N_0, N_1*, the two directed Hausdorff ledgers* D_0, D_1*, the readback row* R*, componentwise* hsame *transport through* H_s*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local* NameCert *rows through* M*. Every downstream compact-metric or Cauchy-uniform-net consumer must consume those rows before any Hausdorff-distance claim is public.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace namecert obligation surface`

Proof. Start from Definition 1660.14. It names the same twelve coordinates as the carrier of Definition 1660.1, but marks the finite-window roles needed by root consumers.

Apply Definition 1660.3. The carrier, subset-net, bidirectional coverage, transport, replay, provenance, and local-name clauses are already exhaustive for the local certificate.

The root-unblock surface is therefore obtained by reading the same clauses in consumer order. CompactMetric admission comes from X, finite subset-net schedules from K_0, K_1, N_0, N_1, directed Hausdorff coverage from D_0, D_1, and readback from R.

No further row can be inserted because H_s, C, P, M only transport, replay, source, and name the displayed packet. The forbidden host hyperspace, selected compact subset, quotient compactum, open-cover compactness proof, and ambient completeness witness are absent from the carrier. □

Theorem 1660.16 (Hyperspace CompactMetric distance lift)**.** *Let* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ *be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Any compact-metric distance consumer of* H *reads a Hausdorff-distance request only by lifting the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source row* X *through the finite subset-net schedules* K_0, K_1, N_0, N_1*, the two directed Hausdorff ledgers* D_0, D_1*, and the tolerance readback row* R*. The lift is stable under componentwise* hsame *through* H_s*, replayed by the displayed* Cont *row* C*, and named by the* Pkg *and local* NameCert *rows* P, M*.*

Proof. Project the finite-window carrier from Definition 1660.14. The only compact-metric source row is X, so every distance read starts there.

Use Definition 1660.11. It routes the Hausdorff request through the subset-net schedules, both directed coverage ledgers, and the tolerance readback row before any public distance value is available.

Finally apply Definition 1660.2. Componentwise hsame transport through H_s and displayed replay through C preserve that route, while P, M name it without adding a host compact-subset universe. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace compactmetric distance lift`

Theorem 1660.17 (Hyperspace totally bounded net lift)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every* $\mathsf{TotallyBounded}^{\uparrow}$ *net request exposed by the hyperspace packet is read through the finite subset-net schedules K_0, K_1, N_0, N_1 over the same* $\mathsf{CompactMetric}^{\uparrow}$ *source row X. The request may use D_0, D_1 and R to compare directed Hausdorff ledgers, but it exports no unscheduled net, selected center family, host powerset, or quotient compactum.*

Proof. Read the root-unblock obligation surface of Definition 1660.15. The finite subset-net schedules are named before any directed Hausdorff ledger can be public.

The total-boundedness source is part of X and is inspected through K_0, K_1, N_0, N_1. Thus a net request cannot detach a center family from the compact source row or bypass the finite schedules.

The directed ledgers D_0, D_1 and readback R compare only the scheduled data. Transport and replay through H_s, C preserve the same rows, and the local naming rows P, M exclude an unscheduled net, host powerset, and quotient compactum. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace totallybounded net lift`

Theorem 1660.18 (Hyperspace Vietoris compact-metric dependency)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every Vietoris-topology or Hausdorff-distance consumer of H must read the* $\mathsf{CompactMetric}^{\uparrow}$ *source row X, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules in K_0, K_1, N_0, N_1, the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary carried by X, the* $\mathsf{Met}^{\uparrow}$ *distance witnesses, and the two directed Hausdorff ledgers D_0, D_1 before any compact-subset topology route is public.*

The dependency route exports no host powerset, open-cover compactness proof, quotient compactum, selected limit, or choice-selected representative.

Proof. Project the carrier of Definition 1660.1. The compact metric source row X is the only source from which metric witnesses, total-boundedness schedules, and completeness support can be read.

Use Definition 1660.3. Its carrier-admission, finite subset-net, bidirectional coverage, transport, and provenance clauses force every public read to pass through $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$.

Apply Definition 1660.11 and Definition 1660.12. They identify the Hausdorff route as a finite two-direction ledger over the displayed compact source and exclude a host compact-subset universe.

Finally use Definition 1660.17. The Vietoris-facing finite-open or finite-hit information can inspect only the scheduled net rows attached to X, and the Hausdorff-facing read must retain both directed ledgers. Since no forbidden host coordinate is present in the carrier, every compact-subset topology consumer inherits exactly the compact-metric dependency named in the statement. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisCompactMetricDependency`

Theorem 1660.19 (Hyperspace CompleteMetric Cauchy lift)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{CauchyUniformNet}^{\uparrow}$ *consumer of the hyperspace route receives completeness only through the support carried by X, after the finite subset-net schedules and the two directed Hausdorff ledgers have been exposed. The lift is replayed through displayed* Cont*, transported componentwise by* hsame*, and named locally by P, M; it does not export selected limits, quotient completion representatives, open-cover compactness, or ambient hyperspace completeness.*

Proof. Begin with Definition 1660.13. Completeness enters the hyperspace packet only through the displayed compact metric source row X and its CompleteMetric support.

Use Definition 1660.17. A Cauchy-uniform-net consumer first sees finite subset-net schedules over the same source row and then the directed ledgers D_0, D_1 with tolerance readback R.

Apply Definition 1660.2 to transport the route. The rows H_s, C, P, M preserve, replay, source, and name the displayed packet, so no selected limit, quotient representative, open-cover compactness proof, or ambient hyperspace completeness coordinate is exported. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompleteMetricCauchyLift`

Theorem 1660.20 (Hyperspace finite-net carrier exhaustion)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* Hyperspace$^\uparrow$ *carrier. Every finite-net inspection of a compact-subset presentation in the* BHist *packet is exhausted by the* CompactMetric$^\uparrow$ *source row X, its* Met$^\uparrow$ *distance witnesses, its* CompleteMetric$^\uparrow$ *support, the displayed subset-net rows K_0, K_1, and the resolution ledgers N_0, N_1. Componentwise* hsame *transport through H_s, displayed* Cont *replay through C, and the* NameCert *row M preserve exactly those rows; no host compact-subset family, selected net, quotient compactum, or ambient completeness coordinate is public.*

Proof. Project the carrier of Definition 1660.1. The only compact source is X, and the only finite compact-subset presentations are K_0, K_1 with their resolution ledgers N_0, N_1.

Use Definition 1660.15. The root-unblock surface orders the public rows as compact-source admission, finite subset-net schedules, directed Hausdorff ledgers, readback, transport, replay, provenance, and local naming.

Thus any finite-net inspection must stop at X, K_0, K_1, N_0, N_1 before reading the directed ledgers. The rows H_s, C, M preserve and name that same visible packet, so no extra compact-subset carrier can be exposed. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace finite net carrier exhaustion`

Theorem 1660.21 (Hyperspace finite Vietoris carrier)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* Hyperspace$^\uparrow$ *carrier. Every Vietoris-facing carrier read of a compact-source finite subset is exposed only through the displayed finite-net rows $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ of Definition 1660.1. The read may inspect the* CompactMetric$^\uparrow$ *source row, the* TotallyBounded$^\uparrow$ *schedules, the* CompleteMetric$^\uparrow$ *support carried by X, and the* CauchyUniformNet$^\uparrow$ *replay row, but it does not export a host compact-subset universe, quotient compactum, open-cover compactness proof, choice-selected representative, or ambient hyperspace completion.*

Proof. Project the carrier of Definition 1660.1. The compact-source finite subsets are represented by K_0, K_1 and their finite resolution ledgers N_0, N_1 over the same source row X.

Use Definition 1660.20. It exhausts every finite-net inspection at X, K_0, K_1, N_0, N_1 before any directed Hausdorff ledger can be read.

Then apply Definition 1660.18 and Definition 1660.11. These force the Vietoris-facing route through the compact metric source, total-bounded schedules, complete-metric support, directed ledgers, and Cauchy-uniform-net replay. Since the carrier has no row for quotient compacta, open-cover compactness, selected representatives, host powersets, or ambient hyperspace completion, the finite Vietoris carrier is exactly the displayed packet. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteVietorisCarrier`

Theorem 1660.22 (Hyperspace hit-miss classifier)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* Hyperspace$^\uparrow$ *carrier. Every hit or miss comparison used by a Vietoris-facing consumer is read through the finite directed-distance rows D_0, D_1 and the tolerance readback row R,*

after the finite subset-net schedules K_0, K_1, N_0, N_1 have been exposed over X. The classifier is therefore a finite directed Hausdorff ledger in the BHist *packet, not a comparison inside a host compact-subset universe.*

Proof. Start from the carrier projection of Definition 1660.1. The only rows that can witness a hit or miss request are the finite subset-net schedules and the two directed coverage ledgers.

Apply Definition 1660.20. It prevents the classifier from reading a compact-subset carrier beyond X, K_0, K_1, N_0, N_1 before the directed ledgers are public.

Use Definition 1660.24. Componentwise hsame transport preserves the same directed ledgers D_0, D_1 and the same readback row R, so a transported classifier cannot replace them by a host distance, quotient compactum, selected representative, or ambient hyperspace metric. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHitMissClassifier`

Theorem 1660.23 (Hyperspace finite-cover ledger)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* Hyperspace$^{\uparrow}$ *carrier. Every finite-cover ledger consumed downstream is routed through the* CompactMetric$^{\uparrow}$ *source row X, the* TotallyBounded$^{\uparrow}$ *schedules in K_0, K_1, N_0, N_1, the* CompleteMetric$^{\uparrow}$ *support carried by X, and the* CauchyUniformNet$^{\uparrow}$ *replay visible through D_0, D_1, R, C. The ledger exports no open-cover compactness principle, quotient compactum, choice-selected representative, host compact-subset universe, selected limit, or ambient hyperspace completion.*

Proof. Project Definition 1660.1. The finite-cover information is not a separate host cover object; it is the displayed subset-net data K_0, K_1, N_0, N_1 attached to X.

Use Definition 1660.27. It identifies the complete-metric and total-boundedness obligations as the source support in X, the finite schedules, the two directed ledgers, and the tolerance readback.

Finally apply Definition 1660.19 and Definition 1660.25. These route downstream Cauchy-uniform-net and compact-complete consumers through the same finite ledger. No row remains from which to read open-cover compactness, quotient compacta, selected representatives, selected limits, host compact subsets, or ambient hyperspace completion. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteCoverLedger`

Theorem 1660.24 (Hyperspace Hausdorff classifier transport)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* Hyperspace$^{\uparrow}$ *carrier. Any Hausdorff-distance classifier comparison transported by* hsame *through the* BHist *packet must carry both directed ledgers D_0, D_1 over the same* CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, *and* CompleteMetric$^{\uparrow}$ *source rows, and must replay through the displayed* Cont *row C before the* NameCert *row M names the comparison. The transport cannot replace either directed ledger by a host distance, quotient compactum, selected limit, or external hyperspace metric.*

Proof. Apply Definition 1660.2. It states that componentwise hsame transport preserves the two directed Hausdorff ledgers and the tolerance readback.

The compact-source part of the comparison is fixed by Definition 1660.18. A classifier comparison must therefore retain the same CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, and CompleteMetric$^{\uparrow}$ source rows before any distance route is public.

Finally use Definition 1660.19. Displayed Cont replay keeps the transported comparison inside the finite Cauchy-uniform-net route, and the local NameCert row names only that packet. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHausdorffClassifierTransport`

Theorem 1660.25 (Hyperspace compact-complete handoff)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every downstream compact-complete consumer receives a handoff whose* BHist *rows are exactly the* $\mathsf{CompactMetric}^{\uparrow}$ *source X, the* $\mathsf{Met}^{\uparrow}$ *distance witnesses inside X, the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary carried by X, the finite subset-net rows K_0, K_1, N_0, N_1, the directed Hausdorff ledgers D_0, D_1, componentwise* hsame *transport H_s, displayed* Cont *replay C, and local* NameCert *naming through M. The handoff exports no ambient hyperspace completeness proof, open-cover compactness proof, selected Cauchy limit, quotient completion representative, or host powerset.*

Proof. Begin with Definition 1660.19. Completeness is handed to downstream Cauchy consumers only through the support carried by X after the finite subset-net schedules and directed Hausdorff ledgers are exposed.

Use Definition 1660.20. It identifies the compact-subset carrier rows that a downstream consumer may inspect before reading the distance ledgers.

Then apply Definition 1660.24. Transport and replay preserve the same compact-source, finite-net, and directed-ledger rows, and M names only the displayed packet. Therefore the compact-complete handoff is exactly the finite BEDC interface stated above. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompactCompleteHandoff`

Definition 1660.26 (Hyperspace finite-net carrier)**.** *The finite-net carrier of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet is the displayed subpacket*

$$F_H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$$

read with X as the $\mathsf{CompactMetric}^{\uparrow}$ *source row, K_0, K_1, N_0, N_1 as compact finite-net data, D_0, D_1 as the two Hausdorff coverage ledgers, R as dyadic and* $\mathsf{Real}^{\uparrow}$ *tolerance readback, H_s as componentwise* hsame *transport, C as displayed* Cont *replay, P as* Pkg *provenance, and M as the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. This carrier has no coordinate for host powersets, selected compact representatives, open-cover compactness, quotient compacta, or ambient hyperspace completeness.*

Lean4 (definition) `BEDC.Derived.HyperspaceUp.HyperspaceFiniteNetCarrier`

Theorem 1660.27 (Hyperspace complete and totally bounded obligations)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. The complete-metric and total-boundedness obligations exposed by the finite-net carrier are exactly the* $\mathsf{CompleteMetric}^{\uparrow}$ *support carried by the compact source row X, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules read by K_0, K_1, N_0, N_1, the two directed Hausdorff coverage ledgers D_0, D_1, the tolerance readback R, componentwise* hsame *transport H_s, displayed* Cont *replay C,* Pkg *provenance P, and local naming M.*

No downstream consumer receives a host powerset of compact subsets, a selected compact representative, open-cover compactness, quotient compactness, or a selected Cauchy limit.

Proof. Start from Definition 1660.26. It records the same finite rows as the accepted carrier and marks the compact finite-net roles used by root consumers.

Apply Definition 1660.13. Completeness is read only through the $\mathsf{CompactMetric}^{\uparrow}$ source row X and its displayed $\mathsf{CompleteMetric}^{\uparrow}$ support.

Apply Definition 1660.17. Total-boundedness is read through the finite schedules K_0, K_1, N_0, N_1 over the same source row. The directed ledgers and tolerance readback can compare only those scheduled rows.

The transport, replay, provenance, and local naming rows preserve this finite packet. Since the excluded host and selection coordinates are absent, the listed rows exhaust the complete and totally bounded obligations. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompleteTotallyBoundedObligations`

Theorem 1660.28 (Hyperspace Cauchy-uniform-net handoff)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyUniformNet}^{\uparrow}$ *handoff from H must pass through the compact finite-net carrier, inspect the* $\mathsf{CompactMetric}^{\uparrow}$ *source X, read the finite subset-net schedules K_0, K_1, N_0, N_1, consume both directed coverage ledgers D_0, D_1, and replay the same route through C after componentwise* hsame *transport in H_s.*

The handoff exports only finite Cauchy-uniform-net data named by P and M. It exports no host powerset, selected compact representative, selected limit, open-cover compactness proof, or quotient compactum.

Proof. Use Definition 1660.19. It sends every $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{CauchyUniformNet}^{\uparrow}$ consumer through the completeness support carried by X, after finite subset-net schedules and directed Hausdorff ledgers are exposed.

The finite-net carrier of Definition 1660.26 fixes the rows available to that handoff. The consumer reads $X, K_0, K_1, N_0, N_1, D_0, D_1, R$ and then follows the structural rows.

Transport and replay are supplied by H_s and C. The local naming and provenance rows P, M record the same route, so no selected compact representative, quotient compactum, open-cover proof, host powerset, or selected limit can be introduced at the handoff. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCauchyUniformNetHandoff`

Theorem 1660.29 (Hyperspace metric compactness unblock)**.** *Every compact-metric downstream consumer of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet can read metric compactness only through the finite-net carrier of Definition 1660.26. The unblocked surface consists of compact finite-net data,* $\mathsf{CompleteMetric}^{\uparrow}$ *support,* $\mathsf{TotallyBounded}^{\uparrow}$ *schedules, the* $\mathsf{CauchyUniformNet}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

The unblock supplies no host powerset, no selected compact representative, no open-cover compactness principle, no quotient compactum, and no ambient hyperspace completeness theorem.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceMetricCompactnessUnblock`

Proof. First read the complete and totally bounded obligations of Definition 1660.27. They give exactly the compact source support, finite schedules, directed ledgers, tolerance readback, transport, replay, provenance, and local naming rows.

Next apply the Cauchy-uniform-net handoff of Definition 1660.28. It routes every Cauchy-uniform-net consumer through the same compact finite-net carrier before any downstream compactness read is public.

Finally use Definition 1660.25. The compact-complete consumer receives only the displayed BHist rows over $X, K_0, K_1, N_0, N_1, D_0, D_1, H_s, C, M$. Thus metric compactness is unblocked as finite BEDC data and not as a host powerset, selected representative, open-cover principle, quotient compactum, or ambient completeness theorem. □

Theorem 1660.30 (Hyperspace compact-metric Vietoris unblock)**.** *Every Vietoris-facing downstream consumer of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must read compact-source support through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, *and* $\mathsf{CauchyUniformNet}^{\uparrow}$ *before any hit/miss or Hausdorff-distance classifier is public. The route exports no host powerset, quotient compactum, selected representative, open-cover compactness, or ambient hyperspace completion.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompactMetricVietorisUnblock`

Proof. Project the carrier of Definition 1660.1. Its rows expose the compact metric source, finite subset-net presentations, directed Hausdorff ledgers, tolerance readback, transport, replay, provenance, and local naming.

Use Definition 1660.20. It forces every compact-source finite-net read through the displayed rows before a downstream consumer can inspect distance or Vietoris data.

Apply Definition 1660.22 and Definition 1660.23. The hit/miss and finite-cover reads are both mediated by the same finite net schedules and directed ledgers, so neither supplies a host powerset or an open-cover compactness principle.

Finally use Definition 1660.29. Compact-metric readiness is public only through the compact source, total-bounded schedules, completeness support, metric-diameter tolerance, net-convergence route, and Cauchy-uniform-net handoff already present in the accepted carrier. The forbidden quotient, representative, powerset, open-cover, and ambient-completion coordinates are absent. □

Theorem 1660.31 (Hyperspace finite-cover selector refusal)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Every finite-cover read exported by H is mediated by the displayed compact finite-net rows, the Vietoris hit/miss rows, the two directed coverage ledgers D_0, D_1, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. The packet cannot export a selected compact representative, a selected point of a cover member, a host powerset element, a quotient compactum, or an open-cover compactness oracle.*

Proof. Project the carrier of Definition 1660.1. Its only compact-subset data are the compact metric source, the finite subset-net schedules, directed ledgers, tolerance readback, and structural rows.

Use Definition 1660.20. It forces every compact finite-net read through $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ so no selected representative or host powerset coordinate is available.

Apply Definition 1660.22, Definition 1660.23, and Definition 1660.30. The hit/miss and finite-cover classifiers are read from the same finite-net and Vietoris rows already required by the compact-metric route. Therefore the finite-cover surface is a refusal of selectors, not a source of hidden compact subsets. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteCoverSelectorRefusal`

Theorem 1660.32 (Hyperspace hit-miss coverage totality)**.** *Every hit/miss coverage read from an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, *and* $\mathsf{CauchyUniformNet}^{\uparrow}$ *rows before it is public. The coverage read is total over the accepted packet precisely because each available route is one of the finite-net, Vietoris, directed Hausdorff, metric-diameter, net-convergence, or Cauchy-uniform handoff rows already stored in the carrier.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHitMissCoverageTotality`

Proof. Start with Definition 1660.30. It lists the compact-source, total-bounded, complete-metric, metric-diameter, net-convergence, and Cauchy-uniform-net rows that must be displayed before a Vietoris-facing consumer can read hit/miss data.

Next use Definition 1660.36 and Definition 1660.28. The first theorem routes the compact-subset topology read through finite-net and Vietoris-hit rows, while the second routes the completion-facing handoff through the same finite carrier.

Finally apply Definition 1660.31. Since the finite-cover surface has no selector, host powerset, quotient compactum, or open-cover oracle, every public hit/miss coverage answer is accounted for by the displayed finite rows. That is the asserted totality of coverage reads over the accepted packet. □

Theorem 1660.33 (Hyperspace root compact-source totality)**.** *Every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet must expose the compact-source row, the metric-distance row, the total-bounded finite-net row, and the completeness-support row before any hit/miss read is admitted. Thus a hit/miss consumer reads the displayed* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *support through the carrier rows of Definition 1660.1, not through a host powerset, selected compact representative, open-cover oracle, or ambient hyperspace completion.*

Proof. Project the carrier of Definition 1660.1. The compact source, finite subset-net schedules, directed Hausdorff ledgers, tolerance readback, transport, replay, provenance, and local naming rows are the only rows exposed to a consumer.

Use Definition 1660.30 and Definition 1660.32. They require compact-metric support, total-bounded schedules, complete-metric support, metric-diameter tolerance, net-convergence routes, and Cauchy-uniform handoff before hit/miss coverage is public.

The root read is therefore total only after those source rows are visible. Since the carrier has no coordinate for host powersets, selected representatives, open-cover oracles, or ambient completion, every admitted hit/miss read factors through the displayed compact-source and metric rows. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootCompactSourceTotality`

Theorem 1660.34 (Hyperspace finite-net hit-miss determinacy)**.** *For an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, the finite-net data* K_0, K_1, N_0, N_1 *determine the public hit/miss ledger under componentwise* hsame *transport and displayed* Cont *replay. Any transported or replayed hit/miss read factors through the same finite-net schedules, directed ledgers* D_0, D_1*, readback row* R*, transport row* H_s*, replay row* C*, provenance row* P*, and local name* M*.*

Proof. Start with Definition 1660.36. It routes compact-subset topology reads through the compact source, finite-net schedules, and Vietoris hit rows before a consumer can inspect compact-subset data.

Apply Definition 1660.20. It identifies $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ as the complete finite carrier available for compact-subset reads.

Now transport or replay the read. Componentwise hsame transport preserves the displayed rows, and Cont replay repeats the same route through C. Therefore finite-net data determine the hit/miss ledger for every accepted transported or replayed read, without adding a selected compact set or host powerset element. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootFiniteNetHitMiss`

Theorem 1660.35 (Hyperspace Hausdorff transport root)**.** *Every Hausdorff-distance readback exported by an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet transports along the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *classifier rows. The readback must pass through the compact source, finite-net schedules, directed Hausdorff ledgers, metric-diameter tolerance row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row before it is public.*

Proof. Use Definition 1660.4. The two directed coverage ledgers D_0, D_1 are the only Hausdorff-facing ledgers in the accepted carrier.

Next apply Definition 1660.11 and Definition 1660.25. The readback tolerance is routed through the metric-diameter and compact-complete support rows, while completion-facing consumers are sent through the displayed $\mathsf{CompleteMetric}^{\uparrow}$ handoff.

Finally use Definition 1660.33. It fixes the compact-source and metric rows as prerequisites for hit/miss and Hausdorff-facing reads. Transport along $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ therefore remains a finite carrier read through $X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$, not a host Hausdorff metric on a powerset. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootHausdorffTransport`

Theorem 1660.36 (Hyperspace Vietoris finite-net obligations)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Before any downstream consumer reads a compact-subset topology route or a Hausdorff-distance route from H, the carrier must expose the* $\mathsf{CompactMetric}^{\uparrow}$ *source X, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules in K_0, K_1, N_0, N_1, and the Vietoris hit rows recorded by the directed ledgers D_0, D_1. Thus every compact-subset read is a finite-net and Vietoris-hit read over the displayed source, not a host powerset, selected compact representative, or open-cover compactness principle.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisFiniteNetObligations`

Proof. Start with Definition 1660.6. It forces every directed Hausdorff hit to pass through the compact source row and the finite-net schedules before tolerance readback is public.

Use Definition 1660.20. The only compact-subset rows available to a consumer are X, K_0, K_1, N_0, N_1 together with the directed ledgers and structural rows.

Finally apply Definition 1660.29. Since the unblocked surface is exactly the finite-net carrier with transport, replay, provenance, and local naming, a Vietoris compact-subset read cannot bypass those obligations. □

Theorem 1660.37 (Hyperspace Cauchy-uniform complete handoff)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. The only completion-facing handoff from H is the route that reads the* $\mathsf{CompleteMetric}^{\uparrow}$ *support carried by X, consumes the* $\mathsf{CauchyUniformNet}^{\uparrow}$ *replay through C, and then names the same finite-net carrier through P and M. No ambient hyperspace completion, selected Cauchy limit, quotient completion representative, or host equality of compact subsets is exported.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCauchyUniformCompleteHandoff`

Proof. Apply Definition 1660.19. It sends complete-metric and Cauchy-uniform-net consumers through the support carried by X after the finite subset-net schedules and directed Hausdorff ledgers are present.

Next use Definition 1660.28. It fixes the Cauchy-uniform handoff as a read of the compact finite-net carrier followed by componentwise hsame transport and displayed Cont replay.

The finite-net carrier of Definition 1660.26 supplies exactly those rows. Therefore completion enters the hyperspace packet only through $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{CauchyUniformNet}^{\uparrow}$ rows already named by the BEDC carrier. □

Theorem 1660.38 (Hyperspace Hausdorff classifier exactness)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$ be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. The Hausdorff classifier exposed by H is exactly componentwise* hsame *transport of the displayed source, compact finite-net rows, directed ledgers, tolerance*

readback, displayed Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *naming. It introduces no quotient equality, no extensional host equality of compact subsets, and no replacement distance outside the two directed ledgers* D_0, D_1*.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHausdorffClassifierExactness`

Proof. First apply Definition 1660.2. Componentwise hsame transport preserves the two directed Hausdorff ledgers and the tolerance readback.

Then use Definition 1660.24. The classifier comparison must retain the same compact-source, complete-metric, finite-net, transport, replay, and local naming rows.

Finally invoke Definition 1660.3. The $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ row names only the displayed packet, so the classifier has no coordinate on which quotient equality or host extensional equality could enter. □

Theorem 1660.39 (Hyperspace Vietoris hit-miss stability)**.** *Let* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ *be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. If a downstream Vietoris consumer reads a hit row or miss row from* H*, then the read is stable under the same componentwise* hsame *transport that preserves the Hausdorff classifier: the compact-source row* X*, finite-net rows* K_0, K_1, N_0, N_1*, directed ledgers* D_0, D_1*, tolerance readback* R*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row* M *remain the public coordinates of the read.*

The stability route exports no host powerset of compact subsets, no open-cover compactness principle, no selected representative of a compactum, and no quotient equality beyond the displayed transport rows.

Proof. First apply Definition 1660.22. It identifies every Vietoris-facing hit or miss read with finite carrier rows rather than with an ambient powerset.

Next use Definition 1660.6 and Definition 1660.23. These force the hit/miss read through compact-source support, finite-net schedules, directed Hausdorff ledgers, and tolerance readback.

Finally apply Definition 1660.38. The same componentwise hsame transport that preserves the Hausdorff classifier preserves the displayed Vietoris rows, so the transported hit/miss route remains a BEDC finite-net route. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisHitMissStability`

Theorem 1660.40 (Hyperspace finite Vietoris obligation basis)**.** *For an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, the finite obligation basis for every compact-metric Vietoris read is exactly the basis consisting of compact-source support through* X*, finite-net presentations through* K_0, K_1, N_0, N_1*, hit/miss and finite-cover ledgers through* D_0, D_1*, complete-metric support through* $\mathsf{CompleteMetric}^{\uparrow}$*, total-bounded schedules through* $\mathsf{TotallyBounded}^{\uparrow}$*, net-convergence routes through* $\mathsf{NetConvergence}^{\uparrow}$*, Cauchy-uniform-net replay through* $\mathsf{CauchyUniformNet}^{\uparrow}$*, componentwise transport through* H_s*, displayed replay through* C*, provenance through* P*, and local naming through* M*.*

No additional Vietoris obligation may be supplied by an ambient compact-subset topology, a host open-cover theorem, a selected compact representative, or a quotient compactum.

Proof. Read the compact-metric source obligations from Definition 1660.27. They provide the $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{TotallyBounded}^{\uparrow}$ support together with the finite compact-source rows.

Use Definition 1660.30 and Definition 1660.36. Together they force every Vietoris-facing read through finite-net presentations, hit/miss rows, finite-cover ledgers, and directed Hausdorff data before the compact-subset route is public.

The handoff through $\mathsf{NetConvergence}^{\uparrow}$ and $\mathsf{CauchyUniformNet}^{\uparrow}$ is fixed by Definition 1660.28. Repacking those rows with H_s, C, P, M gives the stated finite obligation basis and leaves no coordinate for ambient topology or selected representatives. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteVietorisObligationBasis`

Theorem 1660.41 (Hyperspace Hausdorff-net completeness handoff)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s,$ be an accepted $\mathsf{Hyperspace}^{\uparrow}$ carrier. A completeness-facing consumer may pass from the Hausdorff classifier to a net-completeness read only by following the finite route*

$$\begin{gathered} X, K_0, K_1, N_0, N_1, D_0, D_1, R \\ \longrightarrow \mathsf{CompleteMetric}^{\uparrow}, \mathsf{TotallyBounded}^{\uparrow}, \mathsf{NetConvergence}^{\uparrow}, \mathsf{CauchyUniformNet}^{\uparrow} \\ \longrightarrow H_s, C, P, M. \end{gathered}$$

Thus Hausdorff-distance convergence and Cauchy-uniform-net completeness are handed off through the displayed compact-metric rows, not through an ambient complete hyperspace, a selected compact limit, quotient completion, or host equality of compact subsets.

Proof. Start with Definition 1660.38. It fixes the Hausdorff classifier as transport of the displayed compact source, finite-net rows, directed ledgers, tolerance readback, replay, provenance, and local naming.

Next apply Definition 1660.37. That theorem identifies the completion-facing handoff as a read of $\mathsf{CompleteMetric}^{\uparrow}$ support and $\mathsf{CauchyUniformNet}^{\uparrow}$ replay over the same finite-net carrier.

Finally combine Definition 1660.29 with the finite-net carrier of Definition 1660.26. The complete, totally bounded, net-convergent, and Cauchy-uniform rows are all displayed before the handoff reaches H_s, C, P, M, so no ambient complete-hyperspace object or selected compact limit is exported. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHausdorffNetCompletenessHandoff`

Definition 1660.42 (Hyperspace finite carrier basis)**.** *For an accepted $\mathsf{Hyperspace}^{\uparrow}$ carrier $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$, the finite carrier basis is the* BHist *subpacket consisting exactly of the compact-source row X, the finite subset-net rows K_0, K_1, N_0, N_1, the two Hausdorff-distance window rows D_0, D_1, R, the total-bounded schedule and complete-metric handoff rows readable through X, and the structural rows H_s, C, P, M for* hsame, Cont, Pkg, *and* NameCert.

This basis has no coordinate for a host powerset of compact subsets, quotient compactum, selected compact limit, open-cover compactness proof, or external equality of compact sets.

Lean4 (definition) `BEDC.Derived.HyperspaceUp.HyperspaceFiniteCarrierBasis`

Theorem 1660.43 (Hyperspace Hausdorff distance window)**.** *Let $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$ be an accepted $\mathsf{Hyperspace}^{\uparrow}$ carrier. Every public Hausdorff-distance read from H is exhausted by the finite dyadic distance windows displayed in D_0, D_1, R together with the common refinements of the finite subset-net rows K_0, K_1, N_0, N_1. In particular, the read can inspect only source-metric cells from X, scheduled finite centers, the two directed coverage ledgers, the tolerance readback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

No public Hausdorff-distance read may appeal to a host powerset, quotient compactum, selected nearest point, selected compact limit, open-cover compactness theorem, or distance relation outside the displayed dyadic windows and their common refinements.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace hausdorff distance window`

Proof. Start from Definition 1660.42. The finite carrier basis lists the compact source, subset-net schedules, two directed ledgers, tolerance readback, and structural rows as the only readable coordinates.

Apply Definition 1660.38. It identifies the Hausdorff classifier with componentwise transport of those displayed rows, so any distance read must pass through D_0, D_1, R after the source metric and subset nets have been fixed.

Use Definition 1660.41. Completeness-facing consumers inherit the same finite route through $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, and $\mathsf{CauchyUniformNet}^{\uparrow}$, and the handoff never exports an ambient complete hyperspace or selected compact limit. □

Theorem 1660.44 (Hyperspace compact-metric handoff)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, a compact-metric downstream consumer receives only the compact finite-net rows of* X, K_0, K_1, N_0, N_1*, the total-bounded schedules readable through* $\mathsf{TotallyBounded}^{\uparrow}$*, the complete-metric support readable through* $\mathsf{CompleteMetric}^{\uparrow}$*, the metric-distance and Hausdorff-window rows* D_0, D_1, R*, and the structural rows* H_s, C, P, M*.*

The handoff exports no host powerset of compact subsets, no quotient compactum, no open-cover compactness principle, no selected limit, and no untracked distance object outside the finite carrier basis.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompactMetricHandoff`

Proof. Read the basis from Definition 1660.42. It exposes compact finite-net rows, Hausdorff-window rows, total-bounded and complete-metric support through the source row, and structural BEDC rows.

Next apply Definition 1660.40. Every compact-metric Vietoris read is forced through compact-source support, finite-net presentations, hit/miss ledgers, finite-cover ledgers, directed Hausdorff data, and the displayed net and Cauchy-uniform handoff.

Finally use Definition 1660.43. Since the public Hausdorff read is exhausted by finite dyadic windows and common refinements, the compact-metric consumer has no remaining coordinate from which to read host powersets, quotient compacta, selected limits, or open-cover compactness. □

Theorem 1660.45 (Hyperspace finite Vietoris subcover avoidance)**.** *For every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier* $H = (X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M)$*, every Vietoris hit-miss read used by a compact-metric consumer is a finite* BHist *route over the displayed rows* $K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M$*. The route may inspect finite hit rows, finite miss rows, compact-source cells from* X*, finite-cover ledgers internal to the subset nets, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

It has no coordinate for an arbitrary open cover of the hyperspace, a selected finite subcover, a host powerset compactness theorem, a quotient compactum, or a selected compact limit.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisFiniteSubcoverAvoidance`

Proof. Read the finite carrier basis from Definition 1660.42. The basis exposes the compact source, finite subset-net rows, Hausdorff-window rows, and structural rows before any Vietoris consumer can read hit or miss information.

Apply Definition 1660.40. Its obligation surface already lists hit rows, miss rows, finite-cover ledgers, directed Hausdorff data, net-convergence handoff, and Cauchy-uniform-net handoff as finite rows over the same packet.

Finally use Definition 1660.44. A compact-metric consumer receives only those displayed rows and their structural replay. Since no open-cover object or selected subcover occurs in the carrier, the Vietoris read remains a finite hit-miss route. □

Theorem 1660.46 (Hyperspace Cauchy-net compact handoff)**.** *Every Cauchy-net handoff from an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet to a compact-metric or completion-facing consumer factors through finite subset-net rows, the* $\mathsf{NetConvergence}^{\uparrow}$ *schedule readable from those rows, the* $\mathsf{CauchyUniformNet}^{\uparrow}$ *replay row, the* $\mathsf{CompleteMetric}^{\uparrow}$ *support carried by the compact source, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

The handoff may assert only that the displayed finite net route is available to the consumer. It does not select a limiting compact subset, prove open-cover compactness of the hyperspace, identify quotient compacta, or export an ambient complete-hyperspace object.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCauchyNetCompactHandoff`

Proof. Start with the accepted carrier and its finite basis. The rows K_0, K_1, N_0, N_1 display the finite subset nets, while D_0, D_1, R display the Hausdorff-window comparisons used to compare net stages.

Apply Definition 1660.41. The completion-facing read is already forced through $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, and $\mathsf{CauchyUniformNet}^{\uparrow}$ over the displayed finite-net carrier.

Use Definition 1660.44 to restrict the compact-facing consumer to the same rows. The structural rows H_s, C, P, M then transport, replay, source, and name the handoff, with no route to a selected compact limit or host complete hyperspace. □

Theorem 1660.47 (Hyperspace hit-miss directed refinement)**.** *Let H and H' be accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carriers whose compact-source rows and finite subset-net rows are related by componentwise* hsame *transport. If the hit rows of H' refine the hit rows of H and the miss rows of H' refine the miss rows of H by displayed finite witnesses, then every directed Hausdorff or Vietoris read of H' factors through the original finite hit-miss route of H together with the refinement witnesses.*

The refinement may replace a displayed finite row by a finer finite row, but it cannot add open-cover compactness, selected compact limits, host powersets, quotient compacta, or untracked distance objects.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace hit miss directed refinement`

Proof. Project both carriers to their finite bases. The hsame transport identifies the compact source, subset-net schedules, Hausdorff windows, and structural rows before the refinement witnesses are read.

The hit refinement sends every refined hit row to a displayed hit row in the original packet. The miss refinement does the same for finite avoidance rows, so a Vietoris read of H' returns to the hit-miss ledgers of H after inspecting only finite witnesses.

For directed Hausdorff reads, apply Definition 1660.43. The distance windows are exhausted by D_0, D_1, R and common finite refinements, and the structural rows replay the same route. Thus no excluded open-cover, host powerset, quotient, selected-limit, or untracked-distance coordinate is exported. □

Theorem 1660.48 (Hyperspace compact-source carrier obligations)**.** *Let H be an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier. Before any compact-source consumer can read a hyperspace row, the packet must expose the common* $\mathsf{CompactMetric}^{\uparrow}$ *source, the finite subset-net rows, the* $\mathsf{MetricDiameter}^{\uparrow}$ *and*

$\mathsf{TotallyBounded}^{\uparrow}$ *resolution rows, the* $\mathsf{CompleteMetric}^{\uparrow}$ *support carried by the source, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row.*

The exposed surface is a compact-source carrier for finite hyperspace observations only. It does not export a host powerset, quotient compactum, selected compact subset, selected limit, open-cover compactness theorem, or ambient complete-hyperspace object.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompactSourceCarrierObligations`

Proof. Project the accepted carrier. Its compact source is already the $\mathsf{CompactMetric}^{\uparrow}$ row, and the finite subset-net rows are the only hyperspace objects that downstream consumers can inspect.

Apply Definition 1660.44. The compact-facing handoff is forced through the displayed compact metric source, finite subset nets, and structural rows before any consumer receives hyperspace data.

Now use Definition 1660.46. The diameter, total-boundedness, complete-metric, Cauchy-uniform, replay, provenance, and naming rows are the same finite route. Since none of the forbidden host objects is a carrier coordinate, the compact-source obligation surface is exhausted by the displayed packet. □

Theorem 1660.49 (Hyperspace Vietoris root-unblock obligations)**.** *Every Vietoris hit-miss read from an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet factors through finite hit rows, finite miss rows, finite subset-net schedules, Hausdorff-window comparisons, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. Refinement of a Vietoris read is allowed only by replacing displayed finite hit or miss witnesses with finer displayed finite witnesses.*

Thus a Vietoris root consumer receives a finite hit-miss classifier and not a host powerset topology, quotient compactum, selected compact limit, open-cover compactness proof, or untracked distance object.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisRootUnblockObligations`

Proof. Start from the hit and miss rows of the accepted carrier. These rows are finite ledgers, so a Vietoris request can only inspect listed hit witnesses and listed avoidance witnesses.

Apply Definition 1660.39 and Definition 1660.47. Stability keeps the classifier on the displayed hit-miss route, while directed refinement replaces rows only by explicitly displayed finite refinements.

Finally apply Definition 1660.43. The Hausdorff side is already bounded by the finite distance windows and common refinements, so the Vietoris classifier cannot escape to host powersets, quotient compacta, selected limits, open-cover compactness, or untracked distance data. □

Theorem 1660.50 (Hyperspace completion-boundary obligations)**.** *Any completion-boundary read exported by an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet must pass through the finite subset-net carrier, the* $\mathsf{NetConvergence}^{\uparrow}$ *schedule, the* $\mathsf{CauchyUniformNet}^{\uparrow}$ *replay row, the* $\mathsf{CompleteMetric}^{\uparrow}$ *support inherited from the compact source, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row before a boundary-facing consumer receives data.*

The boundary handoff records only this finite Cauchy-uniform completion route. It does not select a limiting compact subset, identify quotient compacta, assert open-cover compactness, import a host powerset, or expose an ambient complete-hyperspace object.

Proof. Read the finite subset-net rows first. They provide the only net stages visible to the packet, and their schedules are the source for the $\mathsf{NetConvergence}^{\uparrow}$ and $\mathsf{CauchyUniformNet}^{\uparrow}$ rows.

Use Definition 1660.41. The completion-facing read is forced through the displayed complete-metric support, net-convergence schedule, Cauchy-uniform replay, and Hausdorff-window carrier.

Then apply Definition 1660.46. The compact-source and completion-boundary routes are the same finite ledger route, so no selected limit, quotient compactum, host powerset, open-cover compactness proof, or ambient complete-hyperspace object is exported. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceCompletionBoundaryObligations`

Theorem 1660.51 (Hyperspace root Vietoris net basis)**.** *Every root Vietoris read from an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must expose the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedules carried by* K_0, K_1, N_0, N_1*, the finite hit and miss ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. The resulting basis is a finite hit/miss window over displayed nets, not a host powerset topology, open-cover compactness proof, selected subcover, quotient compactum, or selected compact limit.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootVietorisNetBasis`

Proof. Project the accepted carrier and its finite basis. The only compact-subset rows available to a Vietoris consumer are the compact source and the displayed finite subset-net schedules.

Apply Definition 1660.49. It routes every Vietoris hit-miss read through finite hit rows, finite miss rows, finite subset-net schedules, Hausdorff-window comparisons, and the structural rows.

Use Definition 1660.47 to account for refinement. Refinement can replace a displayed finite witness by a finer displayed finite witness, but it adds no open-cover compactness, selected subcover, host powerset, quotient compactum, or selected limit. □

Theorem 1660.52 (Hyperspace root Hausdorff finite window)**.** *Every root Hausdorff comparison exported by an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must pass through the* $\mathsf{Met}^{\uparrow}$ *distance witnesses inside the compact source, the terminal* $\mathsf{Real}^{\uparrow}$ *tolerance readback row* R*, and the finite net rows* $K_0, K_1, N_0, N_1, D_0, D_1$ *before any downstream distance consumer receives data. The comparison is a finite directed-window route; it is not a host Hausdorff metric on a powerset, quotient hyperspace equality, selected nearest-point operation, open-cover compactness, or ambient complete-hyperspace claim.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootHausdorffFiniteWindow`

Proof. Start from Definition 1660.43. It exhausts public Hausdorff reads by the displayed dyadic distance windows D_0, D_1, R and common refinements of the finite subset-net rows.

Apply Definition 1660.35. The comparison transports along the displayed $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ classifier rows, while the metric and Real tolerance readback stay inside the carrier.

Finally use Definition 1660.44. A downstream compact-metric consumer receives only compact finite-net rows, total-bounded schedules, complete-metric support, metric-distance windows, and structural rows, so no quotient equality, selected point, host powerset metric, open-cover proof, or ambient completion is exported. □

Theorem 1660.53 (Hyperspace root complete and totally bounded handoff)**.** *Any compact-hyperspace or completion-facing consumer of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet must read the* $\mathsf{CompleteMetric}^{\uparrow}$ *support and* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net rows carried by the compact source before making a compact-hyperspace claim. The handoff may then consume the finite subset-net rows, directed Hausdorff ledgers,* $\mathsf{NetConvergence}^{\uparrow}$ *schedule,* $\mathsf{CauchyUniformNet}^{\uparrow}$ *replay, componentwise transport, displayed*

replay, provenance, and local naming; it does not assert open-cover compactness, selected compact limits, quotient hyperspace equality, or an ambient complete hyperspace.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRootCompleteTotallyBoundedHandoff`

Proof. Read the compact-source carrier obligations in Definition 1660.48. They force the common $\mathsf{CompactMetric}^{\uparrow}$ source, finite subset-net rows, total-bounded resolution, complete-metric support, and structural rows to be visible before a compact-source consumer receives hyperspace data.

Next apply Definition 1660.50. A completion-boundary read must pass through the finite subset-net carrier, $\mathsf{NetConvergence}^{\uparrow}$ schedule, $\mathsf{CauchyUniformNet}^{\uparrow}$ replay, $\mathsf{CompleteMetric}^{\uparrow}$ support, and the structural rows.

Finally use Definition 1660.46. The compact-source and completion-boundary routes are the same finite ledger route, so the consumer receives only the displayed complete and total-bounded rows before any compact-hyperspace claim. □

Theorem 1660.54 (Hyperspace Vietoris refinement factorization)**.** *Every accepted* $\mathsf{Hyperspace}^{\uparrow}$ *Vietoris refinement factors through the displayed compact source row, finite subset-net schedules, hit and miss rows, directed Hausdorff ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. The factorization refines only finite displayed witnesses; it is not a host powerset refinement, selected subcover, quotient compactum, or open-cover compactness argument.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisRefinementFactorization`

Proof. Start from the finite Vietoris obligation basis of Definition 1660.49. It routes every hit-miss read through the listed finite hit rows, finite miss rows, subset-net schedules, Hausdorff-window comparisons, and structural rows.

Then apply the root Vietoris net basis of Definition 1660.51. The compact source and $\mathsf{TotallyBounded}^{\uparrow}$ schedules remain visible before a root consumer receives a Vietoris basis element.

Finally use directed refinement from Definition 1660.47. Refinement replaces a displayed finite witness by a finer displayed finite witness and therefore cannot import host powersets, selected subcovers, quotient compacta, or open-cover compactness. □

Theorem 1660.55 (Hyperspace Vietoris union stability)**.** *The finite union of two accepted finite Vietoris* $\mathsf{Hyperspace}^{\uparrow}$ *packets is routed through the union of their displayed hit rows and the intersection of their displayed miss rows. The resulting packet still reads only the compact source row, finite subset-net schedules, directed Hausdorff ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row; it does not import a host powerset union, open-cover compactness, selected subcover, quotient compactum, or selected compact limit.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisUnionStability`

Proof. Project the two accepted finite Vietoris packets. Their hit rows and miss rows are already exhausted by Definition 1660.49 and by the finite-net carrier data of Definition 1660.1.

Use Definition 1660.54. Directed refinement replaces displayed finite witnesses by displayed finer witnesses, so the union packet can combine hit evidence by finite union and miss evidence by common intersection without leaving the recorded net schedules.

Finally apply Definition 1660.47. The common refinement remains a finite displayed witness over the same Hausdorff ledgers and structural rows, and the excluded host, quotient, selected-limit, and open-cover data have no carrier coordinate. □

Theorem 1660.56 (Hyperspace Hausdorff union boundary)**.** *Every Hausdorff read of the finite union of two accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packets is bounded only by the displayed finite subset-net rows and directed coverage ledgers of the two packets. A downstream consumer may inspect the union through the common compact source, the net rows* $K_0, K_1, N_0, N_1, D_0, D_1$*, the terminal* $\mathsf{Real}^{\uparrow}$ *tolerance readback, and the structural rows, but it receives no host powerset metric, quotient hyperspace equality, selected nearest-point operation, open-cover compactness, or ambient complete-hyperspace object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceHausdorffUnionBoundary`

Proof. Start from the Hausdorff classifier transport of Definition 1660.52. It routes every comparison through the displayed compact source, finite net rows, directed Hausdorff ledgers, and Real tolerance readback.

Apply the finite-net exhaustion used by Definition 1660.53. The union read can only combine the two displayed net families and their coverage ledgers; it cannot select a new host-level compact subset.

Then use the Vietoris union stability theorem above. Since the union packet is already expressed through displayed hit, miss, net, and refinement rows, the Hausdorff read is bounded by those same rows and exports none of the excluded host or quotient data. □

Closure status for $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Hyperspace}^{\uparrow}$ packet is generated from a CompactMetricUp source, two finite compact-subset net presentations, two net-resolution ledgers, two directed Hausdorff-distance coverage ledgers, a dyadic and Real tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1660.1, Definition 1660.3, the root obligation rows of Definition 1660.59, the scoped lattice of Definition 1660.65, the public export witness of Definition 1660.66, the bridged interface route of Definition 1660.67, and the mature envelope of Definition 1660.70 close the paper-side compact-subset, directed Hausdorff, Vietoris-window, completion-facing, transport, replay, provenance, local naming, public-object, bridged-interface, and mature compact-metric Vietoris surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host powersets, quotient compacta, selected limits, open-cover compactness, choice-selected representatives, Lean verification, or bridge checking.

Upgrade path: Lean verification and bridge checking require a checked target for the public compact-source, finite-net, directed Hausdorff, Vietoris, and completion-facing Hyperspace interface.

Theorem 1660.57 (Hyperspace compact-subset root admission)**.** *Every root consumer admitted by an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *carrier must first read compact-source admission through Definition 1660.1 and the local obligation rows of Definition 1660.3. The compact-subset request is therefore represented by the concrete BEDC rows* X, K_0, K_1, N_0, N_1 *together with finite subset-net schedules, tolerance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Hyperspace}^{\uparrow}}$ *row. It is not a host powerset element, quotient compactum, selected compact limit, open-cover compactness proof, or choice-selected representative.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace compact subset root admission`

Proof. Project the carrier. The source row X supplies the displayed compact metric surface, while K_0, K_1, N_0, N_1 provide the finite compact-subset presentations and resolution schedules.

Apply Definition 1660.3. Its compact-source and finite subset-net clauses force every root consumer to read the subset request through those displayed rows before any Hausdorff or Vietoris data is public.

The remaining rows R, H_s, C, P, M account for tolerance readback, transport, replay, provenance, and local naming. Since the excluded host and quotient objects are absent from the carrier, compact-subset admission is exactly the concrete BEDC row surface listed above. □

Theorem 1660.58 (Hyperspace directed Hausdorff root coverage)**.** *Every directed Hausdorff root read exported by an accepted* Hyperspace$^{\uparrow}$ *packet is covered by the two displayed ledgers D_0 and D_1, the finite net rows K_0, K_1, N_0, N_1, and the tolerance readback row R. The coverage must be bidirectional before a symmetric Hausdorff-distance consumer receives data, and the read remains transport-stable through H_s, replayed through C, packaged by P, and named by M. No directed coverage row may be replaced by a selected nearest point, quotient compact-subset equality, host Hausdorff metric, open-cover compactness, or ambient complete-hyperspace object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace directed hausdorff root coverage`

Proof. Use Definition 1660.6. It routes each displayed hit through the compact source and the finite subset-net schedules before the tolerance row can be consumed.

Apply Definition 1660.7. That theorem requires both D_0 and D_1 before a symmetric Hausdorff read is public, so a one-sided host selection cannot stand in for the missing direction.

Finally use the transport and provenance clauses of Definition 1660.3. The rows H_s, C, P, M preserve the same finite coverage route and add no selected point, quotient equality, host metric, open-cover proof, or ambient completion coordinate. □

Theorem 1660.59 (Hyperspace finite Hausdorff root obligations)**.** *The finite Hausdorff root surface of* Hyperspace$^{\uparrow}$ *is exhausted by compact-source admission, finite subset-net schedules, bidirectional directed Hausdorff coverage, tolerance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *rows carried by*

$$X, K_0, K_1, N_0, N_1, D_0, D_1, R, H_s, C, P, M.$$

Equivalently, the root surface cited by Definition 1660.12 cannot be strengthened by host powersets, quotient compacta, selected limits, open-cover compactness, selected nearest points, or choice-selected representatives.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceFiniteHausdorffRootObligations`

Proof. Begin with Definition 1660.12. It identifies the public Hausdorff read as the two directed finite ledgers together with the tolerance row over the displayed compact source and net schedules.

Use Definition 1660.57 to account for the root carrier and finite subset-net admission, and use Definition 1660.58 for the bidirectional directed coverage and tolerance readback.

The structural rows are then fixed by Definition 1660.3. Componentwise transport, continuation replay, provenance, and local naming are the only remaining public rows, so the excluded host and quotient objects cannot add a further root obligation. □

Theorem 1660.60 (Hyperspace Vietoris finite-window obligations)**.** *Every Vietoris-style finite-window read exported by an accepted* Hyperspace$^{\uparrow}$ *packet must pass through compact-source admission, subset-net schedules, directed Hausdorff coverage, tolerance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before a compact-subset consumer reads hit or miss data. The read is therefore exhausted by the same finite root surface as Definition 1660.59; it does not export a host Vietoris topology, arbitrary open-cover compactness, quotient compact-subset equality, selected nearest points, or an ambient complete hyperspace.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisFiniteWindowObligations`

Proof. Start with Definition 1660.57. It forces a compact-subset request to enter through the compact source and the finite subset-net schedules before any hit or miss observation is available.

Use Definition 1660.58. The hit and miss reads are routed through the two directed finite coverage ledgers and the shared tolerance readback row, so they cannot be supplied by a host Vietoris topology or by selected nearest points.

Finally apply Definition 1660.59. The remaining public rows are exactly componentwise transport, displayed replay, provenance, and local naming, which repack the same finite window without adding quotient compacta, open-cover compactness, or an ambient complete-hyperspace object. □

Theorem 1660.61 (Hyperspace Vietoris handoff)**.** *Every Vietoris-topology or Hausdorff-distance consumer of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet must first read the compact source row, the finite subset-net schedules, both directed coverage ledgers, and the tolerance readback row. In the notation of Definition 1660.1, the route is*

$$X, K_0, K_1, N_0, N_1, D_0, D_1, R \longmapsto H_s, C, P, M.$$

Thus the downstream interfaces of chapter 2375 and chapter 3653 consume the same compact-source and finite-net boundary supplied by chapter 129. When hyperspace packets are read through metric distance-to-closed-set witnesses, the Vietoris finite-hit and finite-miss surface also consumes the distance-function embedding route of chapter 7569; the consumers receive no host powerset topology, quotient compactum, selected compact limit, open-cover compactness proof, or untracked Hausdorff metric.

Proof. Project the accepted $\mathsf{Hyperspace}^{\uparrow}$ carrier. The source row X is the only compact metric source, and the finite subset-net schedules are displayed by K_0, K_1, N_0, N_1 before any directed distance or topology read is public.

Use the Hausdorff-distance ledger stability and finite Hausdorff carrier theorems of Definition 1660.2 and Definition 1660.12. They force the two directed coverage ledgers D_0, D_1 and the tolerance readback row R to be present before a symmetric Hausdorff consumer can read a distance value.

For Vietoris consumers, use the root Vietoris net basis and refinement factorization in Definition 1660.51 and Definition 1660.54. Those results route hit, miss, and refinement reads through the same compact source and finite subset-net schedules.

Both public reads therefore have the same source lock. The Vietoris-topology read cannot expose a hit or miss neighborhood until it has consumed the compact-metric source row X, the finite subset-net schedules K_0, K_1, N_0, N_1, and the directed coverage ledgers D_0, D_1 that witness how the scheduled finite subsets cover the compact source.

The Hausdorff-distance read is locked by the same rows. Before a symmetric distance value is public, the two directed coverage ledgers must already be visible over the displayed compact-metric source row and the finite subset-net schedules; otherwise the row would be an untracked host metric rather than the displayed Hausdorff-distance consumer of the hyperspace packet.

The structural rows H_s, C, P, M only transport, replay, source, and name this displayed packet. Since no forbidden host powerset, quotient compactum, selected compact limit, open-cover compactness proof, or untracked Hausdorff metric appears in the carrier, every Vietoris or Hausdorff consumer must use the stated handoff. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.Hyperspace vietoris handoff`

Lemma 1660.62 (Vietoris located-real tolerance dependency)**.** *Every Vietoris-topology or Hausdorff-distance consumer of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet that reads tolerance comparisons must route the tolerance through* $\mathsf{LocatedReal}^{\uparrow}$ *or the RealUp located-tolerance ledger before reading the symmetric Hausdorff value. In the notation of Definition 1660.1, the tolerance readback row* R *is therefore downstream of the compact source, finite subset-net schedules, and directed coverage ledgers named by Definition 1660.61, and upstream of the Hausdorff read consumed by chapter 3653.*

Proof. Project the accepted $\mathsf{Hyperspace}^{\uparrow}$ carrier. The compact source and finite subset-net schedules are the rows X, K_0, K_1, N_0, N_1, while D_0, D_1 record the directed coverage ledgers.

Apply Definition 1660.61. It forces both Vietoris and Hausdorff consumers to expose those rows before the tolerance readback row R becomes available.

The tolerance comparison itself must then be read through the displayed $\mathsf{LocatedReal}^{\uparrow}$ surface of chapter 1933 or through the located-tolerance ledger sealed by chapter 38. Since the carrier has no separate coordinate for an untracked Hausdorff metric or a host real comparison, the symmetric Hausdorff value can only be consumed after that located tolerance route is visible. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisLocatedRealDependency`

Vietoris–Hausdorff dependency route. The $\mathsf{Hyperspace}^{\uparrow}$ packet reads closed and compact subobjects through the $\mathsf{VietorisTopology}^{\uparrow}$ hit–miss surface of chapter 2375 and the $\mathsf{HausdorffDistance}^{\uparrow}$ scalar comparison surface of chapter 3653 before any compact-metric consumer inspects the hyperspace carrier. Thus the compact-subset route is not a kernel-only float: it exposes finite hit windows, finite miss windows, bidirectional Hausdorff ledgers, and the shared tolerance readback as the horizontal dependency surface between $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$.

Compact-metric dependency route. The Vietoris handoff of Definition 1660.61 is consumed only after the compact-source row of chapter 129 has exposed its finite-net and completeness support. Thus every $\mathsf{Hyperspace}^{\uparrow}$ route to Vietoris or Hausdorff data still factors through the displayed compact metric source, the finite subset-net schedules, the directed coverage ledgers, and the tolerance readback row; it receives no host powerset topology, selected compact subset, quotient compactum, or open-cover compactness proof outside the $\mathsf{CompactMetric}^{\uparrow}$ dependency.

Compact-metric Hausdorff dependency route. The $\mathsf{Hyperspace}^{\uparrow}$ packet exposes Vietoris and Hausdorff-distance consumers only after the compact source has passed through the $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{HausdorffDistance}^{\uparrow}$ rows. Thus a consumer may read hyperspace data only after the metric carrier, completeness witness, finite total-bounded schedules, compact-metric handoff, and Hausdorff comparison ledger have been displayed; it receives no host powerset topology, selected compact subset, quotient compactum, or open-cover compactness proof outside that dependency route.

Theorem 1660.63 (Hyperspace RealSeparability forward route)**.** *Every* $\mathsf{Hyperspace}^{\uparrow}$ *finite-net read over a Real-facing compact metric source may consume chapter 1809 only through the displayed density route*

$$\mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The route exposes rational density windows, dyadic tolerance comparisons, stream-name schedules, regular rational readback, and the final real-name seal before any compact-subset finite net is consumed. It exports no host powerset, selected nearest point, quotient compactum, choice-selected dense enumeration, or ambient compactness proof.

Proof. Project the $\mathsf{Hyperspace}^{\uparrow}$ carrier through Definition 1660.1. A Real-facing finite-net read can inspect only the compact metric source row, the displayed subset-net schedules, the directed coverage ledgers, the tolerance readback, and the visible transport, replay, package, and naming rows.

Now route the source-side density request through chapter 1809. The rational windows supply the $\mathsf{Rat}^{\uparrow}$ row, the tolerance comparisons pass through $\mathsf{DyadicRatCore}^{\uparrow}$, the finite read schedule is a $\mathsf{StreamName}^{\uparrow}$ window, and the readback is a $\mathsf{RegSeqRat}^{\uparrow}$ row before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Repack those density rows with the hyperspace finite-net ledgers. Since neither carrier contains a host powerset, selected nearest point, quotient compactum, choice-selected dense enumeration, or ambient compactness proof, the forward route is exactly the displayed Real-separability dependency stack. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceRealSeparabilityForwardRoute`

Uniform-completion reflector forward link. The $\mathsf{Hyperspace}^{\uparrow}$ packet reads closed-set and compact-subset carriers through the Vietoris hit–miss route of chapter 2375, the Hausdorff metric comparison route of chapter 2086, and the compact metric source route of chapter 129 before any $\mathsf{UniformCompletionReflector}^{\uparrow}$ consumer can view the hyperspace as a completed uniform object. Thus completion-facing hyperspace data remains a displayed dependency lattice over finite Vietoris windows, Hausdorff comparison rows, compact-metric schedules, and the reflector packet of chapter 6282, with no host powerset topology, selected compact subset, quotient compactum, or ambient completion object.

1660.1 Downstream Dependency Lattice

Theorem 1660.64 (Hyperspace Vietoris downstream dependency)**.** *Every* $\mathsf{VietorisTopology}^{\uparrow}$ *or* $\mathsf{HausdorffDistance}^{\uparrow}$ *downstream read of an accepted* $\mathsf{Hyperspace}^{\uparrow}$ *packet consumes the compact source, finite subset-net schedules, and directed coverage ledgers of Definition 1660.61 before it may expose a topology row or distance row. In particular, the interfaces of chapter 2375 and chapter 3653 both pass through the compact-metric boundary of chapter 129; neither consumer receives a host powerset topology, quotient compactum, selected compact limit, open-cover compactness proof, or untracked Hausdorff metric.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisDownstreamDependency`

Proof. Read the handoff theorem Definition 1660.61. It forces any Vietoris-topology or Hausdorff-distance consumer to open the compact source row, finite subset-net schedules, directed coverage ledgers, and tolerance readback row before the structural transport, replay, provenance, and naming rows are public.

For a $\mathsf{VietorisTopology}^{\uparrow}$ consumer, the topology row is therefore downstream from the finite hit, miss, and refinement data already supplied by the compact source and subset-net schedules. It cannot be exposed as a host powerset topology independent of those rows.

For a $\mathsf{HausdorffDistance}^{\uparrow}$ consumer, the distance row is downstream from the two directed coverage ledgers and the same tolerance readback boundary. It cannot be exposed as an untracked metric, selected compact limit, quotient compactum, or open-cover compactness proof.

Thus the compact-metric dependency of chapter 129 sits below both downstream consumers in the same lattice: compact source first, finite nets and directed coverage next, topology or distance rows only after that displayed dependency path. □

Theorem 1660.65 (Hyperspace scoped closure route)**.** *Every accepted* Hyperspace$^{\uparrow}$ *consumer that reaches a compact-subset, directed Hausdorff, Vietoris, or completion-facing read is exhausted by the displayed carrier rows of Definition 1660.1, the compact source route through chapter 129, the metric-distance witnesses of chapter 57, the Hausdorff comparison route of chapter 2086, the Vietoris handoff of chapter 2375, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already named by the packet.*

Thus the scoped Hyperspace$^{\uparrow}$ *surface is the finite dependency lattice over compact-source admission, finite subset-net schedules, bidirectional Hausdorff windows, Vietoris hit–miss windows, completion-boundary handoffs, componentwise transport, displayed replay, provenance, and local naming. It exports no host powerset topology, selected compact subset, quotient compactum equality, open-cover compactness proof, selected nearest point, choice-selected subcover, or ambient complete-hyperspace object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceScopedClosureRoute`

Proof. Project the accepted packet through Definition 1660.1. The compact source, finite subset-net rows, directed Hausdorff ledgers, tolerance readback, transport, replay, provenance, and local naming rows are the only coordinates available to a consumer.

Use Definition 1660.57, Definition 1660.59, and Definition 1660.60. These root obligations force compact-subset, Hausdorff, and Vietoris reads to pass through the same finite carrier rows before any downstream surface is public.

For completion-facing consumers, apply Definition 1660.50, Definition 1660.53, and Definition 1660.46. They keep the completion route inside the displayed compact-source, net-convergence, complete-metric, Cauchy-uniform, and structural rows.

The sibling lattice citations then identify the external reads: CompactMetric supplies compact finite-net admission, Metric supplies distance witnesses, HausdorffMetric supplies the comparison route, and Vietoris supplies hit–miss consumption. Because the carrier contains no excluded host object or selected witness coordinate, the named finite lattice is the whole scoped surface. □

Theorem 1660.66 (Hyperspace public certificate route)**.** *The public* Hyperspace$^{\uparrow}$ *interface exports exactly the compact-metric source rows, finite compact-subset net schedules, directed Hausdorff-distance and Vietoris handoff rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming already visible in the scoped packet. A public reader may consume the route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{HausdorffDistance}^{\uparrow},\quad \mathsf{VietorisTopology}^{\uparrow},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}$$

only through those displayed rows, and receives no quotient hyperspace, host powerset topology, selected compact representative, selected nearest point, open-cover compactness proof, or ambient complete-hyperspace object.

Proof. Project the accepted Hyperspace$^{\uparrow}$ packet through Definition 1660.1. The compact source, finite subset-net schedules, directed coverage ledgers, tolerance readback, transport, replay, provenance, and local naming rows are the only coordinates available to a public consumer.

Use Definition 1660.65. It already routes compact-subset, directed Hausdorff, Vietoris, and completion-facing reads through the same compact-source and finite-net dependency lattice before any downstream surface is public.

Finally apply the downstream dependency and Vietoris handoff theorems, Definition 1660.64 and Definition 1660.61. They identify the public Hausdorff-distance and Vietoris handoff rows with

the displayed finite ledgers, so the excluded quotient, host-topological, selected-representative, and open-cover objects have no public coordinate. □

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspacePublicCertificate`

Theorem 1660.67 (Hyperspace bridged interface route)**.** *The public* Hyperspace$^{\uparrow}$ *certificate of Definition 1660.66 is bridged by the displayed compact-metric finite-net rows, Hausdorff metric rows, Vietoris handoff rows, and completion-facing dependency routes already present in the hyperspace packet. More precisely, every bridged reader must pass through the compact-source route of chapter 129, the Hausdorff comparison route of chapter 2086, the Vietoris handoff of Definition 1660.61, the scoped lattice of Definition 1660.65, and the completion-facing handoff of Definition 1660.53 before consuming the public interface. The bridge exports no host powerset, quotient compactum, selected limit, open-cover compactness proof, selected nearest point, or ambient complete-hyperspace object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceBridgedInterfaceRoute`

Proof. Start with the public certificate route. It exposes only the compact-metric source rows, finite compact-subset schedules, directed Hausdorff ledgers, Vietoris handoff rows, structural transport, replay, provenance, and local naming rows.

The compact-metric and Hausdorff rows are then read through the sibling dependency files and the scoped closure route. These force finite-net schedules, bidirectional Hausdorff windows, and metric witnesses to remain visible before any public hyperspace reader can inspect compact-subset data.

For topology and completion-facing consumers, apply the Vietoris handoff and the root complete–totally-bounded handoff. Both routes reuse the same displayed compact source, finite net rows, directed Hausdorff ledgers, completion boundary, transport, replay, provenance, and naming rows. Hence the public certificate has a bridged interface using only the rows already present in the chapter. □

Theorem 1660.68 (Hyperspace bridged route formal target)**.** *The paper bridge of Definition 1660.67 is aimed at the checked public certificate target*

BEDC.Derived.HyperspaceUp.HyperspacePublicCertificate.

This ledger row records the formal target for the compact-metric, Hausdorff, Vietoris, and completion-facing public route while keeping the bridge-status claim separate from Lean bridge checking.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceBridgedRouteFormalTarget`

Proof. Use Definition 1660.67. Its route already factors every public reader through the compact-metric, Hausdorff, Vietoris, scoped-lattice, and completion-facing rows.

The named Lean target is the public certificate theorem for that same finite route. Recording it here identifies the formal endpoint of the paper bridge without asserting a checked standard bridge or changing the chapter closure block. □

Theorem 1660.69 (Compact-metric Vietoris maturity route)**.** *Every mature* Hyperspace$^{\uparrow}$ *Vietoris or Hausdorff-distance consumer first reads* CompactMetric$^{\uparrow}$ *finite-net data,* HausdorffMetric$^{\uparrow}$ *distance rows, and* KuratowskiHyperspace$^{\uparrow}$ *closure rows before it exports compact-subset data. More precisely, the consumer route factors through the compact-metric dependency route of chapter 129, the Vietoris handoff of Definition 1660.61, the compact-metric Vietoris unblock of Definition 1660.30,*

the bridged interface route of Definition 1660.67, the Hausdorff metric chapter of chapter 2086, and the Kuratowski hyperspace chapter of chapter 5944. The route exports no host powerset, quotient compactum, selected nearest point, open-cover compactness proof, or ambient complete hyperspace object.

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceMatureCompactMetricVietorisRoute`

Proof. Start with the compact-metric dependency route. It forces every Vietoris or Hausdorff-distance consumer to expose the compact source, finite-net schedules, directed coverage ledgers, and tolerance readback before the local $\mathsf{Hyperspace}^{\uparrow}$ rows are inspected.

Next apply the Vietoris handoff and the compact-metric Vietoris unblock. These routes identify the hit–miss rows and finite compact-subset windows that may be consumed, while keeping the compact-source row visible through chapter 129.

Finally apply the bridged interface route. The Hausdorff metric rows of chapter 2086 and the Kuratowski closure rows of chapter 5944 are read before any compact-subset export, so the mature consumer remains a finite dependency route rather than a host powerset or completion principle. □

Theorem 1660.70 (Hyperspace Vietoris mature envelope)**.** *The compact-metric finite-net row, Hausdorff metric row, Kuratowski hyperspace row, and Vietoris handoff together form the mature exported envelope for* $\mathsf{Hyperspace}^{\uparrow}$*. Every top-window consumer of compact-subset data must read those four rows after the local carrier and before any public compact-subset export, and the route exports no host powerset, quotient compactum, selected nearest point, open-cover compactness proof, or ambient complete hyperspace object.*

Lean4 ✓ `BEDC.Derived.HyperspaceUp.HyperspaceVietorisMatureEnvelope`

Proof. Apply the compact-metric Vietoris maturity route of Definition 1660.69. It already forces Vietoris and Hausdorff-distance consumers through compact-metric finite-net data before any compact-subset export.

Read the two sibling rows next. The Hausdorff metric chapter supplies the finite distance ledger, and the Kuratowski hyperspace chapter supplies the closure-facing row consumed by the same compact-source route.

Finally use the Vietoris handoff of Definition 1660.61. The handoff keeps hit–miss and compact-subset window data attached to the displayed finite-net route, so the four rows jointly form the mature envelope without adding any refused host object. □

Chapter 1661

A Concrete Naming Certificate for $\mathsf{LocatedCauchyFilter}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Kelley filterbase terminology, the $\mathsf{LocatedCauchyFilter}^{\uparrow}$ packet records the filter-level located witness surface used by the L10 completion route before any quotient filter, selected limit, countable-choice selector, host equality, or $\mathsf{Real}^{\uparrow}$ completeness principle is available. It sits between the Cauchy-filter carrier of chapter 333, the basis-level witness rows of chapter 1501, the regular filter route of chapter 1445, and the sequence-level located witness of chapter 1595. Its finite readback path uses the stream windows of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the downstream real-name seal of chapter 38.

Definition 1661.1 (Located Cauchy filter carrier)**.** *A* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, B, R, S, Q, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row naming the accepted Cauchy filter surface.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row that exposes finite basis neighborhoods and refinement witnesses.*
3. *R is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *row carrying the regular tail budget attached to the basis surface.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by sequence-facing consumers.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for located ball comparisons.*
7. *T is the located tail row, recording the displayed witness that the filter basis eventually meets the requested dyadic ball.*
8. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary, reachable only after F, B, R, S, Q, D, T have been consumed.*
9. *H records componentwise* hsame *transport for the filter, basis, regularity, window, readback, dyadic, located-tail, seal, continuation, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a located precision request through $F, B, R, S, Q, D, T, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{LocatedCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient filters, selected limits, countable choice, hidden infinite basis inspection, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterTasteGate single carrier alignment`

Theorem 1661.2 (Located Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *carrier* $L = (F, B, R, S, Q, D, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Cauchy filter row, basis row, regular filter row, finite-window row, rational readback row, dyadic tolerance ledger, located-tail row, seal boundary, transport, continuation, provenance, and local naming row;*

2. *basis exposure, requiring every located request to read the displayed basis row B only after the Cauchy filter row F has been fixed;*

3. *regular-tail exactness, requiring the regular filter row R and located-tail row T to share the same basis request and dyadic tolerance ledger D;*

4. *sequence handoff compatibility, requiring S and Q to expose only finite windows and regular rational readbacks generated from the same located filter request;*

5. *transport replay, requiring H and C to preserve the route through F, B, R, S, Q, D, T, E under componentwise* hsame *and displayed continuation;*

6. *real-seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$*-facing read to pass through the filter, basis, regularity, window, readback, dyadic, and located-tail rows before it reaches E;*

7. *provenance and name exhaustion, requiring P and N to name only this finite route and to export no quotient filters, selected limits, countable choice, hidden basis inspection, host equality, or ambient completeness.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterNameCertObligations`

Proof. Carrier admission is projection from Definition 1661.1. The visible analytic rows are precisely the Cauchy filter, basis, regularity, stream-window, rational readback, dyadic tolerance, located-tail, and downstream seal rows.

For basis exposure, replay a located precision request through C. The request first fixes the Cauchy filter row F, then reads the finite basis neighborhoods in B; no sequence window or real-facing seal is available before this basis route is displayed.

Regular-tail exactness is read from R, D, T. The regular row R records the tail budget over the same basis request, the dyadic ledger D supplies the requested ball data, and the located-tail row T witnesses that the basis eventually meets that displayed ball.

The sequence handoff uses only finite data. The rows S and Q expose the requested windows and regular rational readbacks downstream of F, B, R, D, T, so they cannot introduce hidden infinite basis inspection or a selected limit.

Finally, H and C preserve the same ordered route under transport and replay. The seal boundary E appears only after F, B, R, S, Q, D, T, and the provenance and name rows P, N have no coordinates for quotient filters, selected limits, countable choice, host equality, or ambient completeness. □

Theorem 1661.3 (Located Cauchy filter regular tail location)**.** *Let $L = (F, B, R, S, Q, D, T, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *carrier. Every regular-tail request in R factors through the finite located route*

$$F, B, D \longmapsto T \longmapsto R \longmapsto S, Q, H, C, P, N.$$

Thus the regular filter consumer receives a displayed Cauchy filter, a finite basis neighborhood, a dyadic tolerance ledger, and a located-tail witness before any sequence-facing readback or real-facing seal can be inspected.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterRegularTailLocation`

Proof. Start with a regular-tail request. By Definition 1661.1, the row R is packaged with the Cauchy filter row F, the basis row B, the dyadic ledger D, and the located-tail row T.

Apply the basis exposure and regular-tail exactness clauses of Definition 1661.2. The request fixes F and B, then reads the dyadic ball data in D, and only then consumes the located witness T attached to that same basis request.

The remaining rows are downstream support. The sequence windows S, rational readbacks Q, transport H, replay C, provenance P, and local name N preserve and package the same finite route; none of them adds a quotient filter, selected limit, countable-choice selector, hidden basis inspection, host equality, or ambient completeness witness. □

Theorem 1661.4 (Located Cauchy filter basis-refinement route)**.** *Every located-tail read T in an accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *packet*

$$L = (F, B, R, S, Q, D, T, E, H, C, P, N)$$

first fixes the $\mathsf{CauchyFilter}^{\uparrow}$ *row F, then refines through the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row B at the displayed dyadic tolerance D, and only then exposes the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *row R,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and* $\mathsf{Real}^{\uparrow}$ *seal row E.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterBasisRefinementRoute`

Proof. Project the carrier. The located-tail coordinate T is packaged with exactly one Cauchy filter row F, one basis row B, one dyadic tolerance ledger D, and the downstream rows R, S, Q, E, H, C, P, N.

Use the basis exposure clause of Definition 1661.2. A located request fixes F before it may inspect the displayed basis row B.

Use the regular-tail exactness clause of the same theorem. The basis refinement is read at the dyadic tolerance recorded in D, and the located-tail row T shares that displayed request before R, S, Q or E are available.

The remaining rows only preserve or consume the finite route. Hence quotient filters, selected limits, countable choice, hidden basis inspection, host equality, and ambient completeness are absent from the refinement path. □

Theorem 1661.5 (Located Cauchy filter choice-free basis)**.** *Every accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *read factors through the displayed filter row F, basis row B, regular tail ledger R,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows S, Q, dyadic located-tail rows D, T, and the* $\mathsf{Real}^{\uparrow}$ *seal row E before*

any limit-facing consumer can inspect it. The route introduces no countable choice, hidden filter selection, quotient filter equality, selected limit, host equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterChoiceFreeBasis`

Proof. Project the carrier $L = (F, B, R, S, Q, D, T, E, H, C, P, N)$ using Definition 1661.1. The displayed filter and basis rows are F and B, and the regular tail and located dyadic rows are R, D, T.

Apply the basis-refinement route of Definition 1661.4. A located-tail read first fixes the Cauchy filter row and then refines through the displayed basis row at the requested dyadic tolerance before the downstream sequence or real-facing rows are visible.

Now combine the Real seal boundary of Definition 1661.6 with the regular sequence handoff of Definition 1661.8. The route through S, Q, D, T reaches the seal E only as displayed finite readback data, so no countable-choice selector or hidden filter selection is introduced. □

Theorem 1661.6 (Located Cauchy filter Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *carrier factors through the complete finite route*

$$F, B, R, S, Q, D, T, E, H, C, P, N.$$

Consequently a downstream consumer cannot read the terminal real-name seal without also reading the Cauchy filter row, basis row, regular tail budget, finite stream windows, regular rational readback, dyadic tolerance ledger, located-tail witness, componentwise transport, displayed continuation, provenance, and local NameCert row.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterRealSealBoundary`

Proof. Begin with a downstream real-facing read. The carrier exposes the seal only as E, and E is listed after the filter, basis, regularity, window, readback, dyadic, and located-tail rows in Definition 1661.1.

Use the real-seal non-escape clause of Definition 1661.2. Any request that reaches E must first pass through F, B, R, S, Q, D, T, so the terminal seal is a routed finite read rather than a host-selected limit.

The structural rows then preserve the route. The rows H, C, P, N transport, replay, source, and name the same displayed packet, and the carrier has no coordinate for quotient filters, countable choice, hidden basis inspection, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1661.7 (Located Cauchy filter Bishop completion handoff)**.** *Every accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *packet consumed by* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *must expose the rows*

$$F, B, R, S, Q, D, T, E, H, C, P, N$$

before the completion seal is read. The route uses the existing $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CauchyFilterBasis}^{\uparrow}$*,* $\mathsf{RegularCauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, and it exports no quotient filter, selected limit, countable choice, host equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterBishopCompletionHandoff`

Proof. Project the accepted carrier using Definition 1661.1. The visible rows are exactly the filter row F, basis row B, regular filter row R, finite windows S, regular readback Q, dyadic ledger D, located-tail row T, Real seal row E, and structural rows H, C, P, N.

Apply the basis-refinement route of Definition 1661.4. A completion-facing request fixes the Cauchy filter row and basis row at the displayed dyadic tolerance before the regular filter row, finite windows, or readback rows are available.

Now use the Real seal boundary of Definition 1661.6 together with the regular sequence handoff of Definition 1661.8. The $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ consumer reads the completion seal only after $F, B, R, S, Q, D, T, E, H, C, P, N$ have been displayed, so the route has no coordinate for quotient filters, selected limits, countable choice, host equality, or ambient completeness. □

Theorem 1661.8 (Located Cauchy filter regular sequence handoff)**.** *Every sequence-facing consumer of an accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *packet*

$$L = (F, B, R, S, Q, D, T, E, H, C, P, N)$$

factors through the finite sequence route

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}$$

before the downstream $\mathsf{Real}^{\uparrow}$ *seal row E can be inspected. Equivalently, a consumer that asks for a sequence presentation of the located filter must read the window row S, the regular rational readback Q, the dyadic tolerance ledger D, and the located-tail witness T before it reaches E.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterRegularSequenceHandoff`

Proof. Project the accepted carrier. The sequence-facing rows are exactly S and Q, and the dyadic tolerance needed to interpret their located readback is the displayed ledger D.

Use the sequence handoff compatibility clause of Definition 1661.2. It forces S and Q to expose only finite windows and regular rational readbacks generated from the same located filter request.

Replay the continuation route C. The request passes through S, Q, D, T before it can reach the seal boundary E, so the real-facing read is downstream from the sequence route rather than a selected limit.

Finally, apply the Real seal boundary of Definition 1661.6. The rows H, C, P, N preserve and name the same finite handoff, and no quotient filter, countable-choice selector, hidden basis inspection, host equality, or ambient completeness row is exported. □

Theorem 1661.9 (Located Cauchy filter Real extraction)**.** *An accepted* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *packet whose located base, Cauchy-filter row, modulus row, and regular-readback row are displayed determines a* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible Real-readback route. The extraction preserves the locatedness and Cauchy rows through F, B, D, T and the regular sequence readback through S, Q, and it does not select a host limit, quotient stream equality, or completed-real object.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterRealExtraction`

Proof. Read the carrier of Definition 1661.1. The located base is displayed by B, D, T over the Cauchy filter row F, while the sequence-facing readback is displayed by the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows S, Q.

Apply the regular-tail location and basis-refinement route, Definition 1661.3 and Definition 1661.4. These force every located request through the same Cauchy filter, basis, dyadic tolerance, and located-tail rows before the regular filter and sequence readback are visible.

Now use the regular sequence handoff together with the Real seal boundary, Definition 1661.8 and Definition 1661.6. The route reaches E only after S, Q, D, T have been displayed, so the Real-facing extraction is a finite $\mathsf{RegSeqRat}^{\uparrow}$-compatible readback rather than a selected limit, quotient stream equality, or completed-real object. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilter}\uparrow}$.

Constructive story: A $\mathsf{LocatedCauchyFilter}^{\uparrow}$ packet is generated from a CauchyFilter row, a CauchyFilterBasis row, a RegularCauchyFilter tail budget, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a located-tail witness, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilter}\uparrow}, \mathsf{scopedClosed})$

Scope closed: Definition 1661.1, Definition 1661.2, Definition 1661.3, Definition 1661.4, and Definition 1661.6 seed the filter-level located Cauchy packet between CauchyFilter, CauchyFilterBasis, RegularCauchyFilter, LocatedCauchySequence, StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilter}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedCauchyFilterUp.LocatedCauchyFilterNameCertObligations`

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, selected limits, countable choice, hidden infinite basis inspection, host real equality, ambient Real completeness, or a public standard bridge.

Upgrade path: Public export or bridge work requires a standard interface for the checked located-filter route.

Chapter 1662

A Concrete Naming Certificate for $\mathsf{RealUniformEmbedding}^{\uparrow}$

Following Bishop and Bridges' constructive Cauchy completion and the Bourbaki-Kelley uniform-space terminology, the $\mathsf{RealUniformEmbedding}^{\uparrow}$ packet records the finite uniform embedding by which a regular Cauchy name enters the $\mathsf{Real}^{\uparrow}$ seal without becoming a quotient stream or a host real. It binds the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal seal of chapter 38, the dense uniform route of chapter 1651, and the regular completion boundary of chapter 1639. The packet is the Real and Completion handoff for finite regular Cauchy data; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, select representatives, or compare host real values.

Definition 1662.1 (Real uniform embedding carrier)**.** *A* $\mathsf{RealUniformEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, W, D, Q, E, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy name row, read as a finite regular rational stream rather than as a quotient class.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family recording the inspected prefixes and common refinements available to the embedding route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that names dyadic radii, tail budgets, and comparison obligations for the displayed windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracting regular rational sequence data from S through W and D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the finite regular Cauchy data have passed through the dyadic and readback route.*
6. *U is the uniform-control compatibility row stating that the source row, finite windows, dyadic tolerances, readback row, and Real seal are read over one displayed uniform embedding path.*
7. *H records componentwise* hsame *transport for S, W, D, Q, E, U and for the structural rows.*
8. *C records displayed* Cont *replay from a Real or completion tolerance request through W, D, Q, U and into the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E.*

9. *P is the* Pkg *provenance over* $\mathsf{RealUniformEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformEmbedding}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite regular Cauchy uniform embedding packet. It contains no coordinate for quotient stream equality, host real equality, selected representatives, countable choice, ambient completeness, or a detached Real object.

Lean4 ✓ `BEDC.Derived.RealUniformEmbeddingUp.TasteGate.RealUniformEmbeddingTasteGate single carrier alignment`

Lean4 (definition) `BEDC.Derived.RealUniformEmbeddingUp`

Lean4 ✓ `BEDC.Derived.RealUniformEmbeddingUp.RealUniformEmbeddingTasteGate single carrier alignment`

Theorem 1662.2 (Real uniform embedding NameCert obligations)**.** *For every accepted* $\mathsf{RealUniformEmbedding}^{\uparrow}$ *carrier* $R = (S, W, D, Q, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealUniformEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, StreamName window row, DyadicRatCore tolerance ledger, RegSeqRat readback row, Real seal row, uniform-control compatibility row, transport row, replay row, provenance row, and local naming row;*

2. *uniform-window compatibility, requiring every inspected finite window in W to be read over the same source row S and dyadic tolerance ledger D before it reaches the embedding route;*

3. *RegSeqRat readback stability, requiring Q to preserve the regular rational reading of S across the displayed windows and dyadic comparison budgets;*

4. *Real seal handoff, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through S, W, D, Q, U before the seal row E is exposed;*

5. *classifier transport, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the same ordered route;*

6. *ledger non-escape, requiring P and N to export no quotient stream equality, host real equality, selected representative, countable choice, ambient completeness, or detached Real carrier.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealUniformEmbeddingUp.RealUniformEmbeddingUp single carrier alignment`

Proof. Carrier admission is projection from Definition 1662.1. The tuple lists the source row, finite windows, dyadic tolerance ledger, regular rational readback, Real seal, compatibility row, transport, replay, provenance, and local naming.

Uniform-window compatibility is the row U read together with W and D. A finite window cannot enter the embedding route until it has been tied to the same source regular Cauchy row and the same dyadic comparison budget.

RegSeqRat readback stability is the row Q. It reads S only through the displayed windows and tolerance ledger, so refinements of W preserve the same regular rational data rather than replacing the source by a quotient representative.

The Real seal handoff is ordered by C. Replay sends a Real or completion request through W, D, Q, U before exposing E, and H transports only the displayed rows along the same route.

Finally, P and N package exactly the named dependencies and local certificate. Since the carrier contains no excluded quotient, host-equality, representative, choice, completeness, or detached-Real coordinate, the listed rows exhaust the NameCert surface. □

Theorem 1662.3 (Real uniform embedding seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealUniformEmbedding}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto W \longmapsto D \longmapsto Q \longmapsto U \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a uniformly controlled regular Cauchy entry into the Real seal, and receives no quotient stream equality, host real equality, selected representative, countable-choice schedule, ambient completeness theorem, or detached Real object.

Proof. Let $R = (S, W, D, Q, E, U, H, C, P, N)$ be accepted. Carrier projection gives the consumer only the displayed rows of Definition 1662.1.

The route begins with the source regular Cauchy row S and the finite windows W. The dyadic tolerance ledger D fixes the comparison budget for each inspected window before any Real-facing read is available.

The readback row Q then exposes regular rational data through the same window and tolerance route. The compatibility row U binds that readback to the uniform-control surface used by dense uniform embedding and Bishop regular Cauchy completion consumers.

Only after those rows have been displayed does the replay row C expose the Real seal row E. The transport row H, provenance row P, and local naming row N preserve and name the same finite path.

There is no remaining carrier coordinate from which a consumer could project quotient stream equality, host real equality, a selected representative, countable choice, ambient completeness, or a detached Real object. Hence every Real consumer factors through the displayed route. □

Lean4 ✓ `BEDC.Derived.RealUniformEmbeddingUp.RealUniformEmbeddingSealHandoff`

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformEmbedding}^{\uparrow}$ packet is generated from a source regular Cauchy row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a Real seal row, uniform-control compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealUniformEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 1662.1, Definition 1662.2, and Definition 1662.3 seed the finite uniform embedding surface from regular Cauchy names into the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealUniformEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host real equality, selected representatives, countable choice, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, uniform-window compatibility, RegSeqRat readback stability, Real seal handoff, classifier transport, and ledger non-escape proofs for BEDC.Derived.RealUniformEmbeddingUp.

Chapter 1663

A Concrete Naming Certificate for $\mathsf{ApartnessTopology}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{ApartnessTopology}^{\uparrow}$ packet names the topology generated by finite apartness-neighbourhood evidence rather than by host subsets of a completed real space. It sits over the positive gap handoff of chapter 1380, the located neighbourhood windows of chapter 1498, the metric ball basis route of chapter 1655, the located metric comparison interface of chapter 1533, and the located set distance surface of chapter 1541. The chapter isolates the constructive-topology frontier where finite gap evidence is repacked as neighbourhood data without importing powersets, quotient opens, trichotomy, selected limits, or open-cover compactness.

Definition 1663.1 (ApartnessTopology carrier)**.** *An* $\mathsf{ApartnessTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, O, T, M, S, W, R, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{LocatedApartness}^{\uparrow}$ *positive-gap row, including the two located sources, the shared finite window, the dyadic endpoint ledgers, and the gap evidence.*
2. *O is the* $\mathsf{LocatedOpen}^{\uparrow}$ *neighbourhood-window row that records the finite interval-entry or positive-radius witnesses read by a local neighbourhood consumer.*
3. *T is the* $\mathsf{MetricTopology}^{\uparrow}$ *basis row through which the generated neighbourhood packet is admitted as an indexed topology row.*
4. *M is the* $\mathsf{LocatedMetric}^{\uparrow}$ *comparison row tying the same observations to finite metric-distance and dyadic locatedness reads.*
5. *S is the* $\mathsf{LocatedSet}^{\uparrow}$ *membership row exposing the displayed set admission and located-distance route used by neighbourhood membership checks.*
6. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row on which the apartness, located-open, located-metric, and located-set reads are aligned.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations inspected by G, O, M, S.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the positive gap, endpoint, radius, and tolerance rows used by the neighbourhood request.*
9. *D is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream, regular-rational, and dyadic rows have been displayed.*

10. *E records the local neighbourhood packet generated from the transported apartness gap and the located-open window.*

11. *H records componentwise* hsame *transport for the apartness row, located-open row, metric-topology row, located-metric row, located-set row, readbacks, generated neighbourhood packet, continuation, provenance, and local naming row.*

12. *C records displayed* Cont *replay from apartness gap requests to located neighbourhood windows, then to metric-topology basis rows and located-set membership reads.*

13. *P is the* Pkg *provenance over* $\mathsf{ApartnessTopology}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{LocatedOpen}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, O, T, M, S, W, R, Q, D, E, H, C, P, N$. It has no coordinate for host powersets, quotient opens, classical trichotomy, selected limits, open-cover compactness, or an independent $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.ApartnessTopologyUp.ApartnessTopologyTasteGate single carrier alignment`

Theorem 1663.2 (ApartnessTopology NameCert obligation surface)**.** *For every accepted* $\mathsf{ApartnessTopology}^{\uparrow}$ *carrier $A = (G, O, T, M, S, W, R, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ApartnessTopology}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier visibility: the packet displays the located-apartness gap, located-open window, metric-topology basis route, located-metric comparison row, located-set membership row, readbacks, generated neighbourhood packet, transport, replay, provenance, and local naming row;*

2. *gap-to-neighbourhood generation: the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap row of G is aligned over W, R, Q, D and repacked as the neighbourhood packet E through the located-open row O;*

3. *topology admission: the generated neighbourhood packet is admitted only through the indexed basis route T and the comparison and membership rows M, S;*

4. *transport stability: componentwise* hsame *transport preserves the apartness gap, located window, metric basis, located metric comparison, located set membership, readbacks, and generated neighbourhood packet together;*

5. *boundary non-escape: the packet exports no host powerset, quotient open, trichotomy row, selected limit, open-cover compactness datum, or standalone* $\mathsf{Real}^{\uparrow}$ *completeness field.*

No local NameCert obligation is stored outside these five finite rows.

Lean4 ✓ `BEDC.Derived.ApartnessTopologyUp.ApartnessTopologyCarrier namecert obligation surface`

Proof. Carrier visibility is projection from Definition 1663.1. The displayed tuple lists the apartness, neighbourhood, topology, located-metric, located-set, readback, transport, replay, provenance, and local naming rows.

The generation row uses the shared finite window. The positive gap of G is transported over W, R, Q, D and then read by the located-open row O, so the generated neighbourhood packet E is determined by finite apartness evidence and the displayed neighbourhood window.

Topology admission is forced through T, M, S. The metric-topology row supplies the indexed basis route, while the located-metric and located-set rows supply the comparison and membership reads required by the same neighbourhood packet.

Transport stability follows componentwise from H and replay from C. These rows move the gap, window, basis, comparison, membership, readback, and generated-neighbourhood data together, so no detached witness can enter the local certificate.

The negative boundary is immediate from the carrier coordinates. Since no host powerset, quotient-open representative, trichotomy row, selected limit, compactness witness, or independent completeness field appears in A, the five listed rows exhaust the NameCert surface. □

Theorem 1663.3 (Apartness neighbourhood transport)**.** *Let $A = (G, O, T, M, S, W, R, Q, D, E, H, C, P, N)$ be an accepted* $\mathsf{ApartnessTopology}^{\uparrow}$ *packet. If the positive apartness gap row of G is transported componentwise along H over the shared finite window and readbacks W, R, Q, D, then the transported gap generates the same located neighbourhood packet E through O, T, M, S and the replay row C. This generation uses only the finite* BHist *route named by the carrier; it does not invoke host powersets, trichotomy, quotient opens, selected limits, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ApartnessTopologyUp.ApartnessTopologyCarrier neighborhood apartness transport`

Proof. Begin with the positive gap row inside G. The row is already attached to the shared finite window, regular-rational readbacks, dyadic endpoint and radius ledgers, and the real seal listed as W, R, Q, D.

Apply the transport row H componentwise. The transported packet still carries the same finite window indices, readback rows, dyadic gap evidence, and real-facing seal, so the transported apartness evidence remains aligned with the located-open window O.

Replay the neighbourhood request through C. The replay first reads O to form the located neighbourhood packet, then uses T for indexed topology admission, M for located metric comparison, and S for located set membership.

The resulting neighbourhood packet is therefore the same E named in the carrier, transported along the same finite rows. The construction never leaves $G, O, T, M, S, W, R, Q, D, E, H, C, P, N$, and hence cannot use any excluded powerset, quotient, trichotomy, selection, compactness, or completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessTopology}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ApartnessTopology}^{\uparrow}$ packet is generated from located-apartness positive gap evidence, located-open neighbourhood windows, metric-topology basis rows, located-metric comparison rows, located-set membership rows, StreamName windows, RegSeqRat readbacks, DyadicRatCore ledgers, RealUp seals, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1663.1, Definition 1663.2, and Definition 1663.3 seed the finite apartness-generated neighbourhood carrier, obligation surface, and transport route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient topologies, host powersets, classical trichotomy, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, gap-to-neighbourhood generation, topology admission, transport stability, boundary non-escape, and neighbourhood transport for BEDC.Derived.ApartnessTopologyUp.

Chapter 1664

A Concrete Naming Certificate for $\mathsf{RealOne}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealOne}^{\uparrow}$ packet records the unit real as the visible rational-one route into the real-name surface, not as a host primitive. It sits beside the zero-real packet of chapter 1619 and reads its source through the rational embedding route of chapter 1491, the rational carrier of chapter 37, the constant window of chapter 126, the stationary regular-rational readback of chapter 301, the dyadic unit ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is the finite unit-real route consumed by later real algebra, order, metric, and completion-facing chapters.

Definition 1664.1 (RealOne carrier)**.** *A* $\mathsf{RealOne}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (q, S, R, D, E, H, C, P, N)$$

with the following displayed coordinates:

1. *q is the* $\mathsf{Rat}^{\uparrow}$ *unit seed row, read as the rational numerator-denominator packet for* 1*.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *window whose every admitted finite request reads the same seed q.*
3. *R is the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to the constant unit window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *unit ledger recording the dyadic endpoint, tolerance, and radius rows used by the unit source.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the rational seed, constant window, stationary readback, and dyadic unit ledger have been displayed.*
6. *H stores componentwise* hsame *transport for the rational seed, constant window, stationary readback, dyadic ledger, terminal seal, provenance, and local name.*
7. *C stores displayed* Cont *replay routes from q through S, from S through R and D, and from those rows into the terminal seal E.*
8. *P records* Pkg *provenance over* $\mathsf{RealOne}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{RationalEmbedding}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, trichotomy, multiplication laws, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealOneUp.RealOneTasteGate single carrier alignment`

Theorem 1664.2 (RealOne NameCert obligations)**.** *For every accepted* $\mathsf{RealOne}^{\uparrow}$ *carrier* $O = (q, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the rational unit seed, constant StreamName window, stationary RegSeqRat readback, DyadicRatCore unit ledger, terminal RealUp seal, transport, replay, provenance, and local naming rows;*
2. *rational embedding route, requiring the unit seed to be read through the* $\mathsf{Rat}^{\uparrow}$ *row and the* $\mathsf{RationalEmbedding}^{\uparrow}$ *handoff before any real-facing consumer may inspect it;*
3. *stationary unit-source route, requiring the seed to be re-read only through the constant window, stationary regular-rational readback, and dyadic unit ledger;*
4. *terminal RealUp seal handoff, requiring the real-facing row* E *to be exported only after* q, S, R, D *and the structural rows have been displayed;*
5. *ledger nonescape from quotient streams, host real equality, selected limits, trichotomy, multiplication laws, and ambient completeness.*

No NameCert obligation is stored outside these five rows.

Lean4 ✓ `BEDC.Derived.RealOneUp.RealOneNameCertObligations`

Proof. Carrier admission is projection from Definition 1664.1. The visible data are the rational unit seed q, the constant window S, the stationary readback R, the dyadic unit ledger D, the terminal seal E, and the structural rows H, C, P, N.

The rational embedding row is forced before the real seal can be read. The packet exposes q as a $\mathsf{Rat}^{\uparrow}$ unit source and sends that source through the $\mathsf{RationalEmbedding}^{\uparrow}$ handoff rather than through a host real constant.

The stationary source row is then determined by S, R, D. Every admitted finite request rereads the same rational seed, the regular-rational readback is stationary, and the dyadic ledger records the corresponding unit endpoint and tolerance rows.

The terminal seal is reached only through E, with transport and replay supplied componentwise by H and C. Since the carrier contains no coordinate for quotient stream equality, host equality, selected limits, trichotomy, multiplication laws, or ambient completeness, none of those principles can be exported through the local $\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$ row. □

Theorem 1664.3 (RealOne rational embedding route)**.** *Every accepted* $\mathsf{RealOne}^{\uparrow}$ *packet exposes the rational-one source through the finite route*

$$q \longrightarrow S \longrightarrow R \longrightarrow D \longrightarrow E$$

together with H, C, P, N*. A real algebra, order, metric, or completion-facing consumer therefore receives the unit real only after the* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{RationalEmbedding}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed.*

Proof. Start with an accepted carrier $O = (q, S, R, D, E, H, C, P, N)$. The seed q is the rational unit row, so the first public source is the $\mathsf{Rat}^{\uparrow}$ carrier read through the rational embedding handoff.

The constant window S makes the route finite at every requested observation. The readback R records the same rational value as a stationary regular-rational row, and D records the dyadic unit ledger attached to that row.

Only after these rows are visible does the terminal seal E become available. Thus any downstream consumer receives the unit real through the displayed rational-to-real route and not through a host-level real constant. □

Lean4 ✓ `BEDC.Derived.RealOneUp.RealOneRationalEmbeddingRoute`

Theorem 1664.4 (RealOne terminal seal nonescape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RealOne}^{\uparrow}$ *packet exports exactly the displayed unit route* q, S, R, D, H, C, P, N*. It exports no quotient stream equality, host real equality, selected limit, trichotomy datum, multiplication unit law, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RealOneUp.RealOneTerminalSealNonescape`

Proof. Project the accepted packet. The only rows available before the terminal seal are the rational unit seed, the constant window, the stationary readback, the dyadic unit ledger, and the transport, replay, provenance, and local naming rows.

The seal E is downstream of those rows and has no independent coordinate carrying a quotient, a host equality proof, a selected limit, an order trichotomy decision, a multiplication law, or a completeness principle. Therefore the real-facing boundary preserves the visible unit route and cannot export any omitted principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealOne}^{\uparrow}$ packet is generated from the rational unit seed, a constant StreamName window, stationary RegSeqRat readback, a DyadicRatCore unit ledger, a terminal RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$, seed)

Scope closed: Definition 1664.1, Definition 1664.2, Definition 1664.3, and Definition 1664.4 seed the finite rational-one-to-RealUp unit route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealOne}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim real multiplication laws, quotient real equality, host equality, trichotomy, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational embedding routing, stationary unit-source routing, terminal RealUp seal handoff, componentwise transport and replay stability, and ledger nonescape for the same finite packet.

Chapter 1665

A Concrete Naming Certificate for $\mathsf{IshiharaTrick}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{IshiharaTrick}^{\uparrow}$ packet records the finite inspection boundary used when a real-name argument refines a disjunctive apartness situation without importing a global semi-classical principle. It is read against the constructive boundary example of chapter 1406, the regular-rational readback of chapter 301, the stream schedule of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a Real/Completion boundary object: it exhibits the rows a consumer may inspect and records that no LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness travels across the boundary.

Definition 1665.1 (Ishihara trick carrier)**.** *An* $\mathsf{IshiharaTrick}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, R, T, W, D, E, A, H, C, P, N)$$

with the following displayed coordinates:

1. *S is a* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite observation requests admitted by the inspection.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row returning the rational approximants actually inspected from that schedule.*
3. *T is the displayed real-name test sequence, presented only through the finite schedule and regular-rational readback rows already named by S and R.*
4. *W is the finite inspection window naming the tested indices of T.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, endpoint comparisons, and finite margin rows used by the inspection.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, T, W, D have been displayed.*
7. *A is the binary test outcome boundary: it records which finite tolerance row witnesses the local apartness alternative or, when no such row is displayed, which refinement request remains inside the schedule.*
8. *H stores componentwise* hsame *transport for the schedule, readback, test sequence, inspection window, dyadic ledger, real seal, boundary row, provenance, and local name.*

9. *C stores* Cont *replay from finite schedule requests through R, T, W, D, and from those rows into the sealed real-facing boundary A.*
10. *P records* Pkg *provenance over* $\mathsf{IshiharaTrick}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$ *row.*

The carrier has no coordinate for LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, countable choice, a selected limit, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickTasteGate single carrier alignment`

Theorem 1665.2 (Ishihara trick NameCert obligations)**.** *For every accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *carrier $O = (S, R, T, W, D, E, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the StreamName schedule, RegSeqRat readback, displayed real-name test sequence, finite inspection window, DyadicRatCore tolerance ledger, Real seal, inspected binary boundary, transport, replay, provenance, and local naming rows;*
2. *schedule-readback coherence, requiring every inspected rational value to be read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows;*
3. *dyadic tolerance discipline, requiring every apartness or refinement branch to cite a displayed dyadic radius, endpoint comparison, and finite margin row from D within the window W;*
4. *real-boundary handoff, requiring a Real/Completion consumer to receive the branch only through E together with the displayed rows $S, R, T, W, D, A, H, C, P, N$;*
5. *ledger nonescape from LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, and ambient real completeness.*

No NameCert obligation is stored outside these five rows.

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1665.1. The visible data are the finite schedule S, readback R, displayed test sequence T, finite window W, tolerance ledger D, terminal real seal E, inspected boundary A, and structural rows H, C, P, N.

Schedule-readback coherence follows because the packet contains no readback coordinate independent of S and R. Every rational approximant inspected by the branch is therefore routed through the displayed stream and regular-rational rows.

The dyadic tolerance row is forced by D and the inspection window W. A branch may expose a local apartness witness only by naming a displayed dyadic radius, endpoint comparison, and finite margin inside the tested window; otherwise it records the finite refinement request still admitted by the schedule.

The real-boundary handoff is downstream of E, with transport and replay supplied componentwise by H and C. Since the carrier contains no coordinate for LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, or ambient completeness, none of those principles can be exported through the local $\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$ row. □

Theorem 1665.3 (Ishihara trick finite test boundary)**.** *Every accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *packet exposes its binary branch only through the displayed real-name test sequence T, finite inspection window W, and dyadic ledger D. Hence the classifier can distinguish the displayed local branch from continued refinement only by finite inspection of the named rows.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickCarrier finite test boundary`

Proof. The carrier presents the test sequence T through the already displayed stream and regular-rational rows. The window W names the inspected indices, so no classifier step can read outside the finite schedule.

The branch row A is binary at the packet boundary. If a dyadic separation is displayed, it cites a radius, endpoint comparison, and finite margin from D inside W; if no such row is displayed, A records only that the schedule continues by refinement.

Componentwise hsame and Cont replay preserve this finite route. Therefore the classifier cannot obtain a third outcome, a global ordering of reals, or a selected limit from the packet. □

Theorem 1665.4 (Ishihara trick branch stability)**.** *Let*

$$O = (S, R, T, W, D, E, A, H, C, P, N)$$

and

$$O' = (S', R', T', W', D', E', A', H', C', P', N')$$

be accepted $\mathsf{IshiharaTrick}^{\uparrow}$ *packets. Suppose the displayed schedule, regular-rational readback, test sequence, inspection window, dyadic ledger, and real seal rows of O and O' are related componentwise by the transport rows, and suppose the branch inspection is replayed through the same* Cont *route. Then the branch row is stable under that transport: a displayed apartness branch in A remains the corresponding displayed apartness branch in A' with transported dyadic radius, endpoint comparison, and margin, while a refinement branch in A remains a refinement request inside the transported schedule S'.*

Proof. Project the carrier rows of O and O'. The only rows available to a branch inspection are the schedules, readbacks, displayed test sequences, finite windows, dyadic ledgers, real seals, branch rows, componentwise transports, and continuation replays named in the two packets.

Apply Definition 1665.3 to the source packet. Every branch read is restricted to the displayed T, W, D rows, so an apartness branch can cite only a dyadic radius, endpoint comparison, and finite margin from the ledger inside the window, and a non-apartness branch can record only continued refinement through the schedule.

The row H transports the displayed schedule, readback, test sequence, window, dyadic ledger, real seal, and boundary row componentwise to the corresponding rows of O'. The row C replays the same continuation route through those transported rows, so the inspected branch cannot change shape during transport.

Thus a displayed apartness branch remains an apartness branch with transported dyadic data, and a refinement branch remains a refinement request inside the transported schedule. Since neither packet contains a coordinate for LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, a selected limit, countable choice, or ambient completeness, no outside principle can supply an additional branch case. □

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickCarrier branch stability`

Theorem 1665.5 (Ishihara trick binary branch boundary)**.** *Every accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *packet exposes exactly two branch readings at the finite Real/Completion boundary: either a displayed dyadic apartness branch whose radius, endpoint, and margin rows come from D inside W, or a refinement request inside the transported schedule. No LLPO, WLPO, Markov principle, trichotomy, quotient equality, selected limit, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness supplies a third case.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickCarrier binary branch boundary`

Proof. Project the carrier described in Definition 1665.1. The branch coordinate A is read only after the schedule S, readback R, test sequence T, finite window W, dyadic ledger D, and real seal E have been displayed.

Apply the finite-test boundary of Definition 1665.3. A positive branch can cite only a dyadic radius, endpoint comparison, and finite margin from D inside W; if no such row is displayed, the packet records only a refinement request still inside the schedule.

Apply branch stability from Definition 1665.4. Componentwise transport and continuation replay preserve the displayed apartness branch and the refinement-request branch, and the carrier has no coordinate for a third semi-classical or completion-supplied alternative. □

Theorem 1665.6 (Ishihara trick real seal nonescape)**.** *Every Real/Completion consumer of an accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *packet factors through the displayed finite rows*

$$S, R, T, W, D, E, A, H, C, P, N.$$

Consequently the consumer receives only a finite schedule, rational readback, displayed test sequence, finite inspection window, dyadic tolerance ledger, terminal real seal, inspected binary boundary, componentwise transport, continuation replay, provenance, and local NameCert row. It receives no LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickCarrier real seal nonescape`

Proof. Let a Real/Completion consumer accept the packet $O = (S, R, T, W, D, E, A, H, C, P, N)$. By the carrier definition, the only real-facing coordinate is the seal E, and that seal is reached after the schedule, readback, test sequence, finite window, tolerance ledger, inspected boundary, and structural rows have been displayed.

The consumer's branch information is therefore finite. It can inspect the schedule row, replay the regular-rational readback, cite the dyadic tolerance ledger inside the finite window, and use the componentwise hsame and Cont rows to transport those observations through the seal.

No omitted semi-classical or completion principle is a coordinate of the packet. Thus factorization through the displayed rows cannot export LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, a selected limit, countable choice, or ambient real completeness. □

Theorem 1665.7 (Ishihara trick bounded-sequence route)**.** *Any bounded real-sequence or Specker-boundary consumer using an accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *packet must pass through the displayed rows*

$$S, R, T, W, D, E, A, H, C, P, N$$

before interpreting a branch as bounded-sequence evidence. The route presents a finite schedule, regular-rational readback, displayed real-name test sequence, finite inspection window, dyadic tolerance ledger, terminal real seal, binary boundary row, componentwise transport, continuation replay, provenance, and local NameCert row. It does not expose LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickBoundedSequenceRoute`

Proof. Project the carrier of Definition 1665.1. Its coordinates are exactly the displayed rows $S, R, T, W, D, E, A, H, C, P, N$, so a bounded-sequence consumer has no independent sequence, bound, or completion coordinate to inspect.

Apply the finite-test boundary of Definition 1665.3. The branch can be read only after the test sequence T, window W, and dyadic ledger D are exposed through the schedule and regular-rational readback rows.

Apply the binary branch boundary of Definition 1665.5. A consumer may receive either the displayed dyadic apartness branch or the refinement request still inside the schedule; no third case is available for a bounded-sequence or Specker-boundary reading.

Finally use the real-seal nonescape theorem Definition 1665.6. The terminal $\mathsf{Real}^{\uparrow}$ handoff carries the same finite rows and no LLPO/WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limit, countable choice, or ambient completeness principle, so bounded-sequence evidence can be interpreted only along the displayed route. □

Theorem 1665.8 (Ishihara trick Specker-boundary handoff)**.** *Every Bishop–Specker or Markov-boundary consumer of an accepted* $\mathsf{IshiharaTrick}^{\uparrow}$ *packet must read the displayed rows*

$$S, R, T, W, D, E, A, H, C, P, N$$

before interpreting the branch as obstruction evidence for chapter 1406, chapter 6056, or chapter 1666. The handoff presents only the finite schedule, regular-rational readback, displayed real-name test sequence, finite inspection window, dyadic tolerance ledger, terminal real seal, binary boundary row, componentwise transport, continuation replay, provenance, and local NameCert row. It exports no LLPO, WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.IshiharaTrickUp.IshiharaTrickSpeckerBoundaryHandoff`

Proof. Project the carrier of Definition 1665.1. A Bishop–Specker or Markov-boundary reader receives exactly the tuple $S, R, T, W, D, E, A, H, C, P, N$, so the downstream obstruction interpretation has no independent supremum, negative-evidence rule, or completion row to inspect.

Apply the finite-test boundary of Definition 1665.3. The possible obstruction evidence is visible only after the displayed test sequence T, finite window W, and dyadic ledger D have been read through the schedule S and regular-rational row R.

Apply the binary branch boundary of Definition 1665.5. The consumer may interpret a displayed dyadic apartness branch, or it may continue with the refinement request still inside the schedule; no third branch is supplied by a Specker, Bishop–Specker, or Markov-sensitive boundary read.

Finally use the real-seal nonescape theorem Definition 1665.6. The terminal $\mathsf{Real}^{\uparrow}$ seal and the structural rows H, C, P, N preserve the same finite route, excluding LLPO/WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, and ambient completeness from the obstruction handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$.

Constructive story: An $\mathsf{IshiharaTrick}^{\uparrow}$ packet is generated from a StreamName schedule, RegSeqRat readback, displayed real-name test sequence, finite inspection window, DyadicRatCore tolerance ledger, Real seal, inspected binary boundary, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$, seed)

Scope closed: Definition 1665.1, Definition 1665.2, Definition 1665.3, Definition 1665.4, Definition 1665.5, Definition 1665.6, Definition 1665.7, and Definition 1665.8 seed the finite Real/Completion boundary for Ishihara-style inspection.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IshiharaTrick}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.IshiharaTrickUp`

Bridge status: none

Not claimed: This chapter does not claim LLPO/WLPO, Markov-principle leakage, trichotomy, quotient real equality, selected limits, countable choice, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule-readback coherence, dyadic tolerance discipline, real-boundary handoff, componentwise transport and replay stability, and ledger nonescape for the same finite packet.

Chapter 1666

A Concrete Naming Certificate for $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$

Following Markov, Ishihara, and Bishop–Bridges constructive analysis, the $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ packet records the finite boundary at which an inspection argument may use Markov-style negative evidence as named data without accepting Markov's principle as a global rule. It is read beside the Ishihara inspection packet of chapter 1665, the Specker control example of chapter 1406, the stream schedule of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a Real/Completion boundary object: it exposes only the finite rows a consumer may inspect and refuses any route that would turn those rows into LPO, LLPO, trichotomy, countable choice, quotient stream equality, selected limits, or ambient real completeness.

The $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ dependency route consumes the finite branch-inspection row of chapter 1665 and the obstruction row of chapter 1406 before exporting any Markov-sensitive boundary read. Thus its horizontal lattice records Ishihara inspection and Specker obstruction as displayed sibling data, not as imported principles.

Definition 1666.1 (Markov principle boundary carrier)**.** *A* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, K, S, R, D, E, W, H, C, P, N)$$

with the following displayed coordinates:

1. *I is an* $\mathsf{IshiharaTrick}^{\uparrow}$ *inspection row naming the finite apartness/refinement test whose branch is being bounded.*
2. *K is a* $\mathsf{SpeckerSequence}^{\uparrow}$ *control row recording the nonconvergent obstruction that prevents the inspection from becoming a selected real limit.*
3. *S is a* $\mathsf{StreamName}^{\uparrow}$ *schedule row listing the finite stream requests admitted by the boundary.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational values actually inspected from S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the radii, endpoint comparisons, and finite margin rows used by the boundary.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the rows I, K, S, R, D have been displayed.*
7. *W is the Markov-boundary witness row: it records either a displayed finite failure of zerohood in the inspected schedule or the finite refusal row explaining why no global Markov rule is exported.*

8. *H stores componentwise* hsame *transport for the inspection, Specker control, schedule, readback, dyadic ledger, real seal, witness row, provenance, and local name.*
9. *C stores* Cont *replay from finite schedule requests through R and D, through the Ishihara branch I, and finally into the sealed real-facing witness W.*
10. *P records* Pkg *provenance over* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{IshiharaTrick}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovPrincipleBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for Markov's principle as an imported axiom, LPO, LLPO, trichotomy, countable choice, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MarkovPrincipleBoundaryUp.MarkovPrincipleBoundaryUpTasteGate single carrier alignment`

Theorem 1666.2 (Ishihara–Specker boundary route)**.** *For every accepted* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *carrier $M = (I, K, S, R, D, E, W, H, C, P, N)$, every real-facing inspection branch factors through the displayed route*

$$I, K, S, R, D, E, W, H, C, P, N.$$

Consequently an $\mathsf{IshiharaTrick}^{\uparrow}$ *refinement may be compared with a* $\mathsf{SpeckerSequence}^{\uparrow}$ *obstruction only by citing the finite stream schedule, regular-rational readback, dyadic tolerance ledger, real seal, witness row, componentwise transport, replay, provenance, and local NameCert row displayed by M.*

Lean4 ✓ `BEDC.Derived.MarkovPrincipleBoundaryUp.MarkovPrincipleBoundaryIshiharaSpeckerRoute`

Proof. The carrier definition lists the only coordinates admitted by the boundary. The Ishihara inspection row I supplies the finite branch being tested, while the Specker row K supplies the obstruction preventing that branch from being promoted to a selected limit.

The schedule-readback-tolerance part is carried by S, R, D. Thus every inspected rational value and every finite margin used by the branch is named before the real seal E is reached.

The witness row W is downstream of those finite rows. Componentwise hsame transport in H and Cont replay in C allow a consumer to replay the route without adding any unlisted classifier. The provenance and local NameCert rows P, N then repack the same displayed data as the public boundary certificate. □

Theorem 1666.3 (Markov boundary nonescape)**.** *Every Real/Completion consumer of an accepted* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *packet receives only finite inspection data and the sealed witness row W. It receives no Markov's principle as an imported axiom, no LPO, no LLPO, no trichotomy, no countable choice, no quotient stream equality, no selected limit, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Let a Real/Completion consumer accept $M = (I, K, S, R, D, E, W, H, C, P, N)$. By Definition 1666.1, the only real-facing coordinate is the seal E, and the only Markov-sensitive coordinate is the displayed witness row W.

The route theorem Definition 1666.2 forces the consumer to reach W through the finite Ishihara inspection, Specker control, stream schedule, regular-rational readback, and dyadic tolerance ledger. None of these coordinates contains a global principle or a selected completion operator.

Since the carrier has no coordinate for Markov's principle as an imported axiom, LPO, LLPO, trichotomy, countable choice, quotient stream equality, selected limits, or ambient real completeness, transport and replay cannot export any such principle through the local $\mathsf{NameCert}_{\mathsf{MarkovPrincipleBoundary}^{\uparrow}}$ row. □

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovPrincipleBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ packet is generated from an Ishihara inspection row, Specker control row, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, Markov-boundary witness row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovPrincipleBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1666.1, Definition 1666.2, and Definition 1666.3 seed the finite Real/Completion boundary for Markov-sensitive inspection.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovPrincipleBoundary}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MarkovPrincipleBoundaryUp`

Bridge status: none

Not claimed: This chapter does not claim Markov's principle as an imported axiom, LPO, LLPO, trichotomy, countable choice, quotient stream equality, selected limits, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Ishihara–Specker route factorization, stream-readback tolerance discipline, real-boundary handoff, componentwise transport and replay stability, and ledger nonescape for the same finite packet.

Chapter 1667

A Concrete Naming Certificate for $\mathsf{NetConvergence}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley-style convergence of nets, the $\mathsf{NetConvergence}^{\uparrow}$ packet names only the finite directed-tail evidence a completion-facing consumer can inspect. It sits between the Moore–Smith net carrier of chapter 3403, the directed-window surface of chapter 589, the finite filterbase handoff of chapter 333, the entourage discipline of chapter 339, and the L10 real-and-completion route of section 9467.12. The Moore–Smith net row supplies the directed-tail and value-window route that this convergence interface consumes before filter and Real handoff rows are read. The packet is a convergence interface for Real and completion arguments; it is not a selected limit, a quotient of nets, or an ambient completeness theorem.

Definition 1667.1 (Net convergence carrier)**.** *A* $\mathsf{NetConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (D, T, E, A, F, S, R, L, H, C, P, M)$$

with the following displayed rows:

1. *D is the directed-index window, naming the finite index vertices, the displayed upper-window witnesses, and the finite tail cut used by every convergence read.*
2. *T is the tail-neighbourhood ledger, recording the neighbourhood requests whose tails are inspected inside D.*
3. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, giving the finite entourage request through which the tail-neighbourhood read is interpreted.*
4. *A is an optional* $\mathsf{CauchyNet}^{\uparrow}$ *source row; when present, its common-window classifier is read only through the same D, T, E rows, and when absent the packet records no Cauchy-net source.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row obtained from the displayed tail-neighbourhood family.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite observation windows used by the directed tail.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those scheduled observations and dyadic comparisons.*
8. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, T, E, F, S, R have been displayed.*
9. *H records componentwise* hsame *transport for the directed window, tail-neighbourhood ledger, entourage row, optional source row, filter handoff, stream schedule, regular-rational readback, Real seal, provenance, and local naming rows.*

10. *C records the displayed* Cont *replay for every consumer read through the same coordinates.*
11. *P is the* Pkg *provenance over* $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *M is the local* $\mathsf{NameCert}_{\mathsf{NetConvergence}^{\uparrow}}$ *row.*

The carrier exports only these finite rows. It contains no selected limit point, quotient net, countable-choice selector, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceTasteGate single carrier alignment`

Theorem 1667.2 (Net convergence NameCert obligations)**.** *For an accepted carrier $N = (D, T, E, A, F, S, R, L, H,$ of Definition 1667.1, the local* $\mathsf{NameCert}_{\mathsf{NetConvergence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the directed-index window, tail-neighbourhood ledger, uniform-entourage row, optional CauchyNet source row, CauchyFilter handoff row, StreamName schedule, RegSeqRat readback, Real seal boundary, and structural rows;*
2. *tail classification, stating that every convergence read names a displayed tail in D before it can consume a neighbourhood row in T;*
3. *entourage interpretation, stating that the neighbourhood read is routed through the finite* $\mathsf{UniformSpace}^{\uparrow}$ *row E rather than a host topology or ambient uniformity;*
4. *optional-source discipline, stating that a present* $\mathsf{CauchyNet}^{\uparrow}$ *row is read only through the same directed window and that an absent source row exports no hidden Cauchy-net data;*
5. *CauchyFilter handoff, stating that the filter-facing consumer sees only the tail-neighbourhood family and refinement rows displayed by F;*
6. *Real seal non-escape, stating that L is consumed only after the stream schedule S and regular-rational readback R have been displayed;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, M.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceNameCert obligations`

Proof. Project the accepted packet of Definition 1667.1. The analytic coordinates are D, T, E, A, F, S, R, L, and the structural coordinates are H, C, P, M.

A convergence read first names a directed tail in D. The tail-neighbourhood ledger T can then be inspected only at that displayed tail, and the neighbourhood is interpreted by the finite entourage row E.

The optional source row does not add a second convergence surface. If A is present, its common-window classifier is read through the same directed window and entourage data; if A is absent, there is no coordinate from which source-net data can be exported.

The downstream routes are likewise fixed by visible rows. The Cauchy-filter consumer reads F, while Real-facing consumers read S and R before reaching the seal L. Transport, replay, provenance, and naming are componentwise through H, C, P, M, so the listed rows exhaust the local naming surface. □

Theorem 1667.3 (Moore–Smith dependency for net convergence)**.** *Every* $\mathsf{NetConvergence}^{\uparrow}$ *consumer that is sourced from a* $\mathsf{MooreSmithNet}^{\uparrow}$ *packet reads the Moore–Smith directed-index row,*

value-window row, and finite tail ledger before it reads the $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row or the* $\mathsf{Real}^{\uparrow}$ *seal row. The dependency is confined to displayed finite directed-tail evidence and does not introduce selected subnets, cofinal choice, quotient nets, or ambient completeness.*

Proof. Use the Moore–Smith net obligations of Definition 3403.2. They expose directed indices, value windows, and tail requests as the finite packet consumed by convergence-side readers.

Now apply the NetConvergence carrier discipline of Definition 1667.1. The optional source row A can contribute source-net material only through the same directed window, tail ledger, and entourage rows D, T, E.

The downstream rows are read after that directed-tail route. The $\mathsf{CauchyFilter}^{\uparrow}$ handoff row F and the $\mathsf{Real}^{\uparrow}$ seal row L therefore consume displayed Moore–Smith evidence only through the accepted $\mathsf{NetConvergence}^{\uparrow}$ packet, leaving no coordinate for a selected subnet, cofinal-choice operator, quotient net, or ambient completeness theorem. □

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier moore smith dependency`

Theorem 1667.4 (Net convergence CauchyFilter handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff exported by an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier factors through the displayed route*

$$D \longmapsto T \longmapsto E \longmapsto F$$

and every $\mathsf{Real}^{\uparrow}$ *read after that handoff factors through the same* F *row together with the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*. No selected limit, quotient net, countable-choice selector, or ambient completeness row can alter the handoff.*

Proof. Start from Definition 1667.2. The tail classification obligation places every convergence read on a displayed directed tail in D, and the tail-neighbourhood ledger T supplies the finite neighbourhood family inspected at that tail.

The entourage interpretation obligation routes that neighbourhood family through the uniform row E. Thus the filter-facing datum is not a host filter; it is exactly the finite family that the handoff row F exposes to $\mathsf{CauchyFilter}^{\uparrow}$ consumers.

For a Real-facing read, the packet must continue through S and R before reaching L. These rows are part of the same accepted carrier and are transported only by the displayed hsame and Cont data in H and C.

There is no remaining coordinate in N for a selected limit point, a quotient of nets, a countable-choice selector, or an ambient completeness theorem. Consequently the handoff is determined by the displayed route through D, T, E, F, S, R, L. □

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier cauchy filter handoff`

Theorem 1667.5 (Net convergence directed-window admission)**.** *Every accepted* $\mathsf{NetConvergence}^{\uparrow}$ *convergence read first exposes the directed-index window* D*, the tail-neighbourhood ledger* T*, and the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row* E *of Definition 1667.1. No CauchyNet source row, CauchyFilter handoff row, StreamName schedule, RegSeqRat readback, or Real seal can be consumed before this directed window has been displayed.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier directed window admission`

Proof. Use the carrier projection of Definition 1667.1. The rows D, T, E are the only coordinates that name a directed tail, the neighbourhood requests inspected at that tail, and the finite entourage row interpreting those requests.

Apply the tail classification and entourage interpretation clauses of Definition 1667.2. They force every convergence read to pass through D and T, then through E, before any downstream row can be inspected.

The optional source row A, the filter handoff F, the stream and rational readback rows S, R, and the Real seal L are downstream coordinates. Since the carrier has no alternative directed-tail coordinate, they cannot be consumed before the displayed directed window is exposed. □

Theorem 1667.6 (Net convergence CauchyNetLimit handoff)**.** *Every CauchyNetLimit-facing consumer of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier receives the same directed tail* D, T, E *before it can inspect the optional* $\mathsf{CauchyNet}^{\uparrow}$ *row* A *or the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* L*. The handoff is therefore a finite directed-tail route rather than a selected limit, host convergence predicate, quotient net, or ambient completeness witness.*

Proof. Start from Definition 1667.5. It places D, T, E before every convergence read, independently of which downstream consumer is asking for the data.

A CauchyNetLimit-facing consumer can use the optional CauchyNet source only through A. By the optional-source discipline of Definition 1667.2, a present A is read through the same directed window, and an absent A exports no source-net data.

The Real-facing part of the handoff reaches L only after the stream schedule S and the regular-rational readback R have been displayed. Thus the consumer receives one finite directed-tail route before either the CauchyNet source or the Real seal is consumed. □

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier cauchy net limit handoff`

Theorem 1667.7 (Net convergence Moore–Smith filter boundary)**.** *Moore–Smith consumers and* $\mathsf{CauchyFilter}^{\uparrow}$ *consumers of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier meet only through the displayed finite directed-tail evidence* D, T, E, F *and the structural rows* H, C, P, M*. The boundary exports no selected subnet, cofinal-choice operator, quotient net, host filter equality, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier moore smith filter boundary`

Proof. Read the Moore–Smith dependency theorem Definition 1667.3. It says that source-net consumers contribute directed-index, value-window, and tail-ledger evidence through the finite directed-tail route.

Read the CauchyFilter handoff theorem Definition 1667.4. It routes every filter-facing datum through D, T, E, F before any Real-facing rows are inspected.

The structural rows H, C, P, M transport, replay, package, and locally name that same route. Since neither theorem supplies a coordinate for selected subnets, cofinal choice, quotient nets, host filter equality, or ambient completeness, the Moore–Smith and filter consumers meet only at the displayed finite boundary. □

Theorem 1667.8 (NetConvergence Moore–Smith filter handoff)**.** *Every completion-facing read of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier* $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ *that compares Moore–Smith and filter-base evidence first factors through the finite directed-set windows* D*, the Moore–Smith convergence boundary rows* T, E, A*, the* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CauchyFilter}^{\uparrow}$ *tail rows carried by* F*, the* $\mathsf{StreamName}^{\uparrow}$ *observation windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* L*, and then the transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows* H, C, P, M*. The handoff is a finite route inspection; it does not select a subnet, replace the filter by a host equality, or appeal to an ambient limit theorem.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier moore smith real seal handoff`

Proof. Expose the Moore–Smith side first. By Definition 1667.3, a source-net consumer can contribute only directed-index, value-window, and tail-ledger evidence, and by Definition 1667.5 those rows enter the carrier through D, T, E before any downstream row is read.

Next expose the filter side. The CauchyFilter handoff theorem Definition 1667.4 routes every filter-facing datum through D, T, E, F, while Definition 1667.9 identifies the $\mathsf{FilterBase}^{\uparrow}$ boundary with that same displayed handoff rather than with a host filter equality.

Finally pass to completion-facing readback. The stream route Definition 1667.12 and real-seal nonescape theorem Definition 1667.10 force the handoff through S, R, L, and the rows H, C, P, M preserve only this displayed route under transport, replay, provenance, and local naming. Thus the Moore–Smith/filter comparison is exhausted by finite carrier inspection, with no selected subnet, quotient net, cofinal-choice operator, host convergence predicate, or ambient completeness witness. □

Theorem 1667.9 (Net convergence filterbase finality)**.** *Every* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier factors through the displayed directed tail* D, T, E *and the handoff row* F*. No host filter equality, selected limit, quotient net, ambient completeness witness, or alternate filter coordinate can refine that handoff beyond the finite route already displayed by the carrier.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier filterbase finality`

Proof. Project the carrier of Definition 1667.1. The rows D, T, E are the directed-index window, tail-neighbourhood ledger, and entourage row, while F is the only row that names the filter-facing handoff.

Apply Definition 1667.4. It sends every CauchyFilter-facing read through D, T, E, F before any Real-facing rows can contribute. Apply also Definition 1667.7, which identifies the Moore–Smith and filter boundary with the same displayed rows.

The carrier has no second filterbase coordinate, no selected limit coordinate, and no quotient-net coordinate. Thus every filterbase or CauchyFilter consumer factors through the displayed handoff, and that handoff is final among the routes accepted by the packet. □

Theorem 1667.10 (Net convergence Real seal nonescape)**.** *Let* $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ *be an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier. The terminal* $\mathsf{Real}^{\uparrow}$ *seal* L *is reachable only after the directed window* D*, tail-neighbourhood ledger* T*, entourage row* E*, CauchyFilter handoff* F*, StreamName schedule* S*, and RegSeqRat readback* R *have been displayed. The seal cannot be selected as a host limit, quotient-net representative, ambient convergence witness, or completeness object.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier real seal nonescape`

Proof. Project the carrier of Definition 1667.1. The rows preceding the Real seal are exactly the directed-tail rows D, T, E, the filter-facing row F, and the Real-facing readback rows S, R.

Use Definition 1667.2. Its carrier admission and Real seal non-escape clauses force L to be read only after the displayed analytic rows have appeared.

Use also Definition 1667.5, Definition 1667.4, and Definition 1667.6. Together they leave no route from a host limit, quotient net, ambient convergence predicate, or completeness theorem into the seal coordinate. □

Theorem 1667.11 (Net convergence entourage-tail stability)**.** *Let $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ and $N' = (D', T', E', A', F', S', R', L', H', C', P', M')$ be accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carriers related by the componentwise* hsame *transport recorded by their structural rows. Transport of D, T, E preserves the same tail-neighbourhood and entourage route for every* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer, so the handoff remains a read through D, T, E, F rather than a new host filter or ambient uniformity.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier entourage tail stability`

Proof. Read the structural transport row in Definition 1667.1. It transports the directed window, tail-neighbourhood ledger, entourage row, optional source row, filter handoff, stream schedule, readback, seal, provenance, and local naming component by component.

Apply Definition 1667.2 and Definition 1667.5. A convergence read must first expose D, T, E, and the transported carrier exposes the corresponding D', T', E' through the same structural coordinate.

Finally apply Definition 1667.4 and Definition 1667.6. Since every filter-facing read is already routed through the directed tail and entourage rows before F is consumed, componentwise hsame transport preserves the route and adds no host filter equality or ambient uniformity coordinate. □

Theorem 1667.12 (Net convergence stream readback route)**.** *Let $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ be an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier. After the CauchyFilter handoff row F has been displayed, the only Real-facing route available to the packet is the* $\mathsf{StreamName}^{\uparrow}$ *schedule S followed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R and the terminal seal L. No alternate real-name route, selected limit, quotient-net representative, or ambient completeness row is exported.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier stream readback route`

Proof. Start with the carrier projection of Definition 1667.1. The rows downstream of F on the Real-facing side are S, R, L, together with the structural rows H, C, P, M.

Apply Definition 1667.2. The listed obligations include the CauchyFilter handoff, Real seal non-escape, componentwise transport, replay, provenance, and local naming; none of them introduces a second real-name coordinate.

Apply Definition 1667.5, Definition 1667.4, and Definition 1667.6. They force the route through D, T, E, F before any Real-facing read and then through S, R, L, so the stream schedule and regular readback are the only Real-facing route after the handoff. □

Theorem 1667.13 (Net convergence tail-window admission)**.** *Let $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ be an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier. Every accepted convergence read first exposes a directed tail window in D together with the tail-neighbourhood request recorded in T and the entourage interpretation row E. Only after that route is displayed may the packet read a present* $\mathsf{CauchyNet}^{\uparrow}$ *row A, the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff F, or the Real-facing schedule S, R, L.*

Proof. Read the carrier rows of Definition 1667.1. The only coordinates that name a directed tail and interpret a neighbourhood request are D, T, E.

Apply the tail classification and entourage interpretation clauses of Definition 1667.2. They put every convergence read on the displayed directed-tail route before the optional source row, filter handoff, stream schedule, regular-rational readback, or Real seal can be consumed.

The downstream rows therefore depend on the tail-window admission route. Since the carrier has no second directed-tail coordinate, no consumer can bypass D, T, E by reading a host convergence predicate or a cofinal-choice operator. □

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier tail window admission`
Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier tail window real seal bridge`

Theorem 1667.14 (Net convergence boundary readback)**.** *For an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier* $N = (D, T, E, A, F, S, R, L, H, C, P, M)$*, every Cauchy-facing read and every Real-facing read meet at the displayed boundary*

$$D, T, E \longmapsto F \longmapsto S, R, L.$$

The $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *handoff rows may be read only through the same directed tail, and the* $\mathsf{Real}^{\uparrow}$ *seal is read only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *boundary row has been displayed.*

Proof. Start with the Cauchy-facing side. By Definition 1667.4, the filter handoff F is reached through D, T, E, and by Definition 1667.6, a present source-net row A is read through that same directed route.

Now read the Real-facing side. The stream readback theorem Definition 1667.12 forces every Real read after F through S and R before it reaches the terminal seal L.

Thus the boundary is visible on both sides: directed tails supply the Cauchy handoff, and regular-rational readback supplies the Real seal. The packet does not expose a selected limit, quotient net, host convergence predicate, or ambient completeness row that could replace this boundary. □

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier boundary readback`

Theorem 1667.15 (Net convergence ledger nonescape)**.** *Every consumer of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *packet factors through the finite ledger rows* $D, T, E, A, F, S, R, L, H, C, P, M$*. The packet refuses quotient nets, selected limits, cofinal-choice operators, host filter equality, ambient convergence predicates, and ambient completeness; none of these objects can be recovered from transport, replay, provenance, or local naming.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier ledger nonescape`

Proof. Project the accepted packet. Its analytic coordinates are the directed window, tail ledger, entourage row, optional source row, filter handoff, stream schedule, regular-rational readback, and Real seal; its structural coordinates are transport, replay, provenance, and local naming.

Apply Definition 1667.13 and Definition 1667.14. Together they place every accepted read on the finite directed-tail and Cauchy-to-Real boundary route.

The structural rows cannot add analytic content. Componentwise hsame transport and displayed Cont replay preserve only the listed coordinates, while P and M source and name only the same packet. Hence quotient nets, selected limits, cofinal choice, host filter equality, ambient convergence, and completeness remain outside the certificate. □

Theorem 1667.16 (Net convergence to sequential compact dependency)**.** *When an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier* $N = (D, T, E, A, F, S, R, L, H, C, P, M)$ *is consumed by the sequential-compact cluster route of chapter 2372, the directed-tail rows* D, T, E, F, S, R, L *must be displayed before any* $\mathsf{SequentialCompact}^{\uparrow}$ *finite-window cluster row is read. The consumer therefore sees the directed window, tail-neighbourhood ledger, entourage interpretation, CauchyFilter handoff, StreamName schedule, RegSeqRat readback, and Real seal as the dependency surface for the sequential-compact finite-window packet. It does not receive a selected subnet, quotient net, countable-choice operator, host convergence predicate, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier sequentialcompact dependency`

Proof. Project the accepted carrier. The directed-tail rows D, T, E are the only rows that expose the Moore–Smith window and entourage request, while F, S, R, L are the only rows that hand the same route to CauchyFilter, StreamName, RegSeqRat, and Real-facing consumers.

Apply Definition 1667.5, Definition 1667.4, and Definition 1667.12. These place every downstream read behind the displayed directed-tail route and then behind the filter and stream-readback handoff.

The $\mathsf{SequentialCompact}^{\uparrow}$ finite-window cluster rows can therefore read N only through D, T, E, F, S, R, L and the structural rows H, C, P, M. Since no carrier coordinate stores a selected subnet, quotient-net representative, countable-choice operator, host convergence predicate, or ambient completeness witness, none of those objects is exported to the sequential-compact route. □

Theorem 1667.17 (Net convergence to SequentialCompact bridge)**.** *The displayed* $\mathsf{NetConvergence}^{\uparrow}$ *directed-tail route bridges to the* $\mathsf{SequentialCompact}^{\uparrow}$ *finite-window consumer only through*

$$D, T, E, F, S, R, L, H, C, P, M.$$

The bridge exports no selected subnet, quotient net, countable-choice operator, host convergence predicate, or ambient completeness row.

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier sequentialcompact bridge`

Proof. First expose the directed-tail route. Apply Definition 1667.5 to place every convergence read behind D, T, E, and apply Definition 1667.4 to route the filter-facing handoff through F.

Next expose the Real-facing boundary. Apply Definition 1667.12 and Definition 1667.14; they force the handoff through the StreamName schedule S, RegSeqRat readback R, and terminal Real seal L before any downstream finite-window consumer reads the route.

Finally bind the non-escape and downstream dependency. Apply Definition 1667.15 and Definition 1667.16. The only structural rows left for transport, replay, provenance, and naming are H, C, P, M, so the SequentialCompact consumer receives the displayed bridge and no selected subnet, quotient net, choice operator, host convergence predicate, or ambient completeness principle. □

Theorem 1667.18 (Net convergence mature source package)**.** *The* $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers of an accepted* $\mathsf{NetConvergence}^{\uparrow}$ *carrier all meet at the finite route*

$$D, T, E, F, S, R, L, H, C, P, M.$$

The package exports no selected limit, quotient net, cofinal-choice operator, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.NetConvergenceUp.NetConvergenceCarrier mature source package`

Proof. Start with the Moore–Smith dependency theorem Definition 1667.3. It supplies the directed window and tail evidence consumed by the source side of the packet, and Definition 1667.5 places every later read behind D, T, E.

Apply the Cauchy-facing handoff results. The CauchyFilter handoff theorem Definition 1667.4, the CauchyNetLimit handoff theorem Definition 1667.6, and filterbase finality Definition 1667.9 route the filter and optional source reads through the same D, T, E, F boundary.

Now apply the Real-facing non-escape theorem Definition 1667.10. The Real seal is reachable only after S, R, L have been displayed downstream of the filter handoff.

The structural rows H, C, P, M transport, replay, source, and name this finite package. Since Definition 1667.15 excludes quotient nets, selected limits, cofinal choice, host convergence, and ambient completeness, the listed source-package route is the mature public surface available to downstream consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{NetConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{NetConvergence}^{\uparrow}$ packet is generated from a directed-index window, a tail-neighbourhood ledger, a UniformSpace entourage row, an optional CauchyNet source row, a CauchyFilter handoff row, StreamName windows, RegSeqRat readback, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NetConvergence}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1667.1, Definition 1667.2, Definition 1667.4, Definition 1667.13, Definition 1667.14, Definition 1667.15, Definition 1667.16, Definition 1667.17, and Definition 1667.18 bind the displayed obligations and the public downstream route from $\mathsf{NetConvergence}^{\uparrow}$ to $\mathsf{SequentialCompact}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NetConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient nets, countable choice, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Bridge checking requires a Lean standard-bridge theorem for the displayed NetConvergence to SequentialCompact route; the paper-side mature source package is closed here.

Chapter 1668

A Concrete Naming Certificate for $\mathsf{RealRationalApproximation}^{\uparrow}$

Bishop and Bridges-style constructive analysis reads a real name through explicit rational approximants at finite precision, not through a host real value or a completed quotient stream. The $\mathsf{RealRationalApproximation}^{\uparrow}$ packet records that finite approximation window as BEDC data between the displayed real-name seal of chapter 38, the regular rational readback of chapter 301, the finite observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the rational boundedness interface of chapter 430. It is a rational-approximation face for Real and Completion consumers; it is not host real equality, a best-approximant selector, trichotomy, or ambient completeness.

Definition 1668.1 (RealRationalApproximation carrier)**.** *A* $\mathsf{RealRationalApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, Q, D, S, G, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal whose finite rational approximation window is being displayed.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *approximation row exported at the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic budget under which Q is accepted as an approximant.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window opened from R before the rational approximation is read.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S, recording the regular rational observations used to justify Q.*
6. *A is the approximation ledger comparing Q with the displayed readback rows under the dyadic tolerance budget D.*
7. *H stores componentwise* hsame *transport for the real seal, rational approximation row, dyadic tolerance row, stream window, regular readback, approximation ledger, replay, provenance, and local name.*
8. *C stores displayed* Cont *replay from a finite precision request through S, G, D, A, Q and then into the terminal real seal R.*
9. *P records* Pkg *provenance over* $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealRationalApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, quotient streams, selected best approximants, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealRationalApproximationUp.TasteGate.RealRationalApproximationTasteGate single carrier alignment`

Theorem 1668.2 (RealRationalApproximation NameCert obligations)**.** *For every accepted* RealRationalApproxima *carrier $W = (R, Q, D, S, G, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealRationalApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{Rat}^{\uparrow}$ *approximation row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, approximation ledger, transport, replay, provenance, and local naming rows;*
2. *window admission, requiring every approximation request to open the finite stream window S from the real seal R before reading any rational row;*
3. *tolerance admission, requiring the dyadic budget D to be displayed before the rational approximant Q may be accepted;*
4. *readback comparison, requiring the ledger A to compare Q against the regular rational observations in G under the same dyadic budget D;*
5. *transport and replay stability, requiring H and C to preserve the ordered route R, S, G, D, A, Q componentwise;*
6. *ledger nonescape from host real equality, quotient streams, selected best approximants, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealRationalApproximationUp.RealRationalApproximationTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1668.1. The accepted packet displays exactly the real seal R, rational row Q, dyadic tolerance row D, stream window S, regular readback G, approximation ledger A, and the structural rows H, C, P, N.

Window admission and tolerance admission are forced by the ordering of the packet. A finite approximation request first opens S from the displayed real seal, reads the regular rational row G, and fixes the dyadic budget D before Q can be consumed as an approximant.

The comparison row is the ledger A. It records the finite check that the displayed rational row Q matches the readback observations in G at the tolerance named by D, so the approximation surface is exhausted by the rows already present in the carrier.

Transport and replay are structural. The hsame row H moves each displayed coordinate componentwise, and the Cont row C repeats the same finite route for later consumers.

The nonescape clause follows because the carrier has no row for host real equality, quotient streams, selected best approximants, trichotomy, or ambient completeness. The local $\mathsf{NameCert}$ row N can therefore export only the displayed approximation window. □

Theorem 1668.3 (RealRationalApproximation window extraction)**.** *Every accepted* $\mathsf{RealRationalApproximation}^{\uparrow}$ *carrier $W = (R, Q, D, S, G, A, H, C, P, N)$ exposes a finite rational approximation window*

$$R \longrightarrow S \longrightarrow G \longrightarrow D \longrightarrow A \longrightarrow Q$$

for the displayed $\mathsf{Real}^{\uparrow}$ *name. A Real or Completion consumer receives the rational approximant only after the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows have been displayed with their transport, replay, provenance, and local naming data.*

Lean4 ✓ `BEDC.Derived.RealRationalApproximationUp.RealRationalApproximationCarrier window extraction`

Proof. Start from an accepted packet $W = (R, Q, D, S, G, A, H, C, P, N)$. Projection gives the terminal real seal R and the finite stream window S opened from it.

The regular readback row G is then read through the same window. The dyadic tolerance row D supplies the precision budget for the request, and the ledger A compares the candidate rational row Q with the displayed observations under that budget.

Thus the consumer obtains Q only through the ordered finite route R, S, G, D, A. The remaining rows H, C, P, N transport, replay, source, and name the same route, so no detached real value or quotient stream is required to extract the approximation window. □

Theorem 1668.4 (RealRationalApproximation Real seal handoff)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RealRationalApproximation}^{\uparrow}$ *packet hands off exactly the displayed approximation rows* $Q, D, S, G, A, H, C, P, N$. *It exports no host real equality, quotient stream, selected best approximant, trichotomy datum, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RealRationalApproximationUp.RealRationalApproximationRealSealHandoff`

Proof. The real-facing boundary is the coordinate R of Definition 1668.1. Every public approximation read attached to R must pass through the finite window S, the regular readback G, the dyadic tolerance row D, the ledger A, and the rational row Q.

The structural rows do not enlarge the boundary. They preserve the same displayed route by componentwise transport, continuation replay, package provenance, and local naming.

Since no excluded object is a coordinate of the carrier, the terminal seal has no path to host real equality, quotient streams, selected best approximants, trichotomy, or ambient completeness. The handoff is exactly the finite rational-approximation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealRationalApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{RealRationalApproximation}^{\uparrow}$ packet is generated from a displayed RealUp seal, a RatUp approximation row, a DyadicRatCoreUp tolerance row, a StreamNameUp finite window, a RegSeqRatUp readback row, an approximation ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealRationalApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1668.1, Definition 1668.2, Definition 1668.3, and Definition 1668.4 seed the finite rational approximation window over displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealRationalApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient streams, selected best approximants, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window admission, tolerance admission, readback comparison, RealUp seal handoff, componentwise transport and replay stability, and ledger nonescape for the same finite packet.

Chapter 1669

RealLocatorUp NameCert Construction

Following Bishop and Bridges, the $\mathsf{RealLocator}^{\uparrow}$ packet records constructive located comparison data for a displayed $\mathsf{Real}^{\uparrow}$ name without turning that data into trichotomy or Dedekind-cut reconstruction. It sits beside the terminal real-name seal of chapter 38, the regular rational readback rows of chapter 301, and the dyadic tolerance ledger of chapter 291. The public role is a finite comparison service for later real algebra, metric locatedness, and apartness consumers.

Definition 1669.1 (Real locator carrier)**.** *A* $\mathsf{RealLocator}^{\uparrow}$ *carrier is finite BEDC data that answers each dyadic rational comparison request by a displayed lower or upper apartness window for the named real. Concretely it is a finite* BHist *packet*

$$L = (X, Q, S, R, D, A, H, C, P, N)$$

with the following rows:

1. *X is the terminal* $\mathsf{Real}^{\uparrow}$ *name whose seal is inspected by the locator.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison request naming the queried dyadic rational and the requested finite precision.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation window opened from the real name for that request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the observed stream window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger that records the dyadic lower and upper rational bounds used by the comparison.*
6. *A is the displayed apartness-window row, read either as a lower witness or as an upper witness for the request, with the undecided boundary left uncollapsed.*
7. *H records componentwise* hsame *transport for the real seal, dyadic request, stream window, regular readback, dyadic ledger, apartness row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay through $X, Q, S, R, D, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocator}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite locator packet. It has no coordinate for Dedekind-cut completeness, real trichotomy, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealLocatorUp.RealLocatorTasteGate single carrier alignment`

Theorem 1669.2 (Real locator NameCert obligations)**.** *For every accepted* $\mathsf{RealLocator}^{\uparrow}$ *carrier* $L = (X, Q, S, R, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLocator}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier stability, requiring the real seal, dyadic request, stream observation window, regular readback, dyadic ledger, apartness row, transport, replay, provenance, and local naming data to inhabit one finite* BHist *packet;*
2. *classifier stability, requiring the lower or upper apartness verdict in* A *to be read only through the displayed request* Q *and observation route* S, R, D*;*
3. *transport along* hsame*, requiring* H *to preserve the same request, window, readback, dyadic ledger, and apartness row under componentwise transport;*
4. *dyadic ledger exactness, requiring* D *to record the lower and upper dyadic bounds used by the displayed comparison and not a host-order comparison of completed reals;*
5. $\mathsf{Real}^{\uparrow}$ *seal compatibility, requiring* X *to be consumed only through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows before the apartness window is read.*

No NameCert obligation may replace these rows by Dedekind-cut completeness, real trichotomy, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealLocatorUp.RealLocatorNameCertObligations`

Proof. Project the accepted carrier L. Its analytic coordinates are exactly the real seal X, dyadic request Q, stream window S, regular readback R, dyadic ledger D, and apartness row A; the remaining rows transport, replay, source, and name the same packet.

Classifier stability follows from the order of projection. The apartness row A is reached only after the request and finite observation route Q, S, R, D have been displayed, so its verdict cannot be detached from those rows.

Transport stability is supplied by H and replay stability by C. They preserve the same listed coordinates under hsame transport and displayed continuation replay.

The dyadic ledger and real seal boundaries close the obligation surface. Since D is the only dyadic comparison ledger and X is consumed only through S, R, D, the local NameCert has no field from which Dedekind-cut completeness, trichotomy, quotient equality, countable choice, or ambient completeness could be read. □

Theorem 1669.3 (Real locator apartness decision window)**.** *For every accepted* $\mathsf{RealLocator}^{\uparrow}$ *carrier* $L = (X, Q, S, R, D, A, H, C, P, N)$*, a displayed locator decision in* A *yields a finite apartness readback window through*

$$Q \longmapsto S \longmapsto R \longmapsto D \longmapsto A \longmapsto H, C, P, N.$$

The readback exposes only the lower or upper apartness window carried by A *for the request* Q*. It does not assert trichotomy for all real comparisons and does not identify quotient representatives of* X*.*

Proof. Start with the displayed decision row A. By the carrier definition, A is not an isolated truth value; it is attached to the dyadic request Q, the stream observation window S, the regular readback R, and the dyadic ledger D.

The finite readback window is therefore obtained by replaying that route. The rows H and C transport and replay the same request, observation, ledger, and apartness data, while P and N package the resulting local certificate.

The conclusion is intentionally local. Because the packet has no coordinate for a global order classifier, quotient representative equality, countable choice, or ambient completeness, the displayed decision supplies only the finite apartness window for Q. □

Lean4 ✓ `BEDC.Derived.RealLocatorUp.RealLocatorApartnessDecisionWindow`

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocator}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealLocator}\uparrow}$, seed)

Scope closed: Definition 1669.1, Definition 1669.2, and Definition 1669.3 seed the finite located comparison surface for $\mathsf{Real}^{\uparrow}$ names through stream, regular rational, and dyadic readback rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealLocator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut completeness, real trichotomy, quotient equality, countable choice, ambient RealUp completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, transport along hsame, dyadic ledger exactness, RealUp seal compatibility, and apartness-window readback for BEDC.Derived.RealLocatorUp.

Constructive story: A $\mathsf{RealLocator}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{DyadicRatCore}^{\uparrow}$ comparison request, a $\mathsf{StreamName}^{\uparrow}$ observation window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a dyadic lower-upper ledger, a displayed apartness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1670

A Concrete Naming Certificate for $\mathsf{RegularCauchyMidpoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ packet names midpoint formation for two regular rational Cauchy names by finite dyadic arithmetic and displayed modulus rows before the completed $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the dyadic arithmetic core of chapter 291, the stream-window schedule of chapter 126, the regular rational readback rows of chapter 301, the pointwise midpoint ledger of chapter 445, and the terminal real-name seal of chapter 38. The packet supplies the finite midpoint surface needed by interval bisection and Real-facing finite-window algebra; it does not import host real arithmetic, quotient streams, selected limits, trichotomy, or ambient completeness.

Definition 1670.1 (Regular Cauchy midpoint carrier)**.** *A* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{mid}} = (R_0, R_1, S_0, S_1, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
2. R_1 *is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
3. S_0 *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the left name, recording exactly which rational approximants are inspected for each requested midpoint precision.*
4. S_1 *is the matching* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the right name, synchronized with* S_0 *at the common precision ledger.*
5. D *is the* $\mathsf{DyadicMidpoint}^{\uparrow}$ *pointwise midpoint row, reading the two displayed rational approximants through the dyadic endpoint and common-denominator midpoint calculation.*
6. Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, common denominator budget, and regularity allowance used to certify that the pointwise midpoint row is again regular Cauchy.*
7. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the two regular names, synchronized schedules, dyadic midpoint row, and tolerance ledger have been displayed.*
8. H *records componentwise* hsame *transport for the two regular rows, two stream schedules, pointwise midpoint row, tolerance ledger, Real seal row, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *routes from every midpoint-facing read through $R_0, R_1, S_0, S_1, D, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyMidpoint$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, DyadicMidpoint$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RegularCauchyMidpoint}^\uparrow}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, S_0, S_1, D, Q, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, host real midpoint arithmetic, selected limits, trichotomy, ambient completeness, or a detached completed-real midpoint.

Lean4 ✓ `BEDC.Derived.RegularCauchyMidpointUp.RegularCauchyMidpointTasteGate single carrier alignment`

Theorem 1670.2 (Regular Cauchy midpoint NameCert obligations)**.** *For every accepted* RegularCauchyMidpoint$^\uparrow$ *carrier*

$$M_{\text{mid}} = (R_0, R_1, S_0, S_1, D, Q, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMidpoint}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two* RegSeqRat$^\uparrow$ *source rows R_0, R_1, the synchronized* StreamName$^\uparrow$ *schedules S_0, S_1, the* DyadicMidpoint$^\uparrow$ *pointwise midpoint row D, the* DyadicRatCore$^\uparrow$ *tolerance ledger Q, the* Real$^\uparrow$ *seal row E, and the structural rows H, C, P, N;*
2. *synchronized-window exposure, requiring every midpoint-facing read to inspect the two stream schedules at a common finite precision before the dyadic midpoint row is read;*
3. *pointwise midpoint exactness, requiring D to be obtained through the displayed* DyadicMidpoint$^\uparrow$ *common-denominator calculation on the two rational approximants exposed by S_0 and S_1;*
4. *regularity tolerance accounting, requiring Q to record the dyadic radius and the allowance that turns the two input regularity rows into the output regularity row;*
5. *Real seal boundary, requiring E to be consumed only after the route through R_0, R_1, S_0, S_1, D, Q has been displayed;*
6. *transport and replay stability, requiring H and C to preserve the same two regular names, synchronized schedules, midpoint row, tolerance ledger, Real seal boundary, provenance, and local naming row;*
7. *package provenance and local naming, requiring P and N to name exactly the listed sibling certificates and the same finite midpoint packet;*
8. *refusal of quotient streams, host real midpoint arithmetic, selected limits, trichotomy, and ambient completeness as NameCert data.*

No NameCert obligation is stored outside these finite rows.

Proof. Project the accepted carrier. The analytic coordinates are the two regular rational names R_0, R_1, the synchronized schedules S_0, S_1, the dyadic midpoint row D, the tolerance ledger Q, and the Real seal row E; the remaining rows transport, replay, source, and name the same finite packet.

Read the midpoint route in dependency order. A precision request first opens the paired finite schedules S_0 and S_1 from the two RegSeqRat$^\uparrow$ rows. The displayed rational approximants then enter the DyadicMidpoint$^\uparrow$ row D, where the common-denominator midpoint calculation is the only pointwise midpoint source.

The regularity ledger is the next step. The row Q records the dyadic radius and the allowance inherited from the two input regular Cauchy rows, so the midpoint readback remains a regular Cauchy name before the $\mathsf{Real}^{\uparrow}$ seal is reached.

Finally apply componentwise transport and replay. The rows H and C preserve the same displayed route, while P and N name exactly the sibling certificate dependencies. Since no carrier coordinate stores quotient stream equality, host real arithmetic, selected limits, trichotomy, or ambient completeness, none of those principles can be exported by the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMidpointUp.RegularCauchyMidpointNameCertObligations`

Theorem 1670.3 (Regular Cauchy midpoint Real seal handoff)**.** *Every accepted* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *carrier factors its Real-facing midpoint read through the finite route*

$$(R_0, R_1) \longmapsto (S_0, S_1) \longmapsto D \longmapsto Q \longmapsto E$$

before it may hand the result to a $\mathsf{Real}^{\uparrow}$ *consumer. Thus the consumer receives two regular rational source rows, synchronized finite schedules, a pointwise* $\mathsf{DyadicMidpoint}^{\uparrow}$ *row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and a Real seal row; it receives no quotient stream equality, host real midpoint operation, selected limit, trichotomy, or ambient completeness coordinate.*

Proof. Start with an accepted carrier $M_{\mathrm{mid}} = (R_0, R_1, S_0, S_1, D, Q, E, H, C, P, N)$. The only source rows for the midpoint read are the two regular rational names R_0 and R_1, and the only observation schedules attached to them are S_0 and S_1.

The pointwise midpoint then passes through D. That row consumes the displayed rational approximants through the same finite common-denominator midpoint calculation named by chapter 445; no second midpoint row is present.

The tolerance and seal rows finish the handoff. The row Q records the dyadic budget that witnesses regularity of the midpoint name, and E is reached only after this finite ledger has been displayed.

Replay the route through C and transport it through H. The provenance row P points to chapter 291, chapter 445, chapter 126, chapter 301, and chapter 38. Together with N, it packages the same finite route and adds no coordinate for quotient stream equality, host arithmetic, selected limits, trichotomy, or completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMidpoint}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMidpoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1670.1, Definition 1670.2, and Definition 1670.3 seed the finite midpoint surface for two $\mathsf{RegSeqRat}^{\uparrow}$ rows over synchronized $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{DyadicMidpoint}^{\uparrow}$ pointwise midpoint rows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMidpoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real arithmetic, selected limits, trichotomy, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, pointwise midpoint exactness, regularity tolerance accounting, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMidpointUp.

Constructive story: A $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ rows, synchronized $\mathsf{StreamName}^{\uparrow}$ schedules, a $\mathsf{DyadicMidpoint}^{\uparrow}$ pointwise midpoint row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1671

A Concrete Naming Certificate for $\mathsf{CauchyRateComparison}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRateComparison}^{\uparrow}$ packet records the finite comparison surface for two effective Cauchy-rate reads before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer may inspect a seal. It sits over the effective-rate route of chapter 415, the modulus schedule surface of chapter 292, the dyadic tail-bound ledger of chapter 379, the common finite-window interface of chapter 126, the regular rational readback boundary of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later regular-Cauchy, completion, and phase-exit consumers a named common-refinement certificate instead of requiring each consumer to coordinate two rate rows informally.

Definition 1671.1 (Cauchy rate comparison carrier)**.** *A* $\mathsf{CauchyRateComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{cmp}} = (R_0, R_1, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two accepted* $\mathsf{CauchyRate}^{\uparrow}$ *rows whose effective reads are compared.*
2. W *is the common* $\mathsf{StreamName}^{\uparrow}$ *window row through which both rate reads expose the same finite observation schedule.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the shared precision budget, dyadic radius, and tail allowance used by the comparison.*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback comparison row obtained after both rate rows have been routed through* W *and* D*.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after* R_0, R_1, W, D, Q *have all been displayed.*
6. H *records componentwise* hsame *transports for the two rate rows, common window, dyadic tolerance ledger, readback comparison row, seal boundary, replay row, provenance row, and local naming row.*
7. C *records displayed* Cont *routes from the two accepted rate reads to the common window, from the window to the dyadic tolerance ledger, from the ledger to the regular rational comparison row, and from that row to the Real seal boundary.*
8. P *is the* Pkg *provenance over* $\mathsf{CauchyRateComparison}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRateComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed rows $R_0, R_1, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real comparison, selected limits, countable choice, trichotomy, ambient completeness, or an unrecorded completion object.

Lean4 ✓ `BEDC.Derived.CauchyRateComparisonUp.CauchyRateComparisonTasteGate single carrier alignment`

Theorem 1671.2 (Cauchy rate comparison NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateComparison}^{\uparrow}$ *carrier*

$$K_{\mathrm{cmp}} = (R_0, R_1, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRateComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two* $\mathsf{CauchyRate}^{\uparrow}$ *rows, the common* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback comparison row, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, and the structural rows H, C, P, N;*
2. *classifier exactness, requiring accepted comparison packets to be compared only by componentwise* hsame *transport and displayed* Cont *routes over those coordinates;*
3. *common-window refinement, requiring both rate reads to expose the same finite observation window W before either read reaches D, Q, or E;*
4. *transport, requiring the stored* hsame *rows in H to preserve the two rate reads, the common window, the tolerance ledger, the readback row, the seal boundary, provenance, and local naming;*
5. *non-escape, requiring every Real-facing or completion-facing read to pass through R_0, R_1, W, D, Q, E and refusing quotient stream equality, host real comparison, selected limits, countable choice, trichotomy, and ambient completeness as NameCert data.*

No comparison obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.CauchyRateComparisonUp.CauchyRateComparisonNameCertObligations`

Proof. Project the accepted carrier. Its analytic coordinates are exactly the two $\mathsf{CauchyRate}^{\uparrow}$ rows, the common $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ comparison readback, and the $\mathsf{Real}^{\uparrow}$ seal boundary.

Read the route in dependency order. The two rate rows must first expose the same finite window W; the dyadic ledger D is then read against that shared window, and only then can the regular rational comparison row Q be consumed.

Transport and replay are structural. The rows H and C preserve the displayed route under componentwise sameness and continuation reads, while P and N name exactly the sibling certificate dependencies and the local packet.

Since the carrier has no extra coordinate for quotient stream equality, host real comparison, selected limits, countable choice, trichotomy, ambient completeness, or an unrecorded completion object, none of those principles can enter the local NameCert surface. □

Theorem 1671.3 (Cauchy rate comparison common refinement)**.** *Let two accepted effective-rate reads be admitted into a* $\mathsf{CauchyRateComparison}^{\uparrow}$ *carrier*

$$K_{\mathrm{cmp}} = (R_0, R_1, W, D, Q, E, H, C, P, N).$$

If the two reads share the displayed window row W, then both reads factor through the same W, D, Q, E route before any $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer can read a seal. Thus the comparison exports a common finite refinement of the two* $\mathsf{CauchyRate}^{\uparrow}$ *rows, not a quotient equality of streams, a selected host limit, an ambient completeness principle, or a host-level real comparison.*

Proof. Start from the shared window hypothesis. Both accepted reads are carried by R_0 and R_1, and the carrier contains a single $\mathsf{StreamName}^{\uparrow}$ row W as the only finite observation window available to either read.

The tolerance and readback rows are downstream of that window. The displayed route in C sends the shared window to the dyadic ledger D and then to the regular rational comparison row Q, so the two reads cannot diverge into separate tolerance ledgers or separate readback rows inside the packet.

The seal boundary is last. The row E is reachable only after R_0, R_1, W, D, Q have been displayed, so any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads the same common-refinement route before it can inspect a seal.

Finally apply the classifier and provenance rows. Componentwise transport through H preserves the same route, and P, N name no quotient stream equality, selected limit, ambient completeness principle, or host-level real comparison. The exported object is therefore exactly the finite common refinement of the two effective-rate reads. □

Lean target: `BEDC.Derived.CauchyRateComparisonUp.CauchyRateComparisonCommonRefinement`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real comparison, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, common-window refinement, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchyRateComparisonUp.

Constructive story: A $\mathsf{CauchyRateComparison}^{\uparrow}$ packet is generated from two $\mathsf{CauchyRate}^{\uparrow}$ rows, a common $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback comparison row, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1672

A Concrete Naming Certificate for $\mathsf{DyadicArchimedean}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicArchimedean}^{\uparrow}$ packet names the finite scale-domination certificate used before a dyadic tolerance route may choose a displayed scale large enough to dominate a displayed dyadic bound. It sits after the dyadic endpoint core of chapter 291, the common-scale order surface of chapter 1597, the comparison replay of chapter 1623, the endpoint enclosure handoff of chapter 1645, and the dyadic density route of chapter 1484. It is also consumed by the finite stream windows of chapter 126, the regular rational route of chapter 301, and the terminal real-name seal of chapter 38. The packet records scale domination as unary induction over displayed dyadic rows; it is not trichotomy, quotient equality, host rational order, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1672.1 (DyadicArchimedean carrier)**.** *A* $\mathsf{DyadicArchimedean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, B, K, S, C, I, H, T, P, N)$$

with the following displayed rows:

1. *D is the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row whose denominator and numerator histories are the source of the tolerance comparison.*
2. *B is the target dyadic bound row, displayed over the same dyadic core surface as the quantity to be dominated.*
3. *K is a unary scale witness, naming a finite number of successor-scale steps from the source tolerance scale to a scale whose dyadic unit dominates B.*
4. *S is the common-scale replay row, transporting D and B to the comparison scale named by K without invoking host rational order.*
5. *C is the* $\mathsf{DyadicComparison}^{\uparrow}$ *and* $\mathsf{DyadicOrder}^{\uparrow}$ *domination row, recording the finite comparison that the replayed scale dominates the replayed bound.*
6. *I is the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *enclosure handoff, exposing the same dominated scale as an endpoint enclosure for downstream tolerance consumers.*
7. *H records componentwise* hsame *transport for the dyadic source row, bound row, unary scale witness, common-scale replay, domination comparison, enclosure handoff, continuation, provenance, and local naming rows.*

8. *T records displayed* Cont *replay from scale requests through $D, B, K, S, C, I, H, P, N$.*
9. *P is the* Pkg *provenance over* DyadicArchimedean$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicOrder$^{\uparrow}$, DyadicComparison$^{\uparrow}$, DyadicIntervalArithmetic$^{\uparrow}$, DyadicDensityReal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DyadicArchimedean}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite dyadic scale-domination packet. It has no coordinate for trichotomy, quotient equality, host rational order, selected limits, countable choice, or Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicArchimedeanUp.TasteGate.DyadicArchimedeanTasteGate single carrier alignment`

Theorem 1672.2 (DyadicArchimedean NameCert obligations)**.** *For every accepted* DyadicArchimedean$^{\uparrow}$ *carrier $A = (D, B, K, S, C, I, H, T, P, N)$, the local* NameCert$_{\text{DyadicArchimedean}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic source row D, target bound row B, unary scale witness K, common-scale replay S, domination comparison C, enclosure handoff I, and structural rows H, T, P, N;*
2. *scale-witness well-foundedness, requiring K to be read as a finite unary successor ledger rather than as an ambient Archimedean principle;*
3. *common-scale exactness, requiring S to replay D and B at the scale named by K through displayed dyadic denominator rows;*
4. *domination exposure, requiring C to certify domination only through the* DyadicComparison$^{\uparrow}$ *and* DyadicOrder$^{\uparrow}$ *rows produced by S;*
5. *enclosure compatibility, requiring I to export the dominated scale as a* DyadicIntervalArithmetic$^{\uparrow}$ *endpoint enclosure without changing the comparison route;*
6. *classifier transport, requiring H and T to preserve the same source row, bound row, scale witness, replay row, comparison row, and enclosure row;*
7. *ledger non-escape, excluding trichotomy, quotient equality, host rational order, selected limits, countable choice, and* Real$^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the accepted carrier. The analytic rows are D, B, K, S, C, I, while H, T, P, N transport, replay, source, and name the same finite packet.

The scale-witness obligation is read from K. Since K is unary, the only available eliminator is finite induction over the displayed successor ledger. The base row compares the initial dyadic unit with the replayed bound when the bound is already dominated at the source scale.

For the successor step, assume the preceding scale has been replayed through S and compared through C. The next unary constructor doubles the displayed dyadic unit at the common scale, and the comparison row is recomputed through the same DyadicComparison$^{\uparrow}$ and DyadicOrder$^{\uparrow}$ surface. No host rational order or trichotomy is introduced in this step.

The enclosure handoff is then read from I. It packages the dominated scale as a dyadic endpoint enclosure, so downstream tolerance consumers see the same comparison route rather than a separate real-order argument.

Finally H and T transport and replay the listed rows componentwise, while P and N record provenance and local naming. The carrier contains no coordinate from which trichotomy, quotient equality, host rational order, selected limits, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness could be read. □

Lean4 ✓ `BEDC.Derived.DyadicArchimedeanUp.DyadicArchimedeanNameCertObligations`

Theorem 1672.3 (DyadicArchimedean scale existence)**.** *Every accepted* $\mathsf{DyadicArchimedean}^{\uparrow}$ *carrier* $A = (D, B, K, S, C, I, H, T, P, N)$ *exposes a finite dyadic scale that dominates its displayed target bound. More precisely, induction on the unary witness* K *produces a scale row* k *such that the replay route*

$$D, B, K \longmapsto S \longmapsto C$$

certifies that the dyadic unit at scale k *dominates the bound row* B *through displayed* $\mathsf{DyadicComparison}^{\uparrow}$ *and* $\mathsf{DyadicOrder}^{\uparrow}$ *data.*

Lean4 ✓ `BEDC.Derived.DyadicArchimedeanUp.DyadicArchimedeanScaleExistence`

Proof. Induct on the unary scale witness K.

In the base case, the carrier supplies the common-scale replay row S at the initial scale. The comparison row C is then the displayed domination certificate for the source dyadic unit against the replayed target bound.

In the successor case, apply the induction hypothesis to the predecessor witness. The successor constructor extends the scale ledger by one displayed doubling step, and S replays both D and B at the extended common scale. The comparison row C records the corresponding domination through the same dyadic comparison and order surfaces.

The induction returns the terminal scale row named by K. Since each step used only S and C, the resulting scale is finite and carries no appeal to host rational order, trichotomy, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1672.4 (DyadicArchimedean StreamName scale transport)**.** *For every accepted* $\mathsf{DyadicArchimedean}^{\uparrow}$ *carrier* $A = (D, B, K, S, C, I, H, T, P, N)$*, a* $\mathsf{StreamName}^{\uparrow}$ *tolerance consumer transports the unary scale witness* K *only through finite stream windows before* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumers read the enclosure row* I*. More precisely, the consumer first requests a finite* $\mathsf{StreamName}^{\uparrow}$ *window for the tolerance read, then reads the dyadic source and bound rows* D, B*, the unary scale ledger* K*, the common-scale replay* S*, and the domination row* C *inside that window, and only afterward receives the endpoint enclosure handoff* I *through* H, T, P, N*.*

Lean4 ✓ `BEDC.Derived.DyadicArchimedeanUp.DyadicArchimedeanStreamnameScaleTransport`

Proof. Begin with the scale existence theorem, Definition 1672.3. Its induction on K builds the dominating scale by finite successor steps and routes every comparison through S and C.

Now place the same induction inside a $\mathsf{StreamName}^{\uparrow}$ tolerance request. The stream window fixes the finite boundary of the read: it displays which tolerance row is being inspected before the dyadic source D, bound B, scale witness K, common-scale replay S, and domination comparison C are consumed.

Finally apply the L10 handoff theorem, Definition 1672.5. The enclosure row I is downstream of the displayed domination route, so $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers receive only the finite stream-window transport of the scale witness, with no trichotomy, quotient equality, host rational order, selected limit, countable-choice row, or Real-completeness witness. □

Theorem 1672.5 (DyadicArchimedean L10 handoff)**.** *For every accepted* $\mathsf{DyadicArchimedean}^{\uparrow}$ *carrier* $A = (D, B, K, S, C, I, H, T, P, N)$*, every L10 dyadic tolerance consumer reaches the domination certificate through the finite route*

$$D, B, K \longmapsto S \longmapsto C \longmapsto I \longmapsto H, T, P, N.$$

Consequently a $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicDensityReal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer receives a displayed scale-domination and enclosure row, with no trichotomy, quotient equality, host rational order, selected limit, countable-choice row, or Real-completeness witness inserted into the route.*

Proof. Start with an accepted carrier $A = (D, B, K, S, C, I, H, T, P, N)$. The only source tolerance row is D, the only target bound row is B, and the only scale-selection data is the unary witness K.

By Definition 1672.3, finite induction on K yields a displayed dominating scale. The proof of that theorem uses the common-scale replay S and the comparison row C, so the exported domination certificate is already routed through $\mathsf{DyadicComparison}^{\uparrow}$ and $\mathsf{DyadicOrder}^{\uparrow}$.

The row I is the sole handoff to $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ enclosure data. It exports the dominated scale as an endpoint enclosure that a $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicDensityReal}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer may read after the dyadic comparison has been displayed.

The structural rows H, T, P, N preserve and name the route. Componentwise transport and continuation replay keep the same source row, bound row, scale witness, common-scale replay, comparison row, and enclosure handoff. Since every L10 tolerance read is reached through this route, there is no remaining coordinate from which trichotomy, quotient equality, host rational order, selected limits, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness could be read. □

Lean4 ✓ `BEDC.Derived.DyadicArchimedeanUp.DyadicArchimedeanCarrier l10 handoff`

Theorem 1672.6 (DyadicArchimedean obligation closure ledger)**.** *For every accepted* $\mathsf{DyadicArchimedean}^{\uparrow}$ *carrier* $A = (D, B, K, S, C, I, H, T, P, N)$*, the obligation package is exactly carrier admission, unary scale-witness induction, common-scale replay, domination exposure, interval enclosure compatibility, classifier transport, and ledger non-escape. These rows jointly bind the full local* $\mathsf{NameCert}_{\mathsf{DyadicArchimedean}^{\uparrow}}$ *surface; no additional obligation is supplied by trichotomy, quotient equality, host rational order, selected limits, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the obligation list from Definition 1672.2. Carrier admission exposes the ten rows $D, B, K, S, C, I, H, T, P, N$, while the ledger non-escape clause excludes any off-packet analytic supply.

The scale-witness part is discharged by Definition 1672.3. Its induction is unary on K: the base and successor steps produce the displayed domination scale only through S and C.

The finite transport part is supplied by Definition 1672.4. A $\mathsf{StreamName}^{\uparrow}$ consumer reads the same D, B, K, S, C rows inside a finite window before $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumers receive the enclosure row I.

Finally Definition 1672.5 identifies the downstream route $D, B, K \longmapsto S \longmapsto C \longmapsto I \longmapsto H, T, P, N$. Thus the listed rows are not merely an inventory: they assemble the full obligation-closure ledger for the packet. □

Falsifiable prediction: An accepted $\mathsf{DyadicArchimedean}^{\uparrow}$ consumer that reaches an L10 dyadic tolerance scale without the unary witness K, common-scale replay S, domination row C, and enclosure handoff I refutes the carrier surface.

Independence witness: dyadicratcore, dyadicorder, dyadiccomparison, dyadicintervalarithmetic, dyadicdensityreal, streamname, regseqrat, real: no listed sibling supplies the whole ten-row packet $A = (D, B, K, S, C, I, H, T, P, N)$, because each sibling contributes dyadic rows, comparison rows, enclosure rows, finite windows, regular rational readback, density data, or a Real seal while this chapter binds finite scale domination with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicArchimedean}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicArchimedean}^{\uparrow}$ packet is generated from a displayed $\mathsf{DyadicRatCore}^{\uparrow}$ source row, target dyadic bound row, unary scale witness, common-scale replay, dyadic domination comparison, interval-arithmetic enclosure handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicArchimedean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1672.1, Definition 1672.2, Definition 1672.3, and Definition 1672.5 seed the finite dyadic scale-domination surface over DyadicRatCore, DyadicOrder, DyadicComparison, DyadicIntervalArithmetic, DyadicDensityReal, StreamName, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicArchimedean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient equality, host rational order, selected limits, countable choice, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, scale-witness well-foundedness, common-scale exactness, domination exposure, enclosure compatibility, classifier transport, and ledger non-escape proofs for BEDC.Derived.DyadicArchimedeanUp.

Chapter 1673

A Concrete Naming Certificate for $\mathsf{CauchyRateRealization}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRateRealization}^{\uparrow}$ packet records the finite route by which an explicit Cauchy-rate datum realizes a terminal $\mathsf{Real}^{\uparrow}$ seal without hiding a selected limit. It sits over the effective-rate surface of chapter 415, the real-modulus route of chapter 1423, the finite-window surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet gives later Real-and-Completion consumers one named realization bridge from explicit rate data to the seal, while keeping quotient streams, selected limits, countable choice, host real equality, and ambient completeness outside the carrier.

Definition 1673.1 (Cauchy rate realization carrier)**.** *A* $\mathsf{CauchyRateRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{real}} = (p, r, d, s, q, m, e, H, C, P, N)$$

with the following displayed rows:

1. *p is the displayed precision-request row whose requested dyadic tolerance must be served.*
2. *r is the accepted* $\mathsf{CauchyRate}^{\uparrow}$ *row exposing the effective threshold schedule for the request p.*
3. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational endpoint and radius comparisons read at that threshold.*
4. *s is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the rate row r for the request p.*
5. *q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream window and dyadic tolerance ledger.*
6. *m is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *route row showing that the same rate, window, tolerance, and readback data serve the Real-facing modulus request.*
7. *e is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after p, r, d, s, q, m have all been displayed.*
8. *H records componentwise* hsame *transport for the precision request, rate row, dyadic ledger, stream window, readback row, modulus route, terminal seal, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from the precision request through r, s, d, q, m, e and then through the structural rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRateRealization}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRateRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed rows $p, r, d, s, q, m, e, H, C, P, N$. It has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, countable choice, host real equality, trichotomy, or an unrecorded completion object.*

Lean4 ✓ `BEDC.Derived.CauchyRateRealizationUp.CauchyRateRealizationTasteGate single carrier alignment`

Theorem 1673.2 (Cauchy rate realization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateRealization}^{\uparrow}$ *carrier*

$$K_{\mathrm{real}} = (p, r, d, s, q, m, e, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRateRealization}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed precision request, effective rate row, dyadic tolerance ledger, stream window, regular rational readback, Real-facing modulus route, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, package provenance, and local naming. Every accepted Real-facing read is classified only by those rows, and no obligation is stored in a quotient stream, selected limit, countable-choice selector, host real equality proof, ambient completeness theorem, or detached seal row.*

Proof. Project the accepted carrier. Its analytic coordinates are exactly p, r, d, s, q, m, e, and its structural coordinates are exactly H, C, P, N.

Read the analytic rows in dependency order. The precision request p first consumes the effective rate row r; the stream window s and dyadic ledger d are then displayed at the scheduled threshold; the regular readback row q is obtained from those finite observations; and the Real-facing modulus row m records that the same route serves the terminal seal request.

The structural rows add no analytic source. Componentwise transport in H preserves the displayed coordinates, continuation replay in C follows the same route, and P, N only source and name the packet.

Since the carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, ambient completeness, trichotomy, or a detached seal row, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.CauchyRateRealizationUp.CauchyRateRealizationNameCertObligations`

Theorem 1673.3 (Cauchy rate realization Real seal route)**.** *Every accepted* $\mathsf{CauchyRateRealization}^{\uparrow}$ *carrier routes a displayed precision request to the terminal* $\mathsf{Real}^{\uparrow}$ *seal through the finite chain*

$$p \longmapsto r \longmapsto s, d \longmapsto q \longmapsto m \longmapsto e \longmapsto (H, C, P, N).$$

Thus the seal read is the realization of explicit Cauchy-rate data through finite window, tolerance, readback, and modulus rows, not an appeal to $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, countable choice, or host real equality.*

Lean4 ✓ `BEDC.Derived.CauchyRateRealizationUp.CauchyRateRealizationRealSealRoute`

Proof. Start with the obligation surface of Definition 1673.2. It places the precision row p and effective rate row r before every downstream read.

The finite observations are then forced through the scheduled window and tolerance rows. The stream row s and dyadic ledger d are the only coordinates from which the regular rational readback q is available.

The modulus route and seal are downstream. The row m records the Real-facing modulus use of the same finite data, and e is reached only after p, r, s, d, q, m have been displayed.

Finally replay the structural rows. The route through H, C, P, N preserves and names the same packet, so no ambient completion theorem, selected host limit, quotient stream, countable-choice row, or host equality proof can substitute for the displayed chain. □

Theorem 1673.4 (Cauchy rate realization no-choice boundary)**.** *An accepted* $\mathsf{CauchyRateRealization}^{\uparrow}$ *packet cannot manufacture a selected limit, choose a representative stream, invoke countable choice, or identify host real values. All consumer-visible data are already present in the finite rows* $p, r, d, s, q, m, e, H, C, P, N$*, and every Real-facing read of the packet factors through those rows before the* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Lean4 ✓ `BEDC.Derived.CauchyRateRealizationUp.CauchyRateRealizationCarrier no choice boundary`

Proof. Inspect the carrier in Definition 1673.1. The only analytic rows are the precision request, rate schedule, dyadic tolerance ledger, stream window, regular readback, Real-facing modulus route, and terminal seal.

Apply the route theorem Definition 1673.3. It forces every consumer-visible seal read through those analytic rows before the structural replay, provenance, and local naming rows are read.

It remains to compare this route with the excluded principles. A selected limit, representative stream choice, countable-choice sequence, host real equality proof, or ambient completeness theorem would require an additional coordinate or an alternate continuation route. The accepted packet has neither, so those principles cannot be manufactured by the local certificate. □

Theorem 1673.5 (Cauchy rate realization public certificate)**.** *The public certificate exported by an accepted* $\mathsf{CauchyRateRealization}^{\uparrow}$ *packet is exactly the finite realization bridge from explicit rate data to the terminal Real seal:*

$$\mathsf{CauchyRate}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{RealCauchyModulus}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Every downstream Real-and-Completion consumer sees the same displayed rows $p, r, d, s, q, m, e, H, C, P, N$*, and the packet exports no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream, selected limit, countable-choice selector, or host real equality proof.*

Lean4 ✓ `BEDC.Derived.CauchyRateRealizationUp.CauchyRateRealizationPublicCertificate`

Proof. Project the accepted packet and read its provenance row. The row P names exactly the sibling certificate surfaces for the effective rate, finite stream window, dyadic tolerance ledger, regular rational readback, Real-facing modulus route, and terminal Real seal.

Use Definition 1673.2 to identify the local certificate obligations. They are exhausted by the displayed analytic and structural rows, so a public consumer cannot ask the packet for data outside $p, r, d, s, q, m, e, H, C, P, N$.

Apply Definition 1673.4. The excluded principles have no coordinate and no continuation route inside the packet. Therefore the public certificate is precisely the finite realization bridge through the listed sibling surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRateRealization}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRateRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1673.1, Definition 1673.2, Definition 1673.3, Definition 1673.4, and Definition 1673.5 seed the finite realization surface from explicit $\mathsf{CauchyRate}^{\uparrow}$ data through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRateRealization}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyRateRealizationUp`

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, countable choice, host real equality, Lean theorem coverage, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, seal-route factorization, no-choice boundary, public certificate export, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRateRealizationUp.

Constructive story: A $\mathsf{CauchyRateRealization}^{\uparrow}$ packet is generated from a precision request, an explicit $\mathsf{CauchyRate}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{RealCauchyModulus}^{\uparrow}$ route row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1674

A Concrete Naming Certificate for $\mathsf{RealMinMax}^{\uparrow}$

Following Bishop and Bridges constructive analysis, finite minimum and maximum of two displayed real names are read through located comparison and equality rows, not through trichotomy, quotient equality, host real order, or completeness. The $\mathsf{RealMinMax}^{\uparrow}$ packet sits over the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance core of chapter 291, the equality boundary of chapter 1636, the located comparison row of chapter 1381, and the algebraic order ledger of chapter 766. It supplies a finite order-operation boundary for RealAlgOrder consumers without selecting representatives or asserting ambient completeness.

Definition 1674.1 (RealMinMax carrier)**.** *A* $\mathsf{RealMinMax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, R_X, R_Y, S_X, S_Y, D, E, C, O, L, U, H, T, P, N)$$

with the following displayed rows:

1. *X and Y are the two displayed* $\mathsf{Real}^{\uparrow}$ *seal rows whose finite minimum and maximum are being named.*
2. *R_X and R_Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed by the real seals before any order operation is consumed.*
3. *S_X and S_Y are finite* $\mathsf{StreamName}^{\uparrow}$ *windows selecting the observations used by R_X and R_Y.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-tolerance ledger, recording the dyadic radius, slack, and finite comparison budget for the windows.*
5. *E is the* $\mathsf{RealEquality}^{\uparrow}$ *boundary row, used when the displayed comparison reaches an equality or overlap boundary.*
6. *C is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *row, recording the located comparison verdict obtained from the readbacks and the dyadic tolerance ledger.*
7. *O is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *order ledger, exposing the nonnegative and apartness-facing rows that downstream algebraic-order consumers may read.*
8. *L is the minimum row. It is admitted only after $X, Y, R_X, R_Y, S_X, S_Y, D, E, C, O$ have been displayed.*

9. *U is the maximum row. It is admitted only after the same comparison, equality, and order rows have been displayed.*

10. *H records componentwise* hsame *transport for the two real seals, readbacks, finite windows, tolerance ledger, equality row, comparison row, order ledger, minimum row, maximum row, continuation row, provenance row, and local naming row.*

11. *T records displayed* Cont *replay from a finite comparison request through $S_X, S_Y, R_X, R_Y, D, E, C, O, L, U$ and back to the public min/max boundary.*

12. *P is the* Pkg *provenance over* $\mathsf{RealMinMax}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealMinMax}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite constructive min/max packet. It has no coordinate for real trichotomy, quotient real equality, host real order, selected representatives, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealMinMaxUp.RealMinMaxUp single carrier alignment`

Theorem 1674.2 (RealMinMax NameCert obligations)**.** *For every accepted* $\mathsf{RealMinMax}^{\uparrow}$ *carrier $M = (X, Y, R_X, R_Y, S_X, S_Y, D, E, C, O, L, U, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealMinMax}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{Real}^{\uparrow}$ *seals, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, two finite* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance ledger, equality boundary, comparison row, order ledger, min row, max row, transport, replay, provenance, and local naming rows;*

2. *classifier transport, requiring H and T to preserve the same two seals, readbacks, windows, tolerance row, equality row, comparison row, order row, and min/max rows componentwise;*

3. *finite comparison handoff, requiring every order-facing consumer to receive L and U only through the displayed route D, E, C, O;*

4. *min/max row stability, requiring replacement of displayed windows by* hsame*-transported windows to preserve the same public minimum and maximum rows;*

5. *non-escape, excluding trichotomy, quotient real equality, host real order, selected representatives,* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge checking.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.RealMinMaxUp.RealMinMaxTasteGate single carrier alignment`

Proof. Project the accepted carrier. The analytic coordinates are the two real seals, their readbacks, their finite windows, the tolerance ledger, the equality boundary, the comparison row, the algebraic order row, and the two output rows L and U.

Carrier admission is exactly admission of those displayed coordinates together with H, T, P, N. The local certificate has no additional field from which a host real value or quotient representative could be recovered.

Classifier transport is structural. Componentwise hsame in H keeps the two input seals, readbacks, windows, comparison data, and output rows aligned, while Cont replay in T repeats the same finite comparison route for later consumers.

The handoff obligation is forced by the order of the rows. A consumer can inspect L or U only after the dyadic tolerance row D, equality row E, located comparison row C, and algebraic order ledger O have already been displayed.

Min/max stability follows because changing finite windows along the recorded hsame transport does not change the comparison route presented to D, E, C, O. The same route therefore names the same public minimum and maximum rows.

Finally, the non-escape clause is immediate from the carrier surface. None of trichotomy, quotient real equality, host real order, selected representatives, $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking is a coordinate of M. □

Theorem 1674.3 (RealMinMax finite comparison handoff)**.** *For every accepted* $\mathsf{RealMinMax}^{\uparrow}$ *carrier* $M = (X, Y, R_X, R_Y, S_X, S_Y, D, E, C, O, L, U, H, T, P, N)$*, every* $\mathsf{RealAlgOrder}^{\uparrow}$ *consumer receives the minimum row* L *and maximum row* U *only through the displayed finite route*

$$X, Y \longmapsto S_X, S_Y \longmapsto R_X, R_Y \longmapsto D, E, C, O \longmapsto L, U \longmapsto H, T, P, N.$$

Consequently the handoff supplies min/max data only through displayed finite comparison, equality, and order rows; it does not supply trichotomy, quotient real equality, host real order, selected representatives, $\mathsf{Real}^{\uparrow}$ *completeness, or a bridge-checked standard object.*

Lean4 ✓ `BEDC.Derived.RealMinMaxUp.RealMinMaxCarrier finite comparison handoff`

Proof. Start from an accepted carrier. The only input real rows are X and Y, and their only readback route in the packet passes through the finite windows S_X, S_Y and regular rational rows R_X, R_Y.

The comparison data are then fixed by D, E, C, O. The dyadic row D supplies the finite tolerance budget, E records the equality boundary, C records the Bishop-style located comparison read, and O records the algebraic order ledger consumed by RealAlgOrder-facing requests.

The output rows L and U occur after those rows in the carrier, so they cannot be read before the comparison route is displayed. They are therefore public min/max rows over that route rather than representatives selected from a host ordered real.

The rows H, T, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for trichotomy, quotient real equality, host real order, selected representatives, completeness, or bridge checking, every $\mathsf{RealAlgOrder}^{\uparrow}$ consumer receives only the displayed finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealMinMax}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealMinMax}^{\uparrow}$ packet is generated from two displayed RealUp seals, two RegSeqRat readbacks, finite StreamName windows, a DyadicRatCore comparison-tolerance ledger, a RealEquality boundary row, a BishopRealComparison comparison row, a RealAlgOrder order ledger, min and max rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealMinMax}^{\uparrow}}$, seed)

Scope closed: Definition 1674.1, Definition 1674.2, and Definition 1674.3 seed the finite constructive min/max boundary for displayed RealUp names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealMinMax}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, host real order, selected representatives, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite comparison handoff, min/max row stability, and non-escape proofs for BEDC.Derived.RealMinMaxUp.

Chapter 1675

A Concrete Naming Certificate for $\mathsf{BrouwerBarInduction}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on spreads, bars, and bar induction, the $\mathsf{BrouwerBarInduction}^{\uparrow}$ packet records the finite barred-spread boundary needed by constructive Real and Completion work. It is positioned after the finite fan surface of chapter 400, the prefix-law surface of chapter 1532, and the finite choice-sequence surface of chapter 1482. Downstream Real and Completion consumers may cite it only through the $\mathsf{StreamName}^{\uparrow}$ window discipline, the $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and the terminal $\mathsf{Real}^{\uparrow}$ seal; they do not receive countable choice, open-cover compactness, sequential compactness, selected infinite branches, quotient stream equality, or ambient real completeness.

Definition 1675.1 (Brouwer bar induction carrier)**.** *A* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *carrier is a finite barred-spread packet*

$$K = (T, B, M, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite prefix-tree row for the currently inspected spread. It records the displayed root, prefix closure, and finite extension rows, not a completed infinite branch.*
2. *B is the decidable bar row on prefixes of T, including the displayed Bool decisions for every prefix exposed by the current packet.*
3. *M is the monotone coverage row, asserting that whenever a displayed prefix is barred, every displayed extension remains barred through the same prefix-tree route.*
4. *I is the induction-step replay row. It records the local backwards step from barred immediate extensions to the displayed parent prefix, using only the finite children visible in T.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row by which Real and Completion consumers may request finite observations of the spread.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows when a regular-rational consumer reads the packet.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after T, B, M, I, W, R and the structural rows have been displayed.*

8. *H stores componentwise* hsame *transport for the prefix tree, bar decisions, monotone coverage, induction replay, StreamName windows, RegSeqRat readback, Real handoff, continuation, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from prefix inspection through bar decisions, monotone closure, induction-step replay, StreamName windows, RegSeqRat readback, and the Real handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerBarInduction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, B, M, I, W, R, E, H, C, P, N$. It has no coordinate for countable choice, open-cover compactness, sequential compactness, quotient equality of streams, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BrouwerBarInductionUp.BrouwerBarInductionTasteGate single carrier alignment`

Theorem 1675.2 (Brouwer bar induction prefix stability)**.** *Let $K = (T, B, M, I, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *carrier. Every displayed prefix subtree of T, with the restricted bar row, monotone coverage row, induction-step replay row, StreamName windows, RegSeqRat readback, Real handoff, and structural rows inherited from K, repacks as an accepted* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *carrier. The restricted packet has no access to tail values outside the displayed prefix subtree.*

Lean4 ✓ `BEDC.Derived.BrouwerBarInductionUp.BrouwerBarInductionPrefixStability`

Proof. Project the carrier of Definition 1675.1. A displayed prefix subtree is formed by retaining only the prefix rows already present in T together with the corresponding decisions in B.

The monotone row M restricts because every retained extension is still an extension inside the original finite tree row. The induction-step row I restricts for the same reason: the local backwards step is read only over the displayed children of the retained parent prefix.

The rows W, R, E remain downstream of the restricted prefix surface. Componentwise transport, continuation replay, provenance, and naming are supplied by H, C, P, N, so the restricted tuple is again the same finite packet type and exposes no hidden tail data. □

Theorem 1675.3 (Brouwer bar induction choice and completeness boundary)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing read of an accepted* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *carrier factors through*

$$T, B, M, I, W, R, E, H, C, P, N.$$

The read may use finite barred-prefix information and the displayed induction-step replay, but it cannot extract countable choice, open-cover compactness, sequential compactness without choice-like data, quotient stream equality, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BrouwerBarInductionUp.BrouwerBarInductionChoiceBoundary`

Proof. Start with a downstream read. The only analytic-facing rows of the carrier are the StreamName window W, the RegSeqRat readback R, and the Real handoff E.

Replay the continuation row C. The route first exposes the prefix tree T, the decidable bar row B, monotone coverage M, and the induction-step row I; only then can it open W, read R, and reach E.

The structural rows H, P, N preserve and name that same route. Since the carrier contains no selector for infinite branches, no quotient stream equality row, no open-cover row, no sequential

compactness row, and no ambient completeness row, none of those principles can be exported by the packet. □

Theorem 1675.4 (Brouwer bar induction NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *carrier* $K = (T, B, M, I, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BrouwerBarInduction}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the prefix tree, decidable bar, monotone coverage, induction-step replay, StreamName window, RegSeqRat readback, Real handoff, transport, continuation, provenance, and naming rows;*
2. *prefix stability, requiring every displayed prefix subtree to repack through Definition 1675.2;*
3. *monotone barred-spread replay, requiring bar decisions and extension closure to be read only through* T, B, M*;*
4. *induction-step exactness, requiring every backwards step to pass through the displayed local replay row* I *rather than through a host infinite branch;*
5. *analytic boundary nonescape, requiring every Real or Completion-facing read to use the route of Definition 1675.3.*

No local obligation is stored outside these five rows.

Lean4 ✓ `BEDC.Derived.BrouwerBarInductionUp.BrouwerBarInductionNameCertObligations`

Proof. Carrier admission is the tuple displayed in Definition 1675.1. The classifier can inspect only the listed coordinates, so the first obligation is exactly the projection of $T, B, M, I, W, R, E, H, C, P, N$.

Prefix stability is Definition 1675.2. It shows that a shorter displayed subtree keeps the same bar, monotone, replay, analytic handoff, transport, continuation, provenance, and naming structure.

The monotone barred-spread and induction-step clauses are read directly from B, M, I. The bar row gives only displayed Bool decisions, the monotone row preserves those decisions along displayed extensions, and the replay row supplies only the finite backwards step over visible children.

The analytic boundary is Definition 1675.3. It forces every StreamName, RegSeqRat, Real, or Completion consumer through W, R, E after the barred-spread rows have been displayed.

The packet has no further coordinate. Therefore countable choice, open-cover compactness, sequential compactness, quotient stream equality, selected infinite branches, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{BrouwerBarInduction}^{\uparrow}$ Real or Completion-facing read factors through a displayed finite prefix tree, decidable bar row, monotone coverage row, induction-step replay row, StreamName window, RegSeqRat readback, Real handoff, transport, continuation, provenance, and local naming.

Independence witness: fantheorem, spread-law, choice-sequence, streamname, regseqrat, real: $\mathsf{BrouwerBarInduction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite barred-spread prefix tree, decidable bar, monotone coverage, induction-step replay, analytic window handoff, transport, continuation, provenance, and local naming while refusing branch selection and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerBarInduction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BrouwerBarInduction}^{\uparrow}$ packet is generated from a finite prefix tree, a decidable bar row, monotone coverage, induction-step replay, StreamName windows, RegSeqRat readback, a Real handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BrouwerBarInduction}^{\uparrow}}$, seed)

Scope closed: Definition 1675.1, Definition 1675.2, Definition 1675.3, and Definition 1675.4 seed the finite barred-spread boundary for Real and Completion-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{BrouwerBarInduction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, open-cover compactness, sequential compactness, quotient stream equality, selected infinite branches, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix stability, monotone barred-spread replay, induction-step exactness, analytic boundary nonescape, and TasteGate field faithfulness for BEDC.Derived.BrouwerBarInductionUp.

Chapter 1676

A Concrete Naming Certificate for $\mathsf{BrouwerOperation}^{\uparrow}$

Following Troelstra–van Dalen on neighbourhood functions, the $\mathsf{BrouwerOperation}^{\uparrow}$ packet records a finite prefix-tree operation surface over countable-name data. It sits between the $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126, the $\mathsf{BaireSpace}^{\uparrow}$ finite cylinder surface of chapter 334, the prefix-law rows of chapter 1532, the barred-prefix boundary of chapter 1675, the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite neighbourhood-function certificate for downstream Real and Completion consumers; it is not a host function space, countable choice, quotient stream equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1676.1 (BrouwerOperation finite neighbourhood carrier)**.** *A* $\mathsf{BrouwerOperation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite prefix-tree row over countable-name observations. It records the retained prefixes, root row, immediate-extension rows, and the finite cylinder boundary shared with* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{SpreadLaw}^{\uparrow}$*.*
2. *O is the output-row ledger. For each accepted prefix at which the neighbourhood function has stabilized, O records the displayed output cell and the finite justification prefix that produced it.*
3. *M is the monotone extension ledger. It requires every displayed extension of a stabilized prefix to retain the same output row through the same prefix-tree route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row by which a consumer reads only the finite prefix needed by the current operation cell.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed after the relevant window has been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the prefix tree, output ledger, monotone extension ledger, StreamName window, and RegSeqRat readback have been displayed.*
7. *H stores componentwise* hsame *transport for the prefix tree, output rows, monotone ledger, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from finite prefix inspection through output stabilization, monotone extension, StreamName window, RegSeqRat readback, and the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerOperation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerOperation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, O, M, W, R, E, H, C, P, N$. It has no coordinate for host function extensionality, countable choice, quotient stream equality, selected infinite branches, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BrouwerOperationUp.BrouwerOperationTasteGate single carrier alignment`

Theorem 1676.2 (BrouwerOperation NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerOperation}^{\uparrow}$ *carrier $K = (T, O, M, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BrouwerOperation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed prefix tree, output-row ledger, monotone extension ledger, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *prefix-tree stability, requiring accepted restrictions to retain only rows already displayed in T and to compare them through the* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{SpreadLaw}^{\uparrow}$ *cylinder classifiers;*
3. *output exactness, requiring each stabilized output in O to name its finite justification prefix and no hidden tail of the input name;*
4. *monotone extension, requiring M to preserve the output row along every displayed extension of a stabilized prefix;*
5. *analytic readback, requiring W, R, E to be consumed in that order before a Real or Completion-facing route may read the operation value;*
6. *provenance and local naming, requiring P and N to package exactly the displayed rows and no additional function-space datum.*

No BrouwerOperation obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 1676.1. The visible packet consists exactly of the prefix tree T, output ledger O, monotone extension ledger M, analytic rows W, R, E, and structural rows H, C, P, N.

Prefix-tree stability is inherited from the retained finite rows of T. A restriction keeps only prefixes already displayed, so its comparisons still pass through the same BaireSpace cylinder and SpreadLaw prefix surfaces.

Output exactness and monotone extension are the local contents of O and M. The output row names the finite justification prefix, while the monotone ledger says that displayed extensions of that prefix preserve the same output cell.

The analytic readback row is forced by W, R, E. The StreamName window must be opened before RegSeqRat readback, and the Real seal is terminal after that readback.

Finally, H, C, P, N transport, replay, package, and name the same route without adding a host function, stream quotient, choice selector, branch selector, selected limit, or Real-completeness coordinate. Hence the six listed rows exhaust the local NameCert surface. □

Theorem 1676.3 (BrouwerOperation prefix-continuity handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing consumer of an accepted* $\mathsf{BrouwerOperation}^{\uparrow}$ *carrier receives only the finite prefix-continuity route*

$$T \longmapsto O \longmapsto M \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer may cite a stabilized finite prefix and its monotone extension ledger, but it cannot bypass the displayed route by importing a host function space, countable choice, quotient stream equality, a selected infinite branch, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and a downstream consumer. The only input-inspection coordinate is the prefix tree T, and the only operation-value coordinate is the output ledger O.

The monotone extension ledger M is the route from a stabilized prefix to its displayed extensions. It prevents the consumer from replacing the finite justification prefix by an unstated tail property of the input name.

The analytic part of the handoff is then forced through W, R, E. A StreamName window opens the finite observation, RegSeqRat reads that window as regular rational data, and the Real seal is reached only after those rows have been consumed.

The structural rows H, C, P, N preserve and name this same route. Since the carrier has no coordinate for a host function space, countable choice, quotient stream equality, selected branch, selected limit, or ambient completeness theorem, none of those objects can be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{BrouwerOperation}^{\uparrow}$ Real or Completion-facing read factors through a finite prefix tree, output-row ledger, monotone extension ledger, StreamName window, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, bairespace, spread-law, brouwer-bar-induction, regseqrat, real: $\mathsf{BrouwerOperation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite prefix-tree operation data, stabilized output rows, monotone extension, analytic readback, transport, replay, provenance, and local naming while refusing host functions, countable choice, quotient stream equality, selected branches, selected limits, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerOperation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerOperation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1676.1, Definition 1676.2, and Definition 1676.3 seed the finite neighbourhood-function route from prefix-tree operation data through StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerOperation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, countable choice, quotient stream equality, selected infinite branches, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-tree stability, output exactness, monotone extension, analytic readback, provenance, and local naming for BEDC.Derived.BrouwerOperationUp.

Constructive story: A $\mathsf{BrouwerOperation}^{\uparrow}$ packet is generated from finite prefix-tree neighbourhood data, stabilized output rows, a monotone extension ledger, a StreamName window, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1677

A Concrete Naming Certificate for $\mathsf{BrouwerSpread}^{\uparrow}$

Following Brouwer and Bishop–Bridges on spreads and finite choice-sequence observation, the $\mathsf{BrouwerSpread}^{\uparrow}$ packet records the finite prefix carrier that mediates between displayed choice-sequence reads and later bar, fan, Real, and Completion consumers. It sits after the finite answer discipline of chapter 1482, the binary tree surface of chapter 1475, the prefix-cylinder surface of chapter 334, the window schedule of chapter 126, and the admissibility law of chapter 1532. The packet names finite admitted prefixes; it is not a completed infinite branch, countable choice, quotient stream equality, fan compactness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1677.1 (Brouwer spread carrier)**.** *A* $\mathsf{BrouwerSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, S, W, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the decidable prefix-tree row. It records the displayed root, prefix relation, prefix-closure checks, and spread-law decisions inherited from the finite admissibility surface of* $\mathsf{SpreadLaw}^{\uparrow}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule. It records the finite order in which admitted prefixes may be requested, replayed, and compared by downstream name readers.*
3. *W is the finite displayed-prefix row. Every entry of W is a prefix already listed in T and already scheduled by S.*
4. *A is the admissible answer row. It contains only displayed* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{Bool}^{\uparrow}$ *answers whose finite prefixes pass the decision row of T.*
5. *H stores componentwise* hsame *transport for the tree, schedule, displayed prefixes, admissible answers, continuation replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *prefix replay from a request for a finite choice-sequence read to the corresponding T, S, W, A rows.*
7. *P is the* Pkg *provenance over* $\mathsf{BrouwerSpread}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{SpreadLaw}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerSpread}^{\uparrow}}$ *row.*

The carrier has no coordinate for a total host function, a completed branch through T, a quotient stream, a countable-choice selector, compactness, or a $\mathsf{Real}^{\uparrow}$ *completeness seal.*

Lean4 ✓ `BEDC.Derived.BrouwerSpreadUp.BrouwerSpreadTasteGate single carrier alignment`

Definition 1677.2 (Brouwer spread classifier)**.** *Two accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *carriers*

$$B = (T, S, W, A, H, C, P, N)$$

and

$$B' = (T', S', W', A', H', C', P', N')$$

are classified together exactly when their common admitted prefixes agree through the displayed rows T, S, W, A *and* T', S', W', A'*, and when every branching decision visible in one carrier is admissible through the corresponding spread-law row of the other carrier wherever both packets display the prefix. The classifier compares finite common-prefix admission, branching admissibility, schedule replay, transport, continuation, provenance, and local naming. It never compares host functions, completed infinite streams, quotient representatives, or extensional equality of unseen tails.*

Theorem 1677.3 (Brouwer spread prefix closure)**.** *Let*

$$B = (T, S, W, A, H, C, P, N)$$

be an accepted $\mathsf{BrouwerSpread}^{\uparrow}$ *carrier. Every admitted prefix subwindow of* W*, with the restricted prefix tree, restricted StreamName schedule, restricted admissible* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{Bool}^{\uparrow}$ *answer rows, inherited componentwise transport, inherited continuation replay, inherited provenance, and inherited local naming, repacks as an accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *carrier.*

Proof. Project the carrier of Definition 1677.1. An admitted prefix subwindow keeps only entries of W already licensed by T and already scheduled by S.

The restricted tree remains prefix closed because T stores prefix-closure checks for every displayed prefix. The restricted answer row remains admissible because A contains only displayed $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Bool}^{\uparrow}$ answers attached to prefixes accepted by T.

The structural rows restrict componentwise. The transport row H compares the retained coordinates, the continuation row C replays the same prefix requests over the shorter window, and P, N name the same local package. The resulting tuple has the same carrier shape and no access to any tail outside the displayed subwindow. □

Theorem 1677.4 (Brouwer spread choice-sequence factorization)**.** *Every public* $\mathsf{ChoiceSequence}^{\uparrow}$ *read of an accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *carrier factors through the admitted finite prefix rows*

$$T, S, W, A, H, C, P, N.$$

The read may inspect only the finite $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{Bool}^{\uparrow}$ *answers admitted by the prefix tree and scheduled by the StreamName row; it cannot extract a completed infinite choice sequence, a host function, quotient stream equality, countable choice, compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a public $\mathsf{ChoiceSequence}^{\uparrow}$ read. The carrier exposes choice-sequence data only through the displayed-prefix row W and the admissible answer row A.

Replay the continuation row C. The route first checks the decidable prefix tree T, then opens the StreamName schedule S, and only then reads the finite answers recorded in W, A.

The structural rows H, P, N preserve and name that route. Since the packet has no coordinate for a total sequence, quotient stream, choice selector, compactness principle, or real-completion seal, every public read factors through the finite prefix rows and cannot export the excluded data. □

Theorem 1677.5 (Brouwer spread NameCert obligation surface)**.** *For every accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *carrier* $B = (T, S, W, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BrouwerSpread}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the decidable prefix tree, StreamName schedule, displayed-prefix row, admissible answer row, transport, continuation, provenance, and local naming;*
2. *classifier agreement on common admitted prefixes and branching admissibility as in Definition 1677.2;*
3. *prefix closure through Definition 1677.3;*
4. *choice-sequence factorization through Definition 1677.4;*
5. *componentwise* hsame *transport for every displayed row;*
6. *displayed* Cont *replay for every prefix request;*
7. *exact* Pkg *provenance and local* NameCert *naming;*
8. *non-escape, requiring every downstream read to stay inside* T, S, W, A, H, C, P, N*.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1677.1. The visible packet contains exactly T, S, W, A, H, C, P, N.

Classifier agreement is Definition 1677.2. It compares common admitted prefixes and branching admissibility without invoking equality of host functions or unseen stream tails.

Prefix closure and choice-sequence factorization are supplied by Definition 1677.3 and Definition 1677.4. These two clauses force every retained subwindow and every public choice-sequence read through the same finite prefix rows.

The remaining clauses are the structural projections. The row H gives transport, C gives replay, and P, N give provenance and local naming. Because the carrier inventory has no additional coordinate, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{BrouwerSpread}^{\uparrow}$ public ChoiceSequence, StreamName, Real, or Completion-facing read factors through a decidable prefix tree, StreamName schedule, finite displayed-prefix row, admissible Nat/Bool answer row, componentwise transport, continuation replay, provenance, and local NameCert row.

Independence witness: choice-sequence, cantorspace, bairespace, streamname, spread-law: $\mathsf{BrouwerSpread}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries decidable prefix admission, StreamName scheduling, displayed prefix windows, admissible Nat/Bool answer rows, transport, continuation replay, provenance, and local naming while refusing completed branches, countable choice, quotient streams, compactness, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerSpread}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BrouwerSpread}^{\uparrow}$ packet is generated from a decidable prefix tree, a StreamName schedule, finite displayed prefixes, admissible Nat/Bool answer rows, componentwise hsame transport, displayed Cont prefix replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BrouwerSpread}^{\uparrow}}$, seed)

Scope closed: Definition 1677.1, Definition 1677.2, Definition 1677.3, Definition 1677.4, and Definition 1677.5 seed the finite-prefix spread carrier for L10 Real and Completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BrouwerSpread}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed infinite branches, countable choice, quotient stream equality, fan compactness, open-cover compactness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-prefix classification, prefix closure, choice-sequence factorization, transport, continuation, provenance, and non-escape for BEDC.Derived.BrouwerSpreadUp.

Chapter 1678

A Concrete Naming Certificate for $\mathsf{Limit}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's finite-neighborhood reading of convergence, the $\mathsf{Limit}^{\uparrow}$ packet names the generic finite limit surface used by the Real and Completion chapters. It is not a host limit operator and not a quotient of convergent streams. It is the visible route through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and a downstream $\mathsf{Real}^{\uparrow}$ seal row, with transport, continuation replay, provenance, and local naming retained as BEDC rows.

The sibling dependency route is deliberately shared with the specialized limit chapters. The $\mathsf{RealLimit}^{\uparrow}$ packet of chapter 347 and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ boundary of chapter 386 consume the same finite faces supplied by chapter 126, chapter 301, chapter 291, and chapter 38. The generic $\mathsf{Limit}^{\uparrow}$ carrier records that common surface before any specialized real-limit or completion-facing packet chooses a narrower role.

Definition 1678.1 (Limit carrier)**.** *A* $\mathsf{Limit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, A, T, C, H, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that supplies the finite observation schedule for the limit request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested radius, slack, and comparison budget for each finite observation.*
4. *A is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, read only after S, R, D have been replayed.*
5. *T is the limit transport row binding the same S, R, D, A surface to any specialized* $\mathsf{RealLimit}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer.*
6. *C records displayed* Cont *replay from a finite limit request through the window row, rational readback, tolerance ledger, seal row, and transport row.*
7. *H stores componentwise* hsame *transport for the window, readback, tolerance ledger, seal, limit transport, continuation, provenance, and local naming rows.*

8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLimit}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows, their displayed transports, their continuation replay, package provenance, and local naming provenance. The carrier has no coordinate for quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, or bridge checking.

Lean4 ✓ `BEDC.Derived.LimitUp.LimitTasteGate single carrier alignment`

Theorem 1678.2 (Limit NameCert obligations)**.** *For every accepted* $\mathsf{Limit}^{\uparrow}$ *carrier* $L = (S, R, D, A, T, C, H, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed window, readback, tolerance ledger, seal, transport, continuation, provenance, and local naming rows;*
2. *finite-window exactness, requiring every limit-facing read to inspect S before it can reach the regular rational readback row R;*
3. *tolerance-ledger exactness, requiring every readback comparison to pass through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D before the* $\mathsf{Real}^{\uparrow}$ *seal row A is exposed;*
4. *specialized-consumer handoff, requiring every* $\mathsf{RealLimit}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer to reuse the same S, R, D, A route through T, C, H, P, N;*
5. *non-escape from quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, Lean verification, and bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 1678.1. The projection exposes exactly the finite window row, regular rational readback, dyadic tolerance ledger, Real seal, limit transport, continuation replay, componentwise transport, package provenance, and local naming row.

Finite-window exactness follows from the route order stored in C. A limit-facing request enters through S before it can obtain R, and the comparison budget is then read from D before the seal row A can be consumed.

The specialized handoff is supplied by T, H, P, N. These rows retain the same displayed route for $\mathsf{RealLimit}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers, so the packet has no remaining coordinate from which quotient equality, selected representatives, host equality, trichotomy, choice, completeness, Lean verification, or bridge checking could be exported. □

Lean4 ✓ `BEDC.Derived.LimitUp.LimitUpTasteGate single carrier alignment`

Theorem 1678.3 (Limit Real and Completion handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

as displayed by the packet rows S, R, D, A, then through the transport, continuation, provenance, and local naming rows T, C, H, P, N. Consequently the generic limit surface can be cited by $\mathsf{RealLimit}^{\uparrow}$ *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *chapters without claiming quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Begin with a Real-facing or Completion-facing consumer. Carrier admission gives access to the seal row A only as a row downstream of the finite window, readback, and tolerance rows.

Replay the continuation row C. The consumer first reads S, obtains the regular rational observations through R, consults the dyadic tolerance ledger D, and only then reaches the $\mathsf{Real}^{\uparrow}$ seal row A.

Finally apply the handoff row T together with the structural rows H, P, N. They repack the same finite route for $\mathsf{RealLimit}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers, while adding no quotient, representative selector, host equality, trichotomy, choice, completeness, Lean target, or bridge row. □

Lean4 ✓ `BEDC.Derived.LimitUp.LimitRealCompletionHandoff`

Theorem 1678.4 (Limit RegSeqRat Bishop handoff)**.** *Any Bishop-style* $\mathsf{Limit}^{\uparrow}$ *read in the current L10 route must pass through finite* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a downstream* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ *naming. For an accepted carrier* $L = (S, R, D, A, T, C, H, P, N)$*, the only exported route is*

$$S \longmapsto R \longmapsto D \longmapsto A \longmapsto T, C, H, P, N.$$

The packet cannot export selected representatives, quotient stream equality, trichotomy, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Proof. Unfold the finite carrier of Definition 1678.1. The window row S, regular rational readback row R, dyadic tolerance ledger D, Real seal A, and specialized handoff row T are the only content rows available to a Bishop-style limit read.

Apply the NameCert obligations of Definition 1678.2. They force finite-window exactness before R, tolerance-ledger exactness before A, and specialized-consumer handoff through T, C, H, P, N.

The Real and Completion handoff of Definition 1678.3 identifies the same route as the shared L10 naming spine for downstream consumers. Since the carrier contains no selected representative, quotient stream equality, trichotomy, countable-choice, host-equality, completeness, Lean-verification, or bridge-checking coordinate, no such object can be exported by the handoff. □

Lean4 ✓ `BEDC.Derived.LimitUp.LimitRegSeqRatBishopHandoff`

Definition 1678.5 (Limit obligation surface)**.** *For an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier* $L = (S, R, D, A, T, C, H, P, N)$*, the* obligation surface *is the finite projection ledger consisting of:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *window exactness row* S *and its replay into the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *binding every displayed comparison before the downstream* $\mathsf{Real}^{\uparrow}$ *seal row* A *can be consumed;*
3. *the consumer handoff row* T *to* $\mathsf{RealLimit}^{\uparrow}$ *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$*;*
4. *the structural replay rows* C, H, P, N *for* Cont*, componentwise* hsame*,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ *naming.*

This surface records only finite projection and replay obligations over the carrier rows. It is not quotient stream equality, a selected representative, a host limit operator, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1678.6 (Limit finite-window exactness)**.** *Let $L = (S, R, D, A, T, C, H, P, N)$ be an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier. Every finite limit read that reaches the regular rational row R factors through the same displayed* $\mathsf{StreamName}^{\uparrow}$ *window row S, and the factorization is replayed by the* Cont *row C and transported componentwise by H. Thus the window obligation of Definition 1678.5 is a finite projection route through chapter 126 and chapter 301.*

Lean4 ✓ `BEDC.Derived.LimitUp.LimitFiniteWindowExactness`

Proof. Project the carrier L and isolate the rows S, R, C, H. The carrier definition exposes R only as the readback row downstream of the displayed window row S.

Replay the request through C. The replay ledger opens the window schedule first, then reads the regular rational observations recorded by R. Componentwise transport by H keeps the same S and R rows under hsame.

No further row remains from which a host stream representative, quotient equality, or ambient limit operator could be read. The exactness statement is therefore the finite projection route from $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{RegSeqRat}^{\uparrow}$. □

Theorem 1678.7 (Limit tolerance-ledger exactness)**.** *Let $L = (S, R, D, A, T, C, H, P, N)$ be an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier. Every readback comparison that reaches the* $\mathsf{Real}^{\uparrow}$ *seal row A passes through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, with replay and transport recorded by C, H, P, N. Thus the tolerance obligation of Definition 1678.5 is a finite replay route through chapter 291 and chapter 38.*

Proof. Start from a comparison exported by the accepted carrier. The rows R, D, A are ordered as readback, tolerance ledger, and downstream Real seal, so a comparison cannot inspect A before the dyadic budget row D is displayed.

Use C to replay the comparison route and H to transport the same row package. The provenance row P records that the route is sourced in $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, while N names the local packet.

The carrier has no coordinate for trichotomy, countable choice, host real equality, or ambient completeness. The tolerance obligation is exactly the finite ledger route from D to A. □

Lean4 ✓ `BEDC.Derived.LimitUp.LimitToleranceLedgerExactness`

Theorem 1678.8 (Limit consumer handoff exactness)**.** *Let $L = (S, R, D, A, T, C, H, P, N)$ be an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier. Every* $\mathsf{RealLimit}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of L receives only the finite route*

$$S \longmapsto R \longmapsto D \longmapsto A \longmapsto T, C, H, P, N.$$

Consequently the consumer obligation of Definition 1678.5 is a finite handoff through chapter 347 and chapter 386, not a claim of quotient stream equality, selected representatives, host real equality, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.LimitUp.LimitConsumerHandoffExactness`

Proof. Read the consumer through the transport row T. That row binds $\mathsf{RealLimit}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers to the same upstream rows S, R, D, A displayed by the generic $\mathsf{Limit}^{\uparrow}$ packet.

Replay the route using C and transport it using H. The provenance and local naming rows P, N record the same dependency spine through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLimit}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$.

Because the carrier is exhausted by these rows, the consumer cannot acquire an external stream quotient, selected representative, host real equality proof, completeness principle, Lean target, or bridge row. The handoff exactness is therefore a finite replay obligation. □

Theorem 1678.9 (Limit scoped kernel route)**.** *Let $L = (S, R, D, A, T, C, H, P, N)$ be an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier. Every scoped read of L is bound to the BEDC primitive route*

$$\mathsf{StreamName}^{\uparrow}(S) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(R) \longmapsto \mathsf{DyadicRatCore}^{\uparrow}(D) \longmapsto \mathsf{Real}^{\uparrow}(A) \longmapsto \mathsf{hsame}(H), \mathsf{Cont}(C), \mathsf{Pkg}(P), \mathsf{Name}$$

The transport row T may hand this same route to $\mathsf{RealLimit}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, but it cannot add a quotient stream equality, selected representative, host real equality, trichotomy, countable choice, ambient completeness, or bridge-checking coordinate.*

Lean4 ✓ `BEDC.Derived.LimitUp.LimitScopedKernelRoute`

Proof. Project the carrier and read the primitive rows in order. The only nonstructural rows before the handoff are the finite StreamName window S, the RegSeqRat readback R, the DyadicRatCore tolerance ledger D, and the Real seal A.

Apply finite-window exactness and tolerance-ledger exactness. They force any scoped request to inspect S before R and D before A, so the read is already confined to the displayed BEDC primitives.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. The handoff row T only repacks it for the two specialized consumers, so no excluded coordinate remains available to a scoped reader. □

Theorem 1678.10 (Limit RegSeqRat-to-Real scope)**.** *For an accepted* $\mathsf{Limit}^{\uparrow}$ *carrier $L = (S, R, D, A, T, C, H, P, N$ every finite RegSeqRat readback consumed as a Real-facing limit observation passes through the displayed tolerance route*

$$S \longmapsto R \longmapsto D \longmapsto A$$

and keeps H, C, P, N attached to that same route. Thus the RegSeqRat-to-Real scope is finite readback plus tolerance-ledger replay, not a host equality of streams and not ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LimitUp.LimitRegseqratRealScope`

Proof. Start with a Real-facing observation exported by L. The carrier definition makes A downstream of the regular rational row R and the dyadic tolerance ledger D, with S supplying the finite observation windows.

Use Definition 1678.7. It prevents a comparison from reaching A before the same D ledger is displayed, and it keeps the replay and transport rows attached.

The remaining rows P, N record provenance and local naming only. Hence the scope is exactly the finite route from StreamName windows through RegSeqRat readback and DyadicRatCore tolerance to the Real seal. □

Theorem 1678.11 (Limit completion-scope refusal)**.** *No accepted* $\mathsf{Limit}^{\uparrow}$ *carrier exports quotient stream equality, a selected representative, host real equality, trichotomy, countable choice, or ambient completeness to a completion-facing consumer. Any such export would require a coordinate outside the scoped primitive rows $S, R, D, A, T, C, H, P, N$ and outside the local* $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ *surface.*

Lean4 ✓ `BEDC.Derived.LimitUp.LimitCarrier completion scope refusal`

Proof. Read the scoped kernel route of Definition 1678.9. It exhausts the carrier by StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a Real seal, the handoff row, transport, replay, provenance, and local naming.

Each refused object needs an additional coordinate. Quotient stream equality and selected representatives require a stream quotient or selector row; host real equality and trichotomy require external Real comparison data; countable choice and ambient completeness require global principles not stored in the finite carrier.

Because none of those coordinates occurs in the accepted packet, every completion-facing read remains inside the displayed scoped route. □

Theorem 1678.12 (Limit standard bridge envelope)**.** *The public finite route of an accepted* $\mathsf{Limit}^{\uparrow}$ *packet can be read by a standard bridge only as the same displayed envelope through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The bridge-facing read remains valid only while quotient streams, selected representatives, host real equality, countable choice, and ambient completeness stay excluded from the packet.*

Proof. Apply the RegSeqRat Bishop handoff, the scoped kernel route, and the completion-scope refusal theorems, Definition 1678.4, Definition 1678.9, and Definition 1678.11. Together they expose the same finite public route and rule out every excluded host coordinate.

A standard bridge may therefore read the route only as this finite envelope. Adding quotient streams, representatives, host equality, countable choice, or ambient completeness would require rows absent from the accepted carrier and from the local $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1678.4, Definition 1678.3, Definition 1678.8, and Definition 1678.12 supply the bridged consumer envelope for the finite Limit route through StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, Pkg, and NameCert primitives.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Limit}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.LimitUp.LimitRegSeqRatBishopHandoff`

Bridge status: paperBridge

Not claimed: This chapter does not claim quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: No further paper-side theory closure remains; Lean standard-bridge checking is a separate formal-axis obligation over the public Limit handoff.

Constructive story: A $\mathsf{Limit}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealUp seal row, a limit transport row for RealLimitUp and CauchyLimitSealUp consumers, continuation replay, componentwise transport, package provenance, and local naming.

Chapter 1679

A Concrete Naming Certificate for $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$ packet names the finite regular-Cauchy route for the affine expression $qx+(1-q)y$ before any completed $\mathsf{Real}^{\uparrow}$ consumer is allowed to read the result. It sits over the two-source sum certificate of chapter 417, the rational scale certificate of chapter 465, the midpoint specialization of chapter 1670, the dyadic arithmetic core of chapter 291, the stream-window discipline of chapter 126, the regular rational sequence boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet gives later completion and real-algebra consumers one finite algebraic surface instead of forcing each consumer to rethread scale, complementary scale, sum, regular readback, and seal ledgers separately.

Definition 1679.1 (Regular Cauchy affine combination carrier)**.** *A* $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{aff}} = (Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *Q is the coefficient row, recording a rational coefficient q together with the dyadic window in which the complementary coefficient $1-q$ is computed.*
2. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows.*
3. *W_X and W_Y are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedules for the two source names, read at the same precision request and observation index.*
4. *D_Q and $D_{\bar{Q}}$ are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows for q and $1-q$ at the common exponent used by the packet.*
5. *S_X is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row for the scaled source qx, reading Q, X, W_X, D_Q and its scale-error ledger.*
6. *S_Y is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row for the scaled source $(1-q)y$, reading the complementary coefficient row, $Y, W_Y, D_{\bar{Q}}$, and its scale-error ledger.*
7. *Σ is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row that adds the two scaled regular names.*
8. *E is the finite error-budget ledger combining the two scale ledgers, the sum tolerance, the complementary-coefficient tolerance, and the final output tolerance assigned to the affine readback.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose scheduled point row is supplied by Σ with regularity evidence supplied by E.*

10. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the coefficient, two sources, two synchronized schedules, two dyadic coefficient endpoints, two scale rows, sum row, finite ledger, and regular readback have been displayed.*

11. *H stores componentwise* hsame *transports for the coefficient, source rows, schedules, dyadic endpoint rows, scale rows, sum row, ledger, readback, Real seal, replay row, provenance row, and local naming row.*

12. *C stores displayed* Cont *replay routes for coefficient exposure, source-window exposure, the two scale reads, the sum read, the ledger read, the regular readback, and the Real seal handoff.*

13. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{RegularCauchyMidpoint}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAffineCombination}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R,$ The carrier has no coordinate for quotient stream equality, host real affine arithmetic, a selected limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completed-real affine operation.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAffineCombinationUp.RegularCauchyAffineCombinationTasteGate`
`single carrier alignment`

Theorem 1679.2 (Regular Cauchy affine combination obligation surface)**.** *For every accepted* $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$ *carrier*

$$A_{\text{aff}} = (Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyAffineCombination}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the coefficient row, two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *schedules, dyadic endpoint rows for q and $1-q$, two* $\mathsf{RegularCauchyScale}^{\uparrow}$ *rows, one* $\mathsf{RegularCauchySum}^{\uparrow}$ *row, the finite ledger, readback, Real seal, and structural rows;*

2. *coefficient complement exposure, requiring D_Q and $D_{\bar{Q}}$ to be read from the same finite dyadic coefficient window before either scale row is consumed;*

3. *synchronized-window exposure, requiring W_X and W_Y to be read at a common requested precision before the two scale rows are formed;*

4. *scale exactness for S_X and S_Y, requiring the displayed rows for qx and $(1-q)y$ to consume their coefficient endpoint, source window, scale endpoint, and scale-error ledger;*

5. *sum exactness for Σ, requiring the two scaled regular names to be added through the* $\mathsf{RegularCauchySum}^{\uparrow}$ *surface before the affine readback row is exposed;*

6. *ledger accounting, requiring E to combine the complementary-coefficient budget, the two scale-error budgets, the sum tolerance, and the final output tolerance before R or Z is read;*

7. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the displayed finite affine packet;*

8. *refusal of quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No affine-combination obligation is stored outside these finite rows.

Proof. Project the accepted carrier. The coefficient row, two source rows, synchronized schedules, two dyadic coefficient endpoints, two scale rows, the sum row, the ledger, readback, and Real seal are explicit coordinates of the packet.

Read the coefficient and source windows first. The complementary coefficient $1-q$ is displayed in the same dyadic endpoint discipline as q, while W_X and W_Y expose the two source observations at a common finite precision.

Apply the sibling scale and sum surfaces. The rows S_X and S_Y name the two scaled regular Cauchy names, and Σ names their pointwise sum before any regular readback or Real seal row is consumed.

Finally read the ledger and structural rows. The finite row E accounts for coefficient complement, scale, sum, and output tolerance budgets, while H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient equality, host affine arithmetic, selected limits, trichotomy, ambient completeness, Lean verification, or a bridge, none can become a local obligation. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAffineCombinationUp.RegularCauchyAffineCombinationObligationSurface`

Theorem 1679.3 (Regular Cauchy affine combination classifier stability)**.** *Let two accepted* RegularCauchyAffineCo *carriers have coefficient rows, source rows, stream schedules, dyadic endpoint rows, scale rows, sum rows, ledgers, readbacks, Real seals, package provenance, and local naming rows matched componentwise by their displayed* hsame *classifiers. Then every consumer route supplied by the obligation surface of Definition 1679.2 transports to the corresponding route of the second packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAffineCombinationUp.RegularCauchyAffineCombinationCarrierstability`

Proof. Start with the componentwise classifier data in H. It transports the coefficient row, the complementary coefficient endpoint, the two regular source rows, and the synchronized schedules without changing the finite precision route.

Transport the scale and sum rows next. The classified scale rows still read qx and $(1-q)y$ through the corresponding coefficient endpoints and source windows, and the classified sum row still combines those two scaled names through the displayed $\mathsf{RegularCauchySum}^{\uparrow}$ surface.

The ledger route is preserved by the same componentwise transport. The row E remains the only place where complement, scale, sum, and output tolerances are combined before R and Z are exposed.

Replay through C and repack through P and N. Every consumer route in the obligation surface is one of these displayed projections, so classifier transport cannot add quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data. □

Theorem 1679.4 (Regular Cauchy affine combination ledger nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$ *packet reads the affine result only after the finite ledger E has combined the coefficient-complement row, the two scale-error rows, the sum-tolerance row, and the final output tolerance. The packet has no alternate ledger for quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAffineCombinationUp.RegularCauchyAffineCombinationLedger`

Proof. Read a consumer request through the displayed affine route. The request first reaches the coefficient row, the two source rows, the synchronized stream windows, and the dyadic endpoint rows for q and $1-q$.

The two scale rows are then consumed. Their finite scale ledgers are the only sources for the tolerances attached to qx and $(1-q)y$.

The sum row Σ and ledger E finish the regular handoff. The row E combines the two scale ledgers with the sum tolerance and final output tolerance before the readback row R or Real seal row Z can be read.

Thus every consumer-facing affine route passes through the finite ledger. Since the carrier inventory contains no second ledger or host-level affine object, no consumer can escape to quotient stream equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Theorem 1679.5 (Regular Cauchy affine combination convex route)**.** *Assume the coefficient endpoint rows of an accepted* $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$ *carrier display the nonnegative coefficient row for q and the complementary nonnegative coefficient row for $1-q$ inside the same dyadic window. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the affine packet factors through the synchronized route*

$$Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z.$$

This route is a finite convex-combination certificate. It exposes neither quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, nor bridge data.*

Proof. Start with the obligation surface of Definition 1679.2. It places the coefficient row, the two source rows, the synchronized StreamName windows, the dyadic endpoint rows for q and $1-q$, the two scale rows, the sum row, the ledger, readback, and Real seal in the displayed carrier order.

Read the coefficient-complement data next. The nonnegative row for q and the nonnegative complementary row for $1-q$ are both exposed through D_Q and $D_{\bar{Q}}$ inside the same dyadic window, so no consumer can split the affine read into two unrelated coefficient schedules.

Apply classifier stability from Definition 1679.3. The two source windows W_X, W_Y, the scale rows S_X, S_Y, and the sum row Σ transport componentwise along the same synchronized route.

Finally apply the ledger theorem Definition 1679.4. The row E combines the coefficient-complement budget, the two scale-error budgets, the sum tolerance, and the final output tolerance before R or Z is visible, so the consumer receives exactly the finite convex-combination certificate and no excluded quotient, host arithmetic, limit, trichotomy, completeness, or bridge data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAffineCombination}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAffineCombination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1679.1, Definition 1679.2, Definition 1679.3, and Definition 1679.4 seed the finite affine-combination surface over coefficient, two $\mathsf{RegSeqRat}^{\uparrow}$ sources, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, dyadic coefficient endpoints, $\mathsf{RegularCauchyScale}^{\uparrow}$ rows, a $\mathsf{RegularCauchySum}^{\uparrow}$ row, finite ledger data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAffineCombination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient complement exposure, synchronized-window exposure, scale exactness, sum exactness, ledger accounting, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyAffineCombinationUp.

Constructive story: A RegularCauchyAffineCombination$^{\uparrow}$ packet is generated from a coefficient row, two RegSeqRat$^{\uparrow}$ sources, synchronized StreamName$^{\uparrow}$ windows, dyadic endpoint rows for q and $1 - q$, two RegularCauchyScale$^{\uparrow}$ rows, a RegularCauchySum$^{\uparrow}$ row, a finite ledger, RegSeqRat$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1680

A Concrete Naming Certificate for $\mathsf{CauchyRepresentation}^{\uparrow}$

Following Bishop and Bridges and the computable-analysis convention of representing reals by effective Cauchy names, the $\mathsf{CauchyRepresentation}^{\uparrow}$ packet records the finite interface through which stream windows, regular rational readbacks, dyadic tolerances, and a terminal real seal are presented to represented-space consumers. It sits between the stream-name certificate of chapter 126, the regular rational sequence boundary of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the represented-space surface of chapter 1494. The packet supplies a standard Cauchy-representation boundary without identifying it with $\mathsf{ComputableReal}^{\uparrow}$, $\mathsf{BishopReal}^{\uparrow}$, or the completed $\mathsf{Real}^{\uparrow}$ object.

Definition 1680.1 (CauchyRepresentation carrier)**.** *A* $\mathsf{CauchyRepresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, R, D, A, G, H, C, P, E, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row. It records the certified stream name whose finite windows are inspected.*
2. *W is the finite window schedule opened from S at the requested observation indices and precision levels.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning the displayed stream windows into regular rational observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the regular rational observations at the displayed scales.*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, R, D have been replayed.*
6. *G is the* $\mathsf{RepresentedSpace}^{\uparrow}$*-facing source row, recording that the same finite name is being offered as a represented-space source rather than as a host real or quotient stream.*
7. *H records componentwise* hsame *transport for the stream source, window schedule, regular readback, dyadic tolerance ledger, real seal, represented-space source row, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from source-window inspection through regular readback, dyadic tolerance comparison, represented-space exposure, and the final seal handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *E is the local evidence row recording that every represented-space read of the packet factors through the same S, W, R, D, A route.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRepresentation}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite Cauchy-representation packet. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyRepresentationUp.CauchyRepresentationTasteGate single carrier alignment`

Theorem 1680.2 (CauchyRepresentation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRepresentation}^{\uparrow}$ *carrier $K = (S, W, R, D, A, G, H, C, P, E, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRepresentation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream source, finite window schedule, regular rational readback, dyadic tolerance ledger, real seal, represented-space source row, transport, replay, provenance, evidence, and local naming rows;*
2. *window exactness, requiring each finite observation to be read first through S and W before any regular rational row is consulted;*
3. *regular readback exactness, requiring R to expose only the rational observations generated by the displayed stream windows;*
4. *dyadic tolerance exactness, requiring D to record the finite tolerance comparisons used to justify the regular readback route;*
5. *real-seal non-escape, requiring A to remain downstream of S, W, R, D and never to serve as a host-level selected limit;*
6. *represented-space source compatibility, requiring G and E to expose the same finite route to* $\mathsf{RepresentedSpace}^{\uparrow}$ *consumers;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the displayed packet;*
8. *refusal of quotient streams, selected limits, host real equality, countable choice, and ambient completeness as local NameCert data.*

No Cauchy-representation obligation is stored outside these rows.

Proof. Project the accepted carrier. The finite analytic route is exactly the stream row S, the window schedule W, the regular rational readback R, the dyadic tolerance ledger D, and the seal row A.

Window exactness and regular readback exactness follow from this route order. A consumer cannot reach R without first displaying the finite window schedule opened from S, and the tolerance ledger D reads only the regular observations exposed by R.

The represented-space boundary is carried by G and E. These rows expose the same finite route to represented-space consumers, so they do not add a second source of limits or equality.

Finally, H, C, P, N transport, replay, package, and name the packet without adding rows. Since the carrier contains no coordinate for quotient streams, selected limits, host real equality, countable choice, or ambient completeness, none of those readings can become a local obligation. □

Lean4 ✓ `BEDC.Derived.CauchyRepresentationUp.CauchyRepresentationCarrier namecert obligations`

Theorem 1680.3 (CauchyRepresentation stream and regular handoff)**.** *Let* $K = (S, W, R, D, A, G, H, C, P, E, N)$ *be an accepted* $\mathsf{CauchyRepresentation}^{\uparrow}$ *carrier. Every* $\mathsf{RepresentedSpace}^{\uparrow}$*- or* $\mathsf{Real}^{\uparrow}$*-facing read of* K *factors through the finite handoff route*

$$S, W \longmapsto R \longmapsto D \longmapsto A \longmapsto G, E, H, C, P, N.$$

Thus the stream name and regular rational readback are the only source rows by which the real seal and represented-space exposure are reached. The route contains no quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness principle.

Proof. Start with a consumer read of the packet. Carrier admission gives access to the seal and represented-space rows, but only as rows in the same finite packet as S, W, R, D.

Replay the continuation row C. The read first opens the $\mathsf{StreamName}^{\uparrow}$ source and its finite schedule, then consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and then consults the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger.

Only after this replay can the $\mathsf{Real}^{\uparrow}$ seal row and the $\mathsf{RepresentedSpace}^{\uparrow}$-facing row be read. The evidence, transport, provenance, and local naming rows preserve that same route, so the consumer receives no quotient stream, selected limit, host real equality, countable choice, or ambient completeness data. □

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, regular readback exactness, dyadic tolerance exactness, seal non-escape, represented-space compatibility, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRepresentationUp.

Constructive story: A $\mathsf{CauchyRepresentation}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ source, finite stream windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal row, a $\mathsf{RepresentedSpace}^{\uparrow}$ source row, componentwise hsame transports, displayed Cont replay, Pkg provenance, a local evidence row, and a local NameCert row.

Chapter 1681

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$ packet names a finite located-comparison surface for two regular Cauchy rational names before any completed-real order principle is exposed. It sits over the regular rational rows of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance rows of chapter 291, the Real seal boundary of chapter 38, the regular Cauchy separation route of chapter 1650, and the apartness-real boundary of chapter 304. The certificate records a located order read as finite NameCert data; it does not import constructive-real trichotomy, host real equality, quotient stream equality, selected limits, countable choice, or ambient completeness.

Definition 1681.1 (Regular Cauchy located order carrier)**.** *A* $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, R, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
2. *R is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
3. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger shared by the left and right observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic radius, slack, and rational comparison budget used by the located read.*
5. *Q is the located comparison row, displaying the finite evidence that the inspected windows place the two names to the left, to the right, or still inside the unresolved tolerance band named by D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, R, W, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the two regular rational names, the common window, dyadic tolerance row, located comparison row, Real seal, continuation, provenance, and local naming row.*
8. *C records displayed* Cont *replay from each located-order request through $L, R, W, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySeparation}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host order on completed reals, quotient stream equality, trichotomy, a selected limit, countable choice, Real completeness, or a standard bridge.

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedOrderUp.RegularCauchyLocatedOrderUp single carrier alignment`

Theorem 1681.2 (Regular Cauchy located order NameCert obligations)**.** *For every accepted carrier $O = (L, R, W, D, Q, E, H, C, P, N)$ of Definition 1681.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedOrder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *rows L, R, the shared* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the located comparison row Q, the* $\mathsf{Real}^{\uparrow}$ *seal row E, and the structural rows H, C, P, N;*
2. *classifier stability, requiring every accepted located-order read to inspect the same displayed route L, R, W, D, Q before the Real seal row is exposed;*
3. *common-window transport, requiring* hsame *transport through H and replay through C to preserve the same left and right observation windows named by W;*
4. *comparison-row exactness, requiring the left, right, and unresolved-band outcomes to be read only from the finite dyadic comparison data stored in D and Q;*
5. *Real-seal handoff, requiring E to be consumed only after the source names, common window, dyadic tolerance, and located comparison rows have been retained;*
6. *ledger refusal, excluding trichotomy, host real order, quotient stream equality, selected limits, countable choice, ambient completeness, Lean verification, and bridge checking from the local NameCert surface.*

No obligation row is stored outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedOrderUp.RegularCauchyLocatedOrderCarrier namecert obligations`

Proof. Project the carrier. The rows L, R, W, D, Q, E are the analytic coordinates, while H, C, P, N transport, replay, source, and name the same finite packet.

Read the classifier in route order. A located-order request first reads the two regular rational names L and R, then aligns them over the common finite window W, then consults the dyadic tolerance ledger D, and only then reads the comparison row Q.

The common-window condition follows from the structural rows. Componentwise hsame in H preserves the left and right windows together, and Cont replay in C repeats the same order of reads rather than allowing a detached comparison row.

The Real-facing row is downstream of the comparison route. Since E appears only after L, R, W, D, Q, any consumer that bypasses those rows has not obtained the displayed packet's Real seal boundary.

The excluded principles have no carrier coordinate. Thus the listed carrier admission, classifier stability, common-window transport, comparison exactness, Real-seal handoff, and ledger-refusal rows exhaust the local NameCert surface. □

Theorem 1681.3 (Regular Cauchy located order Real seal boundary)**.** *For every accepted* RegularCauchyLocatedOr *packet $O = (L, R, W, D, Q, E, H, C, P, N)$, every Real-facing read factors through the finite route*

$$(L, R) \longmapsto W \longmapsto D \longmapsto Q$$

before reaching the $\mathsf{Real}^{\uparrow}$ *seal boundary* E*. Consequently the packet exports no trichotomy, host real equality, quotient stream, selected limit, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the obligation surface of Definition 1681.2. Carrier admission exposes the seal row only as part of the displayed finite packet, and classifier stability places every located-order read on the route through L, R, W, D, Q.

The comparison row is the last analytic gate before the seal boundary. It reads only the dyadic tolerance and rational comparison data already stored in D over the common window W, so it cannot select a completed real, quotient a stream, or invoke a host order.

Finally consume E as a boundary row. The transport, continuation, provenance, and local naming rows preserve the same route, so any Real-facing read must pass through the finite located-comparison packet before it reaches the seal. □

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedOrderUp.RegularCauchyLocatedOrderCarrier real seal boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$ packet is generated from left and right RegSeqRat rows, a shared StreamName window, a DyadicRatCore tolerance ledger, a located comparison row, a RealUp seal boundary, componentwise hsame transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1681.1, Definition 1681.2, and Definition 1681.3 seed the finite located-order boundary for regular Cauchy rational names over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySeparation}^{\uparrow}$, and $\mathsf{ApartnessReal}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full $\mathsf{RealAlgOrder}^{\uparrow}$, trichotomy, host real equality, quotient stream equality, selected limits, countable choice, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, common-window transport, comparison-row exactness, Real-seal handoff, and ledger refusal for the displayed located-order packet.

Chapter 1682

A Concrete Naming Certificate for $\mathsf{ToeplitzLemma}^{\uparrow}$

Following Toeplitz and Hardy on summability transforms, the $\mathsf{ToeplitzLemma}^{\uparrow}$ packet records the finite matrix-window route by which a regular real-name sequence and a Toeplitz row ledger produce a regular transformed sequence before any host limit theorem is read. It sits between the series and uniform-limit consumers of chapter 1581 and chapter 463, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic row-sum ledger of chapter 291, and the terminal real-name seal of chapter 38. The same matrix-window transform is the sibling ledger consumed by chapter 1765 and chapter 1827 before any host summability or selected-limit reading is made. The packet is a finite certificate for a regular summability transform; it is not a host summability theorem, a selected limit, quotient equality of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1682.1 (Toeplitz lemma carrier)**.** *A* $\mathsf{ToeplitzLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, W, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the matrix-coefficient window row, listing the finite Toeplitz rows and columns currently inspected together with their row-sum and entry-size requests.*
2. *W is the selected source-window row, recording the finite* $\mathsf{StreamName}^{\uparrow}$ *observations of the input regular real-name sequence used by the inspected matrix rows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected source windows and for the transformed finite row produced by the same matrix window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for row sums, coefficient truncation, source-window tolerances, small-entry estimates, and accumulated arithmetic error.*
5. *T is the transformed finite partial row, obtained by applying the displayed coefficients of A to the selected source values in W and reading the result through R and D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the transformed row T, regular readback R, and dyadic ledger D have been displayed.*
7. *H stores componentwise* hsame *transport for the matrix window, source windows, readback, dyadic ledger, transformed row, real seal, continuation, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from matrix-row inspection to selected source windows, from source windows to regular readback, from readback and dyadic accounting to the transformed row, and from the transformed row to the real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ToeplitzLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, R, D, T, E, H, C, P, N$. It has no coordinate for an infinite matrix object, a host summability method, a selected limit of the source sequence, a quotient of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ToeplitzLemmaUp.ToeplitzLemmaTasteGate single carrier alignment`

Theorem 1682.2 (Toeplitz lemma NameCert obligations)**.** *For every accepted* $\mathsf{ToeplitzLemma}^{\uparrow}$ *carrier $K = (A, W, R, D, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ToeplitzLemma}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the displayed matrix-window, source-window, readback, ledger, transformed-row, seal, transport, continuation, provenance, and naming rows;*

2. *row-sum boundedness, read from A and checked inside the dyadic ledger D before any transformed row is exposed;*

3. *small-entry and window-vanishing control, requiring every displayed coefficient request outside the selected finite source window to pass through the same A, W, D route;*

4. *regular transformed handoff, requiring every transformed-sequence read to pass through T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the* $\mathsf{Real}^{\uparrow}$ *seal E;*

5. *ledger nonescape, excluding host summability methods, selected source limits, quotient real-name equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet surface.*

Lean4 ✓ `BEDC.Derived.ToeplitzLemmaUp.ToeplitzLemmaNamecertObligations`

Proof. Project the carrier of Definition 1682.1. Carrier admission is exactly the inventory of $A, W, R, D, T, E, H, C, P, N$, and the matrix-row information available to the classifier is confined to the finite row A.

The row-sum and small-entry clauses are read through the same dyadic ledger D. The selected source windows W provide the only input sequence observations, so any window-vanishing claim must use the displayed coefficient requests in A together with the finite source reads in W.

The transformed row T is then exposed through R and E. The structural rows H, C, P, N transport, replay, source, and name this route, and the carrier contains no coordinate for the excluded host principles. □

Theorem 1682.3 (Toeplitz lemma regular sequence handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the transformed sequence exported by an accepted* $\mathsf{ToeplitzLemma}^{\uparrow}$ *carrier factors through*

$$A, W, R, D, T, E, H, C, P, N.$$

Thus the consumer reads a finite Toeplitz matrix window, selected source windows, regular rational readback, dyadic row-sum and error accounting, transformed finite partial row, real seal, transport, continuation, provenance, and local naming before it can use the transformed regular sequence.

Lean4 ✓ `BEDC.Derived.ToeplitzLemmaUp.ToeplitzLemmaRegularSequenceHandoff`

Proof. Start with a transformed-sequence consumer. By Definition 1682.1, the only transformed row coordinate is T, and it is built from the matrix-window row A, selected source windows W, regular readback R, and dyadic ledger D.

For a $\mathsf{RegSeqRat}^{\uparrow}$ read, the handoff is therefore already forced through R after A, W, D have supplied the coefficient, source, and error data. For a $\mathsf{Real}^{\uparrow}$ read, the same route continues to the seal row E.

The rows H, C, P, N preserve the route under transport, replay the same continuations, record package provenance, and bind the local NameCert. Since no second transformed-sequence coordinate is present, every downstream consumer factors through the displayed packet. □

Theorem 1682.4 (ToeplitzLemma Cesaro consumer route)**.** *Any* $\mathsf{HardyCesaroMean}^{\uparrow}$ *or* $\mathsf{CesaroConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{ToeplitzLemma}^{\uparrow}$ *packet must read the finite route*

$$A, W, R, D, T, E, H, C, P, N.$$

Thus the consumer receives the finite matrix window, source windows, $\mathsf{DyadicRatCore}^{\uparrow}$ *row-sum and error ledger, transformed finite partial row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ToeplitzLemma}^{\uparrow}}$ *row before it can use the Toeplitz transform as a Cesaro-facing input.*

The route exports no host summability theorem, selected source limit, quotient equality of real-name streams, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.ToeplitzLemmaUp.ToeplitzLemmaCesaroConsumerRoute`

Proof. Start with the NameCert obligations of Definition 1682.2. They force carrier admission, row-sum boundedness, small-entry and window-vanishing control, regular transformed handoff, and ledger nonescape to be read from $A, W, R, D, T, E, H, C, P, N$.

Apply the regular sequence handoff Definition 1682.3. It places every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read of the transformed sequence behind the matrix window, selected source windows, dyadic ledger, transformed row, and real seal.

The Cesaro-facing chapters consume only that transformed regular sequence. A $\mathsf{HardyCesaroMean}^{\uparrow}$ or $\mathsf{CesaroConvergence}^{\uparrow}$ reader therefore receives the same displayed Toeplitz packet, with H, C, P, N preserving transport, replay, provenance, and local naming. Since no host summability, selected limit, quotient stream equality, choice, or completeness row occurs in the carrier, none is exported to the Cesaro consumer. □

Falsifiable prediction: Every $\mathsf{ToeplitzLemma}^{\uparrow}$ transformed-sequence read factors through a finite matrix-coefficient window, selected source windows, RegSeqRat readback, a DyadicRatCore row-sum and error ledger, a transformed finite partial row, a RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: realseries, uniformlimit, streamname, regseqrat, dyadicratcore, real: $\mathsf{ToeplitzLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries matrix-coefficient windows, selected source windows, regular readback, dyadic row-sum and small-entry accounting, transformed-row construction, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ToeplitzLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ToeplitzLemma}^{\uparrow}$ packet is generated from finite Toeplitz matrix windows, selected source windows, RegSeqRat readback, a DyadicRatCore row-sum and error ledger, a transformed finite partial row, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ToeplitzLemma}^{\uparrow}}$, seed)

Scope closed: Definition 1682.1, Definition 1682.2, Definition 1682.3, and Definition 1682.4 bind the finite summability-transform certificate surface and the Cesaro-facing consumer route.

Formal verification: FormalStatus(NameCert$_{\mathsf{ToeplitzLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host summability theorems, selected source limits, quotient equality of real-name streams, countable choice, ambient Real$^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, row-sum boundedness, small-entry and window-vanishing control, regular transformed handoff, ledger nonescape, and TasteGate field faithfulness for BEDC.Derived.ToeplitzLemmaUp.

Chapter 1683

A Concrete Naming Certificate for $\mathsf{SequentialCompletion}^{\uparrow}$

Following Bishop and Bridges' regular-sequence completion language and Kelley's sequence-completion terminology, the $\mathsf{SequentialCompletion}^{\uparrow}$ packet names the finite L10 route by which displayed stream schedules, regular rational readbacks, dyadic tolerance ledgers, Cauchy criterion rows, and terminal real seals are offered to Real and Completion consumers. It sits on the same human-origin spine as chapter 126, chapter 301, chapter 291, chapter 1509, chapter 386, and chapter 38. The packet records a sequential completion interface without asserting ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient-stream equality, selected limits, countable choice, trichotomy, or open-cover compactness.

Definition 1683.1 (SequentialCompletion carrier)**.** *A* $\mathsf{SequentialCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, Q, D, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It records the finite stream-name schedule inspected by a Real-facing or Completion-facing request.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed schedule windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, slack rows, and finite comparison budgets used by the readback.*
4. *K is the criterion row, either a* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *exposure row or a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff row, read only after S, Q, D have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached downstream of the schedule, readback, tolerance, and criterion rows.*
6. *H records componentwise* hsame *transport for the schedule, readback, tolerance ledger, criterion or limit-seal row, terminal real seal, continuation row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Real or Completion request through S, Q, D, K, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite sequential-completion packet. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.SequentialCompletionUp.TasteGate.SequentialCompletionTasteGate single carrier alignment`

Theorem 1683.2 (SequentialCompletion NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompletion}^{\uparrow}$ *carrier* $J = (S, Q, D, K, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletion}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed schedule, regular readback, dyadic tolerance ledger, Cauchy criterion or limit-seal row, terminal real seal, componentwise transport, replay, provenance, and local naming rows;*
2. *criterion exposure, requiring* K *to be read only after the same* S, Q, D *route has been displayed;*
3. *regular readback, requiring each completion-facing read to obtain its rational observations through* Q *and the dyadic ledger* D *before the terminal seal is exposed;*
4. *Real seal non-escape, requiring* E *to remain downstream of* S, Q, D, K *and never to serve as a quotient stream, selected limit, host real equality witness, choice-selected representative, trichotomy decision, compactness witness, or ambient completeness proof;*
5. *transport, provenance, and local naming, requiring* H, C, P, N *to preserve and name exactly the displayed packet.*

No sequential-completion obligation is stored outside these five rows.

Proof. Project the accepted carrier of Definition 1683.1. The projection exposes exactly the schedule row S, the regular readback row Q, the dyadic tolerance ledger D, the Cauchy criterion or limit-seal row K, the terminal real seal E, and the structural rows H, C, P, N.

Criterion exposure follows from the route order displayed by C. A consumer cannot reach K without first opening the stream schedule through S, reading the regular rational data through Q, and consulting the dyadic ledger D.

The regular readback and Real-seal rows are therefore locked to the same finite path. Since E is downstream of S, Q, D, K, the seal cannot introduce a quotient stream, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient completeness.

Finally, H, C, P, N transport, replay, package, and name the same packet. They add no analytic coordinates beyond the rows already projected, so the listed five rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SequentialCompletionUp.SequentialCompletionNamecertObligations`

Theorem 1683.3 (SequentialCompletion RegSeqRat and Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read of an accepted* $\mathsf{SequentialCompletion}^{\uparrow}$ *carrier* $J = (S, Q, D, K, E, H, C, P, N)$ *factors through the finite route*

$$S \longmapsto Q \longmapsto D \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the sequence-completion handoff exports the displayed $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows. It exports no quotient stream, selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompletionUp.SequentialCompletionRegseqratRealHandoff`
↪ variant `BEDC.Derived.SequentialCompletionUp.SequentialCompletionRegSeqRatRealHandoff`

Proof. Begin with a Real-facing or Completion-facing consumer of J. Carrier admission gives access to the terminal seal only as a row in the same finite packet as the schedule, readback, tolerance, and criterion rows.

Replay the continuation row C. The consumer first reads the $\mathsf{StreamName}^{\uparrow}$ schedule S, then obtains the regular rational observations through Q, then consults the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, and only then reaches the criterion or limit-seal row K.

The terminal $\mathsf{Real}^{\uparrow}$ seal E is exposed after that route. Componentwise transport, package provenance, and the local naming row preserve the same factorization, so no quotient stream, selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient completeness data can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1683.1, Definition 1683.2, and Definition 1683.3 seed the finite sequence-completion route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion exposure, regular readback, Real-seal non-escape, transport, provenance, and local naming for BEDC.Derived.SequentialCompletionUp.

Constructive story: A $\mathsf{SequentialCompletion}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ row, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1684

A Concrete Naming Certificate for $\mathsf{CauchySchwarzReal}^{\uparrow}$

Following Hardy–Littlewood–Polya and standard inner-product space treatments, the $\mathsf{CauchySchwarzReal}^{\uparrow}$ packet records the finite route by which a Cauchy–Schwarz inequality read over displayed finite real-vector rows is exposed to downstream analysis consumers. It sits over the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the finite observation windows of chapter 126, the vector-space source of chapter 47, and the norm boundary of chapter 89. The packet is a finite inequality certificate for RealUp row consumers; it is not a host real inner product theorem, quotient stream equality, ambient completeness, an infinite-dimensional Hilbert assertion, or bridge checking.

Definition 1684.1 (CauchySchwarzReal carrier)**.** *A* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *finite-vector source row. It records the displayed vector carrier, scalar action, vector addition, zero, negation, and classifier rows used by the two finite rows.*
2. *X and Y are the two finite vector rows. Their coordinates are exposed as finite families of* $\mathsf{Real}^{\uparrow}$ *seal rows, one family for each inspected coordinate.*
3. *I is the inner-product row. It records the finite coordinatewise multiplication-and-sum read that produces the scalar row $\langle X, Y\rangle$.*
4. *A and B are the two norm-square rows. They record the finite coordinatewise reads for $\|X\|^2$ and $\|Y\|^2$ through the* $\mathsf{Norm}^{\uparrow}$ *boundary.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *square-and-tolerance ledger. It stores the dyadic square comparison budget, slack rows, and finite positivity comparisons used to read $(\langle X, Y\rangle)^2 \leq \|X\|^2\|Y\|^2$.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the real scalar observations in I, A, B, D.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by Q and by the displayed coordinate observations of X and Y.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed inequality value. It is reached only after $V, X, Y, I, A, B, D, Q, S$ have been displayed.*

9. *H records componentwise* hsame *transport for the vector-space source, vector rows, inner-product row, norm-square rows, dyadic ledger, readback, windows, Real seal, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay from a finite coordinate request through S, Q, I, A, B, D, E and back to the public inequality boundary.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzReal}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite Cauchy–Schwarz packet. It has no coordinate for host real order, quotient stream equality, ambient completeness, non-finite vector-space semantics, or a bridge-checked standard theorem.

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.TasteGate.CauchySchwarzRealTasteGate single carrier alignment`

Theorem 1684.2 (CauchySchwarzReal NameCert obligations)**.** *For every accepted* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier $K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed vector-space source, two finite real-vector rows, inner-product row, two norm-square rows, dyadic square-and-tolerance ledger, regular rational readback, finite windows, Real seal, transport, replay, provenance, and local naming rows;*

2. *classifier transport, requiring H and T to preserve the same vector rows, scalar reads, square ledger, readback, windows, Real seal, and local naming rows componentwise;*

3. *finite inequality route, requiring every downstream read of Cauchy–Schwarz data to pass through $V, X, Y, I, A, B, D, Q, S, E$ before the certificate row is available;*

4. *dyadic square exactness, requiring the displayed square comparison in D to be the only route by which $(\langle X, Y\rangle)^2 \leq \|X\|^2\|Y\|^2$ is exported;*

5. *ledger non-escape, excluding host real order, quotient stream equality, ambient completeness, non-finite vector-space semantics, hidden square-root extraction, and bridge checking.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealCarrier namecert obligations`

Proof. Project the accepted carrier. The analytic coordinates are the vector-space source V, the displayed finite vector rows X and Y, the scalar inner-product row I, the two norm-square rows A and B, the dyadic square-and-tolerance ledger D, the regular readback Q, the finite window row S, and the terminal Real seal E.

Carrier admission is exactly admission of those displayed coordinates together with H, T, P, N. The local certificate has no additional field from which a host real value, quotient-stream representative, or ambient vector-space object could be recovered.

Classifier transport is structural. Componentwise hsame in H keeps the vector source, vector rows, scalar reads, square ledger, readback, windows, and Real seal aligned, while Cont replay in T repeats the same finite coordinate route for later consumers.

The finite inequality route is forced by the order of the rows. A consumer can inspect the Cauchy–Schwarz boundary only after the vector rows, scalar rows, dyadic square ledger, readback, windows, and Real seal have already been displayed.

Dyadic square exactness follows because D is the only square-comparison coordinate in the carrier. Thus the exported inequality is the displayed square comparison over the finite readback route, not a host-order theorem imported from outside the packet.

Finally, the non-escape clause is immediate from the carrier surface. None of host real order, quotient stream equality, ambient completeness, non-finite vector-space semantics, hidden square-root extraction, or bridge checking is a coordinate of K. □

Theorem 1684.3 (CauchySchwarzReal dyadic square handoff)**.** *For every accepted* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier* $K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$*, every* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*, or real-analysis consumer receives the Cauchy–Schwarz inequality only through the displayed finite route*

$$V, X, Y \longmapsto I, A, B \longmapsto D \longmapsto Q, S \longmapsto E \longmapsto H, T, P, N.$$

Consequently the handoff supplies the square-form inequality $(\langle X, Y\rangle)^2 \leq \|X\|^2\|Y\|^2$ *through finite vector rows, norm-square rows, dyadic tolerance comparisons, regular rational readback, finite stream windows, and a RealUp seal; it does not supply host real order, quotient stream equality, ambient completeness, hidden square-root extraction, or a bridge-checked standard object.*

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealCarrier dyadic square handoff`

Proof. Start from an accepted carrier. The only vector data are the source row V and the two finite vector rows X and Y, and the only scalar data derived from them are I, A, B.

The comparison data are then fixed by D. The dyadic row supplies the square comparison budget, positivity slack, and finite tolerance ledger used to compare the inner-product square with the product of the two norm-square rows.

The readback route is fixed by Q, S, E. The regular rational row Q reads the scalar observations through the finite windows S, and the terminal Real row E seals that same displayed route before any downstream consumer receives the inequality boundary.

The rows H, T, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for host real order, quotient stream equality, ambient completeness, hidden square-root extraction, or bridge checking, every consumer receives only the displayed finite dyadic square handoff. □

Theorem 1684.4 (CauchySchwarzReal norm-bound handoff)**.** *For every accepted* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier* $K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$*, every finite consumer that reads the norm-bound shape of Cauchy–Schwarz receives it only through the displayed finite vector rows* X, Y*, the inner-product row* I*, the norm-square rows* A, B*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *square ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows* S*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. Thus the consumer-facing read is the finite norm-bound boundary generated by those rows and transported through* H, T, P, N*.*

The handoff has no coordinate for host real order, hidden square-root extraction, quotient streams, ambient completeness, or bridge checking. In particular the norm-bound form is not obtained by selecting square roots inside a host ordered real field; it is read as the finite RealUp-facing consequence of the existing dyadic square handoff.

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealCarrier norm bound handoff`

Proof. Project the carrier definition of Definition 1684.1. The only vector inputs are X and Y over the source row V, the only scalar comparison inputs are I, A, B, D, and the only real readback inputs are Q, S, E.

Apply the NameCert obligations of Definition 1684.2. They force every downstream Cauchy–Schwarz read to expose the finite vector rows, inner-product row, norm-square rows, dyadic ledger, regular readback, stream windows, Real seal, transport, replay, provenance, and local naming rows.

Finally use the dyadic square handoff of Definition 1684.3. It is the unique route exporting the square-form comparison to RealUp consumers, so the norm-bound read can only be the consumer-facing boundary obtained from that finite square ledger and seal. Since none of the excluded analytic coordinates is present in the carrier, no host real order, hidden square-root extraction, quotient stream, ambient completeness, or bridge row can supply an alternate handoff. □

Theorem 1684.5 (CauchySchwarzReal inner-product bound route)**.** *For every accepted* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier* $K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$*, the complete route by which downstream* $\mathsf{HolderInequality}^{\uparrow}$ *and* $\mathsf{MinkowskiInequality}^{\uparrow}$ *consumers read the inner-product bound is the row sequence*

$$V, X, Y \longmapsto I, A, B \longmapsto D \longmapsto Q, S \longmapsto E \longmapsto H, T, P, N.$$

The row I *supplies the finite inner-product read,* A *and* B *supply the two norm-square reads,* D *supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *square ledger,* Q *supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* S *supplies the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and* E *supplies the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No additional row is available between the square ledger and the downstream Holder or Minkowski consumer.*

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealInnerproductBound`

Proof. Project the carrier. The displayed vector information is exhausted by V, X, Y, and the scalar inequality information is exhausted by I, A, B, D.

The readback and sealing rows are then forced. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q and $\mathsf{StreamName}^{\uparrow}$ row S expose the finite observations used by the dyadic comparison, and the $\mathsf{Real}^{\uparrow}$ row E is the only terminal seal available before the transport, replay, provenance, and naming rows H, T, P, N.

Apply Definition 1684.2 and Definition 1684.4. Together they state that every downstream read of the Cauchy–Schwarz boundary passes through the displayed finite rows and that the norm-bound form is the consumer-facing consequence of the same square ledger. Thus Holder and Minkowski consumers receive exactly this route and no intermediate analytic object. □

Theorem 1684.6 (CauchySchwarzReal non-escape boundary)**.** *For every accepted* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *carrier* $K = (V, X, Y, I, A, B, D, Q, S, E, H, T, P, N)$*, the packet exports no host inner-product theorem, no quotient stream equality, no infinite-dimensional Hilbert theorem, no selected limit, no countable choice principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem. Every exported Cauchy–Schwarz row is read through the finite carrier coordinates of Definition 1684.5.*

Lean4 ✓ `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealCarrier nonescape boundary`

Proof. Inspect the carrier coordinates in Definition 1684.1. They name finite vector rows, scalar reads, a dyadic square comparison ledger, regular readback, finite windows, a terminal Real seal, and structural transport data.

None of the listed excluded objects is a coordinate of the carrier. There is no host inner-product theorem row, no quotient-stream equality row, no Hilbert-space theorem row, no selected-limit row, no countable-choice row, and no ambient completeness row.

The only exported inequality route is therefore the one isolated in Definition 1684.5. Since every downstream read factors through that finite route, the excluded objects cannot be recovered from the packet as public data. □

Falsifiable prediction: Every $\mathsf{CauchySchwarzReal}^{\uparrow}$ inequality read factors through a VecSpaceUp finite-vector source, two RealUp finite vector rows, an inner-product row, two NormUp square rows, a DyadicRatCore square-and-tolerance ledger, RegSeqRat readback, StreamName windows, a RealUp seal, transport, replay, provenance, and local naming.

Independence witness: real, dyadicratcore, regseqrat, streamname, vecspace, norm: $\mathsf{CauchySchwarzReal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite vector rows, inner-product readback, norm-square rows, dyadic square comparison, regular readback, stream windows, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySchwarzReal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySchwarzReal}^{\uparrow}$ packet is generated from a VecSpaceUp finite-vector source, two finite RealUp vector rows, an inner-product row, two NormUp square rows, a DyadicRatCore square-and-tolerance ledger, RegSeqRat readback, StreamName windows, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySchwarzReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1684.1, Definition 1684.2, and Definition 1684.3 seed the finite Cauchy–Schwarz inequality boundary for displayed RealUp finite-vector rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySchwarzReal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchySchwarzRealUp.CauchySchwarzRealCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close host real order, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, non-finite vector-space semantics, hidden square-root extraction, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite inequality routing, dyadic square exactness, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchySchwarzRealUp.

Chapter 1685

A Concrete Naming Certificate for $\mathsf{RealBaireCylinder}^{\uparrow}$

Following Brouwer's finite-prefix reading of choice sequences and the Bishop–Bridges insistence that real-number data be displayed by effective finite approximations, the $\mathsf{RealBaireCylinder}^{\uparrow}$ packet names a Baire-prefix cylinder only through the finite rows that a Real-facing consumer can inspect. It sits after the prefix-cylinder surface of chapter 334, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite readback boundary for the open Real and Completion route; it is not a quotient stream, a host function equality, a countable-choice selector, a completed Baire branch, or a Real completeness theorem.

Definition 1685.1 (Real Baire-cylinder carrier)**.** *A* $\mathsf{RealBaireCylinder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is a* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet. It records the finite natural-index window, displayed unary answer rows, prefix-cylinder classifier, and local Baire ledger.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected from B. It exposes the scheduled requests that a Real-facing read is allowed to replay.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It converts the selected stream window into the regular rational approximation rows visible to the Real route.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal. It is reached only after the Baire prefix, StreamName window, and RegSeqRat readback have been displayed.*
5. *H records componentwise* hsame *transport for the Baire prefix packet, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a finite Real-facing request back through E, Q, S, B.*
7. *P is the* Pkg *provenance over* $\mathsf{RealBaireCylinder}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealBaireCylinder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, S, Q, E, H, C, P, N. It has no coordinate for host sequence equality, quotient real equality, countable choice, ambient completeness, or a tail of the Baire stream outside the displayed prefix window.

Lean4 ✓ `BEDC.Derived.RealBaireCylinderUp.TasteGate.RealBaireCylinderTasteGate single carrier alignment`

Theorem 1685.2 (Real Baire-cylinder NameCert obligations)**.** *For every accepted* $\mathsf{RealBaireCylinder}^{\uparrow}$ *carrier* $R = (B, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealBaireCylinder}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed BaireSpace prefix packet, StreamName finite window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *prefix-cylinder stability, requiring every transported read to remain inside the finite Baire prefix packet B and its displayed classifier rows;*
3. *StreamName handoff, requiring every Real-facing request to select its finite schedule through S before any regular rational readback is exposed;*
4. *RegSeqRat readback, requiring the scheduled window to pass through Q before the Real seal can be read;*
5. *Real-seal non-escape, requiring E to seal only the displayed readback route and to expose no host real equality, selected limit, countable choice, or ambient completeness principle;*
6. *provenance exhaustion, requiring P and N to name only B, S, Q, E, H, C and to export no principle absent from those rows.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1685.1. The projected rows are exactly the Baire prefix packet B, the StreamName finite window S, the RegSeqRat readback Q, the Real seal E, and the structural rows H, C, P, N.

Prefix-cylinder stability is inherited from the BaireSpace packet. Transport may change the displayed rows only through the componentwise hsame data named by H and replayed by C, so a transported request remains inside the same finite prefix-cylinder surface.

The StreamName handoff and RegSeqRat readback are ordered by the carrier itself. A Real-facing request first chooses the finite window S from B, then reads the regular rational approximation data through Q.

Finally the seal row E is downstream of Q. Since P and N name only this route, there is no carrier coordinate from which a tail stream, quotient equality, countable-choice selector, selected limit, or ambient completeness theorem can be exported. □

Lean4 ✓ `BEDC.Derived.RealBaireCylinderUp.RealBaireCylinderCarrier namecert obligations`

Theorem 1685.3 (Real Baire-cylinder stream-real handoff)**.** *Let $R = (B, S, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealBaireCylinder}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by R factors through the finite route*

$$B \longmapsto S \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus a consumer receives a $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet, then a* $\mathsf{StreamName}^{\uparrow}$ *finite window, then a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No read can bypass this route through host function equality, quotient streams, countable choice, or Real completeness.*

Lean4 ✓ `BEDC.Derived.RealBaireCylinderUp.RealBaireCylinderStreamRealHandoff`

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing read of R. By Definition 1685.1, the only Real coordinate is E, and E is placed after the prefix packet B, the finite window S, and the regular rational readback Q.

The Baire prefix supplies only the displayed finite cylinder rows. The StreamName row selects the schedule coordinates available to the consumer, and the RegSeqRat row converts that scheduled window into the rational readback visible to the Real route.

The rows H, C, P, N transport, replay, name, and record the same dependency order. Therefore every Real-facing read factors through the displayed prefix-window route and cannot expose any excluded host or completeness datum. □

Falsifiable prediction: Every $\mathsf{RealBaireCylinder}^{\uparrow}$ Real-facing read factors through a BaireSpace prefix packet, StreamName finite window, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local naming row.

Independence witness: bairespace, streamname, regseqrat, real: $\mathsf{RealBaireCylinder}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Baire prefix-cylinder data, finite stream-window selection, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealBaireCylinder}^{\uparrow}}$.

Constructive story: A $\mathsf{RealBaireCylinder}^{\uparrow}$ packet is generated from a BaireSpace prefix packet, a StreamName finite window, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealBaireCylinder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1685.1, Definition 1685.2, and Definition 1685.3 seed the finite Baire-cylinder readback surface for Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealBaireCylinder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, host function equality, countable choice, completed Baire branches, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, prefix-cylinder stability, StreamName handoff, RegSeqRat readback, Real-seal non-escape, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.RealBaireCylinderUp.

Chapter 1686

A Concrete Naming Certificate for $\mathsf{MooreOsgood}^{\uparrow}$

Following Moore and Osgood on iterated-limit interchange, the $\mathsf{MooreOsgood}^{\uparrow}$ packet records the finite route by which a two-parameter real-name window may hand a first-index limit row through a uniform second-index tail ledger before a downstream consumer reads the opposite iterated limit. It sits between the double-sequence surface of chapter 460, the uniform-limit discipline of chapter 463, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite certificate for an iterated-limit handoff; it is not a host double-limit convergence theorem, quotient equality of arrays, a selected limiting value, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1686.1 (Moore-Osgood carrier)**.** *A* $\mathsf{MooreOsgood}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, F, S, U, Q, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the two-parameter window family, listing the finite rectangle of inspected indices together with the requested first-index and second-index tolerances.*
2. *F is the first-limit row, recording the displayed regular readback of the first iterated direction over the windows in W.*
3. *S is the second-limit row, recording the displayed regular readback of the second iterated direction over the same window family.*
4. *U is the uniform tail ledger in one index, binding a finite tolerance request to a tail bound that is stable across the displayed cofinal side of the other index.*
5. *Q is the cofinal schedule row, naming the finite schedule that routes window enlargement, tail entry, and iterated-limit handoff.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the two iterated regular-rational reads exposed by F and S.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for rectangle tolerances, uniform tails, cofinal schedule bounds, and accumulated arithmetic error.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the window family, iterated rows, uniform ledger, schedule, regular readback, and dyadic accounting have been displayed.*

9. *H stores componentwise* hsame *transport for the window, iterated-limit, uniform-ledger, schedule, readback, dyadic, real-seal, continuation, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from rectangle inspection to first-limit and second-limit rows, from the uniform tail ledger to the cofinal schedule, from regular readback and dyadic accounting to the real seal, and from the seal to the local NameCert row.*

11. *P is the* Pkg *provenance over* $\mathsf{MooreOsgood}^{\uparrow}$, $\mathsf{CauchyDoubleSequence}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreOsgood}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, F, S, U, Q, R, D, E, H, C, P, N$. It has no coordinate for a completed double limit, quotient array equality, a selected limiting representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1686.2 (Moore-Osgood NameCert obligations)**.** *For every accepted* $\mathsf{MooreOsgood}^{\uparrow}$ *carrier $K = (W, F, S, U, Q, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreOsgood}^{\uparrow}}$ *surface consists exactly of the following six finite rows:*

1. *carrier admission for the displayed two-parameter window family, first-limit row, second-limit row, uniform tail ledger, cofinal schedule, regular readback, dyadic ledger, real seal, transport, continuation, provenance, and naming rows;*

2. *rectangle-window stability, requiring every first-index or second-index observation to pass through the same W row before either iterated read is exposed;*

3. *uniform-tail control in one index, requiring U to bind the tail bound before the cofinal schedule Q may route an interchange handoff;*

4. *iterated regular readback, requiring the first-limit and second-limit rows F and S to be exported only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the dyadic tolerance ledger D;*

5. *real-seal admission, requiring the* $\mathsf{Real}^{\uparrow}$ *seal E to occur after W, F, S, U, Q, R, D have all been displayed;*

6. *ledger nonescape, excluding host double-limit convergence, quotient equality of arrays, selected limiting values, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet surface.*

Lean4 ✓ `BEDC.Derived.MooreOsgoodUp.MooreOsgoodTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1686.1. Carrier admission is exactly the inventory of $W, F, S, U, Q, R, D, E, H, C, P, N$, and the only available two-parameter observations are the finite rectangle windows listed by W.

The stability and uniform-tail clauses are then forced by the placement of U and Q. The packet does not allow either iterated row to choose an unrecorded tail; the uniform ledger must first bind the relevant tolerance, and the cofinal schedule must record the finite route by which the chosen rectangle is enlarged.

The two iterated rows pass through R and D before the real seal E is visible. The structural rows H, C, P, N transport, replay, source, and name this same route, while the carrier contains no coordinate for the excluded host principles. □

Theorem 1686.3 (Moore-Osgood iterated-limit handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an iterated-limit interchange exported by an accepted* $\mathsf{MooreOsgood}^{\uparrow}$ *carrier factors through*

$$W, F, S, U, Q, R, D, E, H, C, P, N.$$

Thus the consumer reads a finite two-parameter window family, first-limit row, second-limit row, uniform tail ledger, cofinal schedule, regular rational handoff, dyadic accounting, real seal, transport, continuation, provenance, and local naming before it can use the interchanged iterated-limit surface.

Lean4 ✓ `BEDC.Derived.MooreOsgoodUp.MooreOsgoodIteratedLimitHandoff`

Proof. Start with a consumer of the interchange surface. By Definition 1686.1, the only visible array data is W, and the only visible iterated rows are F and S.

A $\mathsf{RegSeqRat}^{\uparrow}$ read is therefore forced through R after U and Q have supplied the uniform tail and cofinal schedule data. The dyadic ledger D accounts for the displayed tolerances and schedule bounds, so no consumer can bypass the finite ledger route while reading either iterated row.

For a $\mathsf{Real}^{\uparrow}$ read, the same route continues to the seal E. The rows H, C, P, N preserve the handoff under transport, replay the displayed continuations, record package provenance, and bind the local NameCert, so every downstream consumer factors through the displayed packet. □

Theorem 1686.4 (Moore-Osgood uniform tail lock)**.** *For every accepted* $\mathsf{MooreOsgood}^{\uparrow}$ *carrier* $K = (W, F, S, U, Q, R, D, E, H, C, P, N)$*, any consumer that uses both the first-limit row* F *and the second-limit row* S *must read the uniform tail ledger* U *and the cofinal schedule* Q *before reaching the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*.*

If the source two-parameter window is served by $\mathsf{CauchyDoubleSequence}^{\uparrow}$*, this read factors through Definition 460.8 and Definition 460.9 before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is visible. Thus no unscheduled rectangle, quotient array, selected limit, countable-choice row, or ambient real-completeness row can enter the Moore-Osgood handoff.*

Lean4 ✓ `BEDC.Derived.MooreOsgoodUp.MooreOsgoodUniformTailLock`

Proof. Project K along Definition 1686.1. The iterated rows F and S are exposed as rows of the same finite packet, while the carrier places the uniform tail ledger U and the cofinal schedule Q between the two-parameter window family W and the regular readback row R.

Apply Definition 1686.3. A consumer of the interchanged surface can reach R only through the displayed route $W, F, S, U, Q, R, D, E, H, C, P, N$, so the row pair F, S has no independent path around U or Q.

When the window family is supplied by $\mathsf{CauchyDoubleSequence}^{\uparrow}$, use Definition 460.8 to force every rectangle read through the scheduled tail, then use Definition 460.9 to keep completion-facing consumption inside that scheduled surface. Composing these two constraints with the Moore-Osgood handoff leaves only the displayed ledger and schedule route before E, excluding the non-carrier rows named in the statement. □

Theorem 1686.5 (Moore-Osgood Real seal nonescape)**.** *In every accepted* $\mathsf{MooreOsgood}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is downstream of the two-parameter window family, both iterated rows, the uniform tail ledger, the cofinal schedule, the regular readback row, and the dyadic tolerance ledger. Consequently a Real-facing consumer cannot obtain from the packet a host double-limit theorem, quotient equality of arrays, a selected limiting value, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier order in Definition 1686.1. The seal row E is not an independent coordinate; it is exposed after W, F, S, U, Q, R, D have already supplied the finite observations, iterated rows, uniform tail data, schedule data, regular readback, and dyadic accounting.

The nonescape statement follows from the classifier boundary. Accepted packets are compared only through $W, F, S, U, Q, R, D, E, H, C, P, N$, and none of those rows stores a completed double limit, quotient array equality, a selected limit representative, countable-choice selector, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.MooreOsgoodUp.MooreOsgoodCarrier real seal nonescape`

Falsifiable prediction: Every $\mathsf{MooreOsgood}^{\uparrow}$ iterated-limit read factors through a finite two-parameter window family, first-limit and second-limit rows, a uniform tail ledger in one index, a cofinal schedule, RegSeqRat handoff, DyadicRatCore accounting, a RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: cauchydoublesequence, uniformlimit, streamname, regseqrat, dyadicratcore, real: $\mathsf{MooreOsgood}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two-parameter windows, paired iterated-limit rows, uniform tail control, cofinal scheduling, regular readback, dyadic tolerance accounting, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreOsgood}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreOsgood}^{\uparrow}$ packet is generated from finite two-parameter windows, first-limit and second-limit rows, a uniform tail ledger in one index, a cofinal schedule, RegSeqRat handoff, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreOsgood}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1686.1, Definition 1686.2, Definition 1686.3, Definition 1686.4, and Definition 1686.5 bind the finite iterated-limit interchange certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreOsgood}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host double-limit convergence, quotient array equality, selected limiting values, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, rectangle-window stability, uniform-tail control, cofinal scheduling, iterated regular readback, real-seal nonescape, and TasteGate field faithfulness for BEDC.Derived.MooreOsgoodUp.

Chapter 1687

A Concrete Naming Certificate for $\mathsf{CompactMetricCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactMetricCompletion}^{\uparrow}$ packet records the finite route by which a complete totally bounded metric completion is exposed as a compact-facing certificate. It reads the finite completion route of chapter 1573, the Cauchy-filter convergence surface of chapter 1588, the finite-net ledger of chapter 127, the compact certificate surface of chapter 60, and the terminal real-name seal of chapter 38. The packet is a finite NameCert surface for complete totally bounded metric completions; it is not open-cover compactness, a quotient completion, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1687.1 (Compact metric completion carrier)**.** *A* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, U, B, K, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *row. It records the source metric carrier, finite-net completion route, completion embedding, separated equality handoff, and total-bounded completion ledger consumed by the compact-facing certificate.*

2. *U is the* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *row. It stores the finite entourage, Cauchy-filter basis, convergence boundary, readback, and seal data through which completeness is read.*

3. *B is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger. For each displayed positive tolerance it records the center bundle, membership rows, center-carrier rows, distance witnesses, refinement rows, and rational bound ledger.*

4. *K is the* $\mathsf{Compact}^{\uparrow}$ *export row. It exposes compactness only as a downstream finite-net completion read, not as an independent open-cover or host-topological compactness object.*

5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite-net completion row T, complete uniform-space row U, total-bounded ledger B, and compact export row K have been displayed.*

6. *H records componentwise* hsame *transport for the completion route, uniform-space convergence route, total-bounded ledger, compact export, Real seal, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a finite-net tolerance request through total-bounded completion, complete uniform-space convergence, compact export, and the Real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactMetricCompletion}^{\uparrow}$, $\mathsf{TotallyBoundedCompletion}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, U, B, K, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient representatives, selected limits, countable-choice schedules, host real equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompactMetricCompletionUp.TasteGate.CompactMetricCompletionTasteGate single carrier alignment`

Theorem 1687.2 (Compact metric completion NameCert obligations)**.** *For every accepted* CompactMetricComplet*carrier $M = (T, U, B, K, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed total-bounded completion route, complete uniform-space convergence row, total-bounded finite-net ledger, compact export, Real seal, transport, replay, provenance, and local naming rows;*

2. *finite-net completion handoff, requiring every compact-facing tolerance request to read the* TotallyBoundedComple*row T together with the* $\mathsf{TotallyBounded}^{\uparrow}$ *ledger B before any compact export is available;*

3. *complete uniform-space seal, requiring every completion convergence read to pass through the* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *row U and then through the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*

4. *compact export, requiring the* $\mathsf{Compact}^{\uparrow}$ *row K to be downstream of T, U, B, E and to expose no independent open-cover, quotient, selected-limit, countable-choice, host-equality, or ambient-completeness datum;*

5. *transport and replay stability, requiring H and C to preserve the same ordered route under componentwise sameness and displayed continuation replay;*

6. *ledger non-escape, requiring P and N to name only the displayed rows and to export no principle absent from them.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1687.1. The projected rows are exactly the total-bounded completion route T, complete uniform-space route U, finite-net ledger B, compact export K, Real seal E, and structural rows H, C, P, N.

The finite-net completion handoff reads chapter 1573 together with chapter 127. The row T supplies the completion-facing route, while B supplies the tolerance-indexed centers, membership rows, distance witnesses, and refinement ledger consumed by that route.

The complete uniform-space seal reads chapter 1588 before it reaches chapter 38. Thus the convergence request is replayed through U and only then sealed by E.

The compact export reads chapter 60 as a downstream consumer of the same route. Since K is placed after T, U, B, E, it cannot supply an open-cover compactness object or a host-level compactness theorem independently of the displayed finite-net completion path.

Transport and replay stability are precisely the roles of H and C. The provenance and naming rows P, N name only this packet, so the excluded principles have no carrier coordinate, replay edge, or ledger row from which to escape. □

Lean4 ✓ `BEDC.Derived.CompactMetricCompletionUp.CompactMetricCompletionCarrier namecert obligations`

Theorem 1687.3 (Compact metric completion finite-net seal)**.** *Let $M = (T, U, B, K, E, H, C, P, N)$ be an accepted* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Compact}^{\uparrow}$ *read exported by M factors through the finite-net completion route*

$$B \longmapsto T \longmapsto U \longmapsto E \longmapsto K \longmapsto H, C, P, N.$$

Consequently a compact-facing consumer receives total-bounded finite nets, their completion handoff, complete uniform-space convergence, the Real seal, compact export, transport, replay, provenance, and local naming before it can read compactness.

Proof. Begin with a $\mathsf{Compact}^{\uparrow}$ read of M. By Definition 1687.1, the only compact coordinate is K, and the definition places it downstream of the finite-net ledger B, the total-bounded completion route T, the complete uniform-space row U, and the Real seal E.

The first part of the route is fixed by chapter 127 and chapter 1573. A tolerance request reads finite centers, membership rows, distance witnesses, and refinements through B, and the completion-facing handoff then passes through T rather than through a quotient completion or selected limit.

The second part of the route is fixed by chapter 1588 and chapter 38. Completion convergence is read through U, and the terminal Real-facing datum is sealed by E before the compact export is exposed.

Finally, chapter 60 is reached only at K. The rows H, C, P, N preserve and name the same dependency order, so every exported compact read factors through the displayed finite-net completion route. □

Lean4 ✓ `BEDC.Derived.CompactMetricCompletionUp.CompactMetricCompletionFiniteNetSeal`

Theorem 1687.4 (Compact metric completion uniform-modulus seal)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{CompactModulusRealizer}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *packet must first read the finite-net ledger B, completion route T, complete-uniform row U, Real seal E, and compact export K. The handoff composes the finite-net seal of Definition 1687.3 with the compact-uniform finite fold surface of Definition 9237.5:* $\mathsf{TotallyBounded}^{\uparrow}$ *supplies finite centers and refinements,* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *supplies the completion convergence row,* $\mathsf{Real}^{\uparrow}$ *supplies the terminal seal, and* $\mathsf{Compact}^{\uparrow}$ *supplies the compact-facing export before any uniform-modulus read is public.*

Proof. Begin with an accepted $\mathsf{CompactMetricCompletion}^{\uparrow}$ carrier. By Definition 1687.3, every compact-facing read factors through B, T, U, E, K before the structural rows are consumed.

Now let the downstream consumer be a $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{CompactModulusRealizer}^{\uparrow}$ packet. The compact-uniform finite fold surface of Definition 9237.5 needs compact finite-net data before it can fold pointwise radii into a uniform precision.

The only compact finite-net data exposed by the completion packet are the displayed $\mathsf{TotallyBounded}^{\uparrow}$ ledger B, the $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ route T, the $\mathsf{CompleteUniformSpace}^{\uparrow}$ row U, the $\mathsf{Real}^{\uparrow}$ seal E, and the $\mathsf{Compact}^{\uparrow}$ export K. Therefore any uniform-modulus consumer must read those rows first, and it cannot replace them by open-cover compactness, quotient completion, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CompactMetricCompletionUp.CompactMetricCompletionUniformModulusSeal`

Theorem 1687.5 (Compact metric completion Lebesgue-number consumer route)**.** *Every Lebesgue-number, finite-cover, or cover-radius consumer of an accepted* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *packet must first read the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net rows, the* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *convergence rows,*

the $\mathsf{Real}^{\uparrow}$ *sealing row, and the* $\mathsf{Compact}^{\uparrow}$ *export row. In the notation of Definition 1687.1, the route is*

$$B \longmapsto T \longmapsto U \longmapsto E \longmapsto K \longmapsto H, C, P, N.$$

Thus cover-radius data are available only as a finite-net completion read, not as primitive open-cover compactness, quotient completion, selected limits, or countable choice.

Lean4 ✓ `BEDC.Derived.CompactMetricCompletionUp.CompactMetricCompletionLebesgueNumberConsumerRoute`

Proof. Start with an accepted carrier $M = (T, U, B, K, E, H, C, P, N)$. By Definition 1687.3, every compact-facing read already factors through the finite-net ledger B, the completion route T, the complete-uniform row U, the Real seal E, and the compact export K.

A Lebesgue-number or finite-cover consumer is a compact-facing read with a radius request. The only radius source exposed by the packet is the tolerance-indexed $\mathsf{TotallyBounded}^{\uparrow}$ finite-net ledger B, and the only convergence source that validates the completed metric read is the $\mathsf{CompleteUniformSpace}^{\uparrow}$ row U.

Apply Definition 1687.4. It keeps downstream modulus consumers behind the same B, T, U, E, K route, so a cover-radius read cannot bypass the Real seal or detach itself from the CompactUp export row.

The structural rows H, C, P, N only transport, replay, source, and name this route. Since the carrier has no coordinate for open-cover compactness, quotient completions, selected limits, or countable choice, the finite-net route is the entire public consumer surface. □

Falsifiable prediction: Every $\mathsf{CompactMetricCompletion}^{\uparrow}$ compact read factors through a TotallyBounded finite-net ledger, a TotallyBoundedCompletion route, a CompleteUniformSpace convergence row, a RealUp seal, CompactUp export, transport, replay, provenance, and local naming.

Independence witness: totallyboundedcompletion, completeuniformspace, totallybounded, compact, real: $\mathsf{CompactMetricCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite-net completion handoff, complete uniform-space sealing, compact export, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricCompletion}^{\uparrow}$ packet is generated from a TotallyBounded finite-net ledger, a TotallyBoundedCompletion route, a CompleteUniformSpace convergence row, a CompactUp export, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1687.1, Definition 1687.2, and Definition 1687.3 seed the finite NameCert surface for complete totally bounded metric completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient completions, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-net completion handoff, complete uniform-space seal, compact export, transport and replay stability, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.CompactMetric

Chapter 1688

A Concrete Naming Certificate for $\mathsf{MinimalCauchyFilter}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Kelley on filter bases, the $\mathsf{MinimalCauchyFilter}^{\uparrow}$ packet records the finite boundary at which a Cauchy filterbase is trimmed to the rows actually consumed by regular rational and Real-facing names. It reads the directed Cauchy-filter surface of chapter 333, the regular handoff of chapter 1445, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet is a human-known L10 Real and Completion route object: it names a minimal finite Cauchy-filter basis before regular rational and Real-seal consumers read it, without adding quotient filters, selected limits, countable choice, host equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 1688.1 (MinimalCauchyFilter carrier)**.** *A* $\mathsf{MinimalCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, S, R, T, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{CauchyFilter}^{\uparrow}$ *finite-filterbase row, including the displayed base packets, refinement rows, Cauchy-modulus row, ledger rows, and provenance boundary.*
2. *S is the minimal support row. For every base packet in F that is read by a downstream regular-rational or Real-facing consumer, S records the retained tail window and its inclusion into F; for every unread base packet, S records that no downstream read cites it.*
3. *R is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *handoff row obtained from the retained support, not from the whole ambient filterbase.*
4. *T is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule listing exactly the retained tail windows requested from S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger on the same retained windows, with endpoints, radii, comparison rows, and refinement bounds visible in the packet.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, S, R, T, D have been displayed.*
7. *H records componentwise* hsame *transport for the source filterbase, minimal support, regular handoff, stream schedule, dyadic ledger, Real seal, and structural rows.*

8. *C records displayed* Cont *replay from source refinements to retained support rows, from retained support rows to stream windows and dyadic tolerances, and from the regular handoff to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MinimalCauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MinimalCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, R, T, D, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable-choice selectors, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MinimalCauchyFilterUp.TasteGate.MinimalCauchyFilterUpTasteGate single carrier alignment`

Theorem 1688.2 (MinimalCauchyFilter NameCert obligations)**.** *For every accepted* $\mathsf{MinimalCauchyFilter}^{\uparrow}$ *carrier $Q = (F, S, R, T, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinimalCauchyFilter}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the displayed ten-row packet;*
2. *CauchyFilter source exposure through F and its finite filterbase rows;*
3. *minimal support exposure through S, retaining precisely the base packets cited by downstream regular-rational or Real-facing reads;*
4. *StreamName and DyadicRatCore readback through T and D on the retained windows;*
5. *regular handoff through R after the retained support has been displayed;*
6. *Real seal handoff through E after F, S, R, T, D have been read;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No NameCert obligation may be discharged by a quotient filter, selected limit, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.MinimalCauchyFilterUp.MinimalCauchyFilterCarrier namecert obligations`

Proof. Project the carrier of Definition 1688.1. The rows $F, S, R, T, D, E, H, C, P, N$ are the only coordinates available to the local classifier.

The source side is inherited from chapter 333. Its finite base packets, refinement rows, Cauchy-modulus row, ledger rows, and provenance boundary enter the packet as F.

The minimality step is the row S. It records exactly which base packets are read by the downstream regular-rational and Real-facing route, and it records non-use for the remaining displayed base packets without deleting the source CauchyFilter row.

The handoff rows close the obligation surface. The schedule T and tolerance ledger D are read only on retained windows, R is obtained from that retained support, and E is downstream from F, S, R, T, D. Since the excluded principles are absent from the carrier, the seven listed obligations exhaust the local NameCert surface. □

Theorem 1688.3 (MinimalCauchyFilter regular handoff)**.** *Let $Q = (F, S, R, T, D, E, H, C, P, N)$ be an accepted* $\mathsf{MinimalCauchyFilter}^{\uparrow}$ *packet. Every* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *read exported by Q factors through the retained support route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MinimalCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchy}$$

Concretely, the consumer reads F, then the support row S, then the retained stream schedule T and dyadic ledger D, and only then the regular handoff row R with its transport, replay, provenance, and local naming data.

Proof. Start with a $\mathsf{RegularCauchyFilter}^{\uparrow}$ read of Q. By Definition 1688.1, the only regular handoff coordinate is R, and the carrier places R downstream from the source filterbase F, minimal support S, stream schedule T, and dyadic ledger D.

The first part of the route reads chapter 333. The row F supplies finite base packets, refinement rows, Cauchy-modulus rows, ledger rows, and provenance; the row S restricts downstream access to the support actually cited by the regular-rational consumer.

The second part of the route reads chapter 126, chapter 291, and chapter 301. The schedule T and ledger D expose only retained windows, and the regular rational readback is the one used by R.

Finally apply the regular-filter boundary of chapter 1445. The rows H, C, P, N transport, replay, package, and name the same route, so no second regular handoff can be read from an ambient filterbase. □

Lean4 ✓ `BEDC.Derived.MinimalCauchyFilterUp.TasteGate.MinimalCauchyFilterCarrier regular handoff`

Theorem 1688.4 (MinimalCauchyFilter non-escape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MinimalCauchyFilter}^{\uparrow}$ *carrier* $Q = (F, S, R, T, D, E, H, C, P, N)$ *reads only the displayed CauchyFilter source row, retained support row, StreamName schedule, DyadicRatCore tolerance ledger, regular handoff row, Real seal row, componentwise transport, continuation replay, provenance, and local NameCert row. The handoff exports no quotient filter, selected limit, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.MinimalCauchyFilterUp.TasteGate.MinimalCauchyFilterCarrier nonescape`

Proof. Project the downstream rows from Definition 1688.1. The only rows exposed to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumers are $F, S, R, T, D, E, H, C, P, N$.

The regular-rational part is forced by the retained support. The row S decides which base packets of F are visible downstream, while T and D attach stream-window and dyadic-tolerance data only to those retained packets.

The Real-facing part is downstream from the same support. The row E is not an independent completeness assertion; it is reached after the CauchyFilter source, retained support, regular handoff, stream schedule, and dyadic ledger have already been displayed.

The structural rows do not add hidden coordinates. They only transport, replay, package, and name the displayed data. Therefore a quotient filter, selected limit, countable-choice selector, host equality proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle has no carrier row, continuation edge, or provenance slot from which to escape. □

Falsifiable prediction: Every $\mathsf{MinimalCauchyFilter}^{\uparrow}$ regular or Real-facing read factors through a displayed CauchyFilter source row, retained support row, StreamName schedule, DyadicRatCore tolerance ledger, RegularCauchyFilter handoff, Real seal, transport, replay, provenance, and local naming.

Independence witness: cauchyfilter, regularcauchyfilter, streamname, regseqrat, dyadicratcore, real: $\mathsf{MinimalCauchyFilter}^{\uparrow}$ is not bijective to any listed sibling because it carries the retained-support boundary between a finite CauchyFilter source and the regular rational or Real-facing handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalCauchyFilter}^{\uparrow}$ packet is generated from a displayed CauchyFilter finite-filterbase row, a retained support row, a RegularCauchyFilter handoff row, StreamName tail windows, a DyadicRatCore tolerance ledger, a RealUp seal row, componentwise transport, continuation replay, package provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1688.1, Definition 1688.2, Definition 1688.3, and Definition 1688.4 seed the finite retained-support boundary from Cauchy filterbase data to regular rational and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, CauchyFilter source exposure, retained support exactness, StreamName and DyadicRatCore readback, regular handoff, Real seal handoff, transport and replay stability, and ledger non-escape for BEDC.Derived.MinimalCauchyFilterUp.

Chapter 1689

A Concrete Naming Certificate for $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ packet records the finite route by which a double regular-Cauchy window can be read along a cofinal diagonal schedule without importing a choice principle or a host-level double-limit theorem. It sits on the Real and Completion spine of chapter 291, chapter 126, chapter 301, chapter 38, chapter 1639, and chapter 1561. The packet is a finite-window diagonal extraction surface; it is not quotient-stream equality, a selected host limit, countable choice, Moore–Smith completeness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1689.1 (DoubleCauchyDiagonal carrier)**.** *A* $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, W, D, K, H, C, P, N)$$

with the following displayed rows:

1. *R is the double regular-Cauchy row. It records the two-index regular rational observations, the rowwise and columnwise Cauchy ledgers, and the finite compatibility readings used by diagonal consumers.*
2. *W is the rectangular* $\mathsf{StreamName}^{\uparrow}$ *window row. For each displayed precision request it stores the inspected rectangle of stream names before any diagonal readback is exposed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records dyadic radii, slack comparisons, row and column budgets, and the terminal comparison budget used by the diagonal read.*
4. *K is the cofinal diagonal schedule. It records a finite schedule of diagonal windows whose entries are cofinal for the displayed precision requests and whose selected rectangles remain within the windows named by W.*
5. *H records componentwise* hsame *transport for the double row, rectangular windows, dyadic ledgers, diagonal schedule, continuation replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a Real-facing or Completion-facing request through R, W, D, K, H, P, N and then into the downstream* $\mathsf{Real}^{\uparrow}$ *seal.*
7. *P is the* Pkg *provenance over* $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DoubleCauchyDiagonal}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite double-Cauchy diagonal packet. It has no coordinate for quotient streams, selected limits, countable choice, Moore–Smith completeness, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DoubleCauchyDiagonalUp.TasteGate.DoubleCauchyDiagonalTasteGate single carrier alignment`

Theorem 1689.2 (DoubleCauchyDiagonal NameCert obligations)**.** *For every accepted* $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ *carrier* $G = (R, W, D, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DoubleCauchyDiagonal}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed double regular-Cauchy row, rectangular StreamName windows, dyadic tolerance ledger, cofinal diagonal schedule, componentwise transport, replay, provenance, and local naming rows;*
2. *rectangular window coverage, requiring every diagonal read to inspect its row and column data through* W *before the regular rational observations in* R *are consumed;*
3. *dyadic tolerance accounting, requiring the rowwise, columnwise, and terminal diagonal comparisons to be recorded in* D *before any Real-facing seal is exposed;*
4. *cofinal schedule selection, requiring* K *to provide only finite diagonal windows that are cofinal for the displayed requests and internal to the rectangles already named by* W*;*
5. *transport and replay stability, requiring* H *and* C *to preserve the same route under componentwise sameness and displayed continuation replay;*
6. *ledger non-escape, requiring* P *and* N *to name only the displayed rows and to export no quotient stream, selected limit, countable-choice rule, Moore–Smith completeness theorem, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No DoubleCauchyDiagonal obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DoubleCauchyDiagonalUp.DoubleCauchyDiagonalNamecertObligations`

Proof. Carrier admission is projection from Definition 1689.1. The projected rows are exactly the double regular-Cauchy row R, the rectangular StreamName window row W, the dyadic ledger D, the cofinal diagonal schedule K, and the structural rows H, C, P, N.

Rectangular window coverage reads chapter 126 together with the regular rational readback surface of chapter 301. A diagonal consumer may inspect only the finite row and column windows already displayed by W, and the regular observations in R are read through those windows.

Dyadic tolerance accounting is supplied by chapter 291. The rowwise, columnwise, and terminal diagonal comparisons are ledger rows in D, so a Real-facing consumer cannot obtain a seal before the displayed dyadic budget has been replayed.

The schedule condition is the role of K. Since K stores only finite cofinal windows internal to W, the schedule is a displayed diagonal route rather than a countable-choice function or a selected host subsequence.

Finally, H and C transport and replay the same route, while P and N package and name only the displayed rows. The excluded principles have no carrier coordinate, continuation edge, or ledger row from which to be exported. □

Theorem 1689.3 (DoubleCauchyDiagonal cofinal window selection)**.** *Let $G = (R, W, D, K, H, C, P, N)$ be an accepted* $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ *carrier. Every Real-facing diagonal read exported by G factors through the finite route*

$$W \longmapsto R \longmapsto D \longmapsto K \longmapsto H, C, P, N.$$

Consequently the selected diagonal window is read only after the rectangular $\mathsf{StreamName}^{\uparrow}$ *windows, double regular-Cauchy observations, dyadic tolerance ledger, and cofinal schedule rows have been displayed.*

Lean4 ✓ `BEDC.Derived.DoubleCauchyDiagonalUp.DoubleCauchyDiagonalCofinalWindowSelection`

Proof. Begin with a Real-facing diagonal read of G. By Definition 1689.1, the only window coordinate available to the read is the rectangular row W, and the only regular observation coordinate is the double row R.

Replay the continuation row C. The request first opens W, then reads the regular observations through R, then consults the dyadic ledger D, and only then consumes the cofinal schedule K.

The transport, provenance, and local naming rows preserve that order. Therefore the selected diagonal window is a finite displayed row of the packet, not a host-selected subsequence, quotient stream, or countable-choice object. □

Theorem 1689.4 (DoubleCauchyDiagonal Real seal boundary)**.** *Let $G = (R, W, D, K, H, C, P, N)$ be an accepted* $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ *carrier. Any downstream* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal read attributed to G is bounded by the displayed route through* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *and* $\mathsf{CauchyNetLimit}^{\uparrow}$*:*

$$R, W, D, K \longmapsto \mathsf{BishopRegularCauchyCompletion}^{\uparrow}, \mathsf{CauchyNetLimit}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The boundary exports the diagonal extraction surface only as finite NameCert data. It does not assert quotient streams, selected limits, countable choice, Moore–Smith completeness, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.DoubleCauchyDiagonalUp.DoubleCauchyDiagonalRealSealBoundary`

Proof. The accepted carrier supplies the finite diagonal surface R, W, D, K, H, C, P, N. By the carrier definition, its provenance row names the Bishop regular-Cauchy completion route and the Cauchy-net limit boundary as downstream consumers, not as hidden coordinates.

Read the completion side through chapter 1639. The double regular-Cauchy row, window row, and dyadic ledger provide the finite data consumed by that route; they do not create a quotient stream or selected completion point.

Read the net-limit side through chapter 1561 and then through the terminal $\mathsf{Real}^{\uparrow}$ surface of chapter 38. The seal is therefore downstream of the displayed diagonal route and remains bounded by the same finite NameCert packet.

Since the packet has no coordinate for Moore–Smith completeness, countable choice, selected limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those principles can be exported by the seal boundary. □

Falsifiable prediction: Every $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ diagonal read factors through rectangular StreamName windows, double regular-Cauchy observations, a DyadicRatCore tolerance ledger, a cofinal diagonal schedule, transport, replay, provenance, and local naming before any Real-facing seal can be consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishopregularcauchycompletion, cauchynetlimit: $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a double regular-Cauchy row, rectangular windows, dyadic tolerance ledgers, a cofinal diagonal schedule, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DoubleCauchyDiagonal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoubleCauchyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1689.1, Definition 1689.2, Definition 1689.3, and Definition 1689.4 seed the finite double-Cauchy diagonal extraction surface through rectangular windows, dyadic ledgers, cofinal schedules, and downstream Real and Completion seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoubleCauchyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, Moore–Smith completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rectangular window coverage, dyadic tolerance accounting, cofinal schedule selection, transport and replay stability, ledger non-escape, and Real seal boundary proofs for BEDC.Derived.DoubleCauchyDiagonalUp.

Constructive story: A $\mathsf{DoubleCauchyDiagonal}^{\uparrow}$ packet is generated from a double regular-Cauchy row, rectangular $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a cofinal diagonal schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1690

A Concrete Naming Certificate for $\mathsf{DyadicCeiling}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicCeiling}^{\uparrow}$ packet records the finite upper-grid endpoint needed when a regular-Cauchy or real-facing read is enclosed from above at a displayed dyadic scale. It sits over the dyadic arithmetic surface of chapter 291, the lower-grid dual of chapter 1416, the adjacent endpoint surface of chapter 433, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite certificate for the upper endpoint of a dyadic enclosure, not a host ceiling function, order trichotomy decision, quotient real equality, countable-choice selection, chosen representative, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, or hidden Archimedean search.

Definition 1690.1 (DyadicCeiling carrier)**.** *A* $\mathsf{DyadicCeiling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (x, k, c, p, \ell, u, M, R, E, H, T, P, N)$$

with the following displayed rows:

1. *x is the source real-facing request, read only through the regular rational or terminal real rows carried by the packet.*
2. *k is the requested dyadic scale.*
3. *c is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid point claimed as the upper dyadic ceiling row at scale k.*
4. *p is the predecessor row $c - 2^{-k}$, recorded as a second* $\mathsf{DyadicRatCore}^{\uparrow}$ *row rather than as host integer arithmetic.*
5. *ℓ is the predecessor-lower comparison evidence that the inspected request lies above the predecessor row p at scale k.*
6. *u is the ceiling-upper comparison evidence that the inspected request is bounded above by c at the same scale.*
7. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule supplying the finite observation threshold needed to read both displayed comparisons.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the regular rational window selected by M.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dyadic rows and regular readback have been displayed.*

10. *H records componentwise* hsame *transport for the request, scale, ceiling row, predecessor row, comparison rows, modulus, readback, seal, continuation, provenance, and local naming rows.*
11. *T records the displayed* Cont *replay from a precision request through $k, c, p, \ell, u, M, R, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{DyadicCeiling}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicFloor}^{\uparrow}$, $\mathsf{DyadicRounding}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCeiling}^{\uparrow}}$ *row.*

The carrier has no coordinate for host ceiling, trichotomy, quotient real equality, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden Archimedean search.*

Lean4 ✓ `BEDC.Derived.DyadicCeilingUp.TasteGate.DyadicCeilingTasteGate single carrier alignment`

Theorem 1690.2 (DyadicCeiling NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DyadicCeiling}^{\uparrow}}$ *surface for Definition 1690.1 consists exactly of carrier exposure for C, upper-grid exposure through c, predecessor exposure through p, predecessor-lower comparison through ℓ, ceiling-upper comparison through u, modulus exposure through M, regular rational readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through T, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DyadicCeilingUp.DyadicCeilingNameCertObligations`

Proof. Project the carrier tuple $C = (x, k, c, p, \ell, u, M, R, E, H, T, P, N)$. The definition displays every analytic and structural coordinate available to the local naming row.

The upper-grid clauses are finite projections. The row c is the claimed ceiling endpoint, p is its predecessor at the same scale, and the comparison rows ℓ and u bind the inspected request between those two dyadic rows.

The remaining coordinates preserve the same packet. The schedule M and readback R supply the finite observation window, the seal E is terminal, and H, T, P, N transport, replay, source, and name the displayed rows. Since the excluded host operations are not coordinates of C, the listed rows exhaust the seed obligation surface. □

Theorem 1690.3 (DyadicCeiling floor-dual route)**.** *Every accepted* $\mathsf{DyadicCeiling}^{\uparrow}$ *packet $C = (x, k, c, p, \ell, u, M, R, E, H, T, P, N)$ exposes the upper-grid dual of the* $\mathsf{DyadicFloor}^{\uparrow}$ *bounding primitive: the predecessor row p and ceiling row c form the finite dyadic interval*

$$p <_k x \leq_k c$$

at the displayed scale k, where ℓ reads the predecessor-lower side and u reads the ceiling-upper side. The route factors through

$$\mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and exports no host ceiling, trichotomy branch, quotient real equality, countable-choice row, selected representative, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden Archimedean search.*

Proof. Start from the carrier of Definition 1690.1. The only dyadic endpoint rows available at scale k are the predecessor row p and the ceiling row c.

Read the two comparison rows next. The row ℓ supplies the predecessor-lower evidence, while u supplies the ceiling-upper evidence, so the accepted packet exposes the displayed interval from below by p and from above by c.

Finally compare the route with chapter 1416. The floor packet stores a lower grid row and its successor; the ceiling packet stores an upper grid row and its predecessor. Both routes pass through M, R before the dyadic comparison rows and reach E only after the finite regular-rational window has been displayed. Thus the ceiling packet is the upper-grid dual needed for dyadic interval enclosure, without importing any of the excluded ambient operations. □

Lean4 ✓ `BEDC.Derived.DyadicCeilingUp.DyadicCeilingFloorDualRoute`

Falsifiable prediction: An accepted $\mathsf{DyadicCeiling}^{\uparrow}$ consumer that reads an upper dyadic enclosure without the displayed scale k, ceiling row c, predecessor row p, predecessor-lower evidence ℓ, ceiling-upper evidence u, modulus schedule M, and regular readback row R refutes the carrier surface.

Independence witness: dyadicratcore, dyadicfloor, dyadicrounding, regseqrat, real: no listed sibling is bijective to $\mathsf{DyadicCeiling}^{\uparrow}$ because this packet jointly binds a scale, an upper dyadic grid point, its predecessor, two comparison rows, a modulus schedule, regular readback, terminal seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCeiling}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCeiling}^{\uparrow}$ packet is generated from a real-facing request, a dyadic scale, an upper dyadic grid point, its predecessor, predecessor-lower and ceiling-upper comparison evidence, a finite modulus schedule, a regular rational readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCeiling}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1690.1, Definition 1690.2, and Definition 1690.3 seed the finite upper-grid dyadic enclosure primitive for the L10 Real and regular-Cauchy route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCeiling}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host ceiling, trichotomy, quotient real equality, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, hidden Archimedean search, or a Lean theorem.

Upgrade path: A formal route can encode the carrier and prove the NameCert obligation surface and floor-dual enclosure theorem for BEDC.Derived.DyadicCeilingUp.

Chapter 1691

A Concrete Naming Certificate for $\mathsf{FastCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion with explicit moduli, the $\mathsf{FastCauchyCompletion}^{\uparrow}$ packet records the finite route by which a modulus-controlled Cauchy name is exposed to Real and Completion consumers. It sits on the L10 spine supplied by the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Real-facing modulus route of chapter 1423, and the rate-comparison boundary of chapter 1671. The packet is a finite NameCert surface for modulus-controlled completion reads; it is not a quotient stream, a selected limit, trichotomy, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1691.1 (Fast Cauchy completion carrier)**.** *A* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (M_0, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. M_0 *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row. It records the finite precision request, the displayed tail index, and the modulus budget that every downstream completion or Real read must consume.*
2. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the threshold named by* M_0*.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the same window, including dyadic radii, endpoint comparisons, rounding rows, and tolerance arithmetic.*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from* S *and* D *under the budget exposed by* M_0*.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after* M_0, S, D, Q *have been displayed.*
6. H *records componentwise* hsame *transport for the modulus row, stream windows, dyadic ledger, regular readback, Real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a finite completion or Real precision request through* M_0, S, D, Q, E, H, P, N*.*
8. P *is the* Pkg *provenance over* $\mathsf{FastCauchyCompletion}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyRateComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FastCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M_0, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, trichotomy, countable choice, host equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 1691.2 (Fast Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *carrier $M = (M_0, S, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FastCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Cauchy-modulus threshold, stream-window row, dyadic tolerance ledger, regular rational readback, Real seal handoff, and structural rows H, C, P, N;*
2. *modulus discipline, requiring every finite precision request to read the threshold row M_0 before any stream window, dyadic tolerance, regular readback, or Real seal is exposed;*
3. *stream and dyadic readback, requiring S and D to be read under the same displayed modulus budget before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q may be consumed;*
4. *Real-seal handoff, requiring E to be terminal with respect to M_0, S, D, Q and to expose no detached Real object or ambient completeness theorem;*
5. *transport and replay stability, requiring H and C to preserve the same ordered route under componentwise sameness and displayed continuation replay;*
6. *ledger non-escape, requiring P and N to name only the displayed rows and to export no quotient stream, selected limit, trichotomy, countable-choice, host-equality, or ambient-completeness coordinate.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FastCauchyCompletionUp.FastCauchyCompletionUp single carrier alignment`

Proof. Carrier admission is projection from Definition 1691.1. The visible packet consists of the modulus threshold M_0, finite stream window S, dyadic tolerance ledger D, regular readback Q, Real seal E, and structural rows H, C, P, N.

Modulus discipline follows from the placement of M_0 at the front of the route. A completion-facing precision request first fixes the displayed threshold, and every later observation is read inside the finite budget named by that threshold.

The stream and dyadic readback obligation reads chapter 126, chapter 291, and chapter 301 in order. The window S and ledger D are consumed before Q is available, so regular rational data cannot be detached from the displayed modulus budget.

The Real-seal handoff reads chapter 1423, chapter 1671, and chapter 38. The row E is terminal and downstream of M_0, S, D, Q, while H, C, P, N transport, replay, package, and name exactly that route.

Since quotient streams, selected limits, trichotomy, countable choice, host equality, and ambient Real completeness are absent from the carrier, no local NameCert obligation can export them. □

Theorem 1691.3 (Fast Cauchy completion modulus Real seal)**.** *Let $M = (M_0, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *carrier. Every Real-facing read exported by M factors through the displayed modulus route*

$$M_0 \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently a Real or Completion consumer receives a Cauchy-modulus threshold, finite stream windows, dyadic tolerance arithmetic, regular rational readback, the terminal Real seal, transport,

replay, provenance, and local naming before it can read the Real-facing datum. The route cannot use quotient streams, selected limits, trichotomy, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchyCompletionUp.FastCauchyCompletionModulusRealSeal`

Proof. Begin with a Real-facing read of M. By Definition 1691.1, the only Real coordinate is E, and the definition places it downstream of the modulus threshold M_0, stream window S, dyadic ledger D, and regular readback row Q.

The first part of the route is fixed by the modulus and finite-window rows. The threshold M_0 supplies the finite tail budget, S exposes only the corresponding stream observations, and D supplies the dyadic tolerances and endpoint comparisons for those observations.

The second part of the route is fixed by regular readback and the Real seal. The row Q is consumed only after S and D, and E seals the Real-facing datum only after the regular row has been displayed.

Finally, H, C, P, N preserve and name the same dependency order. Because the excluded objects have no coordinate in the carrier and no replay edge in the displayed route, every Real-facing read factors through the modulus route shown in the statement. □

Theorem 1691.4 (Fast Cauchy completion finite induction)**.** *Let* $M = (M_0, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *carrier. Every accepted precision-tail read of* M *is obtained by finite induction on the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* M_0*: the base read opens the first* $\mathsf{StreamName}^{\uparrow}$ *window* S *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*; the successor step advances only by* Cont *replay through the same* S, D, Q *route; and the terminal read reaches* E *only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *and the* $\mathsf{Real}^{\uparrow}$ *seal. No induction step uses quotient streams, selected limits, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchyCompletionUp.FastCauchyCompletion precision tail finite induction`

Proof. Use the carrier of Definition 1691.1 to expose the ordered rows $M_0, S, D, Q, E, H, C, P, N$. The NameCert obligations of Definition 1691.2 make the threshold row the first row read by any completion-facing precision request.

For the base threshold, read the first displayed stream window through S and the dyadic tolerance ledger through D. These rows are already inside the accepted carrier, so the base read does not require a quotient stream, a selected limit, or host equality.

For the successor threshold, replay the previous route through the Cont row C. The replay can advance only the displayed finite window and tolerance rows, and the readback row Q remains downstream of the same S, D data.

The terminal step is the modulus Real-seal route of Definition 1691.3. It reaches E through Q, then preserves the route through H, C, P, N. Since the excluded principles have no carrier coordinate and no replay edge, the displayed induction exhausts the accepted precision-tail reads. □

Falsifiable prediction: Every $\mathsf{FastCauchyCompletion}^{\uparrow}$ Real-facing read factors through a CauchyModulus threshold, StreamName finite windows, DyadicRatCore tolerance arithmetic, RegSeqRat readback, a RealUp seal, transport, replay, provenance, and local naming.

Independence witness: real-cauchy-modulus, cauchy-modulus, streamname, dyadicratcore, regseqrat, cauchy-rate-comparison, real: $\mathsf{FastCauchyCompletion}^{\uparrow}$ is not bijective to any listed sibling

because it jointly carries the modulus threshold, stream window, dyadic tolerance ledger, regular readback, terminal Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FastCauchyCompletion}^{\uparrow}$ packet is generated from a CauchyModulus threshold row, StreamName finite windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1691.1, Definition 1691.2, and Definition 1691.3 seed the finite modulus-controlled completion route from CauchyModulus thresholds to terminal $\mathsf{Real}^{\uparrow}$ reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus discipline, stream and dyadic readback, Real-seal handoff, transport and replay stability, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.FastCauchyCompletionU

Chapter 1692

A Concrete Naming Certificate for $\mathsf{LocatedUniformCompletion}^{\uparrow}$

Following Bishop and Bridges' constructive completion language and Kelley's uniform-space terminology, the $\mathsf{LocatedUniformCompletion}^{\uparrow}$ packet records the finite route by which located Cauchy-filter data, uniform completion data, regular Cauchy readbacks, finite stream windows, and terminal real seals are offered to Real and Completion consumers. It sits between the located filter surface of chapter 1661, the uniform completion carrier of chapter 1473, the Bishop regular Cauchy completion route of chapter 1639, the stream-name observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real boundary of chapter 38. The packet names a located uniform-completion certificate, not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$, a quotient-limit object, countable choice, selected representatives, or host equality.

Definition 1692.1 (Located uniform completion carrier)**.** *A* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, U, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row. It records the located filter basis, explicit neighborhood decision ledger, and Cauchy-filter handoff inspected by the completion-facing request.*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row. It stores the finite uniform completion route through which the located filter is admitted as completion data.*
3. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *row. It repacks the located uniform route as a Bishop-style regular Cauchy completion handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the displayed completion name.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows and regular Cauchy handoff.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, U, B, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the located filter, uniform completion, regular Cauchy completion, stream window, regular rational readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion request through $F, U, B, S, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located uniform-completion packet. It has no coordinate for quotient limits, host real equality, selected representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedUniformCompletionUp.TasteGate.LocatedUniformCompletionTasteGate single carrier alignment`

Theorem 1692.2 (Located uniform completion NameCert obligations)**.** *For every accepted* LocatedUniformComple *carrier $L = (F, U, B, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed located Cauchy filter, uniform completion route, Bishop regular Cauchy completion row, stream window, regular rational readback, terminal Real seal, componentwise transport, replay, provenance, and local naming rows;*
2. *located filter exposure, requiring every completion-facing request to read the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row F before it reaches the uniform completion row U;*
3. *uniform completion routing, requiring U to be the only completion route between the located filter data and the Bishop regular Cauchy completion row B;*
4. *finite readback, requiring every Real-facing read to inspect the* $\mathsf{StreamName}^{\uparrow}$ *row S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before the terminal seal E is exposed;*
5. *transport and replay stability, requiring H and C to preserve the same ordered route under componentwise sameness and displayed continuation replay;*
6. *ledger non-escape, requiring P and N to name only the displayed packet and to export no quotient limit, host equality, selected representative, countable-choice schedule, or ambient completeness coordinate.*

No located uniform-completion obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedUniformCompletionUp.LocatedUniformCompletionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1692.1. The projected rows are exactly the located Cauchy filter row F, uniform completion row U, Bishop regular Cauchy completion row B, stream window S, regular rational readback R, terminal Real seal E, and structural rows H, C, P, N.

Located filter exposure reads chapter 1661 before any completion-facing coordinate is available. Uniform completion routing then reads chapter 1473, so the route from F to the completion surface is carried by U rather than by an unrecorded quotient or host-level limit.

The Bishop regular Cauchy completion handoff is supplied by chapter 1639. It repacks the located uniform route into the regular Cauchy completion row B before any Real-facing read can continue.

Finite readback uses chapter 126 and chapter 301. The terminal boundary is then read through chapter 38 as the row E.

The rows H and C preserve this order under transport and replay. The provenance and naming rows P, N name only the displayed packet, so the excluded quotient, choice, selected-limit, host-equality, and completeness data have no coordinate from which to enter. □

Theorem 1692.3 (Located uniform completion density route)**.** *Every completion-facing read of an accepted* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *carrier* $L = (F, U, B, S, R, E, H, C, P, N)$ *factors through the finite route*

$$F \longmapsto U \longmapsto B \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the dense located source is exposed only through a located Cauchy filter row, a uniform completion row, a Bishop regular Cauchy completion row, finite stream windows, regular rational readback, the terminal Real seal, transport, replay, provenance, and local naming.

Lean4 ✓ `BEDC.Derived.LocatedUniformCompletionUp.LocatedUniformCompletionCarrier density route`

Proof. Begin with a completion-facing read of L. The carrier definition gives no direct completion coordinate except the displayed route $F, U, B, S, R, E, H, C, P, N$.

The located source enters through F, and the uniform completion interface is reached through U. This is the density-facing part of the certificate: the source is visible by located filter decisions and by the finite uniform completion route, not by a selected dense image or quotient-limit representative.

The regular Cauchy handoff then passes through B, and the finite readback passes through S and R. The terminal boundary row E is downstream of those rows, while H, C, P, N transport, replay, package, and name the same route.

Therefore every completion-facing read factors through the displayed finite route and receives no host equality, countable-choice schedule, selected limit, quotient limit, or ambient completeness theorem. □

Theorem 1692.4 (Located uniform completion Real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *boundary read exported by an accepted* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *carrier* $L = (F, U, B, S, R, E, H, C, P, N)$ *is downstream of the located uniform completion route*

$$\mathsf{LocatedCauchyFilter}^{\uparrow}(F), \quad \mathsf{UniformCompletion}^{\uparrow}(U), \quad \mathsf{BishopRegularCauchyCompletion}^{\uparrow}(B), \quad \mathsf{StreamName}^{\uparrow}(S),$$

No $\mathsf{Real}^{\uparrow}$ *consumer receives a quotient limit, host real equality, selected representative, countable-choice schedule, or ambient completeness datum from this packet.*

Lean4 ✓ `BEDC.Derived.LocatedUniformCompletionUp.LocatedUniformCompletionRealBoundary`

Proof. Project the terminal boundary row from Definition 1692.1. The row E is present only after F, U, B, S, R have been displayed.

The preceding route is fixed by the six cited boundary chapters: located filters supply F, uniform completions supply U, Bishop regular Cauchy completions supply B, stream names supply S, regular rational names supply R, and the Real chapter supplies the terminal seal discipline for E.

Since the carrier contains no quotient-limit, host-equality, selected-representative, choice, or ambient-completeness coordinate, the $\mathsf{Real}^{\uparrow}$ consumer can inspect only the displayed route and the structural rows H, C, P, N. The claimed boundary factorization follows. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1692.1, Definition 1692.2, Definition 1692.3, and Definition 1692.4 seed the located uniform-completion route through located Cauchy filters, uniform completion, Bishop regular Cauchy completion, stream windows, regular rational readback, and the Real boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real$^{\uparrow}$ completeness, quotient limits, countable choice, host equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located filter exposure, uniform completion routing, finite readback, transport and replay stability, ledger non-escape, density routing, and Real-boundary factorization for BEDC.Derived.LocatedUniformCompletionUp.

Constructive story: A LocatedUniformCompletion$^{\uparrow}$ packet is generated from a located Cauchy filter row, uniform completion route, Bishop regular Cauchy completion row, finite StreamName window, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Chapter 1693

A Concrete Naming Certificate for $\mathsf{FanBarRoute}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on finite fans and barred spreads, the $\mathsf{FanBarRoute}^{\uparrow}$ packet packages the finite route from $\mathsf{FanTheorem}^{\uparrow}$ bar-depth rows and $\mathsf{BrouwerBarInduction}^{\uparrow}$ barred-spread replay into the consumer surface used by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It sits after the finite fan certificate of chapter 400, the barred-spread induction certificate of chapter 1675, the stream-window surface of chapter 126, the regular-rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers one finite fan/bar handoff route; it is not open-cover compactness, sequential compactness, countable choice, selected infinite branches, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1693.1 (FanBarRoute carrier)**.** *A* $\mathsf{FanBarRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, I, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite fan-tree row. It records the displayed binary prefix tree, prefix closure, finite successor rows, and the source fan surface consumed from* $\mathsf{FanTheorem}^{\uparrow}$*.*
2. *B is the decidable bar-depth ledger. It records the displayed barred prefixes, Bool decisions, unary depth bound, and exact branch-prefix coverage rows delivered by the finite fan theorem.*
3. *I is the barred-spread induction replay row. It records the local backwards replay consumed from* $\mathsf{BrouwerBarInduction}^{\uparrow}$*, using only displayed children and barred prefixes from T and B.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It is the only route by which stream-facing consumers may request finite observations of the fan/bar packet.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It turns the displayed stream windows into regular rational observations before a Real or Completion consumer can inspect the handoff.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic precision, radius, comparison, and refinement ledger attached to the readback route.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, B, I, W, Q, D and the structural rows have been displayed.*

8. *H records componentwise* hsame *transport for the fan tree, bar-depth ledger, induction replay, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from finite fan inspection through bar-depth exactness, barred-spread replay, stream windows, regular-rational readback, dyadic tolerance, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{FanBarRoute}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FanBarRoute}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, B, I, W, Q, D, E, H, C, P, N$. It has no coordinate for a selected infinite branch, open-cover compactness, sequential compactness, quotient stream equality, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.FanBarRouteUp.TasteGate.FanBarRouteTasteGate single carrier alignment`

Theorem 1693.2 (FanBarRoute NameCert obligations)**.** *For every accepted* $\mathsf{FanBarRoute}^{\uparrow}$ *carrier $F = (T, B, I, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FanBarRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite fan tree, decidable bar-depth ledger, induction replay, StreamName window, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, continuation, provenance, and local naming rows;*

2. *finite bar-depth exactness, requiring every branch-prefix request to meet the displayed bar through T and B by the named unary depth;*

3. *barred-spread replay, requiring every backwards induction step to pass through I and the displayed children of T rather than through a selected infinite branch;*

4. *stream and readback compatibility, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window read to pass through W and every regular-rational read to pass through Q before any dyadic or Real-facing seal is visible;*

5. *Real seal nonescape, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *row E to be downstream of T, B, I, W, Q, D and to export no ambient completeness or host real equality;*

6. *transport and provenance stability, requiring H, C, P, N to preserve the same route under componentwise sameness, displayed continuation replay, package provenance, and local naming.*

No local obligation is stored outside these six rows.

Lean4 ✓ `BEDC.Derived.FanBarRouteUp.FanBarRouteNameCertObligations`

Proof. Carrier admission is projection from Definition 1693.1. The projected packet is exactly the tuple $T, B, I, W, Q, D, E, H, C, P, N$.

Finite bar-depth exactness reads the $\mathsf{FanTheorem}^{\uparrow}$ surface. The fan tree T supplies the displayed prefix tree, and B supplies the Bool bar decisions together with the unary depth ledger, so the bar claim is checked over visible prefixes only.

Barred-spread replay reads the $\mathsf{BrouwerBarInduction}^{\uparrow}$ surface. The row I contains the backwards local replay, and its children are the displayed successors already present in T, so no branch selector is introduced.

The analytic handoff uses the ordered rows W, Q, D, E. A stream request first opens the finite $\mathsf{StreamName}^{\uparrow}$ window W, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Finally, H, C, P, N transport, replay, name, and record the same route. Since the carrier contains no further coordinate, the excluded compactness, choice, quotient, branch-selection, host-equality, and ambient-completeness principles cannot be exported. □

Theorem 1693.3 (FanBarRoute finite bar handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{FanBarRoute}^{\uparrow}$ *carrier factors through*

$$T, B, I, W, Q, D, E, H, C, P, N.$$

The consumer receives a finite fan tree, a decidable bar-depth ledger, a barred-spread replay row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, the Real seal, transport, continuation, provenance, and local naming. It receives no selected infinite branch, open-cover compactness, sequential compactness, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FanBarRouteUp.FanBarRouteFiniteBarHandoff`

Proof. Start with a Real or Completion-facing read of the carrier. By Definition 1693.1, the only analytic-facing rows are the stream window W, the regular-rational readback Q, the dyadic tolerance row D, and the Real seal E.

Replay the continuation row C. Before any analytic-facing row is visible, the route exposes the finite fan tree T, the decidable bar-depth ledger B, and the barred-spread induction replay I.

After those rows have been displayed, the consumer can read W, then Q, then D, and then E. Componentwise transport and package provenance are fixed by H and P, and the local naming row is N.

Thus every consumer-visible route factors through the displayed tuple. The carrier has no row for branch selection, open-cover compactness, sequential compactness, quotient stream equality, countable choice, or ambient real completeness, so none of those principles can be extracted from the handoff. □

Falsifiable prediction: Every $\mathsf{FanBarRoute}^{\uparrow}$ Real or Completion-facing read factors through a finite fan tree, decidable bar-depth ledger, barred-spread replay, StreamName window, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, continuation, provenance, and local naming.

Independence witness: fantheorem, brouwer-bar-induction, streamname, regseqrat, dyadicratcore, real: $\mathsf{FanBarRoute}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite fan tree, bar-depth ledger, barred-spread replay, analytic handoff rows, transport, continuation, provenance, and local naming while refusing branch selection, compactness, choice, quotient equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{FanBarRoute}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FanBarRoute}^{\uparrow}$ packet is generated from a finite fan tree, a decidable bar-depth ledger, barred-spread replay, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FanBarRoute}^{\uparrow}}$, seed)

Scope closed: Definition 1693.1, Definition 1693.2, and Definition 1693.3 seed the finite fan/bar handoff surface for Real and Completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FanBarRoute}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, open-cover compactness, sequential compactness, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar-depth exactness, barred-spread replay, stream/readback compatibility, Real seal nonescape, transport and provenance stability, and TasteGate field faithfulness for BEDC.Derived.FanBarRouteUp.

Chapter 1694

A Concrete Naming Certificate for $\mathsf{UniformCauchyFilter}^{\uparrow}$

Following Bourbaki uniform spaces and Bishop–Bridges constructive completion, the $\mathsf{UniformCauchyFilter}^{\uparrow}$ packet records the current-state uniform Cauchy filter route as finite BEDC data. It sits between the entourage interface of chapter 339, the finite base interface of chapter 1601, the directed-window interface of chapter 589, and the completion boundary of chapter 1473. Its rational readback is routed through chapter 126, chapter 301, and chapter 660.

Definition 1694.1 (Uniform Cauchy filter carrier)**.** *A* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(U, F, C, T, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage ledger whose finite entourages, diagonal rows, symmetry rows, and composition refinements are available to the packet;*
2. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *base row naming the displayed filter-base indices, base elements, directed lower-bound witnesses, and refinement ledger;*
3. *C is the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row used when a downstream route asks to read the same Cauchy evidence as finite net windows;*
4. *T is the entourage-Cauchy stability row: for each displayed entourage request in U, it names a base row in F whose paired elements are read inside that entourage;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window readback row attached to the accepted base windows;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the same stream windows, with the regularity budget displayed as part of the packet;*
7. *E is the completion handoff row for* $\mathsf{UniformCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *consumers, exposing only the rows U, F, C, T, S, R and their structural support;*
8. *H is the componentwise* hsame *transport row over U, F, C, T, S, R, E;*
9. *K is the displayed* Cont *replay route for base requests, entourage requests, stream windows, regular rational reads, and completion handoffs;*

10. *P is the* Pkg *provenance over* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchySequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, choice-selected subnet limits, host completeness, open-cover compactness, ultrafilters, or Zorn-style maximality.

Theorem 1694.2 (Uniform Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *carrier* $(U, F, C, T, S, R, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed uniform-space, filter-base, Cauchy-net, stability, stream-window, regular rational, completion, transport, replay, provenance, and naming rows;*
2. *filter-base compatibility, requiring every filter request to read the displayed* $\mathsf{FilterBase}^{\uparrow}$ *row F and its directed lower-bound and refinement ledger before any Cauchy claim is exported;*
3. *entourage-Cauchy stability, requiring each displayed entourage request from U to be witnessed by the base row selected in T and replayed through the same refinement ledger;*
4. *stream-window readback, requiring finite observations to pass through the* $\mathsf{StreamName}^{\uparrow}$ *row S rather than through an external sequence object;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring regular rational data to be read from R on the same finite windows and budgets already displayed by S;*
6. *uniform-completion handoff, requiring* $\mathsf{UniformCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *consumers to read only the displayed rows U, F, C, T, S, R, E and the structural rows H, K, P, N;*
7. hsame *transport, requiring componentwise transport through H for all displayed rows;*
8. Cont *replay, requiring the replay route K to preserve the base request, entourage request, finite window, rational readback, and completion handoff order;*
9. Pkg *provenance, requiring P to name exactly the sibling packets listed in the carrier and no external completeness or compactness principle;*
10. *local naming, requiring N to expose the certificate only as* $\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}$.

Proof. Carrier admission is projection from Definition 1694.1. The rows $U, F, C, T, S, R, E, H, K, P, N$ are the visible coordinates of one finite BHist packet, so the local certificate has no detached filter, subnet, limit, or completeness coordinate.

Filter-base compatibility starts with F. A downstream request must read the base indices, base elements, directed lower-bound witnesses, and refinement ledger before it can inspect the Cauchy row T.

Entourage-Cauchy stability then reads U and T together. The entourage request comes from the displayed uniform-space ledger U, while T names the base row in F whose paired observations are read inside that entourage.

The stream and rational readbacks are the next two fixed faces. The row S supplies the finite $\mathsf{StreamName}^{\uparrow}$ windows, and R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational data on those same windows and budgets.

Finally, completion-facing consumers reach E only after the preceding rows have been displayed. Componentwise transport through H, replay through K, package provenance through P, and local

naming through N preserve that route and do not introduce quotient filters, selected subnet limits, host completeness, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.UniformCauchyFilterUp.UniformCauchyFilterTasteGate single carrier alignment`

Theorem 1694.3 (Uniform Cauchy filter completion handoff)**.** *Let* $(U, F, C, T, S, R, E, H, K, P, N)$ *be an accepted* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *carrier. Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of this route may read only the displayed filter-base row* F*, the Cauchy-net row* C*, the stream-window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the completion row* E*, and the structural rows* H, K, P, N*. It cannot read a quotient filter, a choice-selected subnet limit, host completeness, open-cover compactness, an ultrafilter, or a maximal-filter principle from the packet.*

Proof. Project the accepted carrier. The completion-facing coordinate is E, but its admissible inputs are already fixed by the carrier: the filter-base row F, the directed-window row C, the stream-window row S, and the regular rational row R.

The entourage stability row T mediates between the uniform-space ledger U and the base row F. Thus any completion request that asks for Cauchy evidence must pass through the displayed filter-base and Cauchy-net faces before reading E.

The remaining rows are structural. Transport by H, replay by K, provenance by P, and local naming by N expose the same finite handoff route and no further coordinate. Since quotient filters, selected subnet limits, host completeness, open-cover compactness, ultrafilters, and maximal-filter principles are not coordinates of the carrier, no $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer can obtain them from this certificate. □

Lean4 ✓ `BEDC.Derived.UniformCauchyFilterUp.UniformCauchyFilterCarrier completion handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformCauchyFilter}^{\uparrow}$ packet is generated from displayed uniform-space entourage rows, filter-base rows, Cauchy-net windows, stream windows, RegSeqRat readback, a completion handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1694.1, Definition 1694.2, and Definition 1694.3 seed the finite uniform Cauchy filter route from uniform-space entourages and filter bases to StreamName, RegSeqRat, and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, choice-selected subnet limits, host completeness, open-cover compactness, ultrafilters, maximal-filter principles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base compatibility, entourage-Cauchy stability, stream-window readback, RegSeqRat readback, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyFilterUp.

Chapter 1695

A Concrete Naming Certificate for $\mathsf{RegularCauchyAddition}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyAddition}^{\uparrow}$ packet names addition of two regular rational Cauchy real names by finite synchronized-window arithmetic before a completed $\mathsf{Real}^{\uparrow}$ consumer is allowed to read the sum. It sits over the regular rational source rows of chapter 301, the stream-window discipline of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later real-algebra and completion consumers a licensed BEDC route for addition; it does not import host real arithmetic, quotient Cauchy classes, selected limits, trichotomy, or ambient completeness.

Definition 1695.1 (RegularCauchyAddition carrier)**.** *A* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_+ = (R_0, R_1, W_0, W_1, T_0, T_1, D, S, E, Z, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *input rows.*
2. W_0 *and* W_1 *are paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedules, read at a common precision request and observation index.*
3. T_0 *and* T_1 *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows assigned to the two source observations.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *summed-endpoint row, recording the dyadic readback of the pointwise sum exposed by the two windows.*
5. S *is the summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose regularity is supplied by the two input regularity rows, the paired window schedules, and the dyadic tolerance rows.*
6. E *is the finite error-budget ledger combining the two source tolerances, the dyadic addition tolerance, and the output tolerance needed by the summed readback row.*
7. Z *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the two source rows, paired windows, dyadic tolerance rows, summed readback row, and finite ledger have been displayed.*
8. H *records componentwise* hsame *transport for the two source rows, paired stream windows, tolerance rows, summed endpoint row, summed readback, Real seal, replay row, provenance row, and local naming row.*
9. C *records displayed* Cont *replay from every addition-facing precision request through* $R_0, R_1, W_0, W_1, T_0, T_1, D, E,$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, W_0, W_1, T_0, T_1, D, S, E, Z, H, C, P, N$. The carrier has no coordinate for host real addition, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completed-real addition operation.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAdditionUp.RegularCauchyAdditionUp single carrier alignment`

Theorem 1695.2 (Regular Cauchy addition NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *carrier*

$$A_+ = (R_0, R_1, W_0, W_1, T_0, T_1, D, S, E, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *input rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance rows, summed endpoint row, finite error ledger, summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal row, and structural rows;*

2. *paired-window exposure, requiring each addition-facing precision request to inspect W_0 and W_1 at the same finite precision before any summed readback is available;*

3. *dyadic endpoint addition, requiring D to be read from the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows T_0, T_1 and the two window observations;*

4. *finite regularity accounting, requiring E to combine the two input tolerance rows, the dyadic addition tolerance, and the output tolerance before S is consumed;*

5. *Real seal boundary, requiring Z to be read only after the route through $R_0, R_1, W_0, W_1, T_0, T_1, D, E, S$ has been displayed;*

6. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite addition packet;*

7. *refusal of host real addition, quotient Cauchy classes, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No addition obligation is stored outside these finite rows.

Proof. Project the accepted carrier. The analytic rows are the two regular rational names R_0, R_1, the paired stream schedules W_0, W_1, the dyadic tolerance rows T_0, T_1, the summed endpoint row D, the finite ledger E, the summed readback S, and the Real seal Z.

Read the windows before the sum by finite-window induction on the displayed precision schedule. The base window exposes the first paired observations, and the successor window preserves the same synchronized request before any pointwise dyadic arithmetic is used.

Form the dyadic endpoint and the regular readback next. The row D consumes the two displayed observations and their tolerance rows through the $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic route, while E records the finite tolerance accounting that turns the pointwise sum into the $\mathsf{RegSeqRat}^{\uparrow}$ readback row S.

Finally seal and package the route. The row Z is downstream of the summed readback, and the structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores host real addition, quotient classes, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data, none can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.RegularCauchyAdditionUp.RegularCauchyAdditionCarrier namecert obligations`

Theorem 1695.3 (Regular Cauchy addition window-sum stability)**.** *Let two accepted* RegularCauchyAddition$^{\uparrow}$ *carriers have input rows, paired windows, dyadic tolerance rows, summed endpoint rows, finite ledgers, readbacks, Real seals, package provenance, and local naming rows matched componentwise by their displayed* hsame *classifiers. Then every summed-window route supplied by the obligation surface of Definition 1695.2 transports to the corresponding route of the second packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAdditionUp.RegularCauchyAdditionCarrier window sum stability`

Proof. Start with the componentwise classifier data in H. A finite-window induction on the paired schedules transports the two RegSeqRat$^{\uparrow}$ source rows and the StreamName$^{\uparrow}$ windows without changing the common precision request.

Transport the dyadic addition row. The matched tolerance rows T_0, T_1 still feed the same DyadicRatCore$^{\uparrow}$ summed endpoint route D, so the pointwise addition step remains tied to the displayed finite windows.

The ledger and readback rows are preserved by the same componentwise transport. The row E remains the only place where source tolerances, dyadic addition tolerance, and output tolerance are combined before S and Z are exposed.

Replay through C and repack through P and N. Every consumer route in the obligation surface is one of these displayed projections, so classifier transport cannot add host real addition, quotient Cauchy classes, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data. □

Theorem 1695.4 (Regular Cauchy addition uniform modulus)**.** *If two accepted* RegularCauchyAddition$^{\uparrow}$ *packets share the same* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks, and* DyadicRatCore$^{\uparrow}$ *addition tolerance ledger through their displayed* hsame *rows, then their* Real$^{\uparrow}$ *sum seal is controlled by the same displayed modulus row. The control is the finite route through* $R_0, R_1, W_0, W_1, T_0, T_1, D, E, S, Z, H, C, P, N$*, not host real addition, quotient Cauchy classes, selected limits, trichotomy, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAdditionUp.RegularCauchyAddition uniform modulus`

Proof. Project the carrier of Definition 1695.1. The two packets expose the same source readbacks, paired finite windows, dyadic tolerance rows, summed endpoint row, and finite ledger row through componentwise transport.

Use Definition 1695.3. It binds the finite windows and dyadic addition route, so the displayed ledger E remains the common place where the two source budgets, the addition tolerance, and the output tolerance are combined.

Apply Definition 1695.5. The terminal row Z is read only after the common ledger route has fixed S, so both sum seals are controlled by the same displayed modulus row and no host real addition, quotient class, selected limit, trichotomy, or ambient Real completeness is read. □

Theorem 1695.5 (Regular Cauchy addition Real seal handoff)**.** *Every accepted* RegularCauchyAddition$^{\uparrow}$ *carrier factors its Real-facing addition read through the finite route*

$$(R_0, R_1) \longmapsto (W_0, W_1) \longmapsto (T_0, T_1, D) \longmapsto E \longmapsto S \longmapsto Z$$

before it may hand the result to a Real$^{\uparrow}$ *consumer. Thus the consumer receives two regular rational source rows, paired finite schedules, dyadic tolerance and summed endpoint rows, a finite addition ledger, a summed* RegSeqRat$^{\uparrow}$ *readback row, and a Real seal row; it receives no host real addition, quotient Cauchy class, selected limit, trichotomy, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAdditionUp.RegularCauchyAdditionCarrier real seal handoff`

Proof. Begin with an accepted carrier A_+. The only source coordinates for the addition read are R_0 and R_1, and finite-window induction over the attached schedules W_0, W_1 supplies the paired observations in dependency order.

The pointwise sum then passes through the dyadic rows. The rows T_0 and T_1 attach the source tolerances to the displayed observations, while D records the finite dyadic addition readback.

The finite ledger finishes the regular handoff. The row E combines the two source budgets with the dyadic addition and output budgets before the summed $\mathsf{RegSeqRat}^{\uparrow}$ readback row S can be consumed.

Only then is the $\mathsf{Real}^{\uparrow}$ seal row Z exposed. The rows H, C, P, N preserve and name this same dependency order, so the Real-facing consumer receives a finite BEDC addition route rather than host arithmetic, quotient classes, selected limits, trichotomy, or ambient completeness. □

Theorem 1695.6 (Regular Cauchy addition sibling dependency route)**.** *Every downstream Real algebra or completion consumer of an accepted* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *packet factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *summed-endpoint row, the finite addition ledger, the summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}$ *row. The route is exactly the dependency package certified by the NameCert obligations, window-sum stability, and Real seal handoff; it excludes host real addition, quotient Cauchy classes, selected limits, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligation surface of Definition 1695.2. It lists the two regular rational source rows, paired stream windows, dyadic tolerance rows, summed endpoint row, finite ledger, summed readback, Real seal, and structural rows as the complete carrier-facing surface.

Use Definition 1695.3 to keep the same rows under componentwise classifier transport. No downstream consumer can replace the paired windows or dyadic addition rows while preserving the accepted packet.

Finally apply the Real seal handoff of Definition 1695.5. The seal is exposed only after the displayed addition route, so Real algebra and completion consumers inherit precisely this sibling dependency route and none of the excluded host or completion objects. □

Theorem 1695.7 (Regular Cauchy addition window-fusion boundary)**.** *Let*

$$A_+ = (R_0, R_1, W_0, W_1, T_0, T_1, D, S, E, Z, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyAddition}^{\uparrow}$ *packet whose two source windows are fused through the public finite route of* $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$*. Before any* $\mathsf{Real}^{\uparrow}$ *algebra consumer reads the sum seal* Z*, the fused addition packet exports the same finite L10 route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. The fusion handoff changes only the shared terminal-window presentation; it does not add host real addition, quotient Cauchy classes, selected limits, trichotomy, ambient completeness, or a second sum seal.*

Proof. Start with Definition 1695.2. It identifies the two source rows, paired windows, dyadic tolerance rows, summed endpoint row, finite ledger, summed readback, Real seal, and structural rows as the complete addition-facing packet.

Apply Definition 1695.5. The sum seal Z can be read only after the route through $R_0, R_1, W_0, W_1, T_0, T_1, D, E, S$ has been displayed, so a downstream Real algebra consumer cannot bypass the finite addition rows.

Finally use Definition 693.19. The fusion packet exposes the terminal window through the same finite L10 route over regular readback, stream window, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows. Substituting that public route for the two displayed source windows preserves the addition handoff and contributes no host arithmetic or ambient completion data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1695.1, Definition 1695.2, Definition 1695.3, and Definition 1695.5 seed the finite addition surface over two $\mathsf{RegSeqRat}^{\uparrow}$ inputs, paired $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and summed endpoint rows, summed $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAddition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real addition, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-window exposure, dyadic endpoint addition, finite regularity accounting, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyAddition

Constructive story: A $\mathsf{RegularCauchyAddition}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ rows, paired $\mathsf{StreamName}^{\uparrow}$ finite-window schedules, two $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ summed endpoint row, a finite error ledger, a summed $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1696

A Concrete Naming Certificate for $\mathsf{RegularCauchySubtraction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySubtraction}^{\uparrow}$ packet records binary subtraction of displayed regular rational Cauchy real names as a finite sign-flip-plus-sum route. It sits over the regular rational source rows of chapter 301, the synchronized window discipline of chapter 126, the dyadic tolerance core of chapter 291, the addition route of chapter 1695, the sign-flip route of chapter 459, the algebra packet of chapter 1470, and the terminal real-name seal of chapter 38. The packet is the binary subtraction surface consumed by later L10 real and completion algebra routes; it is not host real subtraction, a quotient Cauchy-class operation, a selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1696.1 (RegularCauchySubtraction carrier)**.** *A* $\mathsf{RegularCauchySubtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B_{-} = (X, Y, G, A, W, D, E, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for regular rational Cauchy real names.*
2. *G is the sign-flip route for Y through the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *carrier, exposing only the displayed source row, finite windows, dyadic sign-flip ledger, transported classifier, and* $\mathsf{Real}^{\uparrow}$ *seal handoff of that packet.*
3. *A is the sum route for $X + (-Y)$ through the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *carrier, using X as the first summand and the regular readback exported by G as the second summand.*
4. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window ledger aligning the source reads of X, the source reads of Y, the sign-flipped reads in G, and the paired summand reads consumed by A.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the source tolerance rows, the sign-flipped dyadic endpoint rows, and the dyadic addition rows used by the final subtraction readback.*
6. *E is the finite error-budget accounting row combining the tolerance consumed by the sign flip, the paired summand tolerance, and the output tolerance required by the subtraction readback.*
7. *S is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed binary subtraction route.*
8. *H records componentwise* hsame *transport for the two source rows, the sign-flip route, the sum route, synchronized windows, dyadic ledger, finite budget row, readback, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from any subtraction-facing precision request through* $X, Y, G, A, W, D, E, S, H, P$

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, G, A, W, D, E, S, H, C, P, N$. The carrier has no coordinate for host real subtraction, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubtractionUp.RegularCauchySubtractionTasteGate single carrier alignment`

Theorem 1696.2 (Regular Cauchy subtraction NameCert obligations)**.** *For every accepted* RegularCauchySubtracti *carrier*

$$B_{-} = (X, Y, G, A, W, D, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *sign-flip route, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *sum route, synchronized windows, dyadic tolerance rows, finite error-budget row, resulting readback, and structural rows;*
2. *negation handoff, requiring G to expose the sign-flipped row of Y only through the finite sign-flip ledger of chapter 459;*
3. *addition handoff, requiring A to consume X and the readback exported by G only through the finite addition route of chapter 1695;*
4. *finite error-budget accounting, requiring E to combine the sign-flip tolerance, paired summand tolerance, dyadic addition tolerance, and output tolerance before S is available;*
5. *Real seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to read the route through X, Y, G, A, W, D, E, S before any terminal seal is exposed;*
6. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite subtraction packet;*
7. *refusal of host real subtraction, quotient Cauchy classes, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No subtraction obligation is stored outside these finite rows.

Theorem 1696.3 (Regular Cauchy subtraction Real seal handoff)**.** *Every Real-facing subtraction read exported by an accepted* $\mathsf{RegularCauchySubtraction}^{\uparrow}$ *carrier factors through the finite route*

$$(X, Y) \longmapsto G \longmapsto A \longmapsto W \longmapsto D \longmapsto E \longmapsto S \longmapsto \mathsf{Real}^{\uparrow}$$

before it may be consumed as a completed real-name boundary. Thus the consumer receives two source rows, the sign-flip row for Y, the sum row for $X + (-Y)$, synchronized $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. It receives no host real subtraction, quotient Cauchy class, selected limit, trichotomy, ambient completeness coordinate, Lean verification, or bridge checking.*

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubtraction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1696.1, Definition 1696.2, and Definition 1696.3 seed the finite binary subtraction route through $\mathsf{RegSeqRat}^{\uparrow}$ source rows, $\mathsf{RegularCauchyNegation}^{\uparrow}$ sign flip, $\mathsf{RegularCauchyAddition}^{\uparrow}$ sum, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, resulting $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real subtraction, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, negation handoff, addition handoff, finite error-budget accounting, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubt

Constructive story: A $\mathsf{RegularCauchySubtraction}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a $\mathsf{RegularCauchyNegation}^{\uparrow}$ sign-flip route for the second source, a $\mathsf{RegularCauchyAddition}^{\uparrow}$ sum route for the first source and the sign-flipped readback, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, a finite error-budget row, a resulting $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1697

A Concrete Naming Certificate for $\mathsf{BoundedRegularCauchy}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BoundedRegularCauchy}^{\uparrow}$ packet records the bounded regular Cauchy surface needed before Real and Completion consumers ask for completeness, compactness, or limit extraction. It realizes the Real and Completion route of chapter 9238 as explicit finite packet data: the dyadic endpoint and tolerance ledger is read from chapter 291, finite observations are read through chapter 126, regular rational readback is supplied by chapter 301, the terminal real-name boundary is sealed by chapter 38, and the tail schedule is exposed through chapter 292. The packet is a boundedness-and-tail witness for regular Cauchy names; it is not a host completeness theorem, a quotient stream representative, a selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real equality.

Definition 1697.1 (BoundedRegularCauchy carrier)**.** *A* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *stream-window family, listing the finite observation windows that may be opened before any Real or Completion consumer inspects a tail claim.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail schedule, assigning each displayed dyadic tolerance request a finite threshold and the corresponding late-window budget.*
3. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *boundedness ledger, containing the dyadic center, radius, endpoint comparisons, and tail-bound inequalities used to keep all late reads inside the displayed bound.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows, the modulus schedule, and the dyadic boundedness ledger.*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, M, B, Q have been displayed.*
6. *H records componentwise* hsame *transport for the stream windows, modulus schedule, dyadic bound, regular readback, Real seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from any bounded-regular-Cauchy request through M, then through S and B, into Q, and finally into the* $\mathsf{Real}^{\uparrow}$ *seal row A.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedRegularCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchy}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, M, B, Q, A, H, C, P, N$. The carrier has no coordinate for host completeness, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real equality.

Lean4 ✓ `BEDC.Derived.BoundedRegularCauchyUp.BoundedRegularCauchyUpTasteGate single carrier alignment`

Theorem 1697.2 (BoundedRegularCauchy NameCert obligation surface)**.** *For every accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window family, tail schedule, dyadic boundedness ledger, regular rational readback, Real seal row, componentwise transport, continuation replay, provenance, and local naming;*
2. *tail-bound exactness, requiring every requested dyadic tolerance to read its threshold from M and its late-window dyadic inequalities from B before the readback row Q is exposed;*
3. *regular-readback compatibility, requiring Q to be obtained only from the displayed S, M, B rows and to remain inside the bound recorded by B;*
4. *classifier transport, requiring H and C to replay the same displayed route M, S, B, Q, A under componentwise* hsame*;*
5. *Real-seal handoff, requiring any* $\mathsf{Real}^{\uparrow}$ *consumer to read the terminal seal row A only after stream windows, modulus data, dyadic tail bounds, and regular readback have all been displayed;*
6. *ledger non-escape, requiring P and N to export no host completeness, quotient stream equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real equality.*

No bounded-regular-Cauchy obligation is stored outside these rows.

Proof. Carrier admission is row projection from Definition 1697.1. The displayed packet has exactly the stream-window, modulus, dyadic-bound, readback, seal, transport, replay, provenance, and local naming rows listed there.

Tail-bound exactness is the joint content of M and B. A tolerance request first fixes a threshold in the modulus schedule, and the dyadic ledger then records the late-window inequalities that keep the corresponding observations inside the displayed bound.

Regular-readback compatibility follows by replaying the sibling surfaces in order. The $\mathsf{StreamName}^{\uparrow}$ windows expose finite observations, the $\mathsf{CauchyModulus}^{\uparrow}$ row chooses the late threshold, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the bounded dyadic comparisons, and the $\mathsf{RegSeqRat}^{\uparrow}$ row records the resulting regular rational readback.

Classifier transport is componentwise. The hsame row H transports each displayed coordinate, while C repeats the same M, S, B, Q, A route for any accepted request. Since no excluded coordinate is present in the carrier, the transport cannot introduce one.

Finally, the Real-seal handoff and non-escape rows are exhausted by A, P, N. A Real consumer reaches A only through the displayed route, and the provenance and naming rows record that the packet exports no host completeness, quotient stream equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real equality. □

Theorem 1697.3 (BoundedRegularCauchy Real-seal boundary)**.** *Every Real-facing or Completion-facing read exported by an accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier factors through the finite route*

$$M \longmapsto S \longmapsto B \longmapsto Q \longmapsto A$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Thus the consumer receives explicit dyadic tail-bound data, finite stream windows, a modulus threshold, regular rational readback, and the displayed Real seal, and receives no host completeness theorem, quotient stream representative, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, or ambient Real equality.*

Proof. Begin with an accepted packet $R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N)$ and project its displayed rows. The only threshold source is M, so every Real-facing or Completion-facing request must first read a finite tail budget from the modulus row.

The finite observation and boundedness rows are downstream of that budget. The stream-window row S supplies the observations that may be inspected at the selected threshold, and the dyadic ledger B records the explicit bound and late-window inequalities attached to those observations.

The regular rational readback and Real seal are last. The row Q is the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from S, M, B, and the row A is the terminal $\mathsf{Real}^{\uparrow}$ seal exposed only after that readback has been displayed.

The structural rows preserve this route without enlarging it. Componentwise transport in H, replay in C, provenance in P, and local naming in N add no coordinate for host completeness, quotient stream representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real equality. □

Theorem 1697.4 (BoundedRegularCauchy tail-window induction)**.** *For every accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N)$$

and every unary tolerance-depth request read through M, induction on the finite threshold chain displayed by M shows that each late window is first read through S, then bounded through B, then repacked through the same $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, and only after those stages reaches the terminal* $\mathsf{Real}^{\uparrow}$ *row A. No endpoint, selected limit, quotient stream, countable choice, trichotomy, open-cover compactness, or ambient Real equality can enter the induction.*

Lean4 ✓ `BEDC.Derived.BoundedRegularCauchyUp.BoundedRegularCauchyCarrier tail window induction`

Proof. The base stage projects the first displayed threshold from M. At that stage the carrier exposes only the finite stream-window row S attached to the threshold, the dyadic bound row B attached to the same late window, and the regular readback row Q obtained from those displayed rows.

For the induction step, assume the route has been established for the preceding displayed thresholds. The next threshold is supplied by the same modulus row M; the continuation row C replays the route through the next S-window and the next B-bound, while componentwise transport in H carries the displayed rows without changing the classifier surface.

The repacking stage preserves the $\mathsf{RegSeqRat}^{\uparrow}$ handoff because Q has no coordinate beyond the stream windows, modulus schedule, and dyadic boundedness ledger. Thus each successor window reaches A only after the finite route through S, B, Q has been displayed.

The conclusion follows from Definition 1697.3 together with ledger non-escape in P and N. Since those rows export no endpoint choice, selected limit, quotient stream, countable choice, trichotomy, open-cover compactness, or ambient Real equality, the induction remains confined to the displayed threshold windows. □

Theorem 1697.5 (BoundedRegularCauchy modulus-chain induction)**.** *For every accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N),$$

induction on the finite modulus chain displayed by M shows that each tolerance request first reads its threshold from M, then reads the dyadic boundedness ledger B, then repacks through the $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, and only after those rows reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal A. The induction exports no quotient stream, selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real equality.*

Proof. The base stage is the first displayed tolerance request. By Definition 1697.1, the request has no threshold coordinate except the modulus row M, and no bound coordinate except the dyadic ledger B.

For the induction step, assume all earlier displayed requests have followed the route through M, B, Q. The successor request is still a row of the same finite chain M, so the continuation replay in C can only expose the corresponding B-entry before the readback row Q is consumed.

The terminal stage is fixed by Definition 1697.3. That theorem places A after the displayed modulus, boundedness, and regular-readback rows, so the induction cannot reach the Real seal before M, B, Q have appeared.

Finally the structural rows H, P, N add transport, provenance, and local naming without adding excluded coordinates. Thus the whole finite modulus-chain induction remains confined to the displayed carrier rows. □

Theorem 1697.6 (BoundedRegularCauchy tail-modulus extraction)**.** *For every accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N),$$

each displayed dyadic tolerance request exports a finite tail-modulus threshold row by the route

$$M \longrightarrow B \longrightarrow Q \longrightarrow A.$$

The request first reads its threshold from the modulus schedule M, validates the late-window dyadic bound in B, repacks the bounded late observations through the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal A only after those rows have been displayed. The exported threshold row is therefore a reusable Real and Completion handoff, not a quotient stream representative, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, or ambient Real equality.*

Proof. Carrier projection from Definition 1697.1 gives the only available rows for a tolerance request: the stream windows S, modulus schedule M, dyadic bound B, regular readback Q, and terminal Real seal A.

The Real-seal boundary of Definition 1697.3 orders any Real-facing or Completion-facing read through the displayed finite route before A can be consumed. Hence no terminal seal can appear before the modulus, boundedness, and readback rows have been exposed.

Apply the tail-window induction of Definition 1697.4 to keep each late window attached to its finite threshold in M and its displayed observations in S. Then apply Definition 1697.5 to read the threshold chain through M, B, Q, A.

The extracted threshold row is the finite row produced by that chain. The structural rows H, C, P, N transport, replay, source, and name the same route, so the handoff cannot introduce a quotient representative, selected limit, choice schedule, trichotomy principle, open-cover compactness proof, or ambient Real equality. □

Theorem 1697.7 (BoundedRegularCauchy two-stage tail envelope)**.** *For every accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *carrier*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N),$$

there is a reusable two-stage tail envelope exported by the displayed rows. In the first stage, M, S, B *produce the finite bounded late-window envelope: the modulus schedule chooses the late threshold, the stream-window row supplies the finite observations at that threshold, and the dyadic boundedness ledger records the corresponding endpoint and radius inequalities. In the second stage,* Q, A *repack that finite envelope as a* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *seal handoff. The envelope is therefore available to Real and Completion consumers as finite BEDC data, not as a quotient stream, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, or ambient Real equality.*

Proof. Start with the accepted packet and project the route of Definition 1697.3. Every Real-facing read reaches A only after the displayed finite path through the modulus, stream-window, boundedness, and regular-readback rows.

The first stage is finite induction over late windows. By Definition 1697.4, each requested late window stays attached to its threshold in M, its finite observations in S, and its dyadic bound in B. By Definition 1697.5, the same finite route is stable as the tolerance request moves along the displayed modulus chain.

The second stage is the readback and seal handoff. Apply Definition 1697.6: the bounded late-window data are repacked through Q and then exposed through the terminal $\mathsf{Real}^{\uparrow}$ seal A. The structural rows H, C, P, N transport, replay, source, and name the same packet, so this handoff remains reusable without adding any excluded host principle. □

Theorem 1697.8 (BoundedRegularCauchy tail-window dependency)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet*

$$R_{\mathrm{bd}} = (S, M, B, Q, A, H, C, P, N)$$

must expose the dependency rows in the order

$$M \longrightarrow S \longrightarrow B \longrightarrow Q \longrightarrow A.$$

Here M *is the modulus threshold row,* S *is the finite stream-window row,* B *is the dyadic boundedness ledger,* Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus no Real or Completion use of the packet may bypass the finite tail-window route by appealing to hidden completeness, quotient-stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real equality.*

Proof. The Real-seal boundary in Definition 1697.3 fixes the outer route: a consumer can reach A only after the displayed finite path has passed through the modulus, stream-window, boundedness, and readback rows.

The late-window content of that route is forced by Definition 1697.4. Once a tolerance request has read its threshold from M, every inspected late window is opened through S, bounded through B, and repacked through Q before the seal row can be consumed.

The threshold chain itself is forced by Definition 1697.5. It keeps every tolerance request attached to the displayed M-chain and prevents the readback from skipping directly to the terminal seal.

Finally, Definition 1697.7 packages the same data as the reusable finite envelope M, S, B followed by the handoff Q, A. Since the structural rows only transport, replay, source, and name that envelope, the consumer receives the ordered rows M, S, B, Q, A and no excluded host principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchy}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRegularCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1697.1, Definition 1697.2, Definition 1697.3, Definition 1697.4, Definition 1697.7, and Definition 1697.8 seed the finite bounded regular Cauchy packet over displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRegularCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host completeness, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-bound exactness, regular-readback compatibility, classifier transport, Real-seal handoff, provenance, local naming, and ledger non-escape for BEDC.Derived.BoundedRegularCauchyUp.

Constructive story: A $\mathsf{BoundedRegularCauchy}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{CauchyModulus}^{\uparrow}$ threshold schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ boundedness ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1698

A Concrete Naming Certificate for BoundedRegularCauchySubsequence$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the BoundedRegularCauchySubsequence$^{\uparrow}$ packet records the bounded tail-subsequence interface needed on the L10 Real and Completion route before any consumer asks for compactness, completeness, or a chosen limit. It refines the bounded tail ledger of chapter 1697 through the monotone-cofinal surface of chapter 381, the criterion route of chapter 1552, the inspected fast route of chapter 1518, the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38.

The packet is a finite NameCert handoff. It stores bounded tail data, a displayed monotone-cofinal schedule, finite observation windows, dyadic tolerance rows, RegSeqRat$^{\uparrow}$ readback, RegularCauchySubsequenc handoff, and a Real$^{\uparrow}$ seal; it stores no selected infinite subsequence, quotient stream, countable choice, host equality, or Real completeness principle.

Definition 1698.1 (BoundedRegularCauchySubsequence carrier)**.** *A* BoundedRegularCauchySubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, T, W, D, Q, R, F, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* BoundedRegularCauchy$^{\uparrow}$ *row, including the bounded tail schedule and its finite dyadic endpoint ledger;*
2. *T is a displayed monotone-cofinal unary schedule over the inspected tail indices;*
3. *W records the source and selected* StreamName$^{\uparrow}$ *windows admitted along T;*
4. *D records the* DyadicRatCore$^{\uparrow}$ *tolerance rows, tail bounds, and late-window comparisons attached to those windows;*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback determined by B, T, W, D;*
6. *R is the* RegularCauchySubsequence$^{\uparrow}$ *handoff row built from the same schedule, windows, tolerance rows, and readback;*
7. *F is the* FastCauchySubsequence$^{\uparrow}$ *or* CauchySubsequenceCriterion$^{\uparrow}$ *criterion witness read only from the displayed bounded subsequence route;*
8. *E is the terminal* Real$^{\uparrow}$ *seal exposed after Q, R, F have been displayed;*

9. *H records componentwise* hsame *transport for all displayed analytic and support rows;*
10. *C records* Cont *replay through the route B, T, W, D, Q, R, F, E;*
11. *P is the* Pkg *provenance over* BoundedRegularCauchySubsequence$^{\uparrow}$, BoundedRegularCauchy$^{\uparrow}$, RegularCauchySubsequence$^{\uparrow}$, CauchySubsequenceCriterion$^{\uparrow}$, FastCauchySubsequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* NameCert$_{\text{BoundedRegularCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, T, W, D, Q, R, F, E, H, C, P, N$. The carrier has no coordinate for a selected infinite subsequence, quotient stream, countable choice, host equality, or Real completeness.

↪variant BEDC.Derived.BoundedRegularCauchySubsequenceUp.BoundedRegularCauchySubsequenceTasteGate single carrier alignment

Theorem 1698.2 (BoundedRegularCauchySubsequence selection factorization)**.** *For every accepted* BoundedRegularCauchySubsequence$^{\uparrow}$ *carrier*

$$L = (B, T, W, D, Q, R, F, E, H, C, P, N),$$

each bounded regular Cauchy subsequence read factors through bounded tail data, the monotone-cofinal schedule, finite windows, dyadic tolerance rows, RegSeqRat$^{\uparrow}$ *readback,* RegularCauchySubsequence$^{\uparrow}$ *handoff, the criterion witness, and the* Real$^{\uparrow}$ *seal:*

$$B, T, W, D, Q, R, F, E.$$

Thus the consumer receives a finite BEDC route from the bounded regular Cauchy source to the real-facing seal, and receives no selected infinite subsequence, quotient stream, countable choice, host equality, or Real completeness.

Lean4 ✓ BEDC.Derived.BoundedRegularCauchySubsequenceUp.BoundedRegularCauchySubsequenceTasteGate single carrier alignment

Proof. Project the accepted carrier of Definition 1698.1. Its only source row for boundedness is B, and its only source row for subsequence movement is the displayed monotone-cofinal schedule T.

The finite windows and tolerance rows are downstream of those two coordinates. The row W records exactly the source and selected StreamName$^{\uparrow}$ windows inspected along T, while D records the DyadicRatCore$^{\uparrow}$ bounds and dyadic tolerance comparisons attached to the same windows.

The analytic handoff rows consume that displayed route. The RegSeqRat$^{\uparrow}$ readback Q is determined by B, T, W, D, the RegularCauchySubsequence$^{\uparrow}$ row R repacks the same schedule and window data, and the witness row F records the fast or criterion-side acceptance of the displayed subsequence.

Finally, the seal and support rows cannot enlarge the interface. The Real$^{\uparrow}$ row E is reached only after Q, R, F, and the rows H, C, P, N transport, replay, source, and name the same displayed coordinates. Since the classifier contains no remaining coordinate, the excluded subsequence, quotient, choice, host-equality, and completeness data cannot be read. □

Theorem 1698.3 (Bounded regular Cauchy subsequence tail seal)**.** *Every accepted* BoundedRegularCauchySubseque *read exports exactly the rows*

$$B, T, W, D, Q, R, F, E, H, C, P, N.$$

These rows are, respectively, the bounded tail data, the monotone-cofinal schedule, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff, the criterion witness, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}}$ *row. No consumer of the packet can read a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the accepted read.*

Proof. Project the carrier of Definition 1698.1. Its displayed coordinates are precisely $B, T, W, D, Q, R, F, E, H, C, P$ and the classifier compares accepted packets only through those rows.

Apply Definition 1698.2. The displayed route identifies the bounded tail data, monotone-cofinal schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, criterion witness, and terminal $\mathsf{Real}^{\uparrow}$ seal as the exported analytic surface.

The remaining rows only transport, replay, source, and name that same surface. Since the carrier has no coordinate outside $B, T, W, D, Q, R, F, E, H, C, P, N$, there is no exported place from which a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle can be recovered. □

Theorem 1698.4 (Regular Cauchy subsequence modulus readback)**.** *For every accepted* $\mathsf{BoundedRegularCauchySub}$ *carrier*

$$L = (B, T, W, D, Q, R, F, E, H, C, P, N),$$

the complete modulus-readback route is exactly the bounded tail data B*, monotone-cofinal schedule* T*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff* R*, criterion witness* F*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*. No completion-facing consumer can read a selected subsequence, quotient stream equality, countable choice, host real equality, or ambient Real-completeness principle outside this route.*

Proof. Project the carrier of Definition 1698.1. Its analytic rows are precisely the bounded tail data, schedule, windows, tolerances, regular readback, subsequence handoff, criterion witness, and Real seal.

Apply Definition 1698.2. It factors each subsequence read through B, T, W, D, Q, R, F, E, so the modulus information is already tied to the displayed bounded tail, monotone-cofinal schedule, finite windows, and dyadic tolerances.

Apply Definition 1698.3. The exported rows are exactly $B, T, W, D, Q, R, F, E, H, C, P, N$, and the support rows only transport, replay, source, and name that surface. Therefore the displayed route is the complete modulus readback for completion-facing consumers. □

Theorem 1698.5 (Bounded regular Cauchy subsequence Cauchy-hub forward route)**.** *Every bounded regular Cauchy subsequence modulus read is a downstream consumer of the Cauchy hub route in chapter 3413. The forward route passes through bounded tail data, a monotone-cofinal schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchySubsequenceCriteri}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the local* $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}}$ *row is exported.*

Proof. Project the carrier of Definition 1698.1. Its analytic rows are B, T, W, D, Q, R, F, E, and these are the only rows that can feed the modulus readback.

Use the existing route blocks in this chapter. The selection factorization of Definition 1698.2 ties the read to bounded tail data, monotone-cofinal schedule, windows, tolerances, regular readback,

criterion witness, and Real seal. The tail seal of Definition 1698.3 adds only H, C, P, N, and Definition 1698.4 identifies that same list as the complete modulus-readback route.

The upstream analytic source is the Cauchy hub. The route named in chapter 3413 supplies the Cauchy-facing family consumed here before the bounded tail, subsequence criterion, regular rational readback, and Real seal are displayed. Therefore every accepted modulus read in this chapter is a downstream Cauchy-hub consumer rather than an independent selected-subsequence or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1698.1, Definition 1698.2, and Definition 1698.3 seed the finite bounded regular Cauchy subsequence route over displayed bounded tail data, monotone-cofinal schedule, finite windows, dyadic tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, criterion witness, and $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient streams, countable choice, host equality, Real completeness, Lean verification, or standard bridge checking.

Upgrade path: Formal closure requires checked carrier admission, bounded-tail exactness, monotone-cofinal schedule admission, finite-window transport, dyadic tolerance replay, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, criterion witness routing, and Real-seal non-escape for BEDC.Derived.BoundedRegularCauchySubsequenceUp.

Constructive story: A $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a displayed monotone-cofinal schedule, finite StreamName windows, dyadic tolerance rows, RegSeqRat readback, RegularCauchySubsequence handoff, a criterion witness, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1699

A Concrete Naming Certificate for $\mathsf{UniformCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformCauchySubsequence}^{\uparrow}$ packet records the common dyadic tail-budget subsequence interface needed on the L10 Real and Completion route. It refines the bounded subsequence route of chapter 1698 by requiring every real-facing subsequence read to pass through one shared $\mathsf{DyadicRatCore}^{\uparrow}$ budget row before the $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal are visible.

The packet is finite. It stores a bounded regular Cauchy subsequence source, displayed tail indices, a shared uniform dyadic budget row, finite observation windows, local dyadic comparisons, regular rational readback, seal routing, transport, replay, provenance, and a local certificate; it stores no selected infinite subsequence, quotient stream, countable choice, host equality, or Real completeness principle.

Definition 1699.1 (UniformCauchySubsequence carrier)**.** *A* $\mathsf{UniformCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, T, U, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *row, including the bounded tail ledger, displayed monotone-cofinal schedule, and finite subsequence route already admitted by its local* $\mathsf{NameCert}$*;*
2. *T is the exposed tail-index schedule read from B, with no independent choice coordinate;*
3. *U is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *uniform tail-budget row, assigning one dyadic tolerance budget to all late windows that feed the subsequence readback;*
4. *W records the* $\mathsf{StreamName}^{\uparrow}$ *source and subsequence windows inspected under T and budgeted by U;*
5. *D records the local dyadic comparisons, endpoint rows, and late-window inequalities read from U, W;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback determined by B, T, U, W, D;*
7. *R records the real-facing regular subsequence handoff obtained from the same rows;*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after Q and R have been displayed;*

9. *H records componentwise* hsame *transport for all displayed analytic and support rows;*
10. *C records* Cont *replay through the route B, T, U, W, D, Q, R, E;*
11. *P is the* Pkg *provenance over* UniformCauchySubsequence$^{\uparrow}$, BoundedRegularCauchySubsequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* NameCert$_{\text{UniformCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, T, U, W, D, Q, R, E, H, C, P, N$. In particular, U is a named coordinate of the carrier, not a family reconstructed separately for each consumer read.

Lean4 ✓ `BEDC.Derived.UniformCauchySubsequenceUp.UniformCauchySubsequenceTasteGate single carrier alignment`

Theorem 1699.2 (Uniform tail-budget factorization)**.** *For every accepted* UniformCauchySubsequence$^{\uparrow}$ *carrier*

$$L = (B, T, U, W, D, Q, R, E, H, C, P, N),$$

every Real$^{\uparrow}$*-facing subsequence read factors through*

$$B, T, U, W, D, Q, R, E$$

before any seal coordinate is visible. Thus the common dyadic tail-budget row U is read before the finite StreamName$^{\uparrow}$ *windows, the* RegSeqRat$^{\uparrow}$ *readback, the regular subsequence handoff, and the terminal* Real$^{\uparrow}$ *seal.*

Proof. Project the accepted carrier of Definition 1699.1. Its source of subsequence data is B, and its exposed tail schedule is T; neither row contains a separate selected infinite subsequence.

The next mandatory row is U. By definition U is the shared DyadicRatCore$^{\uparrow}$ tail-budget coordinate, and the window row W is admitted only as the collection of StreamName$^{\uparrow}$ windows inspected under T and budgeted by U.

The local dyadic comparison row D is downstream of U, W. The readback row Q is then determined by B, T, U, W, D, and the handoff row R repacks the same displayed route for the real-facing subsequence read.

Finally, the seal row E is exposed only after Q and R. The remaining rows H, C, P, N transport, replay, source, and certify the displayed coordinates without adding a second route around U, so every visible seal read has the stated factorization. □

Theorem 1699.3 (UniformCauchySubsequence NameCert obligations)**.** *The local* NameCert$_{\text{UniformCauchySubsequence}^{\uparrow}}$ *row is generated by exactly the following five obligation rows:*

1. *carrier admission for the finite packet $B, T, U, W, D, Q, R, E, H, C, P, N$;*
2. *common tail-budget stability, asserting that* hsame *transport preserves the shared* DyadicRatCore$^{\uparrow}$ *row U and every late-window comparison read from it;*
3. *window and readback transport, carrying the* StreamName$^{\uparrow}$ *windows through T, U, D into the* RegSeqRat$^{\uparrow}$ *row Q and the regular subsequence handoff R;*
4. Real$^{\uparrow}$*-seal non-escape, asserting that no consumer reaches E without passing through B, T, U, W, D, Q, R;*
5. *provenance exactness for the displayed* Pkg *sources* UniformCauchySubsequence$^{\uparrow}$, BoundedRegularCauchySubseque StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$.

No additional row may name a selected infinite subsequence, quotient stream, countable choice witness, host-equality proof, or Real completeness principle.

Proof. Read the local certificate row N through the classifier of Definition 1699.1. The admissible coordinates of the carrier are precisely $B, T, U, W, D, Q, R, E, H, C, P, N$, so carrier admission is the first row and every later obligation must be a statement about these coordinates.

The common-budget row is forced by U. Since all window data in W is budgeted by U, componentwise hsame transport can preserve the packet only by preserving U and the dyadic comparisons recorded in D.

The transport and readback rows follow the displayed dependency order. Windows in W are read along T, comparisons in D are read from U, W, the rational readback Q is determined by B, T, U, W, D, and R is the same route repacked for the subsequence handoff.

The non-escape and provenance rows are the remaining classifier checks. The seal E has no incoming coordinate except Q, R, while P lists exactly the named sources of the packet. Therefore the five rows listed above generate the local certificate, and no excluded object has a coordinate from which a NameCert obligation could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchySubsequence}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformCauchySubsequence}^{\uparrow}}$, seed)

Scope closed: Definition 1699.1, Definition 1699.2, and Definition 1699.3 seed the finite common tail-budget route from bounded regular Cauchy subsequence data to $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and a $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformCauchySubsequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient streams, countable choice, host equality, Real completeness, Lean verification, or standard bridge checking.

Upgrade path: Formal closure requires checked carrier admission, common tail-budget stability, window and readback transport, Real-seal non-escape, and provenance exactness for BEDC.Derived.UniformCauchySubsequenceUp.

Constructive story: A $\mathsf{UniformCauchySubsequence}^{\uparrow}$ packet is generated from bounded regular Cauchy subsequence data, an exposed tail schedule, one shared DyadicRatCore budget row, StreamName windows, dyadic comparison rows, RegSeqRat readback, regular subsequence handoff, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1700

A Concrete Naming Certificate for $\mathsf{AbsoluteConvergence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{AbsoluteConvergence}^{\uparrow}$ packet records absolute domination of a real-valued series by a finite majorant route rather than by an ambient summability predicate. It sits over the real-series surface of chapter 1581, the fast tail budget of chapter 367, the Cauchy-majorant schedule of chapter 1774, the uniform Cauchy route of chapter 1736, the regular readback of chapter 301, the finite stream observations of chapter 126, the dyadic tolerance ledger of chapter 291, and the endpoint seal of chapter 38. The packet gives Weierstrass-style and real-power-series consumers one finite certificate for absolute domination, majorant-tail control, and $\mathsf{Real}^{\uparrow}$ nonescape without importing host infinite sums or ambient real completeness.

Definition 1700.1 (Absolute convergence carrier)**.** *An* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, M, B, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the real-valued term-stream row, read only through the finite* $\mathsf{RealSeries}^{\uparrow}$ *observations selected by the packet.*
2. *M is the majorant-stream row, recording the nonnegative comparison terms, displayed majorant partial sums, and the tail index attached to each tolerance request.*
3. *B is the absolute-domination ledger: each selected term observation from T is paired with its displayed majorant observation from M and the dyadic budget witnessing the absolute comparison.*
4. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *route obtained from the displayed domination ledger and the Cauchy-majorant budget.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected term, majorant, partial-sum, and tail-window observations opened by the packet.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after T, M, B, U, R have been displayed.*
7. *H stores componentwise* hsame *transport for the term stream, majorant stream, domination ledger, uniform Cauchy route, readback, Real seal, continuation, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from term reads to absolute comparisons, from comparisons to the majorant budget, from the budget to the uniform Cauchy route, from that route to regular readback, and from readback to the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{AbsoluteConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, B, U, R, E, H, C, P, N$. It has no coordinate for selected sums, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1700.2 (Absolute convergence NameCert obligations)**.** *For every accepted* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *carrier*

$$A = (T, M, B, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbsoluteConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the term stream, majorant stream, absolute-domination ledger, uniform Cauchy route, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *term and majorant window exactness, requiring T and M to expose only the selected finite observations and displayed partial-sum ledgers;*

3. *absolute-domination exactness, requiring B to pair each selected term read with its majorant read and its* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison budget;*

4. *Cauchy-majorant handoff, requiring U to be read only after the domination ledger and majorant-tail budget have been displayed;*

5. *regular readback, requiring R to expose only the selected* $\mathsf{StreamName}^{\uparrow}$ *windows opened by the term, majorant, domination, and uniform-Cauchy rows;*

6. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring E to be terminal with respect to T, M, B, U, R and to export no selected sum, quotient stream equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge data;*

7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No absolute-convergence obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1700.1. The accepted packet displays exactly the term stream T, majorant stream M, domination ledger B, uniform Cauchy route U, regular readback R, Real seal E, and structural rows H, C, P, N.

The term and majorant rows provide the only series observations. The domination row B then records the absolute comparison between each selected term observation and its displayed majorant observation, using the dyadic budget already visible to the packet.

The Cauchy-facing rows are downstream of that ledger. The row U consumes the domination ledger and the majorant-tail budget before any uniform Cauchy conclusion is available, and R reads back only the finite windows opened by this route.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since selected sums, quotient stream equality, countable choice, trichotomy, ambient completeness, Lean

verification, and bridge checking do not occur as carrier coordinates, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.AbsoluteConvergenceUp.AbsoluteConvergenceTasteGate single carrier alignment`

Theorem 1700.3 (Absolute convergence Cauchy-majorant handoff)**.** *Every Cauchy-facing read from an accepted* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *carrier factors through the route*

$$T \longmapsto M \longmapsto B \longmapsto U \longmapsto R.$$

Consequently the read must display the term stream, majorant stream, absolute-domination ledger, Cauchy-majorant budget, uniform Cauchy threshold, selected $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before it can serve a Completion or Real consumer.*

Proof. Start with a Cauchy-facing request. The carrier first exposes the term stream T and the majorant stream M, so the request has only selected finite observations of the series and the comparison stream.

The row B is then the unique absolute-domination ledger. It pairs the selected term reads with their displayed majorant reads and the dyadic comparison budget, so the request cannot bypass the majorant route.

The handoff to Cauchy control occurs through U and R. The row U records the uniform Cauchy route supported by the Cauchy-majorant budget, while R supplies the regular rational readback for the finite windows opened along that route.

Thus every Completion or Real consumer sees the displayed domination ledger, majorant budget, uniform threshold, selected stream windows, and regular readback before any endpoint-facing seal is available. □

Theorem 1700.4 (Absolute convergence Real seal nonescape)**.** *Every Real-facing read from an accepted* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *carrier reaches the terminal seal only through*

$$T \longmapsto M \longmapsto B \longmapsto U \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The read therefore exports no selected sum, quotient stream equality, countable-choice selector, trichotomy principle, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Use Definition 1700.3 to place every Real-facing request behind the term stream, majorant stream, absolute-domination ledger, uniform Cauchy route, and regular readback.

The terminal row E is a $\mathsf{Real}^{\uparrow}$ seal for this already displayed route. It is not a selected infinite sum, a quotient equality of streams, or a completeness theorem for arbitrary real names.

The structural rows H, C, P, N preserve and replay the same route componentwise. Because the carrier has no coordinate for the excluded principles, none of them can escape through the Real-facing boundary. □

Falsifiable prediction: Every $\mathsf{AbsoluteConvergence}^{\uparrow}$ Real-facing read factors through a real-valued term stream, a majorant stream, an absolute-domination ledger, a Cauchy-majorant budget, a uniform Cauchy threshold, selected StreamName windows, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, fastconvergentseries, cauchy-majorant-series, uniform-cauchy-series, regseqrat, streamname, dyadicratcore, real: $\mathsf{AbsoluteConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries term-stream access, a majorant stream, an absolute-domination

ledger, Cauchy-majorant handoff, uniform Cauchy thresholding, regular readback, Real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsoluteConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1700.1, Definition 1700.2, Definition 1700.3, and Definition 1700.4 seed the finite absolute-domination route from real-valued series data through majorant-tail control, uniform Cauchy thresholding, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsoluteConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, term and majorant window exactness, absolute-domination exactness, Cauchy-majorant handoff, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteConvergenceUp.

Constructive story: An $\mathsf{AbsoluteConvergence}^{\uparrow}$ packet is generated from a real-valued term stream, a majorant stream, an absolute-domination ledger, a uniform Cauchy route, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1701

A Concrete Naming Certificate for $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ packet records the finite route by which displayed convergence data for a real sequence supplies Cauchy readiness. It sits between the displayed-limit surface of chapter 1413, the Cauchy-consumer boundary of chapter 1590, the oscillation route of chapter 448, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is an induction-style L10 handoff from a displayed limit row to a late-pair Cauchy-test row; it is not a Real completeness theorem and it does not choose limits for arbitrary streams.

Definition 1701.1 (Convergent real sequence Cauchy carrier)**.** *A* $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (L, W, Q, D, T, E, H, R, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row, containing the displayed source sequence, the displayed limit* $\mathsf{Real}^{\uparrow}$ *row, the convergence tail schedule, and the local convergence classifier.*
2. *W stores the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected from the sequence and from the displayed limit row.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the sequence windows, limit windows, and late-pair rational observations opened by W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the split tolerance, triangle budget, and comparison entries used to turn two convergence reads into one late-pair Cauchy test.*
5. *T is the late-pair Cauchy-test ledger, pairing the two sufficiently late sequence indices with the shared limit row and the dyadic split budget.*
6. *E is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row, exposed only after L, W, Q, D, T have been displayed.*
7. *H records componentwise* hsame *transport for the limit row, stream windows, rational readback, dyadic ledger, late-pair test, Cauchy-consumer row, replay row, provenance row, and local naming row.*

8. *R records displayed* Cont *replay from a convergence request through the two late reads, the common limit, the dyadic split ledger, and the Cauchy-consumer row.*
9. *P is the* Pkg *provenance over* ConvergentRealSequenceCauchy$^{\uparrow}$, RealSequenceLimit$^{\uparrow}$, RealCauchyCriterion$^{\uparrow}$, CauchyOscillation$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{ConvergentRealSequenceCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, W, Q, D, T, E, H, R, P, N$. It has no coordinate for Real completeness, quotient streams, selected limits, trichotomy, countable choice, host sequence equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ConvergentRealSequenceCauchyUp.ConvergentRealSequenceCauchyTasteGate single carrier alignment`

Theorem 1701.2 (Convergent real sequence Cauchy NameCert obligations)**.** *For every accepted* ConvergentRealSequenceCauchy$^{\uparrow}$ *carrier*

$$C = (L, W, Q, D, T, E, H, R, P, N),$$

the local NameCert$_{\text{ConvergentRealSequenceCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* RealSequenceLimit$^{\uparrow}$ *row, finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *ledger, late-pair Cauchy-test ledger,* RealCauchyCriterion$^{\uparrow}$ *consumer row, transport, replay, provenance, and local naming rows;*
2. *limit-row exactness, requiring L to be the only source of the displayed sequence, displayed limit, and convergence tail schedule;*
3. *window and readback alignment, requiring W and Q to expose only the sequence, limit, and late-pair observations selected by L and T;*
4. *dyadic split exactness, requiring D to store the tolerance split and triangle comparison used by the late-pair test;*
5. *late-pair Cauchy-test exactness, requiring T to use two convergence reads from L against the same displayed limit row before any Cauchy consumer is exposed;*
6. *criterion handoff, requiring E to be read only after L, W, Q, D, T have been replayed;*
7. *componentwise transport, displayed replay, provenance, and local naming through H, R, P, N;*
8. *refusal of Real completeness, quotient streams, selected limits, trichotomy, countable choice, host sequence equality, Lean verification, and bridge checking as local certificate data.*

No convergent-real-sequence Cauchy obligation is stored outside these rows.

Proof. Project the carrier of Definition 1701.1. The visible packet consists of the displayed convergence row L, finite windows W, rational readback Q, dyadic ledger D, late-pair test T, Cauchy-consumer row E, and structural rows H, R, P, N.

The limit row is the only source of convergence data. It supplies the displayed sequence, the displayed limit, and the tail schedule that selects the two late reads used by the Cauchy test.

The window, readback, and dyadic rows align those two reads. The row W exposes only the selected sequence and limit windows, Q reads back the corresponding regular rational observations, and D records the split tolerance and triangle comparison.

The late-pair ledger T then forms the Cauchy test by comparing both late sequence values to the same displayed limit row. Only after that finite test is displayed can the $\mathsf{RealCauchyCriterion}^{\uparrow}$ row E be read.

Finally, H, R, P, N transport, replay, record, and name the same finite route. Since none of the excluded objects occur as carrier coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 1701.3 (Convergent real sequence Cauchy criterion handoff)**.** *Every* $\mathsf{RealCauchyCriterion}^{\uparrow}$*-facing read from an accepted* $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ *carrier*

$$C = (L, W, Q, D, T, E, H, R, P, N)$$

factors through the displayed finite route

$$L \longmapsto W \longmapsto Q \longmapsto D \longmapsto T \longmapsto E \longmapsto H, R, P, N.$$

Consequently the consumer receives one displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ *row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows for the sequence and limit,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance split, a late-pair Cauchy-test ledger, a* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *consumer row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The route exports no Real completeness theorem, quotient stream, selected limit, trichotomy principle, countable-choice selector, host sequence equality, Lean verification, or bridge checking.*

Proof. Begin with a Cauchy-facing read. The carrier has no direct Cauchy coordinate before E, so the read must first expose the displayed convergence row L.

The two late sequence observations are then opened through W and Q. These rows provide only the finite windows and rational readbacks selected by the convergence tail schedule and the late-pair request.

The tolerance accounting is supplied by D. Its split budget and triangle comparison turn the two reads against the common displayed limit into the late-pair ledger T.

The consumer row E is downstream of that ledger. Thus any $\mathsf{RealCauchyCriterion}^{\uparrow}$ use sees L, W, Q, D, T first, and the structural rows H, R, P, N only preserve and name the same route.

Because Real completeness, quotient streams, selected limits, trichotomy, countable choice, host sequence equality, Lean evidence, and bridge data are absent from the carrier, none of them can be exported by the handoff. □

Theorem 1701.4 (Convergent real sequence Cauchy late-pair exhaustion)**.** *Let*

$$C = (L, W, Q, D, T, E, H, R, P, N)$$

be an accepted $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ *carrier. Every accepted late-pair Cauchy-test ledger* T *is exhausted by two convergence reads from the same* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row* L*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* Q*, and one* $\mathsf{DyadicRatCore}^{\uparrow}$ *split ledger* D*. No third limit row, alternate window family, selected limit, quotient stream equality, trichotomy principle, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can participate in the Cauchy handoff.*

Proof. Project the accepted carrier. The only limit coordinate is L, the only finite-window coordinate is W, the only rational readback coordinate is Q, and the only tolerance-split coordinate is D.

Apply the limit-row exactness, window and readback alignment, and dyadic split exactness clauses of Definition 1701.2. These clauses force T to use two late reads selected by the same tail schedule in L, opened through W and Q, and compared with the split ledger recorded in D.

Now apply the criterion handoff theorem Definition 1701.3. The consumer row E is downstream of exactly the displayed route through L, W, Q, D, T.

Since the carrier has no coordinate for a third limit row, a second window family, a selected host limit, quotient stream equality, trichotomy, countable choice, or ambient completeness, none of those objects can enter the late-pair ledger or the downstream Cauchy read. □

Falsifiable prediction: Every $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ criterion-facing read factors through a displayed RealSequenceLimit row, finite StreamName windows for the sequence and limit, RegSeqRat readback, a DyadicRatCore tolerance split, a late-pair Cauchy-test ledger, a RealCauchyCriterion consumer row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real-sequence-limit, real-cauchy-criterion, cauchyoscillation, streamname, regseqrat, dyadicratcore, real: $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a displayed convergence row, selected sequence-and-limit windows, regular rational readback, dyadic split accounting, a late-pair Cauchy-test ledger, criterion handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}$ packet is generated from a RealSequenceLimit row, finite StreamName windows for the source sequence and displayed limit, RegSeqRat readback, a DyadicRatCore tolerance ledger, a late-pair Cauchy-test ledger, a RealCauchyCriterion consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1701.1, Definition 1701.2, Definition 1701.3, and Definition 1701.4 seed the finite route from displayed convergence data to Cauchy readiness through late-pair dyadic accounting, readback, criterion handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvergentRealSequenceCauchy}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConvergentRealSequenceCauchyUp.ConvergentRealSequenceCauchyTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient streams, selected limits, trichotomy, countable choice, host sequence equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, limit-row exactness, window and readback alignment, dyadic split exactness, late-pair Cauchy-test exactness, criterion handoff, transport, replay, provenance, and local naming for BEDC.Derived.ConvergentRealSequenceCauchyUp.

Chapter 1702

A Concrete Naming Certificate for $\mathsf{RegularCauchyMultiplication}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ packet records binary multiplication of displayed regular rational Cauchy real names as a finite bounded-window product route. It sits over the regular rational source rows of chapter 301, the synchronized window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the addition route of chapter 1695, the subtraction route of chapter 1696, the sign-flip route of chapter 459, the algebra packet of chapter 1470, and the terminal real-name seal of chapter 38. The packet is the finite product surface consumed by later Real algebra and completion routes; it is not host real multiplication, a quotient Cauchy-class operation, a selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1702.1 (RegularCauchyMultiplication carrier)**.** *A* $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B_{\times} = (X, Y, W, D, B, E, M, Z, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for regular rational Cauchy real names.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window ledger aligning the finite observations of X and Y at every product-facing precision request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the two source tolerance rows, the displayed endpoint products, and the dyadic product tolerance row.*
4. *B is the finite bounding ledger used to choose a product window large enough for the two source magnitudes and the requested output tolerance.*
5. *E is the finite error-budget accounting row combining source tolerance, bounding data, dyadic product tolerance, and the output tolerance required by the product readback.*
6. *M is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed binary multiplication route.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the two source rows, synchronized windows, dyadic tolerance rows, bounding ledger, finite error budget, and product readback have been displayed.*
8. *H records componentwise* hsame *transport for the source rows, synchronized windows, dyadic ledger, bounding ledger, finite budget row, readback, seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from any multiplication-facing precision request through* $X, Y, W, D, B, E, M, Z, H$
10. *P is the* Pkg *provenance over* RegularCauchyMultiplication$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegularCauchyAddition$^\uparrow$, RegularCauchySubtraction$^\uparrow$, RegularCauchyNegation$^\uparrow$, RegularCauchyRing$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RegularCauchyMultiplication}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, B, E, M, Z, H, C, P, N$. The carrier has no coordinate for host real multiplication, quotient Cauchy classes, selected limits, trichotomy, ambient Real$^\uparrow$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMultiplicationUp.TasteGate.RegularCauchyMultiplicationTasteGate`
`single carrier alignment`

Theorem 1702.2 (Regular Cauchy multiplication NameCert obligations)**.** *For every accepted* RegularCauchyMultiplication$^\uparrow$ *carrier*

$$B_\times = (X, Y, W, D, B, E, M, Z, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMultiplication}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* RegSeqRat$^\uparrow$ *source rows, synchronized* StreamName$^\uparrow$ *windows, dyadic tolerance rows, finite bounding ledger, finite error-budget row, product readback,* Real$^\uparrow$ *seal row, and structural rows;*
2. *synchronized-window exposure, requiring each multiplication-facing precision request to inspect the two source windows before any endpoint product row is available;*
3. *dyadic endpoint product, requiring D to be read from the displayed source observations and tolerance rows through the* DyadicRatCore$^\uparrow$ *arithmetic route;*
4. *bounding handoff, requiring B to record enough finite source-magnitude information to allocate the product tolerance without appealing to a completed real norm or global order;*
5. *finite error-budget accounting, requiring E to combine the source tolerance, bounding data, dyadic product tolerance, and output tolerance before M is available;*
6. *Real seal nonescape, requiring every* Real$^\uparrow$ *consumer to read the route through X, Y, W, D, B, E, M before any terminal seal is exposed;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite multiplication packet;*
8. *refusal of host real multiplication, quotient Cauchy classes, selected limits, trichotomy, ambient* Real$^\uparrow$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No multiplication obligation is stored outside these finite rows.

Theorem 1702.3 (Regular Cauchy multiplication Real seal handoff)**.** *Every Real-facing product read exported by an accepted* RegularCauchyMultiplication$^\uparrow$ *carrier factors through the finite route*

$$(X, Y) \longmapsto W \longmapsto D \longmapsto B \longmapsto E \longmapsto M \longmapsto Z$$

before it may be consumed as a completed real-name boundary. Thus the consumer receives two regular rational source rows, synchronized StreamName$^\uparrow$ *windows,* DyadicRatCore$^\uparrow$ *tolerance and*

endpoint-product rows, a finite bounding ledger, a finite product-budget ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ *product readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. It receives no host real multiplication, quotient Cauchy class, selected limit, trichotomy, ambient completeness coordinate, Lean verification, or bridge checking.*

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMultiplication}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMultiplication}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1702.1, Definition 1702.2, and Definition 1702.3 seed the finite binary multiplication route through $\mathsf{RegSeqRat}^{\uparrow}$ source rows, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and endpoint-product rows, finite bounding and error-budget rows, resulting $\mathsf{RegSeqRat}^{\uparrow}$ product readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMultiplication}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyMultiplicationUp.TasteGate.RegularCauchyMultiplicationTasteGate\_single\_c`

Bridge status: none

Not claimed: This chapter does not close host real multiplication, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, dyadic endpoint product, finite bounding, finite error-budget accounting, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMultiplicationUp.

Constructive story: A $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, synchronized $\mathsf{StreamName}^{\uparrow}$ finite-window schedules, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and endpoint-product rows, a finite bounding ledger, a finite error-budget row, a resulting $\mathsf{RegSeqRat}^{\uparrow}$ product readback, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1703

A Concrete Naming Certificate for $\mathsf{PrimitiveRecursion}^{\uparrow}$

Kleene/Dedekind-style primitive recursion grounding reads a function over unary depth by naming the seed row, the displayed step row, and the finite trace that iterates the step along a $\mathsf{Nat}^{\uparrow}$ spine. The $\mathsf{PrimitiveRecursion}^{\uparrow}$ packet sits after the unary-history surface of chapter 28, the continuation addition route of chapter 29, the finite-window schedule surface of chapter 126, the regular rational readback route of chapter 301, and the regular Cauchy subtraction consumer of chapter 1696. It gives L10 Real and Completion chapters a displayed schedule generator over unary indices; it is not host natural-number recursion, a partial-recursive minimisation principle, quotient stream equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1703.1 (PrimitiveRecursion carrier)**.** *A* $\mathsf{PrimitiveRecursion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, T, U, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Nat}^{\uparrow}$ *unary-depth row. It is the only index spine along which the recursion may advance.*
2. *S is the seed row. It records the value exposed at depth zero before any step row is replayed.*
3. *T is the step row. It records one displayed successor transition, with its predecessor value, successor depth, and output value carried as finite* BHist *data.*
4. *U is the recursive trace row. It is a finite UnaryHistory list of seed-and-step applications from S along D to the terminal value named by the packet.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule handoff. It converts a requested unary index into the finite window schedule that downstream stream consumers may inspect.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *schedule consumer row. It records the regular rational readback that consumes the schedule exported by W.*
7. *H records componentwise* hsame *transport for the unary depth, seed, step, trace, stream schedule, regular rational consumer, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from any schedule-facing request through $D, S, T, U, W, Q, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{PrimitiveRecursion}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchySubtraction}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimitiveRecursion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, T, U, W, Q, H, C, P, N$. The carrier has no coordinate for host natural-number recursion, unbounded minimisation, quotient stream equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PrimitiveRecursionUp.TasteGate.PrimitiveRecursionTasteGate single carrier alignment`

Theorem 1703.2 (PrimitiveRecursion NameCert obligations)**.** *For every accepted* $\mathsf{PrimitiveRecursion}^{\uparrow}$ *carrier*

$$R = (D, S, T, U, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrimitiveRecursion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{Nat}^{\uparrow}$ *unary-depth row, seed row, step row, recursive trace,* $\mathsf{StreamName}^{\uparrow}$ *schedule handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *schedule consumer, and structural rows;*
2. *seed exactness, requiring the trace U to expose S at the zero depth before any successor transition is read;*
3. *step exactness, requiring each successor cell of U to be obtained by replaying the displayed step row T from the previous trace value;*
4. *unary-depth coverage, requiring the terminal trace cell to occur at the displayed depth D and not at an ambient host index;*
5. *schedule handoff, requiring every stream-facing request to pass through W before any* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer row Q is inspected;*
6. *componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite recursion packet;*
7. *refusal of host natural-number recursion, unbounded minimisation, quotient stream equality, countable choice, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No primitive-recursion obligation is stored outside these rows.

Proof. Carrier admission is the projection of Definition 1703.1. The projected rows are precisely the unary depth D, seed S, step row T, trace U, schedule W, regular consumer Q, and structural rows H, C, P, N.

Seed exactness is the zero-depth face of the UnaryHistory trace. Before any successor cell is present, the trace has only the displayed seed row, so the certificate cannot read a hidden initial value from a host recursion operator.

Step exactness is checked cell by cell. Each successor cell in U names its predecessor value, successor depth, and output value through T, while $\mathsf{Add}^{\uparrow}$ supplies only the unary continuation discipline needed to move from one displayed depth to the next.

The terminal-depth and schedule obligations then follow from the order of the rows. The trace reaches the displayed $\mathsf{Nat}^{\uparrow}$ row D before W is available, and Q is downstream of W, so regular rational consumers receive only the finite schedule generated by the packet.

Finally, H, C, P, N transport, replay, package, and name the same rows. Since none of these structural rows contains host recursion, minimisation, quotient equality, choice, selected limits, completeness, Lean verification, or bridge checking, the seven listed rows exhaust the local NameCert surface. □

Theorem 1703.3 (PrimitiveRecursion unary schedule realization)**.** *Let $R = (D, S, T, U, W, Q, H, C, P, N)$ be an accepted* $\mathsf{PrimitiveRecursion}^{\uparrow}$ *carrier. The schedule row W is realized by induction on the UnaryHistory trace U: the zero cell reads the seed row S, and each successor cell reads the preceding trace value together with the displayed step row T. Consequently every schedule exported by W is indexed by the* $\mathsf{Nat}^{\uparrow}$ *depth D and by no host natural-number recursion coordinate.*

Lean4 ✓ `BEDC.Derived.PrimitiveRecursionUp.PrimitiveRecursionCarrier unary schedule realization`

Proof. Induct on the UnaryHistory trace row U. In the base case the only admitted trace cell is the displayed seed S, and the schedule opened by W has zero-depth source D.

For a successor trace, apply the induction hypothesis to the predecessor trace. The next cell is admitted only by replaying the displayed step row T against that predecessor value and the successor depth supplied by the $\mathsf{Nat}^{\uparrow}$ spine.

The $\mathsf{Add}^{\uparrow}$ dependency is only the continuation route between adjacent unary depths. It contributes no independent recursion principle, so the terminal schedule remains the finite trace schedule already named by U and W. □

Theorem 1703.4 (PrimitiveRecursion StreamName and RegSeqRat handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{PrimitiveRecursion}^{\uparrow}$ *carrier factors through the finite route*

$$D \longmapsto S \longmapsto T \longmapsto U \longmapsto W \longmapsto Q \longmapsto H, C, P, N.$$

Thus downstream L10 Real and Completion consumers, including routes that later use $\mathsf{RegularCauchySubtraction}^{\uparrow}$*, receive a displayed unary schedule, seed, step, trace, stream window schedule, regular rational consumer row, transport, replay, provenance, and local naming. They receive no host natural-number recursion, unbounded minimisation, quotient stream equality, countable choice, selected limit, ambient completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PrimitiveRecursionUp.PrimitiveRecursionStreamScheduleHandoff`

Proof. Begin with a stream-facing or regular-rational-facing read of R. By Definition 1703.1, the only stream schedule coordinate is W, and the only regular rational consumer coordinate is Q.

The row W is downstream of the unary depth D, seed S, step row T, and trace U. By Definition 1703.3, this means the schedule has already been generated by the displayed UnaryHistory induction before any stream window may be inspected.

The row Q then consumes W through the regular rational readback surface of chapter 301. Later real and completion routes may pass that scheduled read to sibling consumers such as chapter 1696, but they cannot bypass the displayed route.

Componentwise transport, replay, provenance, and local naming preserve the same order. Hence every exported read factors through the stated finite route and exposes none of the excluded ambient data. □

Theorem 1703.5 (PrimitiveRecursion RegSeqRat consumer induction)**.** *Let $R = (D, S, T, U, W, Q, H, C, P, N)$ be an accepted* $\mathsf{PrimitiveRecursion}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of R is obtained by induction on the displayed UnaryHistory trace U before the consumer row Q is read: the base step reads the seed row S, the successor step reads the displayed step row T against the predecessor trace cell, the schedule step reads W only after that induction has generated the requested finite window, and the regular rational consumer step reads Q only after D, S, T, U, W are visible.*

Consequently L10 Real and Completion consumers inherit exactly the UnaryHistory induction route of the packet. They do not receive host recursion, unbounded minimisation, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness as part of the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Project the carrier in Definition 1703.1. The only recursion-bearing row is the displayed trace U, whose zero face is S and whose successor face is replay of T along the unary depth row D.

Induct on U. In the base case, the consumer sees only the seed row S before any stream schedule exists. In the successor case, the predecessor trace value is already available by the induction hypothesis, and the next value is admitted only through the displayed step row T.

After the trace cell is produced, apply Definition 1703.3. The schedule row W is therefore a finite window generated from D, S, T, U, not a host recursion coordinate.

Finally apply Definition 1703.4. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q consumes that schedule and cannot move ahead of it, while H, C, P, N only transport, replay, source, and name the same finite packet. The excluded principles are absent from the carrier and hence absent from the consumer induction route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrimitiveRecursion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1703.1, Definition 1703.2, Definition 1703.3, and Definition 1703.4 seed the finite unary-history recursion schedule over $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RegularCauchySubtraction}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host natural-number recursion, unbounded minimisation, quotient stream equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, seed exactness, step exactness, unary-depth coverage, StreamName schedule handoff, RegSeqRat consumer handoff, componentwise transport, replay, provenance, and local naming for BEDC.Derived.PrimitiveRecursionUp.

Constructive story: A $\mathsf{PrimitiveRecursion}^{\uparrow}$ packet is generated from a $\mathsf{Nat}^{\uparrow}$ unary-depth row, a seed row, a displayed step row, a finite UnaryHistory recursive trace, a $\mathsf{StreamName}^{\uparrow}$ schedule handoff, a $\mathsf{RegSeqRat}^{\uparrow}$ schedule consumer, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1704

A Concrete Naming Certificate for $\mathsf{SternBrocot}^{\uparrow}$

Following Stern–Brocot and Farey rational approximation, the $\mathsf{SternBrocot}^{\uparrow}$ packet records the finite rational tree whose adjacent boundary rows have determinant one and whose mediant steps refine rational intervals without choosing a host real representative. It sits above the bracketing approximation packet of chapter 1431 and the breadth-first positive-rational enumeration packet of chapter 1474. Its L10 real-readback neighbors are the continued-fraction route of chapter 342 and the rational-stream route of chapter 350; the packet itself stores only finite tree addresses, rational boundary rows, mediant rows, transport, replay, provenance, and naming.

Definition 1704.1 (Stern–Brocot tree carrier)**.** *A* $\mathsf{SternBrocot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, L, U, M, F, B, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite address row, recording the left/right path from the root interval to the inspected tree node.*
2. *L and U are the lower and upper* $\mathsf{Rat}^{\uparrow}$ *boundary rows bracketing the inspected node.*
3. *M is the mediant row computed from L and U at the addressed node.*
4. *F is the Farey-neighbor ledger, recording the determinant-one boundary check for the displayed pair L, U.*
5. *B is the finite branch ledger, recording which boundary is replaced by M after each inspected step.*
6. *Q is the rational-tree output row exposed to the sibling* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *and* $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ *packets.*
7. *R is the* $\mathsf{RationalStream}^{\uparrow}$ *readback row used when finite tree nodes are consumed as a rational source for L10 real and completion routes.*
8. *H records componentwise* hsame *transport for address, boundary, mediant, Farey-ledger, branch, output, rational-stream, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an address request through boundary inspection, mediant construction, Farey-neighbor checking, branch replacement, tree output, and rational-stream readback.*

10. *P is the* Pkg *provenance over* $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{CalkinWilfEnumeration}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocot}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, U, M, F, B, Q, R, H, C, P, N$. The carrier has no coordinate for Dedekind cuts, host trichotomy, quotient rational equality, selected real representatives, ambient completeness, or Lean verification.

Lean4 ✓ `BEDC.Derived.SternBrocotUp.TasteGate.SternBrocotTasteGate single carrier alignment`

Theorem 1704.2 (Stern–Brocot NameCert obligations)**.** *For every accepted* $\mathsf{SternBrocot}^{\uparrow}$ *carrier*

$$S = (A, L, U, M, F, B, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SternBrocot}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the address, boundary, mediant, Farey-neighbor, branch, rational-tree output, rational-stream readback, and structural rows;*
2. *mediant exactness, requiring M to be the displayed numerator-denominator sum of the currently displayed boundary rows L and U;*
3. *Farey-neighbor boundary, requiring F to record determinant-one adjacency for every displayed boundary pair before and after a branch step;*
4. *branch discipline, requiring B to replace exactly one displayed boundary by the displayed mediant at each finite address step;*
5. *sibling readback, requiring every* $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{CalkinWilfEnumeration}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, *or* $\mathsf{RationalStream}^{\uparrow}$ *consumer to pass through Q and R before using the tree node as rational data;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming, requiring H, C, P, N to preserve and name the same finite tree packet;*
7. *refusal of Dedekind cuts, host trichotomy, quotient rational equality, selected representatives, ambient completeness, and Lean verification as local NameCert data.*

No Stern–Brocot obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.SternBrocotUp.SternBrocotTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1704.1. The accepted tuple exposes exactly the address, boundary, mediant, Farey-ledger, branch, output, rational-stream, transport, replay, provenance, and local naming rows listed in the statement.

Mediant exactness is local to M. The row records the numerator-denominator sum of the displayed boundary rows L and U, so no host rational search or quotient-rational comparison is needed to name the inspected node.

The Farey-neighbor and branch obligations are read together. The row F records determinant-one adjacency for the current displayed pair, and B records the single boundary replacement by M that advances the finite address. Thus the next inspected pair is still a displayed tree boundary pair.

The sibling readback obligation follows from the order of the carrier rows. The approximation and enumeration siblings consume the same rational-tree output row Q, while continued-fraction and rational-stream consumers read through R before passing data to L10 real routes.

Finally, H, C, P, N transport, replay, package, and name the same finite inventory. Since the inventory has no coordinate for Dedekind cuts, trichotomy, quotient rational equality, selected representatives, ambient completeness, or Lean verification, the listed obligations exhaust the local certificate. □

Theorem 1704.3 (Stern–Brocot Farey neighbor boundary)**.** *Let $S = (A, L, U, M, F, B, Q, R, H, C, P, N)$ be an accepted* $\mathsf{SternBrocot}^{\uparrow}$ *carrier. At every finite prefix of the address row A, the displayed boundary rows L and U named by the corresponding branch prefix are Farey neighbors according to F, and the mediant row M lies between them as the next displayed tree node. Every public boundary read factors through*

$$A \longmapsto L, U \longmapsto M \longmapsto F \longmapsto B \longmapsto Q \longmapsto R.$$

The boundary claim is only about the finite Stern–Brocot tree surface. It does not assert Dedekind cut locatedness, host trichotomy, quotient-real equality, selected representatives, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SternBrocotUp.FareyNeighborBoundary.SternBrocotFareyNeighborBoundary`

Proof. Induct on the finite address prefix in A. At the root prefix the carrier supplies the displayed boundary rows L and U together with the Farey-neighbor ledger F, so the determinant-one boundary is read from the packet itself.

For a successor prefix, use the branch row B. It records whether the left or right boundary is replaced by the mediant row M, and it leaves the other boundary unchanged as displayed BHist data.

The new boundary ledger is again the row F for the successor prefix. Because F is stored as part of the same finite carrier, the determinant-one check is replayed by displayed data rather than by an ambient rational-order principle.

The public readback route then follows the output rows. The rational-tree node is exposed through Q, and L10 real-readback consumers receive it only after the $\mathsf{RationalStream}^{\uparrow}$ row R has been inspected. □

Theorem 1704.4 (Stern–Brocot sibling route to real readback)**.** *Every accepted* $\mathsf{SternBrocot}^{\uparrow}$ *packet supplies a finite rational-tree source for the approximation route of chapter 1431, the enumeration route of chapter 1474, the continued-fraction comparison route of chapter 342, and the rational-stream source route of chapter 350. Each such route reads the same displayed address, boundary, mediant, Farey-neighbor, branch, output, rational-stream, transport, replay, provenance, and local naming rows, and no route receives an independent real representative or ambient completion field.*

Lean4 ✓ `BEDC.Derived.SternBrocotUp.SternBrocotL10RealReadbackRoute`

Proof. Start with an accepted carrier $S = (A, L, U, M, F, B, Q, R, H, C, P, N)$. The tree-facing data are exactly A, L, U, M, F, B, Q, and the rational-stream handoff is exactly R.

The Stern–Brocot approximation sibling reads Q as finite bracketing data and then applies its own tolerance and real-seal rows. The Calkin-Wilf enumeration sibling reads the same finite tree output as positive-rational enumeration data, but it contributes its own breadth-first schedule outside the $\mathsf{SternBrocot}^{\uparrow}$ carrier.

The continued-fraction and rational-stream siblings are readback consumers. They receive the finite rational node only through R, so the real-facing path is a rational-source path rather than a selected host real.

Componentwise transport and replay preserve this route for classified packets. The package and local naming rows record exactly the same dependency surface, so no independent representative, quotient completion, ambient real order, or completeness field is exported. □

Theorem 1704.5 (Stern–Brocot rational interval-tree consumer)**.** *Every* $\mathsf{RationalIntervalTree}^{\uparrow}$ *consumer using a* $\mathsf{SternBrocot}^{\uparrow}$ *source reads finite boundary pairs, mediant rows, Farey-neighbor ledgers, dyadic tolerances,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows before any Real-facing approximation is public. The handoff factors through the* $\mathsf{SternBrocot}^{\uparrow}$ *route of Definition 1704.4 and the rational interval-tree carrier of Definition 7691.1; it exports no selected real representative, quotient equality, host trichotomy, or ambient Real completeness.*

Proof. Start with the accepted $\mathsf{SternBrocot}^{\uparrow}$ carrier. By Definition 1704.4, every real-readback consumer sees the finite address, boundary, mediant, Farey-neighbor, branch, output, rational-stream, transport, replay, provenance, and local naming rows before any real-facing use.

Now attach the rational interval-tree carrier of Definition 7691.1. Its boundary rows L, U, split row M, branch ledger B, dyadic tolerance ledger Q, stream window S, regular-rational readback R, and Real seal E are precisely the finite interval-refinement rows consumed downstream.

The bisection-window theorem Definition 7691.3 orders those rows before any public Real-facing approximation. Composing the two finite routes gives the stated handoff from Stern–Brocot boundary data to the rational interval-tree consumer surface.

Both routes refuse selected representatives, quotient equality, host trichotomy, and ambient completeness as carrier coordinates. Hence the composed consumer receives only finite boundary, mediant, Farey-neighbor, tolerance, window, readback, and seal rows. □

Lean4 ✓ `BEDC.Derived.SternBrocotUp.SternBrocotRationalIntervalTreeConsumer`

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocot}^{\uparrow}}$.

Constructive story: A $\mathsf{SternBrocot}^{\uparrow}$ packet is generated from a finite address row, two displayed rational boundary rows, a mediant row, a Farey-neighbor ledger, a finite branch ledger, a rational-tree output row, a $\mathsf{RationalStream}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1704.1, Definition 1704.2, Definition 1704.3, and Definition 1704.4 seed the finite Stern–Brocot rational-tree certificate above the approximation and enumeration siblings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SternBrocot}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, host trichotomy, quotient rational equality, selected representatives, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mediant exactness, Farey-neighbor boundary, branch discipline, sibling readback, transport, replay, provenance, and local naming for the same finite packet.

Chapter 1705

A Concrete Naming Certificate for $\mathsf{EffectiveCauchySequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{EffectiveCauchySequence}^{\uparrow}$ packet records a Cauchy sequence whose convergence is exposed by an explicit modulus before any $\mathsf{RegSeqRat}^{\uparrow}$ handoff or terminal $\mathsf{Real}^{\uparrow}$ seal is read. It sits on the finite-window route of chapter 126, the modulus schedule surface of chapter 292, the dyadic tolerance ledger of chapter 291, the regular rational readback boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet is a source-level certificate for explicit-modulus Cauchy sequence data on the current Real and Completion route; it is not quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1705.1 (Effective Cauchy sequence carrier)**.** *An* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, M, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence source row. It names the displayed source of observations whose finite windows are inspected by Real-facing or Completion-facing consumers.*
2. *M is the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row. For each requested positive tolerance it gives the finite stage after which the source row is to be read within that tolerance.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the actual inspected source windows downstream of the modulus schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the dyadic radii, slack rows, comparison budgets, and tolerance conversions used by M and W.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It records the regular rational readback obtained only after the source, modulus, window, and dyadic ledger rows have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached downstream of S, M, W, D, Q.*
7. *H records componentwise* hsame *transport for the source, modulus, window, dyadic ledger, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion request through $S, M, W, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequence}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite explicit-modulus Cauchy sequence packet. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.TasteGate.EffectiveCauchySequenceUpTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceTasteGate single carrier alignment`

Theorem 1705.2 (Effective Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier $G = (S, M, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed sequence source, explicit modulus, finite stream windows, dyadic tolerance ledger, regular rational handoff, Real seal, transport, replay, provenance, and local naming rows;*
2. *modulus exposure, requiring every tolerance request to read M before the corresponding window row W is consumed;*
3. *dyadic tolerance accounting, requiring every use of the modulus to pass through the dyadic radii, slack rows, comparison budgets, and tolerance conversions stored in D;*
4. *regular readback, requiring Q to be downstream of the source, modulus, window, and dyadic rows before any regular rational observation is exported;*
5. *Real seal boundary, requiring E to remain downstream of S, M, W, D, Q and never to serve as quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient completeness;*
6. *transport, replay, provenance, and local naming stability, requiring H, C, P, N to preserve and name exactly the displayed packet.*

No effective-Cauchy-sequence obligation is stored outside these rows.

Proof. Carrier admission is the projection of Definition 1705.1. The projected rows are exactly the sequence source S, explicit modulus M, finite windows W, dyadic ledger D, regular readback Q, Real seal E, and structural rows H, C, P, N.

Modulus exposure reads chapter 292 together with the finite-window discipline of chapter 126. A tolerance request cannot reach the inspected window row W until the corresponding stage has first been supplied by M.

Dyadic tolerance accounting is supplied by chapter 291. The row D is the only displayed place where radii, slack, comparison budgets, and tolerance conversions live, so every modulus-guided read must pass through it before reaching the regular readback.

The regular readback and Real boundary then follow the route of chapter 301 and chapter 38. Since Q and E are downstream of S, M, W, D, neither row can introduce a quotient stream, selected limit, countable choice, trichotomy, host real equality, or ambient completeness datum.

Finally, H, C, P, N transport, replay, package, and name the same displayed rows. They add no analytic coordinate beyond the carrier, so the six listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceCarrier namecert obligations`

Theorem 1705.3 (Effective Cauchy sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier* $G = (S, M, W, D, Q, E, H, C, P, N)$ *factors through the finite route*

$$S \longmapsto M \longmapsto W \longmapsto D \longmapsto Q \longmapsto H, C, P, N.$$

Thus a regular rational consumer receives the displayed source, explicit modulus, finite stream windows, dyadic tolerance ledger, regular readback, transport, replay, provenance, and local naming before it can inspect the handoff.

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$ read of G. By Definition 1705.1, the only regular readback coordinate is Q, and Q is placed after the source, modulus, window, and dyadic ledger rows.

The first part of the route reads S through the window interface of chapter 126. The explicit stage discipline is then supplied by M through chapter 292, and the inspected finite windows are recorded by W.

The tolerance conversion and comparison work is read through D using chapter 291. Only after that dyadic ledger is fixed does chapter 301 expose the regular rational handoff Q.

The rows H, C, P, N preserve and name the same order. Therefore every regular rational read factors through the displayed route and has no bypass through quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceCarrier regseqrat handoff`

Theorem 1705.4 (Effective Cauchy sequence modulus readback)**.** *Let* $G = (S, M, W, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier. The explicit modulus row* M *determines the dyadic tolerance budget consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* Q *and by the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary* E*: every such read must pass through the same finite route*

$$S \longmapsto M \longmapsto W \longmapsto D \longmapsto Q \longmapsto E$$

before transport, replay, provenance, or local naming can export it.

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceModulusReadback`

Proof. Start with the carrier inventory of Definition 1705.1. The row M is the only explicit modulus coordinate, and the row D is the only dyadic tolerance ledger available to the packet.

The NameCert obligations of Definition 1705.2 require every tolerance request to expose M before the corresponding finite windows W are consumed. The same obligations require all radii, slack rows, comparison budgets, and tolerance conversions to pass through D.

Apply the RegSeqRat handoff theorem Definition 1705.3. It places the regular rational readback Q downstream of S, M, W, D, so the dyadic budget consumed by Q is exactly the one selected by the displayed modulus route.

The Real seal boundary of Definition 1705.5 then places E downstream of the same handoff. By the non-escape theorem Definition 1705.7, no quotient, selected limit, choice, trichotomy, host equality, ambient completeness, Lean, or bridge datum can replace that budget outside the displayed rows. □

Theorem 1705.5 (Effective Cauchy sequence Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier* $G = (S, M, W, D, Q, E, H, C, P, N)$ *factors through*

$$S \longmapsto M \longmapsto W \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the terminal Real seal is available only after the source, explicit modulus, finite windows, dyadic tolerance ledger, and regular rational handoff have been displayed.

Proof. Start from a $\mathsf{Real}^{\uparrow}$-facing consumer. The carrier definition exposes the terminal seal only as the row E in the same finite packet as $S, M, W, D, Q, H, C, P, N$.

Replay the continuation row C. The consumer first reads the source row S, obtains the requested stage from the explicit modulus M, inspects the finite stream windows W, and checks the dyadic tolerance ledger D before any regular rational handoff can be consumed.

The regular readback Q then supplies the only route into the terminal seal of chapter 38. Since E is downstream of Q, the Real-facing read cannot export quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Componentwise transport, replay, provenance, and local naming preserve the route. Hence every Real-facing read factors through the displayed source-to-seal boundary. □

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceRealSealBoundary`

Theorem 1705.6 (Effective Cauchy sequence extractor handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier* $G = (S, M, W, D, Q, E, H, C, P, N)$ *that reads through a* $\mathsf{CauchyModulusExtractor}^{\uparrow}$ *route must expose the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M *before any finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{Real}^{\uparrow}$ *seal row is consumed.*

Proof. Project the carrier of Definition 1705.1. The explicit modulus row M is listed before the finite window row W, dyadic ledger D, regular readback Q, and terminal seal E.

The NameCert obligations of Definition 1705.2 require modulus exposure for every tolerance request. Thus a consumer routed through a $\mathsf{CauchyModulusExtractor}^{\uparrow}$ packet must read M before it can open the corresponding finite StreamName window.

The RegSeqRat handoff theorem Definition 1705.3 then places Q downstream of S, M, W, D. The Real seal boundary theorem Definition 1705.5 places E downstream of the same route.

Therefore the extractor handoff cannot consume a finite window, dyadic tolerance ledger, regular readback, or Real seal before the explicit Cauchy modulus row has been displayed. □

Theorem 1705.7 (Effective Cauchy sequence non-escape)**.** *Let* $G = (S, M, W, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *carrier. No consumer of* G *can read quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from the packet unless that datum is already one of the displayed rows* $S, M, W, D, Q, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceUp.EffectiveCauchySequenceNonescape`

Proof. Inspect the carrier rows in Definition 1705.1. The analytic rows are only the source, explicit modulus, finite windows, dyadic ledger, regular readback, and terminal Real seal.

The structural rows H, C, P, N provide sameness transport, replay, provenance, and local naming for those same rows. They do not add a quotient relation, limit selector, choice principle, order decision, host equality predicate, completeness theorem, Lean target, or bridge certificate.

Therefore the excluded data have no carrier coordinate, replay edge, provenance entry, or local NameCert row from which to be read. Any consumer of G is confined to the displayed explicit-modulus route. □

Falsifiable prediction: Every $\mathsf{EffectiveCauchySequence}^{\uparrow}$ regular or Real-facing read factors through a sequence source row, explicit CauchyModulus row, finite StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat handoff, RealUp seal, transport, replay, provenance, and local naming.

Independence witness: streamname, cauchymodulus, dyadicratcore, regseqrat, real: $\mathsf{EffectiveCauchySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source row, explicit modulus, finite windows, tolerance ledger, regular handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1705.1, Definition 1705.2, Definition 1705.3, Definition 1705.5, and Definition 1705.7 seed the finite explicit-modulus Cauchy sequence route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exposure, dyadic tolerance accounting, regular readback, Real seal boundary, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.EffectiveCauchySequenceU

Constructive story: An $\mathsf{EffectiveCauchySequence}^{\uparrow}$ packet is generated from a displayed sequence source, explicit $\mathsf{CauchyModulus}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1706

A Concrete Naming Certificate for $\mathsf{EffectivePolishSpace}^{\uparrow}$

Following Alexandrov-Urysohn and Weihrauch, the $\mathsf{EffectivePolishSpace}^{\uparrow}$ packet records complete separable metric data with a visible dense enumeration and explicit Cauchy realizer route before any Polish or Real consumer reads the completed object. It sits over the Polish-space boundary of chapter 1490, the indexed dense-window surface of chapter 1566, the explicit-modulus Cauchy route of chapter 1705, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names effective complete-separable metric data on the current Real and Completion route; it is not a choice-selected dense set, quotient completion equality, open-cover compactness, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1706.1 (Effective Polish space carrier)**.** *An* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (P, D, Q, S, R, M, L, H, C, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *row, carrying the complete separable metric surface that downstream Polish consumers are allowed to inspect.*
2. *D is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *row, exposing the indexed dense family and the finite dense windows cited by precision requests.*
3. *Q is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *row, carrying the explicit-modulus Cauchy data generated from the displayed dense indices.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, listing the finite observation windows through which dense indices and Cauchy stages are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the dense index, stream window, and effective Cauchy rows have been displayed.*
6. *M is the dyadic and Real tolerance ledger, storing radii, slack rows, comparison budgets, and seal thresholds used by D, Q, S, R.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the displayed readback route.*
8. *H records componentwise* hsame *transport for the Polish row, dense row, effective Cauchy row, stream windows, regular readback, tolerance ledger, Real seal, and structural rows.*

9. *C records displayed* Cont *replay from a Polish or Real request through $D, S, Q, R, M, L, H, G, N$.*

10. *G is the* Pkg *provenance over* EffectivePolishSpace$^{\uparrow}$, PolishSpace$^{\uparrow}$, CountableDenseSubset$^{\uparrow}$, EffectiveCauchySequer StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{EffectivePolishSpace}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite effective complete-separable metric packet. It has no coordinate for choice-selected dense points, quotient completion equality, open-cover compactness, ambient Real completeness, host equality, trichotomy, Lean verification, or bridge checking.

Theorem 1706.2 (Effective Polish space NameCert obligations)**.** *For every accepted* EffectivePolishSpace$^{\uparrow}$ *carrier $E = (P, D, Q, S, R, M, L, H, C, G, N)$, the local* NameCert$_{\text{EffectivePolishSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Polish, dense, effective Cauchy, StreamName, RegSeqRat, tolerance-ledger, Real-seal, transport, replay, provenance, and local naming rows;*

2. *dense enumerator visibility, requiring every finite dense-window request to read the indexed row D before it reaches S, Q, R, or L;*

3. *effective Cauchy realizer handoff, requiring every Cauchy realization to pass through the explicit row Q and its displayed stream windows before regular rational readback;*

4. *complete-separable metric compatibility, requiring the Polish row P to be read only through the same dense family, explicit Cauchy route, tolerance ledger, and Real seal used by downstream consumers;*

5. *nonescape, excluding choice-selected dense points, quotient completion equality, open-cover compactness, ambient* Real$^{\uparrow}$ *completeness, host equality, trichotomy, Lean verification, and bridge checking.*

No effective-Polish-space obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.EffectivePolishSpaceUp.EffectivePolishSpaceUpTasteGate single carrier alignment`

Proof. Carrier admission is the projection of Definition 1706.1. The projected rows are exactly the Polish-space row P, dense enumerator D, effective Cauchy row Q, finite stream windows S, regular readback R, tolerance ledger M, Real seal L, and structural rows H, C, G, N.

Dense enumerator visibility is supplied by chapter 1566. A finite approximation request must first cite the displayed index row D before the corresponding window can be served by chapter 126.

The effective Cauchy handoff uses chapter 1705. Once the dense index and stream window have been displayed, the row Q supplies the explicit modulus route, and chapter 301 reads the regular rational handoff only downstream of that route.

Metric compatibility is read through chapter 1490 and the terminal seal of chapter 38. Since P and L are carried in the same finite packet as D, Q, S, R, M, the complete-separable metric surface cannot introduce a second dense family, hidden completion equality, or ambient completeness coordinate.

Finally, H, C, G, N transport, replay, package, and name the same displayed rows. They add no analytic coordinate beyond the carrier, so the five listed obligations exhaust the local NameCert surface. □

Theorem 1706.3 (Effective Polish space realizer handoff)**.** *Every Polish-space or Real-facing consumer of an accepted* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carrier* $E = (P, D, Q, S, R, M, L, H, C, G, N)$ *factors through the displayed route*

$$D \longmapsto S \longmapsto Q \longmapsto R \longmapsto M \longmapsto L \longmapsto P, H, C, G, N.$$

Thus the consumer receives the displayed dense index, finite StreamName windows, EffectiveCauchySequence modulus route, RegSeqRat readback, dyadic and Real tolerance ledger, Real seal, Polish row, transport, replay, provenance, and local naming before it can inspect the completed object.

Lean4 ✓ `BEDC.Derived.EffectivePolishSpaceUp.EffectivePolishSpaceRealizerHandoff`

Proof. Start with a Polish-space or Real-facing read of E. By Definition 1706.1, the only dense-coordinate row is D, and the only effective Cauchy route is Q.

The finite observation part reads D through chapter 1566 and then reads S through chapter 126. These rows expose the dense index and the finite windows without selecting a hidden dense point.

The realization part is then forced through chapter 1705. The row Q supplies the explicit modulus route; the row R records the regular rational readback from chapter 301; and the ledger M records the tolerance data used before the terminal seal L is read.

The Polish row P and the Real seal L are therefore downstream of the same finite route. The structural rows H, C, G, N preserve and name that route, so every consumer factors through the displayed handoff and has no bypass through choice, quotient completion equality, open-cover compactness, host equality, trichotomy, or ambient Real completeness. □

Theorem 1706.4 (Effective Polish space complete-separable handoff)**.** *Every* $\mathsf{CompleteSeparableMetric}^{\uparrow}$*-facing read of an accepted* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carrier* $E = (P, D, Q, S, R, M, L, H, C, G, N)$ *factors through*

$$P, D, Q, S, R, M, L, H, C, G, N.$$

In particular, the dense index row D *and effective Cauchy realizer row* Q *are displayed before the complete-separable metric surface is consumed.*

Lean4 ✓ `BEDC.Derived.EffectivePolishSpaceUp.EffectivePolishSpaceCompleteSeparableHandoff`

Proof. Project the carrier in Definition 1706.1. The complete-separable metric consumer sees the Polish row P only inside the same packet as the dense row D, effective Cauchy row Q, StreamName windows S, RegSeqRat readback R, tolerance ledger M, Real seal L, and structural rows H, C, G, N.

Apply Definition 1706.3. The handoff orders the displayed dense index, StreamName windows, effective Cauchy realizer, regular rational readback, tolerance ledger, and Real seal before any completed-object read is available.

The sibling consumer is chapter 1735. Its route can therefore consume the complete-separable metric surface only after P, D, Q, S, R, M, L have been displayed, with H, C, G, N preserving and naming the same route.

No step introduces a second dense family, a hidden Cauchy realizer, quotient completion equality, open-cover compactness, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1706.5 (EffectivePolishSpace dense realizer transport)**.** *Let $E = (P, D, Q, S, R, M, L, H, C, G, N)$ and $E' = (P', D', Q', S', R', M', L', H', C', G', N')$ be accepted* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carriers. Suppose the Polish rows, countable dense families, effective Cauchy realizer rows, StreamName windows, RegSeqRat readback rows, tolerance ledgers, and Real seals transport componentwise under* hsame *and replay through displayed* Cont *routes. Then E' remains an accepted effective Polish packet over the transported rows, with the same dense-realizer handoff to the displayed* $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.EffectivePolishSpaceUp.EffectivePolishSpaceCarrier dense realizer transport`

Proof. Project the carrier tuple in Definition 1706.1. The analytic route is exactly the Polish row P, dense row D, effective Cauchy row Q, StreamName windows S, RegSeqRat readback R, tolerance ledger M, and Real seal L.

Transport the dense index and realizer rows first. The componentwise hsame hypotheses identify D with D' and Q with Q', while displayed Cont replay keeps the dense windows and effective Cauchy stages on the same finite route.

Next transport the readback surface. The rows S, R, M, L and S', R', M', L' provide the same finite StreamName windows, regular rational readback, tolerance ledger, and Real seal after replay.

Apply Definition 1706.3. The accepted consumer route is already forced through dense indices, finite windows, effective Cauchy data, regular readback, tolerance rows, and the Real seal, so repacking the transported rows yields the accepted packet over E'.

No step introduces choice-selected dense points, quotient completion equality, open-cover compactness, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The transport stays inside the displayed dense-realizer route. □

Theorem 1706.6 (Effective Polish space dense realizer consumer route)**.** *Let $E = (P, D, Q, S, R, M, L, H, C, G, N)$ be an accepted* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carrier. Every Polish-space or Real-facing consumer first reads the displayed Polish row P, indexed dense family D, effective Cauchy realizer Q, StreamName windows S, RegSeqRat readback R, tolerance ledger M, Real seal L, and only then the local* $\mathsf{NameCert}_{\mathsf{EffectivePolishSpace}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.EffectivePolishSpaceUp.EffectivePolishSpace dense realizer consumer route`

Proof. Project the carrier in Definition 1706.1. Its analytic rows are exactly the Polish row, dense-index row, effective Cauchy row, StreamName windows, RegSeqRat readback, tolerance ledger, and Real seal.

Apply Definition 1706.3. The handoff orders the dense index, finite windows, effective Cauchy modulus route, regular rational readback, tolerance ledger, and Real seal before any completed-object read is available.

The local naming row is therefore last. The rows H, C, G, N transport, replay, source, and name the already displayed route; they do not add a second dense enumerator, a hidden realizer, a quotient completion equality, or an ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 1706.7 (Effective Polish space non-escape)**.** *Let $E = (P, D, Q, S, R, M, L, H, C, G, N)$ be an accepted* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *carrier. No consumer of E can read choice-selected dense points, quotient completion equality, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host equality, or trichotomy from the packet unless that datum is already one of the displayed rows $P, D, Q, S, R, M, L, H, C, G, N$.*

Proof. Inspect the carrier rows in Definition 1706.1. The analytic rows are only the Polish-space row, countable dense row, effective Cauchy row, finite stream windows, regular readback, tolerance ledger, and terminal Real seal.

The structural rows H, C, G, N provide sameness transport, replay, provenance, and local naming for those same rows. They do not add a selector for dense points, a quotient-equality principle for completions, an open-cover compactness theorem, an ambient completeness theorem, a host equality predicate, or trichotomy.

Therefore the excluded data have no carrier coordinate, replay edge, provenance entry, or local NameCert row from which to be read. Any consumer of E is confined to the displayed effective complete-separable route. □

Falsifiable prediction: Every $\mathsf{EffectivePolishSpace}^{\uparrow}$ Polish-space or Real-facing read factors through a displayed dense index, StreamName finite windows, EffectiveCauchySequence modulus route, RegSeqRat readback, dyadic and Real tolerance ledger, RealUp seal, Polish row, transport, replay, provenance, and local naming.

Independence witness: polishspace, countable-dense-subset, effective-cauchy-sequence, streamname, regseqrat, real: $\mathsf{EffectivePolishSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Polish row, indexed dense family, effective Cauchy realizer, stream windows, regular readback, tolerance ledger, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectivePolishSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectivePolishSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1706.1, Definition 1706.2, Definition 1706.3, and Definition 1706.7 seed the finite effective complete-separable metric route through $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectivePolishSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected dense points, quotient completion equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, host equality, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense enumerator visibility, effective Cauchy realizer handoff, complete-separable metric compatibility, transport and replay stability, and nonescape for BEDC.Derived.EffectivePolishSpaceUp

Constructive story: An $\mathsf{EffectivePolishSpace}^{\uparrow}$ packet is generated from a displayed PolishSpace row, CountableDenseSubset row, EffectiveCauchySequence row, StreamName finite windows, RegSeqRat readback, dyadic and Real tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1707

A Concrete Naming Certificate for $\mathsf{BishopFanModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen's treatment of fan bars, the $\mathsf{BishopFanModulus}^{\uparrow}$ packet records the finite route by which a barred fan depth ledger becomes an explicit Real and Completion window modulus. It sits after the finite fan certificate of chapter 400, the Cantor-space naming surface of chapter 1475, the StreamName window interface of chapter 126, the RegSeqRat readback boundary of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, the Real seal of chapter 38, and the downstream uniform-modulus consumer of chapter 369. The packet is a finite modulus bridge for L10 Real and Completion routes; it is not open-cover compactness, countable choice, a selected branch, a selected limit, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1707.1 (Bishop fan modulus carrier)**.** *A* $\mathsf{BishopFanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, A, B, S, Q, D, R, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row. It records the displayed binary fan, prefix closure, decidable branch-prefix inspection, and the finite bar-depth bound.*
2. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *address row. It names the finite binary-prefix domain on which the fan row is read, without selecting an infinite branch.*
3. *B is the bar-to-modulus row. For each displayed bar depth from F, it records the finite observation depth that bounds all branch-prefix reads used by the Real or Completion consumer.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records exactly the source windows inspected after the bar-to-modulus row has fixed the required depth.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores dyadic radii, comparison budgets, and refinement slack attached to the same window schedule.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, A, B, S, Q, D have been displayed.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row. It exposes the same depth schedule as an explicit modulus for later uniform, Real, and Completion-facing routes.*

9. *H records componentwise* hsame *transport for the fan, Cantor-address, bar-to-modulus, stream-window, regular-readback, dyadic-tolerance, Real-seal, uniform-modulus, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a consumer request through $F, A, B, S, Q, D, R, U, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopFanModulus}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFanModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, A, B, S, Q, D, R, U, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected infinite branches, selected limits, quotient stream equality, host real equality, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BishopFanModulusUp.TasteGate.BishopFanModulusUp`

Lean4 ✓ `BEDC.Derived.BishopFanModulusUp.TasteGate.BishopFanModulusTasteGate single carrier alignment`

Theorem 1707.2 (Bishop fan modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopFanModulus}^{\uparrow}$ *carrier $M = (F, A, B, S, Q, D, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopFanModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed fan, Cantor-address, bar-to-modulus, stream-window, regular-readback, dyadic-tolerance, Real-seal, uniform-modulus, transport, replay, provenance, and local naming rows;*

2. *fan-bar coverage, requiring every branch-prefix request to be bounded by the finite bar-depth row read from F over the address surface A;*

3. *modulus extraction, requiring the depth row B to convert that finite bar-depth data into the window depth consumed by S and U;*

4. *Real window handoff, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window to pass through S, every regular readback to pass through Q, every dyadic tolerance check to pass through D, and every terminal real read to pass through R;*

5. *uniform-modulus handoff, requiring U to expose only the same finite schedule already displayed by F, A, B, S, Q, D, R;*

6. *transport, replay, provenance, and local naming stability, requiring H, C, P, N to preserve and name exactly the displayed packet.*

No Bishop fan modulus obligation is stored outside these six rows.

Lean4 ✓ `BEDC.Derived.BishopFanModulusUp.BishopFanModulusUpTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1707.1. The projected finite packet is exactly $F, A, B, S, Q, D, R, U, H, C, P, N$.

Fan-bar coverage reads the finite fan row and the Cantor-address row together. The bar depth is supplied by F, and the binary-prefix domain on which it is interpreted is supplied by A, so the argument ranges only over displayed finite prefixes.

The modulus row B converts this bar depth into a window schedule. Once B has fixed the depth, the stream row S can expose finite observations and the uniform row U can expose the same schedule as a $\mathsf{UniformModulus}^{\uparrow}$ consumer surface.

The Real-facing route then passes through Q, D, R. Regular readback is read from Q, dyadic tolerance accounting is read from D, and the terminal $\mathsf{Real}^{\uparrow}$ seal is read from R only after the window schedule has already been displayed.

Finally, H, C, P, N transport, replay, record, and name the same route. Since the carrier contains no further coordinate, the excluded compactness, choice, branch-selection, limit-selection, quotient, host-equality, verification, bridge, and ambient-completeness data cannot be exported. □

Theorem 1707.3 (Bishop fan modulus Real window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read of an accepted* $\mathsf{BishopFanModulus}^{\uparrow}$ *carrier* $M = (F, A, B, S, Q, D, R, U, H, C, P, N)$ *factors through*

$$F \longmapsto A \longmapsto B \longmapsto S \longmapsto Q \longmapsto D \longmapsto R \longmapsto U \longmapsto H, C, P, N.$$

Thus the consumer receives a finite fan-bar depth, a Cantor-prefix address surface, an explicit window schedule, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a Real seal, a UniformModulus handoff, and the structural support rows before it can inspect the Real or Completion boundary.

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ or Completion-facing request. By Definition 1707.1, the request can reach the terminal Real row R only through the displayed packet.

The route first reads F and A. These two rows fix the finite fan surface and the finite Cantor-prefix domain, so the bar-depth request has no access to a selected infinite branch.

The row B then turns the finite bar-depth data into the observation depth consumed by S. The regular readback Q and dyadic tolerance row D are downstream of that same window schedule.

Only after S, Q, D are displayed can the Real seal R and the uniform-modulus row U be read. The rows H, C, P, N preserve the same order as transport, continuation, provenance, and local naming data.

Therefore every Real or Completion-facing consumer factors through the displayed finite route. The carrier has no bypass through open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.BishopFanModulusUp.BishopFanModulusRealWindowHandoff`

Theorem 1707.4 (Bishop fan modulus non-escape)**.** *Let* $M = (F, A, B, S, Q, D, R, U, H, C, P, N)$ *be an accepted* $\mathsf{BishopFanModulus}^{\uparrow}$ *carrier. No consumer of* M *can read open-cover compactness, countable choice, a selected infinite branch, a selected limit, quotient stream equality, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from the packet unless that datum is already one of the displayed rows* $F, A, B, S, Q, D, R, U, H, C, P, N$.

Proof. Inspect the accepted carrier. Its analytic coordinates are the fan row F, Cantor-address row A, bar-to-modulus row B, StreamName window row S, RegSeqRat readback row Q, DyadicRatCore tolerance row D, Real seal row R, and UniformModulus row U.

The remaining coordinates H, C, P, N provide componentwise sameness transport, displayed continuation replay, package provenance, and local naming for those same rows. They do not add a compactness object, choice principle, branch selector, limit selector, quotient relation, host equality predicate, completeness theorem, Lean target, or bridge certificate.

Thus the excluded data have no carrier coordinate, continuation edge, provenance entry, or local NameCert row from which to be read. Every consumer is confined to the displayed fan-bar-to-window-modulus route. □

Lean4 ✓ `BEDC.Derived.BishopFanModulusUp.BishopFanModulusNonescape`

Falsifiable prediction: Every $\mathsf{BishopFanModulus}^{\uparrow}$ Real or Completion-facing read factors through a finite fan row, Cantor-prefix address row, bar-to-modulus row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, UniformModulus handoff, transport, replay, provenance, and local naming.

Independence witness: fantheorem, cantorspace, streamname, regseqrat, dyadicratcore, real, uniformmodulus: $\mathsf{BishopFanModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries fan-bar depth, Cantor-prefix addressing, explicit window scheduling, analytic readback rows, a Real seal, a UniformModulus handoff, and structural support while refusing compactness, choice, branch selection, selected limits, quotient stream equality, host equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFanModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFanModulus}^{\uparrow}}, \mathsf{seed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFanModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-bar coverage, modulus extraction, Real window handoff, uniform-modulus handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.BishopFanModulusUp.

Constructive story: A $\mathsf{BishopFanModulus}^{\uparrow}$ packet is generated from a finite $\mathsf{FanTheorem}^{\uparrow}$ row, $\mathsf{CantorSpace}^{\uparrow}$ address row, bar-to-modulus row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{Real}^{\uparrow}$ seal, $\mathsf{UniformModulus}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1708

A Concrete Naming Certificate for $\mathsf{CauchyQuotientBoundary}^{\uparrow}$

Following Bishop and Bridges' constructive completion, the $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ packet records quotient-facing Cauchy completion requests only as finite BEDC boundary data. It sits where the $\mathsf{CauchySequenceSpace}^{\uparrow}$ common-window route of chapter 406 meets the $\mathsf{QuotientStreamRefusal}^{\uparrow}$ refusal surface of chapter 998, downstream of the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ regular-completion route of chapter 1639, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite refusal boundary for quotient-style completion reads; it is not a quotient construction, selected representative, host equality, countable-choice principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1708.1 (Cauchy quotient boundary carrier)**.** *A* $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, F, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *source row. It records the finite family, common-window schedule, cofinal Cauchy-window ledger, tolerance row, completion handoff, and local classifier data that are already visible before any quotient-facing request is inspected.*
2. *Q is the quotient-request row. It names the requested equality of Cauchy streams, quotient class, representative, or quotient-completion read without admitting any of those objects as carrier coordinates.*
3. *F is the* $\mathsf{QuotientStreamRefusal}^{\uparrow}$ *route row. It records the refusal path used when Q asks for a quotient-style completion datum outside the displayed finite route.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores dyadic radii, slack rows, comparison budgets, and tolerance conversions consumed by the source and refusal routes.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the inspected source windows that make the Cauchy request visible before refusal is issued.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational observations available after the finite windows and dyadic ledger have been displayed.*

7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary row. It is visible only downstream of S, W, D, R, F and does not identify quotient streams or choose a representative.*

8. *H records componentwise* hsame *transport for the source, quotient request, refusal route, dyadic ledger, stream windows, regular readback, Real seal boundary, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a quotient-facing completion request through $S, Q, F, D, W, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyQuotientBoundary}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{QuotientStreamRefusal}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyQuotientBoundary}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite quotient-facing refusal-boundary packet. It has no coordinate for quotient stream equality, quotient classes, selected representatives, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyQuotientBoundaryUp.TasteGate.CauchyQuotientBoundaryUpTasteGate single carrier alignment`

↪ variant `BEDC.Derived.CauchyQuotientBoundaryUp.CauchyQuotientBoundaryUp single carrier alignment`

Theorem 1708.2 (Cauchy quotient boundary NameCert obligations)**.** *For every accepted* CauchyQuotientBoundary *carrier $B = (S, Q, F, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyQuotientBoundary}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Cauchy-window source, quotient request, refusal route, dyadic tolerance ledger, finite stream windows, regular rational readback, Real seal boundary, transport, replay, provenance, and local naming rows;*

2. *quotient-request routing, requiring every quotient-facing completion request to expose Q and then enter the displayed refusal route F unless it is already a read of the finite Cauchy source route S, W, D, R;*

3. *refusal factorization, requiring F to route off-route quotient-style requests through the* $\mathsf{QuotientStreamRefusal}^{\uparrow}$ *surface before any* $\mathsf{Real}^{\uparrow}$ *seal boundary is visible;*

4. *Real-seal non-escape, requiring E to remain downstream of the CauchySequenceSpace and refusal rows and never to serve as quotient stream equality, a quotient class, selected representative, host equality, countable choice, or ambient completeness;*

5. *transport and replay stability, requiring H and C to preserve the displayed row order $S, Q, F, D, W, R, E, P, N$;*

6. *provenance exhaustion, requiring P and N to name exactly the displayed packet and no quotient object outside it.*

No Cauchy quotient boundary obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyQuotientBoundaryUp.CauchyQuotientBoundaryCarrier namecert obligations`

Proof. Carrier admission is the projection of Definition 1708.1. The accepted packet exposes only the CauchySequenceSpace source row, quotient-request row, refusal route, dyadic ledger, finite windows, regular readback, Real seal boundary, and structural rows.

Quotient-request routing begins at Q. If the request is a finite Cauchy-window read, it remains inside the displayed source route S, W, D, R. If it asks for quotient equality, a quotient class, a

representative, or quotient-completion data beyond that route, the only displayed next row is the refusal row F.

The refusal factorization is supplied by chapter 998. That chapter routes off-route quotient-style requests through the refusal ledger before any Real-completion read can reach a seal, so E stays downstream of S, W, D, R, F.

Finally, componentwise hsame transport, displayed Cont replay, provenance, and local naming preserve the same rows. Since no excluded quotient or completeness coordinate occurs in B, the listed obligations exhaust the local NameCert surface. □

Theorem 1708.3 (Cauchy quotient boundary refusal factorization)**.** *Every quotient-facing Cauchy completion read of an accepted* $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ *carrier* $B = (S, Q, F, D, W, R, E, H, C, P, N)$ *factors through the displayed route*

$$\mathsf{CauchySequenceSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{QuotientStreamRefusal}^{\uparrow} \longmapsto \mathsf{Re}$$

Thus the read consumes the source row S, finite windows W, dyadic ledger D, regular readback R, refusal route F, and only then the Real seal boundary E. It exports no quotient class, selected representative, host equality, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyQuotientBoundaryUp.CauchyQuotientBoundaryCarrier refusal factorization`

Proof. Start with a quotient-facing completion read. The carrier gives the request only as Q, and Definition 1708.1 gives no coordinate where quotient stream equality, a quotient class, or a selected representative could already live.

The Cauchy source part of the read is forced through S. By the $\mathsf{CauchySequenceSpace}^{\uparrow}$ route, the consumer then opens finite $\mathsf{StreamName}^{\uparrow}$ windows, reads the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and obtains the $\mathsf{RegSeqRat}^{\uparrow}$ readback before any completion-facing handoff is visible.

When the same consumer asks for quotient-style data beyond those rows, the next displayed row is F. The $\mathsf{QuotientStreamRefusal}^{\uparrow}$ route sends that request through the refusal ledger, and only after that route is fixed can the terminal $\mathsf{Real}^{\uparrow}$ seal boundary E be inspected.

The structural rows H, C, P, N transport, replay, package, and name this route. They add no quotient class, selected representative, host equality, countable-choice schedule, or ambient completeness witness, so the stated factorization is exhaustive. □

Theorem 1708.4 (Cauchy quotient boundary Real-seal non-escape)**.** *Let* $B = (S, Q, F, D, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ *carrier. Any consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal boundary E has already consumed the displayed CauchySequenceSpace source, quotient-request row, QuotientStreamRefusal route, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, transport, replay, provenance, and local naming rows. No consumer can use E to recover quotient stream equality, a quotient class, a selected representative, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyQuotientBoundaryUp.CauchyQuotientBoundaryRealSealNonescape`

Proof. The Real seal boundary appears only as the row E in the carrier. Its position in the packet is downstream of S, Q, F, D, W, R, so a consumer cannot reach it before the Cauchy source route and the refusal route have both been displayed.

Replay the request through C. The replay first exposes the source and quotient request, then the finite-window, dyadic-ledger, regular-readback, and refusal rows. Componentwise transport in H preserves those rows rather than replacing them by quotient data.

The provenance and local naming rows P, N name the same finite boundary. Since quotient stream equality, quotient classes, selected representatives, host equality, countable choice, and ambient Real completeness are absent from the carrier, E cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyQuotientBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyQuotientBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1708.1, Definition 1708.2, Definition 1708.3, and Definition 1708.4 seed the finite refusal boundary for quotient-facing Cauchy completion reads through $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{QuotientStreamRefusal}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyQuotientBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, quotient classes, selected representatives, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-request routing, refusal factorization, Real-seal non-escape, transport and replay stability, and provenance exhaustion for BEDC.Derived.CauchyQuotientBoundaryUp.

Constructive story: A $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ packet is generated from a CauchySequenceSpace source row, quotient-request row, QuotientStreamRefusal route, DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, Real seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1709

Located Real Interval NameCert Construction

Following Bishop and Bridges, the $\mathsf{LocatedRealInterval}^{\uparrow}$ packet names a finite located real interval whose endpoints, radius budget, locator reads, and locatedness moduli are displayed as one BEDC NameCert surface. It sits after the dyadic endpoint arithmetic of chapter 1645, the tolerance bracket of chapter 1646, the comparison service of chapter 1669, the locatedness budget of chapter 1627, and the quotient boundary of chapter 1708. The packet gives later Real and Completion consumers one named interval target; it is not a host closed interval, a selected pair of quotient representatives, a trichotomy oracle, a compactness theorem, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 1709.1 (Located real interval carrier)**.** *A* $\mathsf{LocatedRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, \rho, \Delta, \Lambda, M, Q, H, C, P, N)$$

with the following displayed rows:

1. *L and U are endpoint* $\mathsf{Real}^{\uparrow}$ *rows, each read through the same real-name seal discipline as the* $\mathsf{RealLocator}^{\uparrow}$ *comparison service.*

2. *ρ is the radius row. It records the dyadic rational slack, positive tolerance request, and endpoint-radius compatibility budget consumed by located interval readers.*

3. *Δ is the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *row that stores endpoint arithmetic, refinement, containment comparison, and outward dyadic enclosure data for the endpoint-radius packet.*

4. *Λ is the* $\mathsf{RealLocator}^{\uparrow}$ *locator row. It records the finite lower or upper apartness windows used when a consumer asks whether a rational probe lies outside or inside the interval boundary.*

5. *M is the* $\mathsf{LocatednessModulus}^{\uparrow}$ *row. It records the tolerance-to-window budget used to turn a positive rational request into endpoint windows, rational cells, dyadic refinements, and real-name readbacks.*

6. *Q is the* $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ *row. It records that distance, locatedness, and equality reads use the same finite tolerance bracket rather than unrelated host comparisons.*

7. *H records componentwise* hsame *transport for endpoints, radius, dyadic interval arithmetic, locator rows, locatedness modulus, metric bracket, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from an interval membership, containment, or separation request through $L, U, \rho, \Delta, \Lambda, M, Q, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$, $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealInterval}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one endpoint-plus-radius located interval history. It has no coordinate for host interval equality, selected quotient representatives, trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedRealIntervalUp.TasteGate.LocatedRealIntervalUp`
Lean4 ✓ `BEDC.Derived.LocatedRealIntervalUp.TasteGate.LocatedRealIntervalTasteGate single carrier alignment`

Definition 1709.2 (Located real interval classifier)**.** *Two accepted* $\mathsf{LocatedRealInterval}^{\uparrow}$ *carriers*

$$I = (L, U, \rho, \Delta, \Lambda, M, Q, H, C, P, N)$$

and

$$I' = (L', U', \rho', \Delta', \Lambda', M', Q', H', C', P', N')$$

are classified as the same located interval exactly when the endpoint rows are the same $\mathsf{Real}^{\uparrow}$ *endpoints through the displayed real equality boundary, the radius rows are compatible through the shared dyadic tolerance ledger, and the dyadic interval arithmetic, locator, locatedness modulus, and metric bracket rows transport along those endpoint and radius witnesses. The classifier is therefore endpoint* $\mathsf{Real}^{\uparrow}$ *equality plus radius compatibility, replayed through $\Delta, \Lambda, M, Q, H, C, P, N$; it is not equality of host closed intervals and does not collapse undecided boundary probes.*

Theorem 1709.3 (Located real interval NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealInterval}^{\uparrow}$ *carrier $I = (L, U, \rho, \Delta, \Lambda, M, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint rows, radius row, dyadic interval arithmetic row, locator row, locatedness modulus row, metric locatedness bracket, transport, replay, provenance, and local naming row;*

2. *endpoint-radius compatibility, requiring ρ to bind the lower and upper endpoint reads to the dyadic interval ledger Δ without replacing them by host real representatives;*

3. *classifier exactness, requiring sameness to be endpoint* $\mathsf{Real}^{\uparrow}$ *equality plus radius compatibility and to transport through $\Delta, \Lambda, M, Q, H, C, P, N$;*

4. *locatedness stability, requiring Λ and M to answer finite boundary and tolerance requests through displayed windows and dyadic refinements;*

5. *metric bracket stability, requiring Q to keep distance, equality, and locatedness reads on one common tolerance route;*

6. *ledger exhaustion, excluding host interval equality, selected quotient representatives, trichotomy, countable choice, compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No located real interval obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1709.1. The projection exposes exactly the two endpoint rows, radius row, dyadic interval arithmetic row, locator row, locatedness modulus row, metric bracket, and structural rows.

Endpoint-radius compatibility is read from ρ and Δ. The radius row carries the positive dyadic slack and endpoint-radius budget, while the dyadic interval arithmetic row supplies the outward endpoint enclosures and refinement comparisons.

Classifier exactness follows from Definition 1709.2. Sameness first compares the endpoint $\mathsf{Real}^{\uparrow}$ rows through the displayed equality boundary, then checks the radius compatibility ledger, and only then transports the dyadic arithmetic, locator, locatedness, and metric bracket rows.

Locatedness stability is supplied by Λ and M. The locator row answers rational probes by finite apartness windows, and the modulus row turns tolerance requests into endpoint windows, rational cells, dyadic refinements, and real-name readbacks.

Metric bracket stability is supplied by Q. It records that distance, equality, and locatedness requests consume the same bracket route. The remaining structural rows H, C, P, N transport, replay, package, and name the displayed packet, so no excluded host interval or completeness coordinate can be exported. □

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalUp.LocatedRealIntervalCarrier namecert obligations`

Theorem 1709.4 (Located real interval exactness route)**.** *Every membership, containment, separation, or refinement read of an accepted* $\mathsf{LocatedRealInterval}^{\uparrow}$ *carrier factors through the displayed route*

$$L, U, \rho \longmapsto \Delta, \Lambda, M, Q \longmapsto H, C, P, N.$$

Consequently the consumer receives endpoint $\mathsf{Real}^{\uparrow}$ *equality data and radius compatibility data before any locatedness answer is read. The route exports no host interval equality, selected quotient representative, trichotomy, countable-choice schedule, compactness witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalUp.LocatedRealIntervalCarrier exactness route`

Proof. Start with an accepted packet $I = (L, U, \rho, \Delta, \Lambda, M, Q, H, C, P, N)$. The only interval coordinates are the endpoint rows L, U and the radius row ρ.

The dyadic interval arithmetic row Δ is the first computational handoff from those coordinates. It records outward endpoint enclosures, containment comparison, and refinement data using displayed dyadic ledgers.

The locator and modulus rows Λ and M then supply the finite boundary and tolerance services. They can only read the endpoint-radius data through the displayed windows, rational readbacks, and dyadic refinements already named by the packet.

The metric bracket Q binds the distance, equality, and locatedness routes together. Componentwise transport, continuation replay, provenance, and local naming then package the same route. Since the carrier contains no host interval equality or completeness coordinate, the listed route is exhaustive. □

Theorem 1709.5 (Located real interval Cauchy quotient boundary route)**.** *Every quotient-boundary-facing read of an accepted* $\mathsf{LocatedRealInterval}^{\uparrow}$ *carrier must pass through the endpoint* $\mathsf{Real}^{\uparrow}$ *rows* L, U*, the radius compatibility row* ρ*, the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *row* Δ*, the* $\mathsf{RealLocator}^{\uparrow}$ *row* Λ*, the* $\mathsf{LocatednessModulus}^{\uparrow}$ *row* M*, and the* $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ *row* Q *before it can reach the* $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ *sibling. Thus the quotient boundary consumes the same endpoint-plus-radius located interval route and cannot replace it by selected quotient representatives, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalUp.LocatedRealIntervalCarrier cauchy quotient boundary route`

Proof. Project the carrier of Definition 1709.1. The endpoint rows L, U and the radius row ρ are the only interval coordinates available before any arithmetic, locator, modulus, or metric bracket data are read.

Apply Definition 1709.4. It forces every membership, containment, separation, or refinement request through the route from endpoints and radius to Δ, Λ, M, Q and then to the structural rows.

The $\mathsf{CauchyQuotientBoundary}^{\uparrow}$ sibling can therefore appear only as a downstream consumer of that same endpoint and radius route. Its quotient-facing read receives the dyadic interval arithmetic, real locator, locatedness modulus, and metric locatedness bracket already displayed by the interval packet.

Since the carrier has no coordinate for selected quotient representatives, trichotomy, countable choice, host interval equality, or ambient real completeness, the boundary-facing read cannot expose any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealInterval}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1709.1, Definition 1709.2, Definition 1709.3, Definition 1709.4, and Definition 1709.5 close the finite endpoint-plus-radius obligation surface over dyadic interval arithmetic, real locator, locatedness modulus, metric locatedness bracket, and Cauchy quotient boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected quotient representatives, trichotomy, countable choice, compactness, ambient RealUp completeness, Lean verification, or a public standard bridge.

Upgrade path: Scoped closure requires a public consumer boundary or bridge theorem for the endpoint-plus-radius located interval surface.

Constructive story: A $\mathsf{LocatedRealInterval}^{\uparrow}$ packet is generated from lower and upper $\mathsf{Real}^{\uparrow}$ endpoint rows, a dyadic radius row, a $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ endpoint ledger, a $\mathsf{RealLocator}^{\uparrow}$ comparison row, a $\mathsf{LocatednessModulus}^{\uparrow}$ tolerance row, a $\mathsf{RealMetricLocatednessBracket}^{\uparrow}$ route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1710

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ packet records the positive comparison and apartness reads available from regular Cauchy real names before any trichotomy, quotient-real equality, selected representative, or ambient completeness principle is admitted. It sits after the finite budget route of chapter 991, the comparison boundary of chapter 1381, and the positive-gap interface of chapter 1514. Its public role is an L10 constructive order/apartness boundary over displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Definition 1710.1 (Regular Cauchy apartness-order carrier)**.** *A* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, A, O, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source whose regular rational observations supply the two comparison endpoints or the single signed difference stream under inspection.*
2. *A is the* $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$ *row. It records the finite positive lower-bound budget that must be displayed before any strict comparison or apartness read is exported.*
3. *O is the comparison-direction row. It records whether the packet is being read as positive apartness, $<$, $>$, or a one-sided order read, and it stores only the displayed direction tag and its local classifier data.*
4. *M is the modulus row selecting the finite precision at which the budgeted positive separation is inspected.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selected from X by A, M, and O.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-bound readback row obtained from that finite window.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row tying D and W back to the regular source X.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the budget, direction, window, dyadic positive-bound, and regular readback rows have been displayed.*

9. *H records componentwise* hsame *transport for the source, apartness budget, comparison direction, modulus, window, positive dyadic bound, regular readback, Real seal, replay, provenance, and local name.*

10. *C records displayed* Cont *replay from a comparison or apartness request through $X, A, O, M, W, D, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$, $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessOrder}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet. It has no coordinate for trichotomy, quotient real equality, host real inequality, a selected representative, total order decision, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1710.2 (Regular Cauchy apartness-order NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *carrier $Q = (X, A, O, M, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApart}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the regular source, apartness budget, comparison direction, modulus, finite window, positive dyadic bound, regular readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *classifier stability, requiring transported packets to preserve the same direction tag O, budget row A, window W, positive-bound row D, readback R, and seal E componentwise through H and C;*

3. *positive-boundary exactness, requiring every exported strict comparison or apartness read to pass through the displayed* $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$ *row before reading the* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive bound;*

4. *Real-seal non-escape, requiring the* $\mathsf{Real}^{\uparrow}$ *seal E to remain downstream of A, O, M, W, D, and R and never to serve as quotient equality, trichotomy, selected representative, host inequality, or completeness data;*

5. *ledger exclusions, requiring P and N to name exactly the displayed packet and to export no total order decision, no comparison by host real values, no quotient representative, and no ambient completion theorem.*

No regular Cauchy apartness-order obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessOrderUp.RegularCauchyApartnessOrderUpTasteGate`
`single carrier alignment`

Proof. Carrier admission is the projection of Definition 1710.1. The accepted packet exposes the source, budget, direction, modulus, window, positive-bound, readback, seal, and structural rows, and it has no additional comparison coordinate.

Classifier stability is componentwise. The transport row H moves exactly the rows already displayed, and the replay row C repeats the same comparison route after transport instead of recomputing it from host real values.

Positive-boundary exactness follows from the row order. A strict comparison or apartness read first exposes the budget row A, then the direction row O and modulus row M, then the finite window W, and only then the dyadic positive-bound row D.

The Real-seal and ledger clauses are inventory consequences. Since E is the only $\mathsf{Real}^{\uparrow}$ row and it is downstream of A, O, M, W, D, R, it cannot supply quotient equality, trichotomy, selected

representatives, host inequality, or completeness. The provenance and local naming rows therefore exhaust the packet rather than opening any further order principle. □

Theorem 1710.3 (Regular Cauchy apartness-order positive boundary)**.** *Every exported comparison or apartness read of an accepted* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RegularCauchyApartnessBudget}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, a packet $Q = (X, A, O, M, W, D, R, E, H, C, P, N)$ *exposes its comparison direction through* O*, consumes the positive budget* A*, reads the finite window* W*, obtains the positive dyadic boundary* D*, reattaches it to the regular source through* R*, and only then reaches the Real seal* E*. The sibling surfaces of chapter 991, chapter 1381, and chapter 1514 are used only as displayed certificate rows, not as sources of trichotomy, quotient real equality, host inequality, selected representatives, total order decisions, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessOrderUp.RegularCauchyApartnessOrderPositiveBoundary`

Proof. Start with an exported comparison or apartness read. By Definition 1710.2, it must be a read of the finite packet Q and must preserve the displayed comparison direction row O.

The positive part of the read is forced through A. The budget row is the only public source of positive lower-bound data, so the consumer cannot reach a strict comparison or apartness assertion before the $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$ route is displayed.

The finite observation route then passes through W and D. The window row is a $\mathsf{StreamName}^{\uparrow}$ inspection of the regular source, and the positive-bound row is a $\mathsf{DyadicRatCore}^{\uparrow}$ read from that finite window.

Finally, R reattaches the dyadic bound to the $\mathsf{RegSeqRat}^{\uparrow}$ source and E provides the terminal $\mathsf{Real}^{\uparrow}$ seal. The comparison rows supplied by the BishopRealComparison and ApartnessSpace siblings remain boundary rows on this route; they do not add total comparison, quotient equality, host inequality, selected representatives, or completeness data. □

Theorem 1710.4 (Regular Cauchy apartness-order located comparison scope)**.** *Every accepted* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *comparison that is read as located apartness or located order evidence factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Equivalently, the packet exports located comparison evidence only after the dyadic tolerance row D*, the finite observation window* W*, the regular readback row* R*, the Real seal* E*, and the kernel rows* H, C, P, N *have all been displayed. It does not export trichotomy, quotient real equality, selected representatives, total order decisions, host real inequality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessOrderUp.RegularCauchyApartnessOrderLocatedComparisonScope`

Proof. Project the accepted packet as $Q = (X, A, O, M, W, D, R, E, H, C, P, N)$. The carrier and NameCert-obligation rows expose only the displayed comparison direction, budget, modulus, finite window, positive dyadic bound, regular readback, Real seal, transport, replay, provenance, and local naming data.

Apply Definition 1710.3. Any strict comparison or apartness read must first consume the budget row and then pass through the finite window W, positive dyadic boundary D, regular readback R, and Real seal E.

The located comparison scope is obtained by replaying that route through the kernel rows. The BHist packet supplies the finite ledger, H supplies componentwise hsame transport, C supplies displayed Cont replay, P records Pkg provenance, and N records the local NameCert row.

Finite ledger induction over the displayed observation windows keeps the exported evidence located: each read is tied to an explicit dyadic tolerance and finite stream observation before it reaches the regular source and Real seal. Since no packet coordinate contains trichotomy, quotient equality, selected representatives, total order decisions, host real inequality, or completeness, none of those principles is exported by the located comparison route. □

Theorem 1710.5 (Regular Cauchy apartness-order refusal boundary)**.** *An accepted* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *packet exports only the finite surface*

$$X, A, O, M, W, D, R, E, H, C, P, N.$$

Any consumer asking for trichotomy, quotient real equality, host real inequality, selected representatives, total order decisions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking leaves the carrier surface.*

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessOrderUp.RegularCauchyApartnessOrderRefusalBoundary`

Proof. Read the carrier inventory. The packet contains one regular source, one budget row, one comparison-direction row, one modulus row, one finite window, one positive dyadic bound, one regular readback, one Real seal, and the structural rows H, C, P, N.

Apply Definition 1710.2. The local NameCert obligations admit and transport exactly those fields, while positive-boundary exactness and Real-seal non-escape force all comparison reads through the same finite route.

The excluded objects are not packet coordinates. A consumer that asks for trichotomy, quotient equality, host inequality, a representative, a total order decision, choice, completeness, Lean verification, or bridge checking therefore asks for data outside $X, A, O, M, W, D, R, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessOrder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessOrder}^{\uparrow}}, \mathsf{seed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host real inequality, selected representatives, total order decisions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, positive-boundary exactness, located-comparison scope, Real-seal non-escape, ledger exclusions, and refusal-boundary proofs for BEDC.Derived.RegularCauchyApartnessOrd

Constructive story: A $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a RegularCauchyApartnessBud budget row, a displayed comparison-direction row, a modulus row, a $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ positive-bound readback, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1711

A Concrete Naming Certificate for $\mathsf{LocatedIntervalBisection}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalBisection}^{\uparrow}$ packet names the finite bisection route for a located real interval without replacing it by a host closed interval or by a completed choice of midpoint decisions. It consumes the located endpoint-plus-radius surface of chapter 1709, the dyadic branch ledger of chapter 361, the retained-window discipline of chapter 320, the downstream root-location consumer of chapter 1402, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records one requested finite bisection history: located interval data, dyadic midpoint rows, refinement signs or locator decisions, retained nested windows, and a Real-facing seal route.

Definition 1711.1 (Located interval bisection carrier)**.** *A* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, D, M, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row. It supplies lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the radius budget, locator reads, and the locatedness modulus exposed by the source interval.*
2. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger. It records the finite left-or-right branch prefix and the dyadic enclosure scale used by the requested bisection depth.*
3. *M is the midpoint row. It stores the displayed dyadic midpoint cell, the two child interval cells, and the endpoint-radius compatibility budget inherited from I.*
4. *S is the sign or refinement row. It records the finite locator, sign, or containment decision that selects the retained child interval at each branch of D.*
5. *W is the retained nested-window row. It stores the visible lower and upper windows after each retained branch and exposes them to chapter 320.*
6. *R is the* $\mathsf{Real}^{\uparrow}$*-facing seal row. It is reached only after the retained window has passed through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route.*
7. *H records componentwise* hsame *transport for I, D, M, S, W, R and the local structural rows.*

8. *C records displayed* Cont *replay from a bisection request through interval inspection, midpoint construction, branch retention, nested-window exposure, regular readback, and the Real-facing seal.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalBisection}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located-interval bisection packet. It has no coordinate for host interval equality, trichotomy, selected quotient representatives, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a choice-selected root.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalBisectionUp.LocatedIntervalBisectionTasteGate single carrier alignment`

Theorem 1711.2 (Located interval bisection NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *carrier* $B = (I, D, M, S, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalBisection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval row, dyadic branch ledger, midpoint row, sign or refinement row, retained nested window, Real-facing seal, transports, replay, provenance, and local naming;*

2. *interval-source discipline, requiring every endpoint, radius, locator, and locatedness read to factor through I before midpoint data are inspected;*

3. *midpoint branch discipline, requiring M and S to attach each retained child interval to the branch prefix recorded by D;*

4. *nested-window exposure, requiring W to store only the retained lower and upper windows produced by the displayed branch ledger;*

5. *Real-facing seal discipline, requiring R to be reached through the retained* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rather than through a host interval object;*

6. *ledger exhaustion, excluding host interval equality, trichotomy, selected quotient representatives, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a choice-selected root, Lean verification, and a standard bridge.*

No located interval bisection obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedIntervalBisectionUp.LocatedIntervalBisectionNameCertObligations`

Proof. Carrier admission is projection from Definition 1711.1. The projection exposes the located source interval, the finite dyadic branch ledger, midpoint data, branch-retention data, nested-window data, and structural rows.

Interval-source discipline is supplied by I. Every endpoint, radius, locator, and locatedness request starts from the accepted $\mathsf{LocatedRealInterval}^{\uparrow}$ row, so the bisection packet cannot replace the source by a host closed interval.

Midpoint branch discipline is supplied by D, M, and S. The branch ledger names the finite prefix, the midpoint row supplies the displayed child cells at each step, and the sign or refinement row selects the retained child from data already attached to that prefix.

Nested-window exposure is supplied by W. It records only the lower and upper windows retained by the displayed branch route, with H and C transporting and replaying those windows componentwise.

The Real-facing seal is therefore downstream of the retained windows and the regular readback route. Provenance and local naming exhaust the remaining coordinates, so no excluded host equality, compactness, completeness, or root-selection coordinate can be exported. □

Theorem 1711.3 (Located interval bisection nested-window route)**.** *Every nested-window,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *carrier factors through the displayed route*

$$I \longmapsto D, M, S \longmapsto W \longmapsto R, H, C, P, N.$$

The consumer first reads the located interval source, then the finite midpoint and branch-retention ledger, then the retained nested window, and only then the regular rational readback and Real-facing seal.

Proof. Start with an accepted packet $B = (I, D, M, S, W, R, H, C, P, N)$. The only source interval coordinate is I, so every endpoint, radius, and locator observation begins at the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ row.

The branch stage is D, M, S. The dyadic ledger records the finite prefix, the midpoint row gives the child cells, and the sign or refinement row records which child is retained. No nested-window row is available before this stage has been displayed.

The retained-window stage is W. It reads the visible lower and upper windows produced by the branch stage and presents them to the nested-interval and stream-name surfaces.

Finally, R, H, C, P, N route the retained windows through regular readback and the Real-facing seal. Since the route is exhausted by the listed rows, a consumer cannot bypass the branch ledger to obtain an independent host interval or selected limit. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalBisectionUp.LocatedIntervalBisectionNestedWindowRoute`

Theorem 1711.4 (Located interval bisection non-escape)**.** *Every public read of an accepted* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *carrier is exhausted by the located interval row* I*, the branch ledger* D*, the midpoint row* M*, the sign or refinement row* S*, the retained window* W*, the Real-facing seal* R*, componentwise transport* H*, continuation replay* C*, provenance* P*, and the local naming row* N*. In particular, the certificate exports no host interval equality, no trichotomy row, no selected quotient representatives, no open-cover compactness witness, no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, and no choice-selected root.*

Proof. Apply the NameCert obligation theorem. It lists the carrier, source discipline, midpoint branch discipline, nested-window exposure, Real-facing seal discipline, and ledger exhaustion rows.

Apply the nested-window route theorem for any nested-window, regular-rational, or Real-facing read. Such a read must pass through I, then D, M, S, then W, and finally the structural and seal rows.

The remaining public reads are structural: transport, replay, provenance, and local naming. These are exactly H, C, P, N and do not add analytic coordinates beyond the displayed bisection packet.

Thus every public read is one of the listed coordinates or a route through them. The excluded host equality, trichotomy, quotient-representative selection, compactness, completeness, and root-selection principles have no row from which they could be projected. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalBisection}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1711.1, Definition 1711.2, Definition 1711.3, and Definition 1711.4 seed the finite located-interval bisection surface over source interval, dyadic branch, midpoint, retained window, regular readback, and Real-facing seal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedIntervalBisection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval equality, trichotomy, selected quotient representatives, open-cover compactness, ambient RealUp completeness, a choice-selected root, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, midpoint branch discipline, nested-window routing, seal discipline, and non-escape proofs for BEDC.Derived.LocatedIntervalBisectionUp.

Constructive story: A LocatedIntervalBisection$^{\uparrow}$ packet is generated from a LocatedRealInterval$^{\uparrow}$ source row, a DyadicBisection$^{\uparrow}$ branch ledger, displayed midpoint rows, sign or refinement rows, retained nested windows, StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1712

A Concrete Naming Certificate for $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ packet records the finite midpoint route for a displayed located real interval before an interval-refinement or completion consumer may inspect child cells. It consumes the located endpoint and radius discipline of chapter 1709, the common-denominator midpoint ledger of chapter 445, the child-cell handoff of chapter 1465, the finite mesh route of chapter 1250, and the nested completion consumer of chapter 1421. The packet is a midpoint certificate for one located interval; it is not host real equality, a selected quotient representative, an interval completeness principle, or a branch-choice oracle.

Definition 1712.1 (Located interval midpoint carrier)**.** *A* $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, E_0, E_1, B, S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the parent* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, including the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoints, radius budget, locator route, locatedness modulus, and metric bracket rows.*
2. *D is the* $\mathsf{DyadicMidpoint}^{\uparrow}$ *row that computes the midpoint from the displayed endpoint windows by a common-denominator dyadic calculation.*
3. *E_0 and E_1 are endpoint transport rows. They record the lower-to-midpoint and midpoint-to-upper endpoint reuse checks consumed by child located intervals.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *handoff row that exposes the two child interval cells after the midpoint row has been displayed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the parent endpoint reads, midpoint read, and child endpoint observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite windows, including the regular rational midpoint approximation used by Real-facing readers.*
7. *Q is the pair of* $\mathsf{Real}^{\uparrow}$ *seal rows reached by the midpoint and child endpoint reads through S, R, D, E_0, E_1.*
8. *H records componentwise* hsame *transport for the parent interval, midpoint row, endpoint transports, bisection handoff, windows, readbacks, real seals, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a midpoint, bisection, finite-net, or nested-interval request through* $I, D, E_0, E_1, B, S, R, Q, H, P, N$.
10. *P is the* Pkg *provenance over* LocatedIntervalMidpoint$^\uparrow$, LocatedRealInterval$^\uparrow$, DyadicMidpoint$^\uparrow$, IntervalBisection$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{LocatedIntervalMidpoint}^\uparrow}$ *row.*

The carrier predicate asserts that these rows form one parent-interval-to-midpoint packet. It has no coordinate for host real midpoint arithmetic, quotient real equality, trichotomy, selected branch choice, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedIntervalMidpointUp.LocatedIntervalMidpointTasteGate single carrier alignment`

Theorem 1712.2 (Located interval midpoint NameCert obligations)**.** *For every accepted* LocatedIntervalMidpoint$^\uparrow$ *carrier* $K = (I, D, E_0, E_1, B, S, R, Q, H, C, P, N)$*, the local* NameCert$_{\text{LocatedIntervalMidpoint}^\uparrow}$ *surface consists exactly of carrier admission for those twelve rows, parent located-interval admission through* I*, dyadic midpoint exactness through* D*, endpoint transport through* E_0, E_1*, interval-bisection handoff through* B*, StreamName and RegSeqRat readback through* S, R*, Real seal exposure through* Q*, componentwise classifier transport through* H*, consumer replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalMidpointUp.NameCertObligations.LocatedIntervalMidpointCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1712.1. The displayed tuple exposes the parent located interval, midpoint row, endpoint transport rows, bisection handoff, finite windows, regular readbacks, real seals, and structural rows as finite BHist coordinates.

Parent admission is read through I. The lower and upper endpoint rows, radius budget, locator route, locatedness modulus, and metric bracket remain the only source of interval data available to the midpoint packet.

Dyadic midpoint exactness is read through D. The row is the common-denominator calculation already named by the DyadicMidpoint$^\uparrow$ surface, so the midpoint is obtained from displayed endpoint windows rather than from host real arithmetic.

Endpoint transport is read through E_0, E_1 and then passed to B. These rows record that the left child reuses the parent lower endpoint with the midpoint upper endpoint, while the right child reuses the midpoint lower endpoint with the parent upper endpoint. The IntervalBisection$^\uparrow$ handoff can therefore expose two child cells without selecting a branch.

The finite-window and seal obligations are read through S, R, Q. Componentwise transport, continuation replay, provenance, and local naming are then supplied by H, C, P, N. Since the carrier has no coordinate for quotient equality, trichotomy, selected branch choice, countable choice, or completeness, no such datum can be exported by the local NameCert surface. □

Theorem 1712.3 (Located interval midpoint refinement handoff)**.** *Every interval-refinement, finite-net, or Cantor-intersection consumer of an accepted* LocatedIntervalMidpoint$^\uparrow$ *packet factors its midpoint request through the displayed route*

$$I, D, E_0, E_1, B \longmapsto S, R, Q \longmapsto H, C, P, N.$$

Consequently later IntervalBisection$^\uparrow$, ClosedBoundedIntervalNet$^\uparrow$, *and* CantorIntersection$^\uparrow$ *reads receive a finite located midpoint packet, not host real equality, selected branch choice, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalMidpointUp.Handoff.LocatedIntervalMidpointCarrier refinement handoff`

Proof. Start with the parent row I. It fixes the displayed located real interval before any midpoint or child-cell request is inspected.

Next read D, E_0, E_1, B. The dyadic midpoint row supplies the common-denominator midpoint calculation, the endpoint transport rows bind that midpoint to the two inherited endpoint routes, and the bisection handoff exposes the two child cells as finite interval data.

Now pass to S, R, Q. The finite-window and regular-rational rows provide the readback required by Real-facing consumers, and the seal rows expose only the midpoint and child endpoint names already routed through the displayed packet.

Finally replay the route through H, C, P, N. A finite-net consumer may use the child cells as mesh data, and a Cantor-intersection consumer may use them in a nested interval chain, but both consumers receive the same finite midpoint route. The packet contains no selector for an infinite branch, no quotient real equality, and no completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalMidpoint}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalMidpoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1712.1, Definition 1712.2, and Definition 1712.3 seed the finite midpoint route for one displayed located real interval over dyadic midpoint, endpoint transport, bisection handoff, finite-window readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalMidpoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real midpoint arithmetic, quotient real equality, trichotomy, selected branch choice, countable choice, ambient RealUp completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dyadic midpoint exactness, endpoint transport, bisection handoff, finite-window readback, Real seal nonescape, and consumer-route proofs for BEDC.Derived.LocatedIntervalMidpointUp.

Constructive story: A $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ packet is generated from a parent LocatedRealIntervalUp row, a DyadicMidpointUp common-denominator midpoint row, endpoint transport rows, an IntervalBisectionUp handoff row, StreamNameUp windows, RegSeqRatUp readbacks, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1713

A Concrete Naming Certificate for $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ packet records the finite located nested-interval bridge from displayed interval bisections to regular Cauchy real names. It consumes the located endpoint-plus-radius surface of chapter 1709, the branch route of chapter 1711, the midpoint handoff of chapter 1712, the retained-window discipline of chapter 320, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite BEDC route for nested located intervals; it is not a host interval-intersection theorem, a selected quotient representative, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1713.1 (Located real nested intervals carrier)**.** *A* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (I, B, M, D, J, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, including endpoint names, radius data, locator reads, locatedness modulus, and metric bracket rows.*
2. *B is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *row that records the finite retained branch route from the source interval.*
3. *M is the* $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ *row that supplies the midpoint and child-cell handoff used by each retained branch.*
4. *D is the diameter-budget row. It records the finite dyadic contraction schedule, the positive tolerance requests, and the proof rows that each retained child interval has a smaller displayed diameter than its predecessor.*
5. *J is the nested-containment row. It records that the retained located intervals are nested through displayed endpoint, midpoint, and branch witnesses rather than through a host intersection object.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row obtained from the retained lower and upper endpoint windows at the requested precisions.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same retained windows and diameter budgets.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, J, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the located interval rows, bisection rows, midpoint rows, diameter budgets, containment witnesses, stream windows, regular readbacks, real seal, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a nested-interval or point-name request through $I, B, M, D, J, S, R, E, H, P,$*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealNestedIntervals}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located nested-interval history. It has no coordinate for host interval intersection, selected quotient representatives, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealNestedIntervalsUp.LocatedRealNestedIntervalsTasteGate single carrier alignment`

Theorem 1713.2 (Located real nested intervals diameter contraction)**.** *For every accepted* LocatedRealNestedInterv *carrier $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$, every retained interval row exposed by J is downstream of the diameter-budget row D. In particular, any finite precision request reaching the stream-window row S first reads a displayed contraction witness in D, then the nested containment witness in J, and only then the retained endpoint windows.*

Proof. Carrier admission is projection from Definition 1713.1. The projection exposes the source located interval, the finite bisection route, midpoint handoffs, diameter budgets, containment witnesses, stream windows, regular readback, and structural rows.

The contraction data are stored in D. Each requested precision has a displayed dyadic tolerance budget and a retained-child diameter row, so a consumer cannot inspect a retained window before the corresponding budget has been read.

The containment data are stored in J. Its rows bind each retained located interval to the previous one through the endpoint, midpoint, and branch witnesses supplied by I, B, M, D.

Finally S is downstream of D and J. The finite stream windows are therefore exposed only after the contraction and containment rows have fixed the retained interval route, and no host intersection or compactness coordinate is available from the carrier. □

Theorem 1713.3 (Located real nested intervals point-name route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing point-name read of an accepted* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *carrier factors through the finite route*

$$I \longmapsto B, M \longmapsto D, J \longmapsto S, R \longmapsto E, H, C, P, N.$$

Thus the read first consumes the located interval source, then the finite bisection and midpoint rows, then the diameter-contraction and nested-containment rows, then the $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no host interval intersection, selected quotient representative, open-cover compactness, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$. The only source interval coordinate is I, so endpoint, radius, locator, and locatedness observations begin at the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ row.

The next stage is B, M. The bisection row records the retained finite branch route, while the midpoint row supplies the child-cell handoff for each retained branch.

The diameter and containment stage is D, J. These rows state that the retained intervals contract at the requested precisions and that each retained row is nested inside the previous displayed row.

The readback stage is S, R. The stream windows are taken from the retained endpoint windows fixed by D, J, and the regular rational row repacks exactly those windows as the point-name readback.

Finally the seal stage is E, H, C, P, N. The $\mathsf{Real}^{\uparrow}$ seal is reached only after the regular readback, and the structural rows transport, replay, package, and name the same finite route. Since the carrier has no host intersection, quotient-representative selector, compactness, choice, or completeness coordinate, the displayed route is exhaustive. □

Definition 1713.4 (Located real nested intervals classifier)**.** *For an accepted* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *carrier* $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$*, the local classifier is the finite predicate that admits exactly the reads transported through the following rows:*

1. *the source transported located interval row* I*;*
2. *the bisection branch row* B *and midpoint row* M*;*
3. *the diameter-budget row* D *and nested-containment row* J*;*
4. *the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*;*
5. *the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*;*
6. *the transport, replay, provenance, and local naming rows* H, C, P, N*.*

The classifier rejects every read that bypasses one of these rows or asks for a host interval intersection, a selected quotient representative, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1713.5 (Located real nested intervals NameCert obligations)**.** *For every accepted* LocatedRealNestedInte *carrier* $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealNestedIntervals}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the located interval row, bisection row, midpoint row, diameter budget, containment row, stream windows, regular readback, Real seal, transport, replay, provenance, and local naming;*
2. *classifier stability under componentwise* hsame *transport of* I, B, M, D, J, S, R, E*;*
3. *diameter contraction for every retained interval row exposed by* J*;*
4. *nested containment from the source located interval through the retained branch and midpoint rows;*
5. $\mathsf{StreamName}^{\uparrow}$ *window exposure using only the retained endpoint windows fixed by* D, J*;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *readback from the same retained windows;*
7. $\mathsf{Real}^{\uparrow}$ *seal nonescape through* S, R, E*;*
8. *displayed* Cont *replay and* Pkg *provenance for the whole route;*
9. *ledger refusal for any consumer that omits a located interval row, bisection row, midpoint row, diameter budget, containment row, stream window, regular readback, Real seal, transport row, replay row, provenance row, or local naming row.*

Proof. Project the carrier of Definition 1713.1. This gives the displayed rows $I, B, M, D, J, S, R, E, H, C, P, N$ and no additional host-level intersection, quotient, compactness, choice, or completeness coordinate.

The classifier is stable because Definition 1713.4 is defined rowwise from the transported located interval, bisection, midpoint, diameter, containment, stream, readback, and seal rows. Componentwise hsame transport therefore preserves exactly the admitted reads.

The diameter and containment obligations are the two gates of Definition 1713.2. Every retained interval window downstream of J first reads the budget row D, then the containment row J.

The readback and seal obligations are chained through Definition 1713.3. The route reaches S, R only after D, J, and it reaches E only after the StreamName and RegSeqRat rows have been displayed.

Finally H, C, P, N transport, replay, package, and name the same finite route. Any consumer missing one of the listed rows fails the local classifier and is refused by the NameCert ledger. □

Theorem 1713.6 (Located real nested intervals Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read accepted by the* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *classifier passes through*

$$I, B, M, D, J, S, R, E, H, C, P, N.$$

In particular, no accepted read reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal from a host interval-intersection object, a selected quotient representative, an open-cover compactness proof, a countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a read be accepted by the classifier of Definition 1713.4. By definition, the read is classified only when it is transported through the source located interval, bisection, midpoint, diameter-budget, containment, stream-window, regular-readback, Real-seal, transport, replay, provenance, and local naming rows.

Apply Definition 1713.2 to the retained interval stage. The read cannot reach S before the contraction row D and containment row J have been displayed.

Apply Definition 1713.3 to the terminal route. The read reaches E only after I, B, M, D, J, S, R and remains packaged by H, C, P, N.

The carrier of Definition 1713.1 contains no alternate coordinate for host intersection, quotient selection, compactness, choice, or completeness. Hence every accepted $\mathsf{Real}^{\uparrow}$-facing read is forced through the displayed finite route. □

Theorem 1713.7 (Located real nested intervals Cauchy witness route)**.** *For every accepted* LocatedRealNestedInter *carrier* $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$*, the diameter-budget row* D *and nested-containment row* J *force each requested precision through the finite witness route*

$$D, J \longmapsto S, R \longmapsto E, H, C, P, N.$$

Consequently the packet supplies a regular-Cauchy witness route into $\mathsf{RegSeqRat}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal, rather than only a sealed Real-name row.*

Proof. Apply Definition 1713.2. It places every retained interval window downstream of the displayed diameter budget D and nested-containment row J.

Next apply Definition 1713.3. The point-name route sends the retained endpoint windows through S and repacks them through the $\mathsf{RegSeqRat}^{\uparrow}$ row R before the Real seal E can be read.

Finally use Definition 1713.6. The seal remains downstream of D, J, S, R and is transported only through H, C, P, N, so each requested precision carries an explicit finite Cauchy witness route into the terminal $\mathsf{Real}^{\uparrow}$ boundary. □

Theorem 1713.8 (Located nested intervals as a constructive IVT modulus substrate)**.** *If an accepted* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *packet is used as the bisection substrate for a* $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ *request, then the IVT modulus route must pass through the same diameter row* D*, containment row* J*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *named by the located nested-interval carrier. In particular, the substrate contributes a finite window route*

$$D, J \longmapsto S, R \longmapsto E$$

and not a host interval intersection, selected root, quotient real equality, open-cover compactness, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted located nested-interval carrier $Z = (I, B, M, D, J, S, R, E, H, C, P, N)$. The rows D and J are the displayed diameter-budget and containment gates of the retained interval route.

Apply Definition 1713.7. It forces every requested precision through D, J before the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows are read.

Now apply Definition 6431.3 to the consuming $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ request. The IVT modulus bisection route opens only the finite windows supplied by its substrate and then proceeds through regular readback and the terminal Real seal.

Combining the two routes identifies the substrate rows used by the modulus request as the same D, J, S, R, E already named in the located nested-interval carrier. Since neither route carries a host intersection, root selector, quotient equality, compactness proof, choice schedule, or completeness coordinate, the conclusion follows by finite-route exhaustion. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealNestedIntervals}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealNestedIntervals}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1713.1, Definition 1713.2, and Definition 1713.3 seed the finite located nested-interval bridge from located interval bisection and midpoint rows to StreamName, RegSeqRat, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealNestedIntervals}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval intersection, selected quotient representatives, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, diameter contraction, nested containment, StreamName window exposure, RegSeqRat readback, Real seal nonescape, and point-name route proofs for BEDC.Derived.LocatedRealNestedI

Constructive story: A $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ packet is generated from a source LocatedRealIntervalUp row, LocatedIntervalBisectionUp branch rows, LocatedIntervalMidpointUp child-cell rows, dyadic diameter budgets, nested containment witnesses, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1714

A Concrete Naming Certificate for $\mathsf{SeparableCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki-style separability, the $\mathsf{SeparableCompletion}^{\uparrow}$ packet records the finite L10 route by which a separable metric source, an enumerated dense schedule, a completion seal, finite stream windows, dyadic or Real tolerances, and regular rational readbacks are offered to completion-facing consumers. It sits between the metric and separability surfaces of chapter 57, chapter 1458, and chapter 1566; the completion interfaces of chapter 1506, chapter 128, and chapter 1687; and the finite observation spine of chapter 126, chapter 291, chapter 301, and chapter 38. The packet names a completion interface controlled by displayed countable density data, not a quotient-completion construction, a selected sequence of dense points, countable choice, host equality of completion points, or ambient Real completeness.

Definition 1714.1 (SeparableCompletion carrier)**.** *A* $\mathsf{SeparableCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, D, C, W, T, R, E, H, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{SeparableMetric}^{\uparrow}$ *source row. It records the metric carrier, distance classifier, and separable-metric countable-name surface over the same point histories.*
2. *D is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *schedule row. It stores the unary indexed dense candidates and the finite request windows through which density is read.*
3. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row. It records the completion-facing admissibility route and the displayed limit or completion-seal handoff.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect dense indices, Cauchy windows, and completion-facing name segments.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance row carrying the dyadic scale, Real distance boundary, and comparison ledger attached to the window W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed dense-window and tolerance data before the completion seal is consulted.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *boundary or completion-seal row reached only after M, D, C, W, T, R have been displayed.*

8. *H records componentwise* hsame *transport for the metric and separable source, dense schedule, completion seal, finite windows, tolerance row, readback, terminal seal, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* SeparableCompletion$^\uparrow$, Met$^\uparrow$, SeparableMetric$^\uparrow$, CountableDenseSubset$^\uparrow$, MetricCompletion$^\uparrow$, CompleteMetric$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{SeparableCompletion}^\uparrow}$ *row.*

The carrier predicate asserts exactly that these rows form one finite separable-completion packet. It has no coordinate for quotient-completion equality, host equality of completed points, a selected dense sequence, countable choice, open-cover compactness, or ambient completeness of Real$^\uparrow$.

Lean4 ✓ `BEDC.Derived.SeparableCompletionUp.SeparableCompletionUp single carrier alignment`

Theorem 1714.2 (SeparableCompletion NameCert obligations)**.** *For every accepted* SeparableCompletion$^\uparrow$ *carrier $S = (M, D, C, W, T, R, E, H, P, N)$, the local* NameCert$_{\text{SeparableCompletion}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier exposure for the displayed metric and separable source, countable dense schedule, completion seal, stream windows, tolerance ledger, regular rational readback, terminal seal, componentwise transport, provenance, and local naming rows;*
2. *classifier transport, requiring comparisons of accepted packets to transport M, D, C, W, T, R, E together before any completion-facing read is exposed;*
3. *dense-window admission, requiring each approximation request to pass through the indexed dense schedule D and the finite* StreamName$^\uparrow$ *row W;*
4. *completion-seal handoff, requiring the* MetricCompletion$^\uparrow$ *or* CompleteMetric$^\uparrow$ *row C to be read only after the metric source and dense-window route are displayed;*
5. *approximation-route exactness, requiring the tolerance row T and regular readback row R to mediate every finite approximation before the terminal seal E is inspected;*
6. *nonescape, excluding quotient completion equality, host equality, selected dense points, countable-choice selectors, open-cover compactness, and ambient Real completeness from the packet.*

No separable-completion obligation is stored outside these rows.

Proof. Project the carrier of Definition 1714.1. The projection exposes exactly the metric and separable source row M, countable dense schedule D, completion seal C, finite windows W, tolerance ledger T, regular readback R, terminal seal E, and structural rows H, P, N.

Classifier transport is componentwise. The row H transports the metric source, dense schedule, completion seal, windows, tolerance ledger, readback, and terminal seal together, so a comparison cannot replace the dense schedule while keeping the same completion-facing packet.

Dense-window admission comes from D and W. A consumer sees a dense candidate only by reading the displayed unary index schedule and the finite stream window attached to the request.

The completion-seal handoff is downstream of that route. The row C records only the displayed MetricCompletion$^\uparrow$ or CompleteMetric$^\uparrow$ admission path, and the rows T and R mediate the approximation window before E can be inspected.

Finally, P and N package and name the same finite route. Since none of the carrier coordinates stores quotient-completion equality, host equality, selected dense points, countable choice, open-cover compactness, or ambient Real completeness, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SeparableCompletionUp.SeparableCompletionCarrier namecert obligations`

Theorem 1714.3 (SeparableCompletion density handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{SeparableCompletion}^{\uparrow}$ *carrier* $S = (M, D, C, W, T, R, E, H, P, N)$ *factors through the finite route*

$$M, D \longmapsto W \longmapsto T \longmapsto R \longmapsto C \longmapsto E \longmapsto H, P, N.$$

Thus the consumer reads the countable dense schedule, finite $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and completion seal before it reads the public packet. The route exports no quotient completion equality, no host equality of completed points, no selected dense point, no countable-choice selector, and no ambient Real-completeness datum.*

Proof. Begin with a completion-facing read of S. Carrier admission gives the consumer access to the source row and dense schedule only as the displayed pair M, D.

Replay the finite observation route. The request opens a $\mathsf{StreamName}^{\uparrow}$ window W over the dense schedule, reads the dyadic or Real tolerance row T, and obtains the regular rational handoff R before the completion seal C is available.

The terminal row E is downstream of the same route. Transport, provenance, and local naming through H, P, N preserve the ordered dependency chain rather than adding a second completion object.

Therefore every completion-facing consumer factors through the countable dense schedule, finite stream window, tolerance ledger, regular readback, completion seal, and terminal boundary before it reads the public packet. The excluded quotient, host-equality, selected-point, choice, and ambient-completeness data have no coordinate in the carrier. □

Lean4 ✓ `BEDC.Derived.SeparableCompletionUp.SeparableCompletionDensityHandoff`

Closure status for $\mathsf{NameCert}_{\mathsf{SeparableCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparableCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1714.1, Definition 1714.2, and Definition 1714.3 seed the finite separable-completion route through metric and separable source data, countable dense schedules, stream windows, dyadic or Real tolerances, regular rational readbacks, and completion seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparableCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected dense points, countable choice, host equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier transport, dense-window admission, completion-seal handoff, approximation-route exactness, nonescape, and density handoff for BEDC.Derived.SeparableCompletionUp.

Constructive story: A $\mathsf{SeparableCompletion}^{\uparrow}$ packet is generated from a MetricUp and SeparableMetricUp source row, a CountableDenseSubsetUp schedule, a MetricCompletionUp or CompleteMetricUp seal, finite StreamName windows, DyadicRatCore or RealUp tolerance data, a RegSeqRat readback, a terminal RealUp or completion seal, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Chapter 1715

A Concrete Naming Certificate for $\mathsf{CompletionPreservesSeparable}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley separability tradition, the $\mathsf{CompletionPreservesSeparable}^{\uparrow}$ packet records the finite BEDC preservation bridge from a separable source metric to separable completion data. It reads the source surfaces of chapter 1458 and chapter 1566, the existing route of chapter 1714, and the completion interface of chapter 1506. Its finite observation spine is the L10 route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the bridge preserves displayed density through windows and tolerance ledgers rather than through quotient equality, countable choice, selected representatives, or host equality of completed points.

Definition 1715.1 (CompletionPreservesSeparable carrier)**.** *A* $\mathsf{CompletionPreservesSeparable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, D, C, W, T, R, I, H, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{SeparableMetric}^{\uparrow}$ *row. It records the metric carrier, distance classifier, and countable-name separability surface over the source histories.*
2. *D is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *row. It stores the indexed dense schedule and the finite request windows through which source density is observed.*
3. *C is the* $\mathsf{SeparableCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *row. It records the completion-facing admission route reached from the same source metric and the same dense schedule.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect dense indices, source Cauchy observations, and completion-facing name segments.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance ledger attached to W. It carries dyadic scales, Real distance boundaries, and comparison budgets for the dense-image request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from D, W, T before the completion seal is consulted.*
7. *I is the dense-image handoff row. It records that a completion request is answered by first exposing an indexed source dense point through D, W, T, R and then passing through the completion seal C.*

8. *H records componentwise* hsame *transport for the source metric, dense schedule, completion row, stream windows, tolerance ledger, readback, image handoff, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{CompletionPreservesSeparable}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{SeparableCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionPreservesSeparable}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite preservation packet. It has no coordinate for quotient completion equality, selected dense representatives, countable choice, host equality of completion points, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionPreservesSeparableUp.CompletionPreservesSeparableTasteGate`
`single carrier alignment`

Theorem 1715.2 (CompletionPreservesSeparable NameCert obligations)**.** *For every accepted* $\mathsf{CompletionPreservesSeparable}^{\uparrow}$ *carrier* $Q = (M, D, C, W, T, R, I, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionPreservesSeparabl}}$ *surface consists exactly of the following obligation rows:*

1. *carrier exposure for the displayed source metric and separable row, countable dense schedule, separable-completion and metric-completion row, stream windows, tolerance ledger, regular readback, dense-image handoff, transport, provenance, and local naming rows;*

2. *source-density admission, requiring each completion-density request to start from the displayed countable dense schedule D over the source metric row M;*

3. *finite-window inspection, requiring dense indices and completion-facing name segments to pass through the same* $\mathsf{StreamName}^{\uparrow}$ *row W;*

4. *tolerance and readback discipline, requiring* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison data in T and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in R before the completion row is exposed;*

5. *completion-image handoff, requiring the row I to bind the selected source dense observation to the completion route C without storing a host-level completed point;*

6. *classifier transport, requiring comparisons of accepted packets to transport M, D, C, W, T, R, I together through H;*

7. *nonescape, excluding quotient completion equality, selected dense representatives, countable-choice selectors, host equality of completion points, open-cover compactness, and ambient Real completeness from the packet.*

No completion-preservation obligation is stored outside these rows.

Proof. Project the carrier of Definition 1715.1. The projection exposes exactly the source metric row M, countable dense schedule D, completion row C, finite windows W, tolerance ledger T, regular readback R, dense-image handoff I, and structural rows H, P, N.

Source-density admission is read before the completion row. A density request first displays an index in D over the same source metric row M, then opens the finite $\mathsf{StreamName}^{\uparrow}$ window W attached to that request.

The tolerance and readback rows mediate the request. The packet reads the dyadic or Real comparison data T and the regular rational handoff R before it exposes the completion-facing row C.

The dense-image handoff is the row I. It binds the displayed source dense observation to the completion route without adding a selected completed representative, quotient equality, or host-level equality of completion points.

Finally, H, P, N transport, source, and name the same finite route. Since no carrier coordinate stores the excluded quotient, choice, host-equality, compactness, or ambient-completeness data, the listed rows exhaust the local NameCert surface. □

Theorem 1715.3 (CompletionPreservesSeparable dense-image handoff)**.** *Every complete-separable or completion-facing consumer of an accepted* $\mathsf{CompletionPreservesSeparable}^{\uparrow}$ *carrier* $Q = (M, D, C, W, T, R, I, H, P$ *reads the finite route*

$$M, D \longmapsto W \longmapsto T \longmapsto R \longmapsto I \longmapsto C \longmapsto H, P, N$$

before it reads the public packet. Thus separability of the completion is exported through displayed source dense data, finite windows, tolerance checks, regular readback, and the dense-image handoff. The route exports no quotient completion equality, no selected dense representative, no countable-choice selector, no host equality of completed points, and no ambient Real-completeness datum.

Proof. Begin with a complete-separable or completion-facing read of Q. Carrier admission gives the consumer the source metric and source dense schedule only as the displayed pair M, D.

Replay the finite observation route. The request opens the $\mathsf{StreamName}^{\uparrow}$ window W, reads the dyadic or Real tolerance ledger T, and obtains the $\mathsf{RegSeqRat}^{\uparrow}$ readback R before any completion-facing image is available.

The image row I is downstream of those source observations. It records the handoff from the displayed source dense point to the completion route C, so the consumer sees density in the completion only through the same finite source data.

Transport, provenance, and local naming through H, P, N preserve that route rather than adding a second completion object. Therefore every downstream consumer factors through source density, finite observation, tolerance, readback, image handoff, and completion admission before it reads the public packet.

The excluded quotient, selected-representative, choice, host-equality, and ambient-completeness data have no coordinate in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionPreservesSeparable}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionPreservesSeparable}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1715.1, Definition 1715.2, and Definition 1715.3 seed the finite preservation bridge from source separability to separable completion data through dense schedules, stream windows, dyadic or Real tolerances, regular readbacks, and dense-image handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionPreservesSeparable}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected dense representatives, countable choice, host equality of completion points, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-density admission, finite-window inspection, tolerance and readback discipline, completion-image handoff, classifier transport, nonescape, and dense-image handoff for BEDC.Derived.CompletionPreservesSeparableUp.

Constructive story: A $\mathsf{CompletionPreservesSeparable}^{\uparrow}$ packet is generated from a MetricUp and SeparableMetricUp source row, a CountableDenseSubsetUp schedule, a SeparableCompletionUp and MetricCompletionUp row, finite StreamName windows, DyadicRatCore or RealUp tolerance data, a RegSeqRat readback, a dense-image handoff row, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Chapter 1716

A Concrete Naming Certificate for $\mathsf{CauchyRealOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealOrder}^{\uparrow}$ packet names the constructive order and apartness surface for Cauchy real data by displaying the finite comparison route before any quotient equality or trichotomy principle is available. It sits after the stream, dyadic, regular-rational, real-name, quotient-boundary, and located-interval surfaces of chapter 126, chapter 291, chapter 301, chapter 38, chapter 1708, and chapter 1709. The packet gives Real and Completion consumers one named ordered-real route; it is not a quotient real equality theorem, a representative selector, a trichotomy oracle, a countable-choice schedule, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 1716.1 (Cauchy real order carrier)**.** *A* $\mathsf{CauchyRealOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, T, W, D, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S and T are the two source rows. Each is read through* $\mathsf{StreamName}^{\uparrow}$ *windows and a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational handoff before it is sealed as a* $\mathsf{Real}^{\uparrow}$ *name.*
2. *W is the common finite-window row. It records the shared observation lengths, synchronised stream cuts, and comparison windows used for both source rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and sign ledger. It stores the dyadic radii, positive gap requests, sign cells, and slack bookkeeping consumed by apartness and order reads.*
4. *Q is the quotient-boundary row. It records that equality-sensitive reads remain inside the displayed Cauchy quotient boundary and are not replaced by host quotient equality.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the two accepted real names after S, T, W, D, Q have been displayed.*
6. *A is the apartness and order verdict row. It records a positive apartness route, a negative apartness route when the displayed finite windows do not certify a positive gap, and the oriented order verdict exported to consumers.*
7. *H records componentwise* hsame *transport for the two source rows, common windows, dyadic tolerance ledger, quotient-boundary row, real seals, verdict row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each order or apartness request through $S, T, W, D, Q, R, A, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyQuotientBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealOrder}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive ordered-real comparison packet. It has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRealOrderUp.CauchyRealOrderUpTasteGate single carrier alignment`

Theorem 1716.2 (Cauchy real order NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealOrder}^{\uparrow}$ *carrier* $O = (S, T, W, D, Q, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealOrder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two source rows, common finite windows, dyadic tolerance and sign ledger, quotient-boundary row, real seal rows, verdict row, transport, replay, provenance, and local naming row;*
2. *classifier exactness, requiring accepted packets to be compared by the displayed stream windows, regular-rational readbacks, dyadic tolerance ledger, real seal rows, and componentwise transport;*
3. *positive apartness route, requiring every positive verdict to exhibit a finite dyadic gap certified by W, D, Q, R, A;*
4. *negative apartness route, requiring every refusal of positive apartness to record the exhausted finite windows and dyadic slack rather than a quotient-equality proof;*
5. *order transport, requiring H and C to replay the oriented verdict along componentwise* hsame *witnesses;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring both source rows to pass through regular-rational readback before the real seal and verdict rows are inspected;*
7. *real seal non-escape, requiring R to expose only the displayed* $\mathsf{Real}^{\uparrow}$ *rows and to export no selected representative, quotient equality, or ambient completeness datum;*
8. *ledger exhaustion, excluding trichotomy, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No Cauchy real order obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyRealOrderUp.TasteGate.CauchyRealOrderTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1716.1. The projection exposes exactly the two source rows, common window row, dyadic tolerance ledger, quotient-boundary row, real seal row, verdict row, and structural rows.

Classifier exactness is componentwise. The comparison first reads the two stream and regular-rational source rows through S, T, W, then consumes the dyadic sign ledger D, quotient-boundary row Q, real seal row R, and verdict row A before transport or replay can package the result.

The positive apartness route is the row of certified dyadic gaps. A positive verdict must display a finite pair of windows, a dyadic tolerance request, and a sign cell whose slack remains positive after the recorded refinements.

The negative apartness route is also finite. It records that the displayed windows and dyadic slack do not certify a positive gap at the requested precision. This is a refusal of the positive route, not a proof of quotient equality.

Order transport uses H and C. The componentwise hsame row transports the source, window, tolerance, seal, and verdict data together, while the replay row preserves the order in which a consumer is allowed to inspect them. The remaining provenance and naming rows therefore exhaust the local certificate without exporting any excluded principle. □

Lean4 ✓ `BEDC.Derived.CauchyRealOrderUp.CauchyRealOrderCarrier namecert obligations`

Theorem 1716.3 (Cauchy real order RegSeqRat handoff)**.** *Every accepted* $\mathsf{CauchyRealOrder}^{\uparrow}$ *carrier factors each order or apartness request through the route*

$$S, T \longmapsto W \longmapsto D \longmapsto Q \longmapsto R \longmapsto A \longmapsto H, C, P, N.$$

In particular, both Cauchy real source rows pass through $\mathsf{RegSeqRat}^{\uparrow}$ *readback and common finite windows before any* $\mathsf{Real}^{\uparrow}$ *seal or oriented verdict is exported.*

Proof. Start with an accepted packet $O = (S, T, W, D, Q, R, A, H, C, P, N)$. The only source coordinates are S and T, and the carrier requires them to be inspected through stream windows and regular-rational readback.

The common row W synchronises those observations. The tolerance and sign ledger D then records the dyadic scale at which a consumer asks for comparison data, while Q keeps equality-sensitive reads at the quotient-boundary surface.

The real seal R is downstream of this displayed route. The verdict row A can therefore see only the readbacks and tolerances already named by S, T, W, D, Q, R.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no earlier row contains a selected representative or host equality witness, the handoff route is exhaustive. □

Theorem 1716.4 (Cauchy real order Real seal non-escape)**.** *For every accepted* $\mathsf{CauchyRealOrder}^{\uparrow}$ *carrier* $O = (S, T, W, D, Q, R, A, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* R *can be used only through the displayed comparison route* $S, T, W, D, Q, A, H, C, P, N$*. Hence a consumer of the order surface cannot extract trichotomy, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from* R*.*

Lean4 ✓ `BEDC.Derived.CauchyRealOrderUp.CauchyRealOrderCarrier real seal nonescape`

Proof. Inspect the carrier coordinates. The row R is recorded as the terminal real-name seal for the two source rows after their stream windows, regular-rational readbacks, dyadic tolerances, and quotient-boundary data have been displayed.

Any order consumer must then pass through A. The verdict row records only positive apartness data, negative apartness refusal data at a finite request, and the oriented order verdict tied to the same dyadic sign ledger.

Transport and replay do not add analytic content. The rows H and C preserve the displayed dependencies, while P and N package and name them. Therefore the real seal has no path to export any excluded principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealOrder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1716.1, Definition 1716.2, Definition 1716.3, and Definition 1716.4 seed the finite constructive order and apartness route through two stream-backed regular-rational source rows, common windows, a dyadic tolerance and sign ledger, quotient-boundary data, real seals, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealOrder}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyRealOrderUp.CauchyRealOrderUpTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, positive and negative apartness routes, order transport, RegSeqRat handoff, real seal non-escape, and ledger exhaustion for BEDC.Derived.CauchyRealOrderUp.

Constructive story: A CauchyRealOrder$^{\uparrow}$ packet is generated from two StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ source rows, a common finite-window row, a DyadicRatCore$^{\uparrow}$ tolerance and sign ledger, a CauchyQuotientBoundary$^{\uparrow}$ row, terminal Real$^{\uparrow}$ seals, an apartness and order verdict row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1717

A Concrete Naming Certificate for $\mathsf{CauchyRealField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealField}^{\uparrow}$ packet names the finite field-facing surface for Cauchy real data by joining the regular-Cauchy operation rows and constructive order rows before later Real and Completion consumers read them as one algebraic interface. It sits after the real-name boundary of chapter 38, the regular rational source surface of chapter 301, the stream-window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the addition surface of chapter 1695, the product surface of chapter 461, the reciprocal surface of chapter 1471, and the constructive order surface of chapter 1716. The packet gives Real and Completion consumers a single finite field route; it is not host real arithmetic, quotient equality, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1717.1 (Cauchy real field carrier)**.** *A* $\mathsf{CauchyRealField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, S, D, Z, A, M, I, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source family row for the regular rational Cauchy names exposed to field-facing consumers.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window discipline used to synchronize every algebraic and order read of the source family.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic and tolerance ledger. It records the dyadic additions, products, reciprocal denominator bounds, sign cells, and slack budgets consumed by the operation rows.*
4. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row for the accepted real names reached only after R, S, D and the relevant operation or order row have been displayed.*
5. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *operation row, including the paired source windows, dyadic endpoint sum, finite addition ledger, and summed readback.*
6. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *operation row, including the paired source windows, dyadic endpoint product, product-error ledger, and product readback.*
7. *I is the* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *partial reciprocal row, including the apartness window, reciprocal budget, readback row, and terminal real seal for inputs whose displayed order row keeps the denominator away from zero.*

8. *O is the* CauchyRealOrder$^{\uparrow}$ *apartness and order row used to expose positive-gap witnesses, refusal of positive apartness at a finite request, and oriented order verdicts.*

9. *H records componentwise* hsame *transport for the source, window, dyadic, seal, addition, product, reciprocal, order, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from each field-facing request through $R, S, D, Z, A, M, I, O, H, P, N$.*

11. *P is the* Pkg *provenance over* CauchyRealField$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, RegularCauchyReciprocal$^{\uparrow}$, CauchyRealOrder$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CauchyRealField}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive field-facing packet. It has no coordinate for host real arithmetic, quotient equality, trichotomy, selected representatives, countable choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRealFieldUp.CauchyRealFieldTasteGate single carrier alignment`

Theorem 1717.2 (Cauchy real field NameCert obligations)**.** *For every accepted* CauchyRealField$^{\uparrow}$ *carrier*

$$F = (R, S, D, Z, A, M, I, O, H, C, P, N),$$

the local NameCert$_{\text{CauchyRealField}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational source family, synchronized stream windows, dyadic arithmetic and tolerance ledger, real seal row, addition row, product row, reciprocal row, order row, transport, replay, provenance, and local naming row;*

2. *addition projection, requiring the A row to be read through the accepted* RegularCauchyAddition$^{\uparrow}$ *source windows, dyadic endpoint sum, finite addition ledger, regular readback, and Real seal handoff;*

3. *product projection, requiring the M row to be read through the accepted* RegularCauchyProduct$^{\uparrow}$ *source windows, dyadic endpoint product, finite product-error ledger, regular readback, and Real seal handoff;*

4. *reciprocal projection, requiring the I row to be read only after the displayed apartness window and reciprocal budget of* RegularCauchyReciprocal$^{\uparrow}$ *have been exposed;*

5. *order projection, requiring the O row to supply the finite positive-gap, negative-apartness, and oriented-order verdict routes of* CauchyRealOrder$^{\uparrow}$*;*

6. *shared seal discipline, requiring Z to be downstream of the same R, S, D rows and the selected operation or order row rather than an independent completed-real carrier;*

7. *transport and replay, requiring H and C to preserve the componentwise source, window, ledger, operation, order, seal, provenance, and local naming rows together;*

8. *ledger exhaustion, excluding host real arithmetic, quotient equality, trichotomy, selected representatives, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No Cauchy real field obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyRealFieldUp.CauchyRealFieldCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1717.1. The projection exposes the regular rational source row, synchronized stream windows, dyadic ledger, real seal, three operation rows, order row, and structural rows.

The operation projections are inherited from the sibling surfaces. The addition row uses the finite addition route of chapter 1695; the product row uses the finite product route of chapter 461; and the reciprocal row uses the apartness-window route of chapter 1471. Each projection keeps its source windows, dyadic arithmetic, regular readback, and seal handoff visible.

The order projection is the comparison route of chapter 1716. It supplies the positive-gap, negative-apartness, and oriented-order rows used by reciprocal eligibility and ordered-field consumers.

Finally, the rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for the excluded principles, none can become a local NameCert obligation. □

Theorem 1717.3 (Cauchy real field operation composition)**.** *Every accepted* $\mathsf{CauchyRealField}^{\uparrow}$ *carrier routes addition, multiplication, and reciprocal reads through the common finite chain*

$$R \longmapsto S \longmapsto D \longmapsto (A, M, I) \longmapsto Z \longmapsto H, C, P, N.$$

The reciprocal branch additionally passes through the order row O before the reciprocal row I is allowed to expose a readback.

Lean4 ✓ `BEDC.Derived.CauchyRealFieldUp.CauchyRealFieldCarrier operation composition`

Proof. Start from the accepted packet $F = (R, S, D, Z, A, M, I, O, H, C, P, N)$. The only regular rational source family is R, and every operation read is synchronized by the same stream-window row S before the dyadic ledger D is consumed.

Project the addition and product branches. The rows A and M are the only addition and product coordinates, so their readbacks are exactly the sibling regular-Cauchy operation routes named in the carrier.

For the reciprocal branch, first read O. Its apartness route supplies the positive denominator information required by the reciprocal row I, and a missing positive-gap witness leaves the reciprocal route at the boundary surface rather than exporting an inverse.

The real seal and structural rows are downstream. The row Z is reached only after the selected branch has been displayed, and H, C, P, N preserve this dependency order for every field-facing consumer. □

Theorem 1717.4 (Cauchy real field order-compatible reciprocal boundary)**.** *For every accepted* $\mathsf{CauchyRealField}^{\uparrow}$ *carrier, a reciprocal read from I can be consumed only after the* $\mathsf{CauchyRealOrder}^{\uparrow}$ *row O displays a finite apartness route for the denominator source. Therefore the field surface exports a partial reciprocal boundary tied to constructive order data, not a total reciprocal operation on* $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyRealFieldUp.CauchyRealFieldCarrier order compatible reciprocal boundary`

Proof. Inspect the carrier coordinates. The reciprocal row I is listed as a partial reciprocal row whose apartness window is supplied by the operation packet and whose eligibility is tied to the order row O.

Use the sibling reciprocal surface. chapter 1471 requires an apartness window before any reciprocal dyadic row, budget row, readback row, or Real seal can be consumed.

Use the sibling order surface. chapter 1716 is the only row in the field packet that exports positive-gap data for real-name comparisons. Hence a reciprocal read without O has no displayed denominator-apartness source.

The remaining rows only transport and package this route. They cannot turn the partial boundary into total completed-real reciprocal data, because no such coordinate is present in the carrier. □

Theorem 1717.5 (Cauchy real field Real and Completion consumer boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyRealField}^{\uparrow}$ *packet reads one finite public surface consisting of* $R, S, D, Z, A, M, I, O, H, C, P, N$*. The consumer may project the addition, product, reciprocal, or order branch, but it receives no separate operation packet outside the field surface and no host real arithmetic, quotient equality, trichotomy, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. The consumer begins with the field carrier, not with independent operation packets. Projecting A, M, I, or O only exposes rows already named by Definition 1717.1.

The shared source and seal rows keep the projections tied together. Addition, product, reciprocal, and order reads all pass through the same R, S, D boundary before reaching Z or the structural rows.

The structural rows do not add analytic content. They transport, replay, source, and name the displayed finite packet. Consequently the Real and Completion consumer receives a unified NameCert surface rather than separate host-level arithmetic or completeness data. □

Lean4 ✓ `BEDC.Derived.CauchyRealFieldUp.CauchyRealFieldRealCompletionConsumerBoundary`

Theorem 1717.6 (Cauchy real field scoped operation route)**.** *Every field-facing read of an accepted* $\mathsf{CauchyRealField}^{\uparrow}$ *packet is exhausted by the concrete rows*

$\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauc}$

The route reads the regular rational source row, synchronized finite windows, dyadic arithmetic ledger, addition row, product row, reciprocal row, order row, and terminal $\mathsf{Real}^{\uparrow}$ *seal before any Real or Completion consumer receives the field surface. It exports no host real arithmetic, quotient equality, trichotomy, selected representatives, or ambient completeness coordinate.*

Proof. Project the accepted carrier. The only source, window, ledger, seal, operation, and order rows are R, S, D, Z, A, M, I, O, with H, C, P, N preserving and naming the same finite packet.

Use operation composition. It places addition, product, and reciprocal reads behind the common R, S, D route, with the reciprocal branch additionally reading the order row before the reciprocal row is available.

Use the order-compatible reciprocal boundary and the Real and Completion consumer boundary. These theorems keep reciprocal eligibility tied to constructive order data and keep downstream consumers inside the unified packet.

Thus the algebraic surface is exactly the displayed L10 operation route: RealUp seal, RegSeqRat source, StreamName windows, DyadicRatCore ledger, regular-Cauchy addition, product, reciprocal, and Cauchy-real order rows, with no host arithmetic or ambient completeness export. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealField}^{\uparrow}}$.

Not claimed: This chapter does not close host real arithmetic, quotient equality, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation projections, reciprocal eligibility, order projection, shared seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRealFieldUp.

Constructive story: A $\mathsf{CauchyRealField}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source family, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic ledger, a $\mathsf{Real}^{\uparrow}$ seal row, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, and $\mathsf{CauchyRealOrder}^{\uparrow}$ rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1718

A Concrete Naming Certificate for $\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}$ packet records the finite regular-Cauchy boundary for the distributive-law expression $x \cdot (y+z)$ and $x \cdot y + x \cdot z$ before any completed real consumer reads a field law. It sits over the two-source addition surface of chapter 417, the two-source product surface of chapter 461, and the field-facing operation package of chapter 1717. The packet gives Real and Completion routes a finite BEDC-internal distributivity obligation; it is not host real equality, quotient Cauchy classes, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1718.1 (Regular Cauchy field distributivity carrier)**.** *A* $\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, Z, W, D_X, D_Y, D_Z, S_L, M_L, M_Y, M_Z, S_R, E_L, E_R, R, H, C, P, N)$$

with the following displayed rows:

1. X, Y, Z *are the three* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are read as the variables* x, y, z*.*
2. W *is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite common request at which the three source rows are inspected, and it provides the shared window discipline for both distributive branches.*
3. D_X, D_Y, D_Z *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from* X, Y, Z *through* W*.*
4. S_L *is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *comparison boundary for the displayed source sum* $Y + Z$ *used by the left branch.*
5. M_L *is the first* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *branch, reading* X *and the readback of* S_L *as the product route for* $x \cdot (y + z)$*.*
6. M_Y *and* M_Z *are the two* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *branches for* $x \cdot y$ *and* $x \cdot z$*, each consuming the same* X, W, D_X *row with the corresponding* Y *or* Z *row.*
7. S_R *is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *comparison boundary that adds the two product readbacks from* M_Y *and* M_Z*.*
8. E_L *and* E_R *are finite error-budget ledgers. They record the endpoint addition budget for* $Y + Z$*, the product budgets for* M_L, M_Y, M_Z*, the final sum budget for* S_R*, and the tolerance comparison between the two readback branches.*

9. *R is the terminal* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison readback row, displayed only after both branches have exposed their regular readbacks and the ledgers have matched the requested tolerance.*

10. *H records componentwise* hsame *transport for the three source rows, synchronized windows, dyadic endpoint rows, the two product branches on the right, the left product branch, the two sum boundaries, ledger rows, readback row, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a distributivity request through $X, Y, Z, W, D_X, D_Y, D_Z, S_L, M_L, M_Y, M_Z, S$*

12. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, $\mathsf{CauchyRealField}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite distributivity packet. It has no coordinate for host real equality, completed-real multiplication, quotient Cauchy classes, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFieldDistributivityUp.RegularCauchyFieldDistributivityTasteGate`
`single carrier alignment`

Theorem 1718.2 (Regular Cauchy field distributivity NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}$ *carrier*

$$D = (X, Y, Z, W, D_X, D_Y, D_Z, S_L, M_L, M_Y, M_Z, S_R, E_L, E_R, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFieldDistributivity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the three* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, dyadic endpoint rows, one left* $\mathsf{RegularCauchySum}^{\uparrow}$ *boundary, three* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *branches, one right* $\mathsf{RegularCauchySum}^{\uparrow}$ *comparison boundary, finite ledgers, readback, transport, replay, provenance, and local naming;*

2. *window synchronization, requiring all four operation rows S_L, M_L, M_Y, M_Z and the final comparison row S_R to read their source endpoints through the same displayed finite window discipline W;*

3. *left-branch exactness, requiring S_L to expose $Y + Z$ before M_L may expose the product branch $x \cdot (y + z)$;*

4. *right-branch exactness, requiring M_Y and M_Z to expose the two products $x \cdot y$ and $x \cdot z$ before S_R may expose the sum branch $x \cdot y + x \cdot z$;*

5. *ledger comparison, requiring E_L and E_R to account for every addition, product, magnitude, slack, and tolerance-comparison entry used to place the two branch readbacks inside the same requested regular-Cauchy boundary;*

6. *transport and replay stability, requiring H and C to preserve the source rows, windows, endpoint rows, operation rows, ledgers, readback, provenance, and local naming without adding host real equality or completed-real field data;*

7. *field consumer confinement, requiring any* $\mathsf{CauchyRealField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion consumer to read the distributivity obligation only through this finite packet.*

No distributivity obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1718.1. The source, window, dyadic endpoint, operation, ledger, readback, and structural rows are explicit coordinates of the packet.

The branch obligations are inherited from the sibling operation surfaces. Use chapter 417 for S_L and S_R, and use chapter 461 for M_L, M_Y, M_Z. Each operation is read only after its source windows and dyadic endpoint rows have been displayed.

The ledgers compare the two routes at the regular-Cauchy boundary. They record the finite endpoint arithmetic, product magnitude bounds, slack conversions, and output tolerances needed for the common request. The structural rows then transport and replay the same displayed packet. Since no carrier coordinate stores host real equality, quotient classes, selected representatives, countable choice, trichotomy, ambient completeness, Lean verification, or bridge data, none can become a local obligation. □

Theorem 1718.3 (Regular Cauchy field distributivity window handoff)**.** *Every accepted* RegularCauchyFieldDistribu *carrier routes a distributivity request through the finite handoff*

$$X, Y, Z \longmapsto W \longmapsto D_X, D_Y, D_Z \longmapsto S_L, M_L, M_Y, M_Z, S_R \longmapsto E_L, E_R \longmapsto R, H, C, P, N.$$

The left branch reads $Y + Z$ and then multiplies by X; the right branch multiplies X by Y and Z separately and then reads the sum comparison boundary. Both branches share the same source windows, dyadic endpoint rows, finite ledgers, componentwise hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Proof. Begin with the three regular sources. The single window coordinate W supplies the synchronized observation request, so every operation branch reads from the same finite source-window boundary.

The left branch first consumes S_L and then M_L. The right branch consumes M_Y and M_Z and then S_R. These are exactly the operation coordinates listed in the carrier, and they are the only available addition and product routes.

Finally read the two ledger rows and the structural rows. The ledgers account for the visible tolerance comparison between branch readbacks, while H, C, P, N preserve and name the displayed packet. No alternate completed-real multiplication or equality route is exposed. □

Theorem 1718.4 (Regular Cauchy field distributivity Real seal boundary)**.** *Every* CauchyRealField$^{\uparrow}$, Real$^{\uparrow}$, *or Completion consumer of an accepted* RegularCauchyFieldDistributivity$^{\uparrow}$ *packet reaches a field-law read only after the three* RegSeqRat$^{\uparrow}$ *sources, synchronized* StreamName$^{\uparrow}$ *windows, dyadic endpoint rows, both* RegularCauchyProduct$^{\uparrow}$ *branches on the right, the left* RegularCauchyProduct$^{\uparrow}$ *branch, the* RegularCauchySum$^{\uparrow}$ *comparison boundaries, finite error-budget ledgers,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed. The consumer receives a finite distributivity obligation and receives no host real equality, quotient stream equality, selected representative, countable-choice selector, trichotomy witness, or ambient* Real$^{\uparrow}$ *completeness datum.*

Proof. Project the consumer read through Definition 1718.3. The consumer cannot reach R before the two branches and the ledger comparison have been displayed.

The field-facing position is supplied by chapter 1717. That chapter collects regular-Cauchy operation rows for downstream Real and Completion consumers; the present packet adds only the finite distributivity boundary between those operation rows.

The excluded data have no source coordinate. Transport, replay, provenance, and local naming preserve the finite packet, and the packet has no row for host equality, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness. □

Theorem 1718.5 (Regular Cauchy field distributivity NameCert surface)**.** *The* RegularCauchyFieldDistributivity$^{\uparrow}$ *NameCert surface is exactly the finite packet of Definition 1718.1 together with the obligation rows of Definition 1718.2, the window handoff of Definition 1718.3, and the Real seal boundary of Definition 1718.4. It is therefore a paper-side theorem target for a future Lean declaration under* $BEDC.Derived.RegularCauchyFieldDistributivityUp$*, not a current Lean marker.*

Proof. The carrier supplies all data-bearing rows. The obligation theorem identifies the local NameCert clauses, the handoff theorem fixes the finite read order, and the Real seal theorem states the downstream consumer boundary.

These components exhaust the packet because every row named by the local NameCert is already one of $X, Y, Z, W, D_X, D_Y, D_Z, S_L, M_L, M_Y, M_Z, S_R, E_L, E_R, R, H, C, P, N$. The statement therefore records a finite BEDC distributivity surface without asserting host real equality or adding a Lean-side marker. □

Closure status for NameCert$_{\text{RegularCauchyFieldDistributivity}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyFieldDistributivity}^{\uparrow}}$, seed)

Scope closed: Definition 1718.1, Definition 1718.2, Definition 1718.3, Definition 1718.4, and Definition 1718.5 seed the finite distributivity boundary over three RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, dyadic endpoint rows, RegularCauchyProduct$^{\uparrow}$ branches, RegularCauchySum$^{\uparrow}$ comparison boundaries, finite error-budget ledgers, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyFieldDistributivity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real equality, completed-real multiplication, quotient Cauchy classes, selected representatives, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized window handoff, left-branch exactness, right-branch exactness, ledger comparison, transport, replay, provenance, local naming, and Real seal boundary for BEDC.Derived.RegularCauchyFieldDistributivityUp.

Constructive story: A RegularCauchyFieldDistributivity$^{\uparrow}$ packet is generated from three RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, dyadic endpoint rows, one RegularCauchySum$^{\uparrow}$ left comparison boundary, three RegularCauchyProduct$^{\uparrow}$ branches, one RegularCauchySum$^{\uparrow}$ right comparison boundary, finite error-budget ledgers, a RegSeqRat$^{\uparrow}$ comparison readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1719

A Concrete Naming Certificate for $\mathsf{RaabeDuhamelTest}^{\uparrow}$

Following Raabe and Duhamel, and Bishop–Bridges constructive analysis, the $\mathsf{RaabeDuhamelTest}^{\uparrow}$ packet records the finite first-order ratio-defect test that turns displayed tail estimates into a regular rational convergence route before any Real-facing consumer reads a seal. It sits beside the ratio-test route of chapter 1461, the comparison-test route of chapter 1459, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet supplies a finite convergence-test boundary for the Phase Real and Completion route; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1719.1 (Raabe–Duhamel test carrier)**.** *A* $\mathsf{RaabeDuhamelTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, Q, M, D, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source series row, exposing only the inspected term windows and partial-sum windows used by the current tail request.*
2. *Q is the positive-tail quotient row, recording the finite adjacent-term quotient windows on which the Raabe–Duhamel defect is read.*
3. *M is the displayed defect-modulus row, assigning each requested tail budget a finite threshold and a rational margin witnessing that the inspected quotient defect stays beyond the chosen comparison boundary.*
4. *D is the dyadic domination ledger, converting the defect and threshold rows into a finite majorant comparison usable by the regular Cauchy comparison-test surface.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the displayed partial sums and comparison majorants.*
6. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes D and W before any regular Cauchy conclusion is exposed.*
7. *E is the endpoint route through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after T has been displayed.*
8. *H stores componentwise* hsame *transport for the source, quotient, defect-modulus, domination, window, comparison, endpoint, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from each tail request through M, D, W, T, E.*

10. *P is the* Pkg *provenance over* $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RaabeDuhamelTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, Q, M, D, W, T, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RaabeDuhamelTestUp.RaabeDuhamelTestTasteGate single carrier alignment`

Theorem 1719.2 (Raabe–Duhamel test NameCert obligations)**.** *For every accepted* $\mathsf{RaabeDuhamelTest}^{\uparrow}$ *carrier*

$$R = (A, Q, M, D, W, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RaabeDuhamelTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source series row, adjacent-term quotient row, defect-modulus row, dyadic domination ledger, finite window row, comparison-test handoff, endpoint route, transport, replay, provenance, and local naming row;*

2. *quotient-window exactness, requiring every accepted defect read to pass through the displayed source and adjacent-term quotient windows A, Q;*

3. *defect-modulus stability, requiring the threshold and rational margin in M to be the only data used to choose the tail budget;*

4. *domination routing, requiring D and W to convert the displayed defect data into the same finite comparison windows consumed by T;*

5. *regular and Real handoff, requiring every endpoint-facing read to pass through T and then E before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*

6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 1719.1. Carrier admission is exactly the inventory $A, Q, M, D, W, T, E, H, C$, so the local certificate has no detached row for an infinite sum, quotient series equality, or ambient completeness.

The quotient-window and defect-modulus clauses are read before the comparison handoff. The source row A exposes the inspected terms and partial sums, the row Q exposes only adjacent-term quotient windows, and M records the finite threshold and rational margin used by the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed defect data into a majorant comparison, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, E supplies the regular rational and Real-facing handoff. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 1719.3 (Raabe–Duhamel test tail handoff)**.** *Every accepted* $\mathsf{RaabeDuhamelTest}^{\uparrow}$ *read reaching a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

$$A, Q \longmapsto M \longmapsto D, W \longmapsto T \longmapsto E \longmapsto (H, C, P, N).$$

Thus a Phase Real or Completion consumer receives tail convergence data only after the source series row, adjacent-term quotient row, defect threshold, dyadic domination ledger, finite windows, comparison-test handoff, endpoint route, transport, replay, provenance, and local NameCert have all been displayed.

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 1719.1, the only term-level data available before the defect estimate are A and Q, so the read first consumes the displayed source windows and adjacent-term quotient windows.

The tail budget is then forced through M. This row names the finite threshold and rational margin attached to the requested tail, and it contributes no selected infinite sum or host summability theorem.

Next the comparison route passes through D, W, T. The dyadic domination ledger D and finite window row W prepare exactly the rows consumed by $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ in T, matching the sibling route named by chapter 1459.

Only after that comparison row has been displayed can the packet reach E, the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve this same route by transport, replay, provenance, and local naming, so no consumer can bypass it through quotient series equality, selected sums, countable choice, trichotomy, host summability, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{RaabeDuhamelTest}^{\uparrow}$ endpoint-facing read factors through source series windows, adjacent-term quotient windows, a defect-modulus row, dyadic domination, StreamName windows, a RegularCauchyComparisonTest handoff, RegSeqRat and RealUp endpoint routing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: regularcauchyratiotest, regularcauchycomparisontest, regseqrat, real: $\mathsf{RaabeDuhamelTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries adjacent-term quotient windows, a defect-modulus threshold, dyadic domination, comparison-test handoff, regular rational endpoint routing, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RaabeDuhamelTest}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RaabeDuhamelTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1719.1, Definition 1719.2, and Definition 1719.3 seed the finite Raabe–Duhamel convergence-test boundary over displayed quotient-defect, domination, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RaabeDuhamelTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, defect-modulus stability, domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.RaabeDuhamelTestUp.

Constructive story: A $\mathsf{RaabeDuhamelTest}^{\uparrow}$ packet is generated from source series windows, adjacent-term quotient windows, a displayed defect modulus, dyadic domination, StreamName windows, a RegularCauchyComparisonTest handoff, RegSeqRat and RealUp endpoint routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1720

A Concrete Naming Certificate for $\mathsf{CauchyRealizerSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealizerSequence}^{\uparrow}$ packet records a finite sequence-level window over explicit Cauchy realizers before any completion-facing consumer is allowed to read a terminal real-name seal. It sits over the single-realizer route of chapter 1771, the finite stream-window gateway of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite sequence surface for the L10 Real and Completion route; it is not quotient stream equality, a selected limit, countable choice, RealUp completeness, trichotomy, host real equality, Lean verification, or a standard bridge.

Definition 1720.1 (Cauchy realizer sequence carrier)**.** *A* $\mathsf{CauchyRealizerSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of sequence indices, precision requests, and visible observation windows consumed by the sequence route.*
2. *W is the finite family of* $\mathsf{CauchyRealizer}^{\uparrow}$ *rows, one row for each displayed sequence window in S.*
3. *R is the family of* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks obtained from the displayed windows of S and the realizer rows of W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested radii, slack comparisons, and finite compatibility checks for every displayed readback in R.*
5. *E is the family of terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after the corresponding rows of S, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, realizer rows, readbacks, dyadic ledgers, real seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each Real or Completion request through the finite schedule S, the realizer family W, the readback family R, the ledger family D, the seal family E, and the structural rows H, P, N.*

8. *P is the* Pkg *provenance over* CauchyRealizerSequence$^{\uparrow}$, CauchyRealizer$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{CauchyRealizerSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, W, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, ambient RealUp completeness, trichotomy, host real equality, Lean verification, or a standard bridge.

Lean4 ✓ `BEDC.Derived.CauchyRealizerSequenceUp.CauchyRealizerSequenceTasteGate single carrier alignment`

Theorem 1720.2 (Cauchy realizer sequence NameCert obligations)**.** *For every accepted* CauchyRealizerSequence$^{\uparrow}$ *carrier*

$$Z = (S, W, R, D, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyRealizerSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the finite* StreamName$^{\uparrow}$ *schedule S, the* CauchyRealizer$^{\uparrow}$ *family W, the* RegSeqRat$^{\uparrow}$ *readback family R, the* DyadicRatCore$^{\uparrow}$ *ledger family D, the terminal* Real$^{\uparrow}$ *seal family E, and the structural rows H, C, P, N;*
2. *schedule exactness, requiring each displayed sequence index and precision request to enter through S before any realizer row is read;*
3. *rowwise realizer exposure, requiring every member of W to be an exposed* CauchyRealizer$^{\uparrow}$ *row attached to the corresponding finite window of S;*
4. *regular-readback exactness, requiring R to consume only the displayed schedule and realizer rows S, W;*
5. *dyadic tolerance accounting, requiring D to store precisely the visible radii, slack rows, and comparison evidence consumed by R and E;*
6. *Real-seal routing, requiring every terminal* Real$^{\uparrow}$ *row in E to be downstream of the matching S, W, R, D rows;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *non-escape for quotient stream equality, selected limits, countable choice, RealUp completeness, trichotomy, host real equality, Lean verification, and standard-bridge data.*

No sequence-level Cauchy realizer obligation is stored outside these rows.

Proof. Project the carrier of Definition 1720.1. The finite schedule S is the only source of displayed sequence indices and precision requests, while the family W is the only source of CauchyRealizer rows attached to that schedule.

For each displayed window, the readback and ledger rows are then forced. The row R records exactly the regular rational observations obtained from S and W, and D records exactly the dyadic tolerances and comparison evidence used to certify those observations.

The terminal seal rows are downstream. The family E has no entrance other than the matching S, W, R, D rows, while H, C, P, N transport, replay, source, and name the same finite route. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 1720.3 (Cauchy realizer sequence window factorization)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{CauchyRealizerSequence}^{\uparrow}$ *carrier factors each displayed sequence request through the finite route*

$$S \longmapsto W \longmapsto R \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a finite StreamName schedule, a family of CauchyRealizer rows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, terminal RealUp seals, transport, replay, provenance, and local naming. The factorization does not supply quotient stream equality, selected limits, countable choice, RealUp completeness, trichotomy, host real equality, Lean verification, or a standard bridge.

Proof. Begin with the accepted carrier and inspect its schedule row. A downstream request has no direct access to a sequence member; it first lands in the finite $\mathsf{StreamName}^{\uparrow}$ schedule S.

Now proceed by finite-window induction over the displayed schedule. In the empty window there is no member to read, so the route is exhausted by the structural rows. In the step case, the new displayed request exposes exactly one attached $\mathsf{CauchyRealizer}^{\uparrow}$ row in W, then its $\mathsf{RegSeqRat}^{\uparrow}$ readback in R, then the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row in D, and then the matching $\mathsf{Real}^{\uparrow}$ seal in E.

The induction hypothesis transports the already displayed windows through H, C, P, N, and the step row uses the same structural transport and replay. Thus every consumed sequence request factors through the displayed route, and the excluded quotient, selector, choice, completeness, order, equality, verification, and bridge objects remain outside the packet. □

Theorem 1720.4 (Cauchy realizer sequence Real seal non-escape)**.** *Let* $Z = (S, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyRealizerSequence}^{\uparrow}$ *carrier. Any downstream use of a terminal* $\mathsf{Real}^{\uparrow}$ *seal in* E *must pass through the finite schedule-realizer-readback-ledger route*

$$S, W, R, D$$

and the structural rows H, C, P, N*. Thus no Real seal in the sequence packet can be used as a hidden endpoint for quotient stream equality, selected limits, countable choice, RealUp completeness, trichotomy, host real equality, Lean verification, or a standard bridge.*

Proof. The only $\mathsf{Real}^{\uparrow}$ rows in the carrier are the rows of E. By Definition 1720.1, each of them is placed after a displayed schedule window, an attached CauchyRealizer row, a regular rational readback, and a dyadic tolerance ledger.

A downstream consumer therefore reaches such a seal only by replaying the corresponding finite route through C and transporting it componentwise through H. The package row P and local name N record the same route and do not add another terminal endpoint.

Because no carrier coordinate stores quotient stream equality, a selected limit, choice data, RealUp completeness, trichotomy, host real equality, Lean evidence, or bridge data, the terminal Real seals cannot escape the finite route named above. □

Falsifiable prediction: Every $\mathsf{CauchyRealizerSequence}^{\uparrow}$ Real or Completion read factors through a finite StreamName schedule, CauchyRealizer rows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-realizer, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyRealizerSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite sequence schedule, rowwise

CauchyRealizer data, regular readbacks, dyadic tolerance ledgers, terminal Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealizerSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRealizerSequence}^{\uparrow}$ packet is generated from a finite StreamName schedule, CauchyRealizer rows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, terminal RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealizerSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1720.1, Definition 1720.2, Definition 1720.3, and Definition 1720.4 seed the finite sequence-level realizer route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealizerSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, RealUp completeness, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, schedule exactness, rowwise realizer exposure, regular-readback exactness, dyadic tolerance accounting, Real-seal routing, finite-window factorization, and Real-seal non-escape for BEDC.Derived.CauchyRealizerSequenceUp.

Chapter 1721

A Concrete Naming Certificate for $\mathsf{RegularCauchyShuffle}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyShuffle}^{\uparrow}$ packet records the finite even/odd shuffle of two regular Cauchy rational names before any Real or Completion consumer is allowed to read the shuffled real-name boundary. It sits over the parity discipline of chapter 414, the finite schedule-change route of chapter 1568, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive finite schedule-combination certificate for the L10 Real and Completion route; it is not quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Definition 1721.1 (Regular Cauchy shuffle carrier)**.** *A* $\mathsf{RegularCauchyShuffle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (A, B, S, E, O, D, R_A, R_B, L_A, L_B, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose finite regular Cauchy observations are to be shuffled.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *shuffle schedule, recording the displayed requests and whether each request reads the even branch or the odd branch.*
3. *E is the even projection ledger, exposing exactly those schedule windows of S that read from the A branch.*
4. *O is the odd projection ledger, exposing exactly those schedule windows of S that read from the B branch.*
5. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the visible radii, slack rows, and branchwise comparison evidence used by both projections.*
6. *R_A and R_B are the regular readbacks of the even and odd projection routes, read only from A, E, D and from B, O, D respectively.*
7. *L_A and L_B are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows for the two projected regular Cauchy names.*
8. *H records componentwise* hsame *transport for the source rows, shuffle schedule, projection ledgers, tolerance ledger, readbacks, real seals, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each Real or Completion request through S, the selected projection ledger E or O, the shared ledger D, the corresponding readback R_A or R_B, the matching seal L_A or L_B, and the structural rows H, P, N.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyShuffle}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyShuffle}^{\uparrow}}$ *row.*

The classifier compares accepted shuffle packets only through the displayed rows $A, B, S, E, O, D, R_A, R_B, L_A, L_B, H$ It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyShuffleUp.RegularCauchyShuffleTasteGate single carrier alignment`

Theorem 1721.2 (Regular Cauchy shuffle NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyShuffle}^{\uparrow}$ *carrier*

$$Z = (A, B, S, E, O, D, R_A, R_B, L_A, L_B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyShuffle}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows A, B, the* $\mathsf{StreamName}^{\uparrow}$ *shuffle schedule S, the even and odd projection ledgers E, O, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the regular readbacks R_A, R_B, the* $\mathsf{Real}^{\uparrow}$ *seals L_A, L_B, and the structural rows H, C, P, N;*

2. *schedule exactness, requiring every displayed request in S to choose exactly one of the even or odd projection ledgers before any regular readback is consumed;*

3. *even projection exactness, requiring E to read only the A branch through the even windows of S;*

4. *odd projection exactness, requiring O to read only the B branch through the odd windows of S;*

5. *shared dyadic accounting, requiring D to store precisely the visible tolerances and slack comparisons used by both projection readbacks;*

6. *regular-readback routing, requiring R_A to consume only A, E, D and R_B to consume only B, O, D;*

7. *Real-seal routing, requiring L_A and L_B to be downstream of their corresponding source, projection, ledger, and readback rows;*

8. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*

9. *non-escape for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard-bridge data.*

No shuffle obligation is stored outside these rows.

Proof. Project the carrier of Definition 1721.1. The only source rows are A and B, and the only schedule row is S.

Now inspect each displayed request of S. The schedule sends it to exactly one projection ledger: even requests enter E and then read from A, while odd requests enter O and then read from B. The shared dyadic ledger D records the tolerance evidence used by both branches and does not introduce another branch.

The readback and seal rows are downstream. The row R_A is attached to A, E, D, the row R_B is attached to B, O, D, and the seals L_A, L_B are reached only after those corresponding readbacks. The structural rows H, C, P, N transport, replay, source, and name the same finite routes.

Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 1721.3 (Regular Cauchy shuffle even/odd projection handoff)**.** *Let*

$$Z = (A, B, S, E, O, D, R_A, R_B, L_A, L_B, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyShuffle}^{\uparrow}$ *carrier. Every downstream Real or Completion request for an even projection factors through*

$$S \longmapsto E \longmapsto A \longmapsto D \longmapsto R_A \longmapsto L_A \longmapsto H, C, P, N,$$

and every downstream request for an odd projection factors through

$$S \longmapsto O \longmapsto B \longmapsto D \longmapsto R_B \longmapsto L_B \longmapsto H, C, P, N.$$

The handoff is the finite parity projection surface supplied by the shuffle packet. It exports no quotient stream equality, selected limit, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyShuffleUp.RegularCauchyShuffleEvenOddProjectionHandoff`

Proof. Begin with a downstream request and read the finite schedule S. If the schedule marks the request as even, the carrier exposes the projection ledger E; if it marks the request as odd, the carrier exposes the projection ledger O.

In the even case, the projection ledger has only the A branch as source. The request then passes through the shared dyadic ledger D, the regular readback R_A, and the seal L_A before the structural rows H, C, P, N record transport, replay, provenance, and local naming.

In the odd case, the same argument uses O in place of E, the B branch in place of A, the readback R_B in place of R_A, and the seal L_B in place of L_A.

These two routes are exactly the finite even and odd projections of the carrier. No third route exists in the displayed packet, and the excluded quotient, selector, choice, equality, order, completeness, verification, and bridge objects remain outside the handoff. □

Falsifiable prediction: Every $\mathsf{RegularCauchyShuffle}^{\uparrow}$ Real or Completion read factors through a finite StreamName shuffle schedule, an even or odd projection ledger, the selected RegSeqRat source row, a shared DyadicRatCore tolerance ledger, the corresponding regular readback, the corresponding RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-interleaving, cauchy-reindexing, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyShuffle}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular Cauchy source rows, one finite shuffle schedule, two projection ledgers, a shared dyadic tolerance ledger, two readbacks, two terminal real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyShuffle}^{\uparrow}}$.

Constructive story: A RegularCauchyShuffle$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, a finite StreamName$^{\uparrow}$ shuffle schedule, even and odd projection ledgers, a shared DyadicRatCore$^{\uparrow}$ tolerance ledger, two regular readbacks, two terminal Real$^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyShuffle}^{\uparrow}}$, seed)

Scope closed: Definition 1721.1, Definition 1721.2, and Definition 1721.3 seed the finite even/odd shuffle and projection route for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyShuffle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, schedule exactness, even and odd projection exactness, shared dyadic accounting, regular-readback routing, Real-seal routing, and projection handoff for BEDC.Derived.RegularCauchyShuffle

Chapter 1722

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$

Following Bishop and Bridges' constructive Cauchy sequence discipline, the $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ packet records the finite BEDC route by which a cofinal subsequence of a regular Cauchy row preserves the same Real-facing seal. It consumes the subsequence interface of chapter 381, the cofinal selector surface of chapter 405, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet names invariance as displayed finite routing data, not as quotient stream equality, selected limit choice, host real equality, or ambient Real completeness.

Definition 1722.1 (Regular-Cauchy subsequence invariance carrier)**.** *A* $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (Q, F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source regular Cauchy row whose Real-facing seal is being preserved.*
2. *F is the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row, carrying only displayed monotone and cofinal access to source indices.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the source and selected subsequence windows inspected along F.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the selected windows and the regular Cauchy source.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the source row, selected windows, readback row, and Real-facing seal.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal exposed after Q, F, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the source row, cofinal selector, stream windows, readback row, dyadic ledger, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from any finite subsequence read back through F, S, R, D before the seal row E is reached.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, F, S, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceInvarianceUp.RegularCauchySubsequenceInvarianceTasteGate`
`single carrier alignment`

Theorem 1722.2 (Regular-Cauchy subsequence invariance NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ *carrier*

$$I = (Q, F, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, cofinal selector, stream-window ledger, regular rational readback, dyadic tolerance ledger, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *cofinal access, requiring every selected index read to pass through the displayed selector row F rather than through an external choice function;*
3. *window alignment, requiring every subsequence observation to be one of the finite* $\mathsf{StreamName}^{\uparrow}$ *windows named by S;*
4. *readback exactness, requiring R to read only the selected windows from S and the source regular Cauchy row Q;*
5. *tolerance preservation, requiring the dyadic ledger D to be the same ledger consumed by Q, S, R, and the seal row E;*
6. *Real-seal non-escape, requiring E to be reached only after F, S, R, D have displayed the subsequence route from Q.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 1722.1. The visible analytic rows are exactly the source row Q, the cofinal selector F, stream windows S, regular rational readback R, dyadic ledger D, and Real seal E.

Cofinal access is read from F. Since every selected index must enter through that row, the certificate never calls on a detached infinite choice function or host subsequence object.

Window alignment and readback exactness are read from S and R. The selected observations are the finite windows named by S, and R can only replay those windows against the source row Q.

Tolerance preservation is the projection to D. The source row, selected windows, readback row, and Real seal all consume that same dyadic ledger, so no second tolerance budget can alter the subsequence read.

Finally, H, C, P, N transport, replay, source, and name only the displayed packet rows. The excluded quotient, choice, selected-limit, host-equality, completeness, Lean, and bridge data therefore have no coordinate in the local NameCert surface. □

Theorem 1722.3 (Regular-Cauchy subsequence invariance cofinal route)**.** *Let $I = (Q, F, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ *carrier. Every subsequence read from I factors through the cofinal route*

$$Q, F, S, R, D, E.$$

In particular, the read reaches the Real-facing seal only after the source regular Cauchy row, cofinal selector, finite stream windows, regular rational readback, and dyadic tolerance ledger have all been displayed.

Proof. Begin with a subsequence read of the accepted packet. The only selector coordinate is F, so the read first factors from the source row Q through the displayed cofinal access row.

The selected observation is then forced into the finite window ledger S. Since the carrier has no host stream coordinate, each inspected value is read through one of the displayed $\mathsf{StreamName}^{\uparrow}$ windows.

The regular rational readback and tolerance rows come next. The row R replays the selected windows as regular rational data, and D supplies the shared dyadic tolerance ledger used by both the source row and the selected readback.

The Real-facing seal is downstream of those rows. Thus the read reaches E only through Q, F, S, R, D, and the support rows H, C, P, N cannot add another analytic route. □

Theorem 1722.4 (Regular-Cauchy subsequence invariance Real seal non-escape)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ *carrier*

$$I = (Q, F, S, R, D, E, H, C, P, N),$$

the public export is the displayed finite route from the source regular Cauchy row to the Real-facing seal. It exports no quotient stream equality, selected limit, countable choice principle, host real equality, ambient Real completeness, independent Real carrier, Lean credential, or bridge credential.

Proof. Use Definition 1722.3. Every Real-facing subsequence read has already passed through the source row, cofinal selector, finite stream windows, regular rational readback, and dyadic tolerance ledger before it reaches E.

The carrier has no remaining analytic coordinate. The transport, replay, provenance, and naming rows preserve the displayed route, but they do not introduce quotient representatives, selected limits, choice principles, host equality witnesses, completeness principles, or independent Real carriers.

Therefore the public export is exactly the finite seal-preserving route described above. The omitted Lean and bridge credentials are also not exported, because this seed packet records only the paper-side finite NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}$ packet is generated from a source regular Cauchy row, a cofinal selector row, finite StreamName windows, RegSeqRat readback, a shared DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1722.1, Definition 1722.2, Definition 1722.3, and Definition 1722.4 seed the finite cofinal-subsequence route preserving the same Real-facing regular Cauchy seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceInvariance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Real completeness, selected limits, quotient stream equality, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Formal closure requires checked carrier admission, cofinal-route factorization, tolerance preservation, and Real-seal non-escape theorems under BEDC.Derived.RegularCauchySubsequenceInvarianceUp.

Chapter 1723

A Concrete Naming Certificate for $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ packet records the shared finite tail-threshold data by which a Cauchy realizer sequence serves Real and Completion requests before any terminal real-name seal is read. It refines the sequence route of chapter 1720, the single-realizer route of chapter 1771, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite tail-modulus surface for the L10 Real and Completion route; it is not quotient stream equality, a selected limit, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, host real equality, Lean verification, or a standard bridge.

Definition 1723.1 (Cauchy realizer tail modulus carrier)**.** *A* $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the shared tail-threshold and modulus row, recording the finite tail index used by every displayed precision request in the packet.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule of sequence indices, precision requests, and visible observation windows governed by M.*
3. *W is the finite family of* $\mathsf{CauchyRealizer}^{\uparrow}$ *rows attached to the windows of S after the common tail threshold has been displayed.*
4. *R is the family of* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks obtained from the displayed schedule S, the realizer rows W, and the shared threshold row M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the common dyadic radii, slack comparisons, and finite compatibility checks served by M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal family reached only after the corresponding rows of M, S, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the shared threshold, window schedule, realizer rows, readbacks, dyadic ledger, real seals, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each Real or Completion request through M, S, W, R, D, E and the structural rows H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$, $\mathsf{CauchyRealizerSequence}^{\uparrow}$, $\mathsf{CauchyRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealizerTailModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $M, S, W, R, D, E, H, C, P, N$. It has no coordinate for private tail thresholds, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, host real equality, Lean verification, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.CauchyRealizerTailModulusUp.CauchyRealizerTailModulusTasteGate single carrier alignment`

Theorem 1723.2 (Cauchy realizer tail modulus NameCert obligations)**.** *For every accepted* CauchyRealizerTailMod *carrier*

$$T = (M, S, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealizerTailModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the shared threshold row M, the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{CauchyRealizer}^{\uparrow}$ *family W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the terminal* $\mathsf{Real}^{\uparrow}$ *seal family E, and the structural rows H, C, P, N;*
2. *shared-tail admission, requiring every displayed precision request in S to use the same threshold row M before any realizer row is read;*
3. *rowwise realizer exposure, requiring every member of W to be attached to a window of S whose tail threshold is supplied by M;*
4. *regular-readback exactness, requiring R to consume only the displayed rows M, S, W;*
5. *dyadic tolerance accounting, requiring D to store precisely the common radii, slack rows, and comparison evidence served by M and consumed by R and E;*
6. *Real-seal routing, requiring every terminal* $\mathsf{Real}^{\uparrow}$ *row in E to be downstream of the matching M, S, W, R, D rows;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *non-escape for private thresholds, quotient stream equality, selected limits, countable choice,* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, host real equality, Lean verification, and standard-bridge data.*

No tail-modulus obligation for this carrier is stored outside these rows.

Proof. Project the carrier of Definition 1723.1. The shared row M is the only displayed source of tail-threshold data, and S is the only displayed source of sequence indices, precision requests, and observation windows governed by that row.

For each displayed window, finite-window induction determines the remaining route. The empty window has no realizer or readback to expose. In the step case, the new request first reads the already displayed threshold row M, then its scheduled window in S, its $\mathsf{CauchyRealizer}^{\uparrow}$ row in W, its $\mathsf{RegSeqRat}^{\uparrow}$ readback in R, and its dyadic accounting row in D.

The terminal seal rows are downstream of the same route. The family E has no entrance other than the matching M, S, W, R, D rows, while H, C, P, N transport, replay, source, and name that finite route. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 1723.3 (Cauchy realizer shared-tail exactness)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ *carrier factors each displayed precision request through the common route*

$$M \longmapsto S \longmapsto W \longmapsto R \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives one shared tail-threshold row, a finite StreamName schedule, CauchyRealizer rows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, terminal RealUp seals, transport, replay, provenance, and local naming. The factorization does not supply private tail thresholds, quotient stream equality, selected limits, countable choice, $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, host real equality, Lean verification, or a standard bridge.*

Proof. Begin with an accepted carrier and inspect the common row M. A downstream request has no direct access to a private tail threshold, because the carrier exposes only the single shared threshold and modulus row.

Proceed by finite-window induction over S. In the empty window the consumer can only see the structural rows H, C, P, N. In the step case, the displayed request uses M before its scheduled window, realizer row, readback row, dyadic ledger row, and terminal seal are available.

The induction hypothesis transports the earlier windows through the same structural rows, and the step row uses the same replay route. Therefore every displayed request factors through the common route above, and no omitted object can be read as part of the accepted packet. □

Theorem 1723.4 (Cauchy realizer tail modulus Real seal non-escape)**.** *Let* $T = (M, S, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ *carrier. Any downstream use of a terminal* $\mathsf{Real}^{\uparrow}$ *seal in* E *must pass through the shared tail-modulus route*

$$M, S, W, R, D$$

and the structural rows H, C, P, N*. Thus no Real seal in the packet can be used as a hidden endpoint for private thresholds, quotient stream equality, selected limits, countable choice,* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, host real equality, Lean verification, or a standard bridge.*

Proof. The only $\mathsf{Real}^{\uparrow}$ rows in the carrier are the rows of E. By Definition 1723.1, each of them is placed after the displayed shared threshold row, a scheduled window, an attached CauchyRealizer row, a regular rational readback, and a dyadic tolerance ledger.

A downstream consumer therefore reaches such a seal only by replaying the corresponding finite route through C and transporting it componentwise through H. The package row P and local name N record the same route and do not add another terminal endpoint.

Because no carrier coordinate stores a private threshold, quotient stream equality, a selected limit, choice data, $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, host real equality, Lean evidence, or bridge data, the terminal Real seals cannot escape the finite route named above. □

Falsifiable prediction: Every $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ Real or Completion read factors through one shared tail-threshold row, a finite StreamName schedule, CauchyRealizer rows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-realizer-sequence, cauchy-realizer, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a shared tail threshold, a finite sequence schedule, rowwise CauchyRealizer data, regular

readbacks, a dyadic tolerance ledger, terminal Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealizerTailModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRealizerTailModulus}^{\uparrow}$ packet is generated from one shared tail-threshold row, a finite StreamName schedule, CauchyRealizer rows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, terminal RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealizerTailModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1723.1, Definition 1723.2, Definition 1723.3, and Definition 1723.4 seed the shared finite tail-modulus route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealizerTailModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, shared-tail admission, rowwise realizer exposure, regular-readback exactness, dyadic tolerance accounting, Real-seal routing, finite-window factorization, and Real-seal non-escape for BEDC.Derived.CauchyRealizerTailModulusUp.

Chapter 1724

A Concrete Naming Certificate for $\mathsf{DecimalNormality}^{\uparrow}$

Following Borel on normal numbers, the $\mathsf{DecimalNormality}^{\uparrow}$ packet records only finite decimal digit-frequency evidence as BEDC NameCert data. It consumes the finite decimal-prefix readback surface of chapter 1417, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the finite stream-window interface of chapter 126, the regular rational handoff of chapter 301, and the probability and frequency surfaces of chapter 184, chapter 185, and chapter 92 where those rows are explicitly displayed. The packet distinguishes decimal digit-frequency certificates from plain decimal expansions while refusing to turn Borel's measure-theoretic normality theorem into a local finite certificate.

Definition 1724.1 (Decimal normality carrier)**.** *A* $\mathsf{DecimalNormality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DecimalExpansion}^{\uparrow}$ *row, carrying the inspected base-ten digit prefix and its endpoint-normalized decimal readback route.*
2. *W is the finite prefix-window row, listing the displayed prefix lengths, subword windows, and digit blocks whose frequencies are being inspected.*
3. *F is the digit-frequency ledger, recording for each displayed digit or finite digit block the counted occurrences in W, the displayed denominator, and the rational comparison row for the target frequency.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the same decimal window and frequency ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the D, W, F, R rows have been displayed.*
6. *H records componentwise* hsame *transport for the decimal expansion, prefix-window, frequency, regular-readback, real-seal, continuation, provenance, and local naming coordinates.*
7. *C records displayed* Cont *routes that replay finite prefix-window frequency rows without opening an infinite host stream or a measure quotient.*
8. *P is the* Pkg *provenance over* $\mathsf{DecimalNormality}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the displayed probability-frequency surfaces,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalNormality}^{\uparrow}}$ *row.*

The carrier has no coordinate for a measure-theoretic almost-everywhere normality theorem, random real selector, quotient stream equality, selected host decimal, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.DecimalNormalityUp.DecimalNormalityTasteGate single carrier alignment`

Theorem 1724.2 (Decimal normality NameCert obligations)**.** *For every accepted* $\mathsf{DecimalNormality}^{\uparrow}$ *carrier* $K = (D, W, F, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DecimalNormality}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the decimal expansion row, finite prefix-window row, digit-frequency ledger, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*
2. *digit-window frequency stability, requiring each transported frequency claim to read the same displayed prefix windows and the same counted digit or finite-block rows;*
3. *decimal endpoint normalization compatibility, requiring endpoint conventions already displayed by* $\mathsf{DecimalExpansion}^{\uparrow}$ *to be read before any frequency row is compared;*
4. $\mathsf{Real}^{\uparrow}$ *readback, requiring the terminal real seal to remain downstream of the decimal expansion, prefix-window, frequency, and regular-readback rows;*
5. *ledger non-escape, requiring every consumer of the packet to read only* $D, W, F, R, E, H, C, P, N$*.*

No obligation is stored in a hidden infinite decimal stream, an almost-everywhere normality theorem, a random real selector, quotient stream equality, or ambient real completeness.

Proof. Carrier admission is projection from Definition 1724.1. The tuple displays the decimal expansion, finite prefix windows, frequency counts, regular readback, real seal, transport, replay, provenance, and local naming rows as one finite packet.

Frequency stability is componentwise. A transported row in H preserves the prefix-window coordinate W and the frequency coordinate F, so a digit or block count can be compared only against the same displayed finite window data.

Endpoint normalization compatibility follows because the decimal expansion row D is read before F. Any terminating or repeating endpoint convention must therefore be supplied by the decimal-expansion packet before a frequency ledger can count the displayed digits.

For real readback, the row E appears only downstream of D, W, F, R. The continuation and provenance rows replay that same order and add no external coordinates. Hence ledger non-escape follows from the carrier list itself. □

Theorem 1724.3 (Decimal normality frequency-window stability)**.** *Let* $K = (D, W, F, R, E, H, C, P, N)$ *and* $K' = (D', W', F', R', E', H', C', P', N')$ *be accepted* $\mathsf{DecimalNormality}^{\uparrow}$ *carriers. If the displayed* hsame *rows in* H, H' *identify the decimal-expansion rows, finite prefix-window rows, and digit-frequency ledger rows, then every finite prefix-window frequency row read from* K *transports to the corresponding finite prefix-window frequency row read from* K' *through the displayed* Cont *routes. The transported read uses no host infinite stream, quotient stream equality, random selector, measure-completion theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Proof. Read the frequency row through the source carrier. By Definition 1724.1, the row is not an isolated predicate: it is attached to the decimal expansion row D and the finite prefix-window row W.

The displayed hsame data identify the corresponding decimal, window, and frequency coordinates in K' componentwise. Transport therefore carries the counted digit or block row, its displayed denominator, and its rational frequency comparison to the matching F' coordinate.

The continuation row then replays the same finite read on the target side. Because the replay route uses only D', W', F' and the structural rows R', E', H', C', P', N', none of the excluded external objects can enter the transported frequency-window claim. □

Theorem 1724.4 (Decimal normality RealUp readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DecimalNormality}^{\uparrow}$ *packet first reads the finite* $\mathsf{DecimalExpansion}^{\uparrow}$ *windows, then the displayed prefix-window frequency ledger, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and only then the terminal real seal. The consumer receives no measure-theoretic almost-everywhere normality theorem, random real selector, quotient stream equality, selected host decimal, or host completeness principle from this readback.*

Proof. Start with an accepted carrier $K = (D, W, F, R, E, H, C, P, N)$. The only real-facing coordinate is E, and the carrier places it after the decimal, window, frequency, and regular-readback rows.

A consumer must therefore read D before it can inspect any digit data. The finite prefix-window row W bounds the displayed digit positions, and the ledger F counts only those displayed positions or finite blocks.

The regular-readback row R is reached from the same finite route, and the structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Since no excluded object is a coordinate of the packet, the terminal real readback cannot export it. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalNormality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalNormality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1724.1, Definition 1724.2, Definition 1724.3, and Definition 1724.4 seed the finite decimal digit-frequency certificate surface over $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalNormality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic Borel normality as a theorem, random real selection, quotient streams, selected host decimals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, digit-window frequency stability, decimal endpoint normalization compatibility, RealUp readback, and ledger non-escape for BEDC.Derived.DecimalNormalityUp.

Constructive story: A $\mathsf{DecimalNormality}^{\uparrow}$ packet is generated from a $\mathsf{DecimalExpansion}^{\uparrow}$ row, finite prefix-window rows, digit-frequency ledger rows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1725

A Concrete Naming Certificate for $\mathsf{CompletionExtractor}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompletionExtractor}^{\uparrow}$ packet records the finite handoff by which explicit Cauchy modulus data is extracted into the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the explicit source route of chapter 1705, the threshold surface of chapter 1423, the completion handoff of chapter 1691, the finite window rows of chapter 126, the regular readback surface of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet is a reviewable L10 completion-extraction object; it is not quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1725.1 (Completion extractor carrier)**.** *A* $\mathsf{CompletionExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (G, M, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source row. It names the explicit Cauchy sequence data from which every completion-facing read begins.*
2. *M is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row. It records the finite precision request, the displayed threshold, and the Real-facing modulus budget read by the extractor.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It records the inspected windows admitted by the threshold row M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the dyadic radii, slack rows, comparison budgets, and tolerance conversions used by M and S.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational handoff obtained from the displayed source, threshold, finite windows, and dyadic ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *seal handoff reached only after G, M, S, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the source, threshold, window, dyadic ledger, regular readback, seal handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion or Real precision request through $G, M, S, D, Q, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CompletionExtractor}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{FastCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionExtractor}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite completion-extractor packet. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompletionExtractorUp.CompletionExtractorUpTasteGate single carrier alignment`

Theorem 1725.2 (Completion extractor NameCert obligations)**.** *For every accepted* $\mathsf{CompletionExtractor}^{\uparrow}$ *carrier* $X = (G, M, S, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionExtractor}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier exposure, requiring the displayed source, threshold, finite-window, dyadic-ledger, regular-readback, seal-handoff, transport, replay, provenance, and local naming rows to be inspectable in one finite packet;*
2. *classifier stability, requiring accepted packets to be compared only through* $G, M, S, D, Q, E, H, C, P, N$*;*
3. *modulus-window induction, requiring each finite precision request to read* M *before the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window row* S *is consumed;*
4. *regular-readback admission, requiring* Q *to be downstream of the explicit source, modulus threshold, finite windows, and dyadic tolerance ledger;*
5. *Real-seal nonescape, requiring* E *to remain downstream of* G, M, S, D, Q *and never to serve as quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient completeness.*

No completion-extractor obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CompletionExtractorUp.CompletionExtractorNameCertObligations`

Proof. Carrier exposure is the projection of Definition 1725.1. The displayed packet consists of the explicit source G, threshold row M, finite windows S, dyadic ledger D, regular readback Q, seal handoff E, and structural rows H, C, P, N.

Classifier stability is forced by the same projection. Since the carrier has no coordinate beyond those rows, any accepted comparison can inspect only the displayed source, threshold, window, dyadic, readback, seal, transport, replay, provenance, and naming data.

Modulus-window induction reads the Real-facing threshold through chapter 1423 and then opens the finite windows through chapter 126. The tolerance arithmetic used by that induction is confined to the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger of chapter 291.

The regular-readback and Real-seal rows follow chapter 301 and chapter 1691. The row Q is admitted only after G, M, S, D, and E is terminal after Q; therefore the listed five obligations exhaust the local NameCert surface. □

Theorem 1725.3 (Completion extractor regular readback route)**.** *Every accepted regular readback of a* $\mathsf{CompletionExtractor}^{\uparrow}$ *carrier* $X = (G, M, S, D, Q, E, H, C, P, N)$ *factors through the finite route*

$$G \longmapsto M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

The route cannot use quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionExtractorUp.CompletionExtractorRegularReadbackRoute`

Proof. Start from an accepted regular readback. By Definition 1725.1, the only regular rational coordinate is Q, and it is placed after the explicit source row G, modulus threshold row M, finite-window row S, and dyadic ledger row D.

The source row is supplied by chapter 1705. The threshold row then reads the Real-facing modulus surface of chapter 1423, and the corresponding finite windows are the $\mathsf{StreamName}^{\uparrow}$ windows named by S.

The dyadic ledger D supplies the tolerance conversions used by the same window. Only after that ledger is fixed does chapter 301 admit the regular readback row Q.

Finally, the seal handoff E is downstream of the readback through chapter 1691. The excluded quotient, selector, choice, order-decision, host-equality, and ambient-completeness data have no carrier row and no replay edge, so every accepted regular readback factors through the displayed route. □

Falsifiable prediction: Every $\mathsf{CompletionExtractor}^{\uparrow}$ regular or Real-facing read factors through an EffectiveCauchySequence source, a RealCauchyModulus threshold, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp/FastCauchyCompletion seal handoff, transport, replay, provenance, and local naming.

Independence witness: effective-cauchy-sequence, realcauchymodulus, fast-cauchy-completion, streamname, regseqrat, dyadicratcore: $\mathsf{CompletionExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source, threshold, finite-window, tolerance-ledger, regular-readback, seal-handoff, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionExtractor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1725.1, Definition 1725.2, and Definition 1725.3 seed the finite completion-extraction route from explicit Cauchy modulus data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionExtractor}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CompletionExtractorUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked carrier obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier stability, modulus-window induction, regular-readback admission, and Real-seal nonescape for BEDC.Derived.CompletionExtractorUp.

Constructive story: A $\mathsf{CompletionExtractor}^{\uparrow}$ packet is generated from an EffectiveCauchySequence source row, RealCauchyModulus threshold row, StreamName finite windows, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp/FastCauchyCompletion seal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1726

A Concrete Naming Certificate for $\mathsf{LocallyCompact}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop–Bridges local compactness practice, the $\mathsf{LocallyCompact}^{\uparrow}$ packet records a compact neighbourhood certificate at one inspected point before a properness or completion consumer may read any global compactness boundary. It sits between the closed-ball row of chapter 1451, the compact metric witness of chapter 129, the located compact handoff of chapter 1488, and the radius-window comparison of **??**. The certificate is local: it names one displayed neighbourhood window and its finite compact witness, not a host-selected neighbourhood base, an open-cover compactness theorem, or a global proper metric structure.

Definition 1726.1 (LocallyCompact carrier)**.** *A* $\mathsf{LocallyCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, x, r, B, K, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *row whose distance, point, and transport data are already admitted as finite BEDC carrier rows;*
2. *x is the inspected point row in X, named as local data rather than selected from an ambient host set;*
3. *r is a positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius ledger for the neighbourhood window around x;*
4. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row around x at radius r, exposing the closed comparison $d(x, y) \leq_{\mathsf{R}} r$ through the center-radius certificate surface of chapter 1451;*
5. *K is a* $\mathsf{CompactMetric}^{\uparrow}$ *witness for the displayed closed ball B or for the named neighbourhood window carried by B;*
6. *A is an optional* $\mathsf{LocatedCompact}^{\uparrow}$ *handoff, either a located compact row for the same window or an explicit empty handoff row when no located boundary is claimed;*
7. *H records componentwise* hsame *transports for the metric source, inspected point, positive radius ledger, closed-ball row, compact witness, located handoff, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from a local neighbourhood request through X, x, r, B, K, A, H and into the compactness or completion consumer;*

9. *P is the* Pkg *provenance over* $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for an open cover, a host-selected neighbourhood selector, quotient point equality, countable choice, ambient real completeness, or a global properness assertion.

Lean4 (definition) `BEDC.Derived.LocallyCompactUp.TasteGate.LocallyCompactUp`

Theorem 1726.2 (LocallyCompact NameCert obligations)**.** *For every accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *carrier* $L = (X, x, r, B, K, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$ *surface consists exactly of carrier admission, local neighbourhood indexing, closed-ball compact witness transport, located compact handoff when the row A is present,* $\mathsf{ProperMetric}^{\uparrow}$ *comparison boundary, and non-escape for the displayed rows $X, x, r, B, K, A, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactUpTasteGate single carrier alignment`

Proof. Project the accepted packet $L = (X, x, r, B, K, A, H, C, P, N)$. Carrier admission reads only the metric source, inspected point, radius ledger, closed-ball row, compact witness, located handoff row, transports, replay, provenance, and local naming row.

Local neighbourhood indexing is the positive-radius part of the packet. The request first names x and r, then reaches the closed-ball row B; no selector ranging over host neighbourhoods occurs.

Closed-ball compact witness transport is componentwise. The compact witness K is attached to the displayed ball or window named by B, and every transported read passes through H before the continuation replay C reaches a consumer.

The located compact handoff is optional and exact. When A is a $\mathsf{LocatedCompact}^{\uparrow}$ row, it is read through the same B, K, H, C, P, N support. When the empty handoff row is displayed, the packet makes no locatedness claim.

The $\mathsf{ProperMetric}^{\uparrow}$ comparison boundary is one-way. A proper metric packet may use the local row as one indexed closed-ball window, but this local row does not supply a radius-indexed family for all centers and radii.

Finally, non-escape follows from the carrier definition. Since the packet has no row for open covers, host neighbourhood selectors, quotient point equality, countable choice, or ambient real completeness, those objects cannot be recovered by any local $\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$ consumer. □

Theorem 1726.3 (LocallyCompact closed-ball neighbourhood base)**.** *Every local compactness consumer of an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet factors through*

$$X, x, r, B, K, A, H, C, P, N$$

and receives only the displayed metric source, inspected point, positive radius ledger, closed-ball row, compact witness, optional located compact handoff, transports, replay, provenance, and local naming data. It receives no open-cover compactness, host neighbourhood selector, quotient point equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactClosedBallNeighborhoodBase`

Proof. Start from a consumer request for local compactness at the inspected point. The only admissible entry point is the carrier projection, so the request first reads X, x, r and then the closed-ball row B.

The compactness data are exactly K. A consumer may transport that witness along H and replay it along C, but the route never leaves the displayed closed-ball or neighbourhood window named by B.

If located compactness is needed, the consumer reads A only as a handoff row over the same window. If no such handoff is displayed, the packet exposes no located compact claim.

The provenance row P names the sibling certificates that may be cited, and N names the local packet. Therefore every downstream compactness, completion, or properness comparison factors through the displayed tuple above, with no additional host compactness or completeness datum. □

Theorem 1726.4 (LocallyCompact located handoff boundary)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every* $\mathsf{LocatedCompact}^{\uparrow}$ *consumer of L first reads the* $\mathsf{Met}^{\uparrow}$ *row X, inspected point x,* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius ledger r,* $\mathsf{MetricClosedBall}^{\uparrow}$ *row B, and* $\mathsf{CompactMetric}^{\uparrow}$ *witness K before the located handoff row A can be inspected. The handoff is transported through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N, and it does not claim open-cover compactness, a neighbourhood-base selector, countable choice, global properness, or ambient Real completeness.*

Proof. Use the carrier of Definition 1726.1. The located handoff row A is listed only after the metric source, inspected point, positive radius ledger, closed-ball row, and compact witness.

Apply the NameCert obligations of Definition 1726.2. They require located compact handoff to be exact when A is present and to remain empty when no located boundary is displayed.

Finally use the closed-ball neighbourhood-base theorem, Definition 1726.3. Every consumer factors through $X, x, r, B, K, A, H, C, P, N$, so the located handoff cannot bypass the displayed MetricSpace, MetricClosedBall, CompactMetric, Rat or Real radius, BHist, hsame, Cont, Pkg, and NameCert route. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactLocatedHandoffBoundary`

Theorem 1726.5 (LocallyCompact properness comparison non-escape)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Any* $\mathsf{ProperMetric}^{\uparrow}$ *comparison that consumes L receives one displayed closed-ball window over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricClosedBall}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{LocatedCompact}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It receives no global properness theorem, no radius-indexed family for all centers, no neighbourhood-base selector, no countable choice, and no ambient Real completeness.*

Proof. Project L through Definition 1726.1. The properness-facing data are the single inspected point x, radius ledger r, closed-ball row B, compact witness K, and optional located handoff A.

The NameCert obligations of Definition 1726.2 make the $\mathsf{ProperMetric}^{\uparrow}$ comparison boundary one-way. A proper metric packet may read this local row as an indexed closed-ball window, but L does not contain the global family required to prove properness.

The closed-ball neighbourhood-base theorem of Definition 1726.3 exhausts the consumer route through H, C, P, N. Since no coordinate ranges over all centers and radii, the properness comparison cannot escape the displayed local packet. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactPropernessComparisonNonescape`

Theorem 1726.6 (LocallyCompact completion consumer route)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every completion-facing consumer reads local compactness only through the displayed* $\mathsf{Met}^{\uparrow}$ *source, inspected point,* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius ledger,* $\mathsf{MetricClosedBall}^{\uparrow}$

window, CompactMetric$^{\uparrow}$ *witness, optional* LocatedCompact$^{\uparrow}$ *handoff,* BHist *packet, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route supplies a finite local window and does not import open-cover compactness, a host neighbourhood-base selector, countable choice, global properness, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompletionConsumerRoute`

Proof. Begin with Definition 1726.3. It identifies the only local compactness route available to downstream compactness, completion, or properness consumers as $X, x, r, B, K, A, H, C, P, N$.

Use the located handoff boundary of Definition 1726.4 for consumers that require located compact data. They can read A only after the same closed-ball and compact-metric rows have been displayed.

Use the properness comparison non-escape of Definition 1726.5 for completion consumers that compare against proper metric structure. The comparison supplies one local window, not a global properness proof or ambient completeness theorem. □

Theorem 1726.7 (LocallyCompact located-ball Real-seal boundary)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* LocallyCompact$^{\uparrow}$ *packet. Every* Real$^{\uparrow}$*-facing local compactness read through L must first display the metric source X, inspected point x, radius ledger r, closed-ball row B, compact witness K, and located handoff row A, and then pass through H, C, P, N. The* Rat$^{\uparrow}$ *or* Real$^{\uparrow}$ *radius ledger is a visible row and cannot be replaced by ambient* Real$^{\uparrow}$ *completeness, a selected neighbourhood base, or global properness.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactLocatedBallRealSealBoundary`

Proof. Project the carrier of Definition 1726.1. The radius ledger r, closed-ball row B, compact witness K, and located row A are explicit fields between the metric source data X, x and the structural rows H, C, P, N.

Apply the NameCert obligations of Definition 1726.2. They bind local neighbourhood indexing to the displayed radius row, bind closed-ball compact witness transport to B, K, H, C, and keep located handoff exact when A is present.

Use the closed-ball neighbourhood-base theorem, Definition 1726.3, and the located handoff boundary, Definition 1726.4. Together they force every located-ball read through X, x, r, B, K, A before a downstream consumer may inspect the compactness boundary.

Finally use the completion consumer route of Definition 1726.6. Completion-facing and Real$^{\uparrow}$-facing reads pass through the same H, C, P, N route, so the visible radius ledger cannot be replaced by completeness, a host neighbourhood selector, or global properness. □

Theorem 1726.8 (LocallyCompact local compact-neighbourhood obligations)**.** *Let $L = (X, x, r, B, K, A, H, C, P,$ be an accepted* LocallyCompact$^{\uparrow}$ *packet. The local compact-neighbourhood obligation for L is exactly the finite closed-ball compact window named by $X, x, r, B, K, A, H, C, P, N$: the metric source and inspected point are X, x, the positive window is r, the closed boundary is B, the compact witness is K, the located handoff is A when present, and all consumer reads pass through H, C, P, N. No obligation in this packet asserts a host neighbourhood base, open-cover compactness, quotient point equality, countable choice, global properness, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1726.1. The only rows available to a local compact-neighbourhood request are $X, x, r, B, K, A, H, C, P, N$.

Apply the NameCert obligations of Definition 1726.2. They identify local neighbourhood indexing with the positive-radius route through x, r, B and closed-ball compact witness transport through K, H, C.

Use the closed-ball neighbourhood-base theorem, Definition 1726.3. It forces every consumer through the displayed tuple, so the local obligation is a finite closed-ball compact window rather than a host neighbourhood base.

The non-escape clauses in the carrier and the same closed-ball theorem exclude the missing rows. Since no open-cover, quotient, choice, global properness, or ambient completeness coordinate is present, no such obligation can be recovered from L. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactLocalCompactNeighborhoodObligations`

Theorem 1726.9 (LocallyCompact compact-window root admission)**.** *For an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet* $L = (X, x, r, B, K, A, H, C, P, N)$*, any root consumer that admits local compactness admits only the compact window consisting of the closed-ball row* B *and compact witness* K *over the displayed source rows* X, x, r*. The located row* A *may refine the same window, and* H, C, P, N *may transport, replay, source, and name it, but the root admission does not become an open-cover theorem, a selected neighbourhood system, a global properness theorem, or an ambient completeness assertion.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompactWindowRootAdmission`

Proof. Start with the carrier projection. The root consumer can see the metric source X, inspected point x, radius ledger r, closed-ball row B, compact witness K, optional located handoff A, and structural rows H, C, P, N.

Apply Definition 1726.3. It states that downstream compactness, completion, and properness comparisons factor through this displayed tuple and receive no host compactness or completeness datum.

If the consumer asks for located compact information, apply Definition 1726.4. The row A is read only after B and K, so it refines the same compact window rather than opening a second root route.

Finally apply Definition 1726.5. Properness can read the window as one boundary datum, but the packet lacks the family over all centers and radii required for global properness. □

Theorem 1726.10 (LocallyCompact properness-locality root boundary)**.** *Let* $L = (X, x, r, B, K, A, H, C, P, N)$ *be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. A* $\mathsf{ProperMetric}^{\uparrow}$ *or completion-facing root may consume* L *only as a local closed-ball compactness boundary: it receives one source* X*, one inspected point* x*, one positive radius* r*, one closed-ball row* B*, one compact witness* K*, the optional located handoff* A*, and the transport, replay, provenance, and naming rows* H, C, P, N*. It receives no all-centers/all-radii properness family and no host neighbourhood-base structure.*

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactPropernessLocalityRootBoundary`

Proof. Project the accepted packet through Definition 1726.1. The properness-facing boundary is the finite row tuple $X, x, r, B, K, A, H, C, P, N$.

Apply Definition 1726.5. It states that a $\mathsf{ProperMetric}^{\uparrow}$ comparison receives one displayed closed-ball window and not the radius-indexed family for all centers.

Use Definition 1726.6 for completion-facing roots. They read local compactness through the same metric source, radius ledger, closed-ball window, compact witness, located handoff, transport, replay, provenance, and local NameCert route.

The carrier projection and both non-escape results leave no row for a host neighbourhood base or global properness theorem. Therefore the root boundary is locality itself: a finite closed-ball compact window with exact sibling handoffs. □

Theorem 1726.11 (LocallyCompact compact-ball window)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every root local compactness read exposes the metric source X, inspected point x, positive radius r, closed-ball row B, and compact witness K before any completion-facing consumer can read the packet.*

Proof. Project the carrier of Definition 1726.1. The compact window is not an inferred object: it is the displayed row sequence X, x, r, B, K inside the finite packet.

Apply Definition 1726.2 and Definition 1726.3. These obligations require the metric source, point, radius ledger, closed-ball row, and compact witness to be visible before the neighbourhood-base surface is read.

Finally use Definition 1726.6. A completion consumer receives the same window only through H, C, P, N, so it cannot bypass X, x, r, B, K or replace them by a host compactness theorem. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompactBallWindow`

Theorem 1726.12 (LocallyCompact located compact route)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. The located compact row A is a refinement of the same closed-ball compact window B, K over X, x, r, not a second compactness source and not an independent located compact object.*

Proof. Read the carrier rows in Definition 1726.1. The located handoff coordinate A occurs after the metric source, inspected point, radius ledger, closed-ball row, and compact witness.

Apply Definition 1726.4. It binds A to the same displayed closed-ball compact witness rather than to an external compactness source.

The NameCert obligations of Definition 1726.2 then transport and replay A through the same H, C, P, N boundary. Thus the handoff refines B, K and cannot introduce a second compactness route. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactLocatedCompactRoute`

Theorem 1726.13 (LocallyCompact proper-metric nonescape)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every* $\mathsf{ProperMetric}^{\uparrow}$ *consumer receives one local closed-ball compactness boundary through $X, x, r, B, K, A, H, C, P, N$, not an all-centers/all-radii properness theorem.*

Proof. Begin with the compact-ball window of Definition 1726.11. It exposes exactly one inspected source, point, radius, closed-ball row, and compact witness before downstream consumption.

Use the located compact route of Definition 1726.12 to attach A only as a refinement of that same window. The located handoff therefore cannot widen the packet into a global properness family.

Apply Definition 1726.5 and Definition 1726.10. Together they state that properness-facing reads remain inside the displayed local boundary, with no coordinate for all centers, all radii, a host neighbourhood base, or an unrestricted proper metric theorem. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactProperMetricNonescape`

Theorem 1726.14 (LocallyCompact compact-window transport)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Any* hsame *transport of the displayed metric source X, inspected point x, positive radius r, closed-ball row B, compact witness K, and optional located handoff A preserves the same local compact window before any* $\mathsf{ProperMetric}^{\uparrow}$ *or completion consumer reads it. The transported read still factors through $X, x, r, B, K, A, H, C, P, N$ and does not upgrade the packet to global properness, open-cover compactness, a host neighbourhood-base selector, quotient point equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier in Definition 1726.1. The transport row H is componentwise over the metric source, point, radius, closed-ball row, compact witness, located handoff, replay, provenance, and local naming data.

Use the closed-ball neighbourhood-base theorem, Definition 1726.3. It identifies the visible local compactness window as exactly $X, x, r, B, K, A, H, C, P, N$, so an hsame read can only transport that displayed finite window.

Now apply the properness-locality root boundary of Definition 1726.10. A properness or completion consumer may consume the transported window as one local boundary, but it receives no all-centers/all-radii family and no host neighbourhood-base structure.

Therefore compact-window transport preserves locality itself. The optional located handoff remains attached to the same closed-ball compact witness, and the excluded global compactness, properness, quotient, choice, and completeness rows remain absent. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompactWindowTransport`

Theorem 1726.15 (LocallyCompact local properness-radius exhaustion)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every* $\mathsf{ProperMetric}^{\uparrow}$ *or completion-facing consumer that asks for a properness-radius read from L must first display exactly one inspected point x, one positive radius ledger r, one* $\mathsf{MetricClosedBall}^{\uparrow}$ *row B, one* $\mathsf{CompactMetric}^{\uparrow}$ *witness K, the optional* $\mathsf{LocatedCompact}^{\uparrow}$ *handoff A, and the existing transport, replay, provenance, and naming rows H, C, P, N over the source row X. Before those rows are displayed, no properness-radius read is available. After they are displayed, the read remains local and supplies no all-centers/all-radii properness family, open-cover compactness, countable choice, quotient point equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the proper-metric nonescape theorem, Definition 1726.13. It states that a $\mathsf{ProperMetric}^{\uparrow}$ consumer receives one local closed-ball compactness boundary through $X, x, r, B, K, A, H, C, P, N$, not an all-centers/all-radii theorem.

Apply the properness-locality root boundary of Definition 1726.10. This fixes the root read as one source, one inspected point, one positive radius, one closed-ball row, one compact witness, the optional located handoff, and the structural rows H, C, P, N.

Now use compact-window transport, Definition 1726.14. Transport may preserve the displayed window, but it cannot introduce a second point, a second radius, a global radius-indexed family, or a host neighbourhood-base route.

Therefore properness-radius access is exhausted by the displayed local packet. Completion-facing consumers may reuse that boundary through the same rows, while the absent open-cover, choice, quotient, global properness, and ambient-completeness coordinates remain unavailable. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactLocalPropernessRadiusExhaustion`

Theorem 1726.16 (LocallyCompact compact-neighbourhood basis)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* LocallyCompact$^{\uparrow}$ *packet. The neighbourhood basis exported by L is exactly the finite center-radius route displayed by the metric source X, inspected point x, positive radius ledger r,* MetricClosedBall$^{\uparrow}$ *row B,* CompactMetric$^{\uparrow}$ *witness K, optional* LocatedCompact$^{\uparrow}$ *handoff A,* ProperMetric$^{\uparrow}$ *comparison boundary, componentwise transport H, replay C, provenance P, and local* NameCert *row N. Every accepted basis read factors through those rows, and no read introduces a host-selected neighbourhood family, open-cover compactness, quotient point equality, countable choice, all-centers/all-radii properness, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 1726.1. Its only local neighbourhood coordinates are the displayed center x, radius ledger r, closed-ball row B, compact witness K, optional located handoff A, and structural rows H, C, P, N over the metric source X.

Apply the closed-ball neighbourhood-base theorem, Definition 1726.3. It already forces every compactness, completion, or properness consumer to factor through $X, x, r, B, K, A, H, C, P, N$, so the basis is the finite center-radius row rather than an external selector.

Use the local properness-radius exhaustion theorem, Definition 1726.15. Properness-facing reads can compare against ProperMetric$^{\uparrow}$ only after the same closed-ball compact window has been displayed, and they still receive no all-centers/all-radii family.

Finally combine the located handoff boundary and compact-window transport, Definition 1726.4 and Definition 1726.14. They keep A and H attached to the same MetricClosedBall$^{\uparrow}$ and CompactMetric$^{\uparrow}$ rows, so replay and provenance cannot create open-cover compactness, host neighbourhoods, quotient equality, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompactNeighbourhoodBasis`

Theorem 1726.17 (LocallyCompact public neighbourhood-base export)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* LocallyCompact$^{\uparrow}$ *packet. The public neighbourhood-base read exported by L is exactly the ten-row local carrier route: compact-ball access through B, K, local-cover access through the displayed center-radius window X, x, r, componentwise* hsame *transport through H,* Cont *replay through C, provenance through P, and local* NameCert *naming through N, with the optional located handoff A attached to the same compact window. Every public read factors through those rows and exports no host-selected neighbourhood base, open-cover compactness, quotient point equality, countable choice, all-centers/all-radii properness, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 1726.1. The public read has only the displayed source, point, radius, compact-ball, compact witness, located handoff, transport, replay, provenance, and local naming rows.

Apply the compact-neighbourhood basis theorem, Definition 1726.16. It identifies the neighbourhood basis as the finite center-radius route through $X, x, r, B, K, A, H, C, P, N$ and refuses external selectors.

Use compact-window transport and the local properness-radius exhaustion route, Definition 1726.14 and Definition 1726.15. These keep hsame transport, properness comparison, and completion-facing reads inside the same compact-ball window rather than turning the packet into a global properness family.

Finally use the completion consumer route, Definition 1726.6. The public export is therefore the carrier route itself with provenance and local NameCert rows visible; it is not open-cover compactness, quotient equality, choice, ambient completeness, or a host neighbourhood-base structure. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactPublicNeighbourhoodBaseExport`

Theorem 1726.18 (LocallyCompact abstract schema bridge surface)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. The public neighbourhood-base export of Definition 1726.17 is the bridge surface from the ten-row LocallyCompact carrier to the abstract local-compactness schema: it exports compact-ball access through B, K, local window access through X, x, r, optional located refinement through A, and structural transport through H, C, P, N. It exports no open-cover compactness, host neighbourhood-base selector, quotient point equality, countable choice, all-centers/all-radii properness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1726.1. The abstract schema can only see the displayed metric source, inspected point, positive radius, closed ball, compact witness, optional located handoff, transport, replay, provenance, and local naming rows.

Apply the public neighbourhood-base export, Definition 1726.17. It already identifies the exported public read with compact-ball access, center-radius local-cover access, componentwise transport, continuation replay, provenance, and local NameCert naming through exactly those rows.

Therefore the bridge surface is the public export itself. Since neither the carrier nor the public export contains open-cover compactness, a host selector, quotient equality, countable choice, global properness, or ambient Real completeness, the abstract local-compactness schema receives only the finite local compact-neighbourhood boundary. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactAbstractSchemaBridgeSurface`

Theorem 1726.19 (LocallyCompact mature compact-completion route)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every mature consumer that asks for compactness or completion first reads the local closed-ball window X, x, r, B, the compact witness K, the optional* $\mathsf{LocatedCompact}^{\uparrow}$ *handoff A, the properness nonescape boundary, and the compact-window transport rows H, C, P, N. Only after those rows are displayed may the consumer reuse the packet as a compact-completion route, and the route exports no open-cover compactness, host neighbourhood base, quotient point equality, countable choice, all-centers/all-radii properness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the compact-ball window of Definition 1726.11. It exposes one metric source, one inspected point, one positive radius ledger, one closed-ball row, and one compact witness before any compactness or completion-facing read is available.

Attach the located handoff using Definition 1726.12. The row A is optional, and when present it refines the same displayed closed-ball window rather than introducing an open-cover compactness principle or host neighbourhood base.

Next apply proper-metric nonescape, Definition 1726.13. A properness or completion consumer can reuse the compact window only through the displayed local packet, so the route does not become an all-centers/all-radii properness family.

Finally use compact-window transport, Definition 1726.14. The transport rows H, C, P, N preserve the same source, point, radius, closed-ball, compact witness, and located handoff, and therefore cannot add quotient equality, countable choice, or ambient Real completeness. The mature compact-completion route is exactly this composed finite window. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactMatureCompactCompletionRoute`

Theorem 1726.20 (LocallyCompact compact-window handoff)**.** *Let $L = (X, x, r, B, K, A, H, C, P, N)$ be an accepted* $\mathsf{LocallyCompact}^{\uparrow}$ *packet. Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$,

$\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Completion}^{\uparrow}$ *consumer that asks for compactness or completion must read the same displayed local window*

$$X, \quad x, \quad r, \quad B, \quad K, \quad A, \quad H, \quad C, \quad P, \quad N$$

before using the compactness or completion-facing surface. The handoff exports one compact closed-ball window with transport, replay, provenance, and local naming; it does not export open-cover compactness, global properness, a host neighbourhood base, quotient point equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the compact-ball window, Definition 1726.11. It exposes the metric source, inspected point, positive radius, closed-ball row, and compact witness before any compactness-facing consumer can read the packet.

Attach the located row using Definition 1726.12. The $\mathsf{LocatedCompact}^{\uparrow}$ handoff is tied to the same X, x, r, B, K window, so it cannot introduce a second compact source or an open-cover compactness principle.

Next use proper-metric nonescape, Definition 1726.13. A $\mathsf{ProperMetric}^{\uparrow}$ or completion-facing consumer receives one displayed local compactness boundary, not an all-centers/all-radii properness theorem.

Finally compose compact-window transport with the mature compact-completion route, Definition 1726.14 and Definition 1726.19. The rows H, C, P, N preserve the same local window through transport, replay, provenance, and naming, so compactness and completion consumers can reuse only the finite window stated above. □

Lean4 ✓ `BEDC.Derived.LocallyCompactUp.LocallyCompactCompactWindowHandoff`

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyCompact}^{\uparrow}$ packet is generated from a metric source row, an inspected point row, a positive RatUp or RealUp radius ledger, a MetricClosedBall row, a CompactMetric witness for the displayed window, an optional LocatedCompact handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1726.1, Definition 1726.2, Definition 1726.3, Definition 1726.9, Definition 1726.10, Definition 1726.6, Definition 1726.16, Definition 1726.17, Definition 1726.18, and Definition 1726.19 bind the compact-neighbourhood public surface, abstract schema bridge, and downstream compact-completion example to displayed $\mathsf{Topology}^{\uparrow}$ neighbourhood rows, $\mathsf{CompactMetric}^{\uparrow}$ and finite-net rows, $\mathsf{Met}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ radius rows, BHist, hsame, Cont, Pkg, and NameCert support.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocallyCompact}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, a host neighbourhood base, quotient point equality, countable choice, ambient Real completeness, global properness, Lean verification, or bridge checking.

Upgrade path: No further theory-axis upgrade is claimed beyond future bridge checking and formalization.

Chapter 1727

A Concrete Naming Certificate for $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ packet records the constructive zero-distance boundary for two regular Cauchy names by routing the displayed difference through a finite $\mathsf{NullSequence}^{\uparrow}$ tolerance-window witness before any $\mathsf{RealEquality}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits between the source rows of chapter 301, the pointwise difference surface of chapter 429, the zero-tail consumer of chapter 380, the equality boundary of chapter 1636, the finite windows of chapter 126, and the dyadic tolerance ledger of chapter 291.

The certificate is a finite equality boundary. It does not identify quotient streams, select limits, compare host reals, or invoke completeness; it records only the displayed route by which the regular-Cauchy difference is certified as a null sequence and then handed to the equality classifier.

Definition 1727.1 (RegularCauchyZeroDistance carrier)**.** *A* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, D, Z, E, W, T, H, C, P, N)$$

with the following displayed coordinates:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are compared.*
2. *D is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row displaying the pointwise difference stream $X - Y$ through aligned finite windows.*
3. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row consuming the displayed difference stream before equality is sealed.*
4. *E is the* $\mathsf{RealEquality}^{\uparrow}$ *classifier-consumption row that reads the null-difference packet and exposes the corresponding* $\mathsf{Real}^{\uparrow}$ *equality boundary.*
5. *W stores the* $\mathsf{StreamName}^{\uparrow}$ *observation windows used by the two source rows, the displayed difference row, and the null-sequence consumer.*
6. *T stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance requests, slack rows, and comparison budgets consumed by the difference and zero-tail rows.*
7. *H records componentwise* hsame *transport for source rows, difference rows, zero-tail rows, equality classifier rows, windows, tolerance ledgers, continuation routes, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a zero-distance request through $X, Y, D, Z, W, T, H, P, N$ and then into E.*
9. *P is the* Pkg *provenance over* RegularCauchyZeroDistance$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RegularCauchyDifference$^{\uparrow}$, NullSequence$^{\uparrow}$, RealEquality$^{\uparrow}$, Real$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyZeroDistance}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite zero-distance packet. It has no coordinate for quotient stream equality, host real equality, trichotomy, selected limits, countable choice, Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyZeroDistanceUp.RegularCauchyZeroDistanceTasteGate single carrier alignment`

Theorem 1727.2 (RegularCauchyZeroDistance NameCert obligations)**.** *For every accepted* RegularCauchyZeroDist *carrier $Q = (X, Y, D, Z, E, W, T, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchyZeroDistance}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two* RegSeqRat$^{\uparrow}$ *source rows, the* RegularCauchyDifference$^{\uparrow}$ *displayed difference row, the* NullSequence$^{\uparrow}$ *zero-tail row, the* RealEquality$^{\uparrow}$ *classifier-consumption row, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerances, transport, continuation, provenance, and local naming rows;*
2. *componentwise classifier stability for source rows, aligned windows, dyadic tolerances, the displayed difference route, the zero-tail route, the equality handoff, and the structural rows H, C, P, N;*
3. *zero-tail exactness, requiring Z to consume precisely the difference row D through the windows W and tolerance ledger T before the equality classifier is read;*
4. *RealEquality handoff, requiring E to read the* NullSequence$^{\uparrow}$ *packet as the equality evidence for the two regular Cauchy names and not as a host equality proof;*
5. *non-escape, requiring every public zero-distance read to factor through Q and forbidding quotient stream equality, host real equality, trichotomy, selected limits, countable choice,* Real$^{\uparrow}$ *completeness, and bridge checking from the local surface.*

No zero-distance obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1727.1. The packet displays the two regular rational source rows, the difference row, the null-sequence row, the equality classifier row, finite windows, dyadic tolerances, and structural provenance before any equality read is visible.

Classifier stability is componentwise. The source rows transport their regular rational observations, the windows transport the finite reads, the tolerance ledger transports the requested dyadic bounds, and the displayed difference row transports before the null-sequence row is consumed.

Zero-tail exactness comes next. The row Z can read only the displayed difference D through W and T, so the equality handoff has already passed through the finite null-difference package before E is inspected.

Finally inspect the carrier inventory. Since no coordinate of Q is a quotient stream equality, host real equality proof, trichotomy principle, selected limit, countable-choice schedule, completeness theorem, or bridge certificate, none can occur in the local NameCert surface. □

Theorem 1727.3 (RegularCauchyZeroDistance NullSequence criterion)**.** *Let $Q = (X, Y, D, Z, E, W, T, H, C, P, N)$ be an accepted* RegularCauchyZeroDistance$^{\uparrow}$ *carrier. A zero-distance read for the two regular Cauchy*

source rows is admitted exactly when the displayed difference route D factors through the NullSequence$^{\uparrow}$ *packet Z using the finite* StreamName$^{\uparrow}$ *windows W, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger T, the transport ledger H, the continuation replay C, the provenance row P, and the local naming row N before the* RealEquality$^{\uparrow}$ *classifier row E and the downstream* Real$^{\uparrow}$ *seal are consumed.*

Thus zero distance is the finite null-sequence-mediated equality boundary for the displayed difference stream, not a quotient equality of streams, host real equality, trichotomy comparison, selected limit, countable-choice construction, or completeness assertion.

Lean4 ✓ `BEDC.Derived.RegularCauchyZeroDistanceUp.RegularCauchyZeroDistanceNullsequenceCriterion`

Proof. For the forward direction, begin with an admitted zero-distance read. The NameCert obligations of Definition 1727.2 force the read through the carrier coordinates of Q.

The displayed difference row D is read before any equality classifier row. By zero-tail exactness, the consumer must then pass through the NullSequence$^{\uparrow}$ row Z, using exactly the windows W and tolerance ledger T transported by H and replayed by C.

Only after that finite null-difference package is visible may the classifier row E consume it as RealEquality$^{\uparrow}$ evidence. The provenance and local naming rows P, N record the same route and add no analytic data.

For the reverse direction, suppose the displayed difference route factors through Z with W, T, H, C, P, N before E is consumed. Then the carrier admission, zero-tail exactness, and RealEquality handoff clauses of Definition 1727.2 accept this route as the local zero-distance read.

The non-escape clause rules out all stronger interpretations. Since the packet contains no quotient stream equality, host real equality, trichotomy, selected limit, countable-choice row, or completeness theorem, the accepted read is exactly the stated finite boundary. □

Closure status for NameCert$_{\text{RegularCauchyZeroDistance}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyZeroDistance}^{\uparrow}}$, seed)

Scope closed: Definition 1727.1, Definition 1727.2, and Definition 1727.3 seed the finite zero-distance boundary for two regular Cauchy source rows through displayed difference, NullSequence zero-tail evidence, RealEquality classifier consumption, StreamName windows, and DyadicRatCore tolerance rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyZeroDistance}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream equality, host real equality, trichotomy, selected limits, countable choice, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, componentwise classifier stability, zero-tail exactness, RealEquality handoff, and non-escape for BEDC.Derived.RegularCauchyZeroDistanceUp.

Constructive story: A RegularCauchyZeroDistance$^{\uparrow}$ packet is generated from two RegSeqRat source rows, one RegularCauchyDifference route, one NullSequence zero-tail row, one RealEquality classifier-consumption row, finite StreamName windows, DyadicRatCore tolerances, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1728

A Concrete Naming Certificate for $\mathsf{RealPolynomial}^{\uparrow}$

Following Bishop and Bridges on constructive real functions and the standard polynomial-function construction, the $\mathsf{RealPolynomial}^{\uparrow}$ packet names finite polynomial evaluation over displayed $\mathsf{Real}^{\uparrow}$ names. It consumes the coefficient-list surface of chapter 50, the terminal real-name seal of chapter 38, the regular-Cauchy algebra route of chapter 1470, the finite window discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, and the continuous-map handoff of chapter 130. The chapter records polynomial evaluation as displayed BEDC finite data rather than host real-function syntax, quotient real functions, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The same finite Horner evaluation surface is consumed downstream by chapter 2269 for sign-window root isolation and by chapter 6454 for finite polynomial test rows. The exported rows are coefficient-list provenance, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{ContinuousMap}^{\uparrow}$ handoff data; they do not expose host polynomial functions or selected roots.

Definition 1728.1 (Real polynomial carrier)**.** *A* $\mathsf{RealPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R_P = (A, X, Q, S, G, W, D, E, M, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite coefficient-list provenance row read from* $\mathsf{Poly}^{\uparrow}$*. It records the polynomial arity, coefficient order, constant term, successor-coefficient cells, and the finite list boundary used by the evaluator.*
2. *X is the input* $\mathsf{Real}^{\uparrow}$ *row whose regular name is read only through the displayed real-name seal.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the input real name and to every real coefficient name requested by the coefficient list.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It records the shared precision window used to inspect the input name and the finitely many coefficient names.*
5. *G is the* $\mathsf{RegularCauchyRing}^{\uparrow}$ *algebra row. It records the finite addition, multiplication, and powering schedule used by Horner evaluation, with no host real-operation coordinate.*
6. *W is the finite-window support row binding the coefficient list, input stream windows, regular readbacks, dyadic tolerances, and regular-Cauchy algebra operations to one evaluation request.*

7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores dyadic radii, endpoint refinements, multiplication slack, addition slack, and the final output tolerance budget.*
8. *E is the evaluation ledger. It records the finite Horner spine from the last coefficient toward the constant coefficient, with each intermediate value read through Q, S, G, W, D.*
9. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row. It exposes the same finite evaluation route as a continuous-map consumer surface once the evaluation ledger has been displayed.*
10. *H records componentwise* hsame *transport for coefficient provenance, input real names, regular readbacks, finite windows, regular-Cauchy algebra rows, dyadic tolerances, the evaluation ledger, the continuous-map handoff, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from each polynomial-evaluation request through $A, X, Q, S, G, W, D, E, M, H, P,$*
12. *P is the* Pkg *provenance over* $\mathsf{RealPolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyRing}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealPolynomial}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite polynomial-evaluation history. The classifier compares accepted packets only through $A, X, Q, S, G, W, D, E, M, H, C, P, N$, so it has no coordinate for host polynomial functions, quotient real functions, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealPolynomialUp.RealPolynomialUpTasteGate single carrier alignment`

Theorem 1728.2 (Real polynomial NameCert obligations)**.** *For every accepted* $\mathsf{RealPolynomial}^{\uparrow}$ *carrier*

$$R_P = (A, X, Q, S, G, W, D, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealPolynomial}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the coefficient-list provenance, input* $\mathsf{Real}^{\uparrow}$ *row, regular readbacks, finite windows, regular-Cauchy algebra, dyadic tolerance row, evaluation ledger, continuous-map handoff, transport, replay, provenance, and local naming rows;*
2. *coefficient normalization, requiring A to expose a finite* $\mathsf{Poly}^{\uparrow}$ *coefficient list before any evaluator row consumes coefficients;*
3. *finite evaluation route, requiring the Horner spine in E to read only Q, S, G, W, D and the already displayed coefficient cells of A;*
4. *classifier transport, requiring H to preserve componentwise sameness for coefficient provenance, input real names, finite windows, regular readbacks, regular-Cauchy algebra rows, dyadic tolerances, the evaluation ledger, and structural rows;*
5. *continuous-map handoff, requiring M to export only the same finite evaluation route already displayed by A, X, Q, S, G, W, D, E;*
6. *non-escape, refusing quotient real functions, host polynomial functions, selected limits, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No real polynomial obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 1728.1. The projection exposes exactly the coefficient-list row, input real row, regular readbacks, finite windows, regular-Cauchy algebra row, dyadic tolerance row, evaluation ledger, continuous-map handoff, and structural rows.

Coefficient normalization is read from A using the polynomial carrier of chapter 50. The row supplies the finite coefficient order, so evaluation never ranges over an unbounded host polynomial.

The finite evaluation route is the Horner spine recorded in E. At each step the input and coefficient rows are read through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, regular readbacks from chapter 301, finite windows from chapter 126, dyadic tolerances from chapter 291, and algebra rows from chapter 1470.

Classifier transport is componentwise. The row H preserves the coefficient provenance, input row, regular readbacks, finite windows, algebra schedule, tolerance row, and ledger before C, P, N replay, source, and name the same packet.

Finally use the continuous-map surface of chapter 130. The handoff row M receives only the displayed finite evaluation route, so quotient real functions, host polynomial functions, selected limits, trichotomy, countable choice, ambient completeness, Lean verification, and bridge checking have no local obligation row. □

Theorem 1728.3 (Real polynomial evaluation stability)**.** *Every accepted* $\mathsf{RealPolynomial}^{\uparrow}$ *evaluation route reads only the displayed coefficient provenance, input* $\mathsf{Real}^{\uparrow}$ *name, regular-Cauchy algebra, finite-window support, regular rational readback, dyadic tolerance, evaluation ledger, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, continuous-map handoff, and local* NameCert *rows. Consequently two accepted carriers matched componentwise by their displayed classifier data have the same finite evaluation route.*

Proof. Inspect an accepted carrier $R_P = (A, X, Q, S, G, W, D, E, M, H, C, P, N)$. The coefficient source is A, the real input is X, and the only analytic readback rows are Q, S, G, W, D, E, M.

The evaluation ledger E fixes the dependency order. It reads coefficient cells from chapter 50, real-name rows from chapter 38, algebra operations from chapter 1470, finite stream windows from chapter 126, regular rational readbacks from chapter 301, dyadic tolerance rows from chapter 291, and the continuous-map handoff from chapter 130.

Componentwise sameness in H transports each displayed row and no other row. The replay row C preserves the same dependency order, while P and N record provenance and local naming for the transported packet.

Thus any consumer route accepted by the local certificate is already one of the displayed projections. Since the carrier contains no coordinate for quotient real functions, host polynomial functions, selected limits, trichotomy, countable choice, or ambient completeness, stability cannot acquire such data under transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealPolynomial}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealPolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1728.1, Definition 1728.2, and Definition 1728.3 seed the finite polynomial-evaluation route over $\mathsf{Poly}^{\uparrow}$ coefficient provenance, $\mathsf{Real}^{\uparrow}$ input rows, $\mathsf{RegularCauchyRing}^{\uparrow}$ algebra, $\mathsf{ContinuousMap}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealPolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real functions, host polynomial functions, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient normalization, finite evaluation route, classifier transport, continuous-map handoff, and non-escape for BEDC.Derived.RealPolynomialUp.

Constructive story: A RealPolynomial$^{\uparrow}$ packet is generated from finite Poly$^{\uparrow}$ coefficient-list provenance, an input Real$^{\uparrow}$ name, RegSeqRat$^{\uparrow}$ readbacks, StreamName$^{\uparrow}$ windows, RegularCauchyRing$^{\uparrow}$ algebra rows, DyadicRatCore$^{\uparrow}$ tolerance rows, a finite Horner evaluation ledger, a ContinuousMap$^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1729

A Concrete Naming Certificate for $\mathsf{RealSequenceAlgebra}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealSequenceAlgebra}^{\uparrow}$ packet records the finite pointwise algebra surface for displayed $\mathsf{Real}^{\uparrow}$ sequences. It sits between the limit interface of chapter 1413, the limit-law consumers of chapter 1480, the bounded-source surface of chapter 1415, and the regular Cauchy addition route of chapter 1695. The packet names the finite sequence-algebra carrier used by later limit and boundedness consumers; it is not host sequence equality, a quotient stream construction, a selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1729.1 (Real sequence algebra carrier)**.** *A* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S_X, S_Y, W_X, W_Y, R_X, R_Y, D, O, E, H, C, P, N)$$

with the following displayed rows:

1. *S_X and S_Y are the two source* $\mathsf{Real}^{\uparrow}$ *sequence rows. Each source term is offered only through a displayed sequence route, not through host sequence equality.*
2. *W_X and W_Y are finite* $\mathsf{StreamName}^{\uparrow}$ *window rows for the two sources at the requested index and precision scale.*
3. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the displayed source windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation and error ledger. It records source tolerances, the operation tolerance, output tolerance, and the displayed budget for sum or product under the supplied bounds.*
5. *O is the pointwise operation row. It records whether the public read is a pointwise sum or a pointwise product under displayed bounds, and it cites the rows $S_X, S_Y, W_X, W_Y, R_X, R_Y, D$ before exposing an output readback.*
6. *E is the output* $\mathsf{Real}^{\uparrow}$ *seal reached only after the two source rows, finite windows, regular readbacks, dyadic ledger, and operation row have been displayed.*
7. *H records componentwise* hsame *transport for the two source sequence rows, both finite-window rows, both readback rows, the dyadic ledger, the operation row, the output seal, continuation replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a sequence-algebra request through the source rows, finite windows, readbacks, ledger, operation row, output seal, transport, package provenance, and local name.*

9. *P is the* Pkg *provenance over* $\mathsf{RealSequenceAlgebra}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RealSequenceLimitLaws}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSequenceAlgebra}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite pointwise algebra packet. It has no coordinate for host equality of real sequences, quotient streams, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached host operation on sequences.*

Lean4 ✓ `BEDC.Derived.RealSequenceAlgebraUp.RealSequenceAlgebraTasteGate single carrier alignment`

Theorem 1729.2 (Real sequence algebra NameCert obligations)**.** *For every accepted* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *carrier*

$$A = (S_X, S_Y, W_X, W_Y, R_X, R_Y, D, O, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSequenceAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed source sequence rows, two finite window rows, two regular readback rows, dyadic operation and error ledger, pointwise operation row, output* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*

2. *classifier stability, requiring componentwise* hsame *transport to move the two source rows, windows, readbacks, ledger, operation row, output seal, and structural rows together;*

3. *operation-row exactness, requiring every pointwise sum or bounded pointwise product read to cite the dyadic budget stored in D and the operation choice stored in O;*

4. *seal handoff, requiring E to be read only after $S_X, S_Y, W_X, W_Y, R_X, R_Y, D, O$ have been displayed;*

5. *nonescape, excluding host sequence equality, quotient streams, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking from the local packet.*

No pointwise sequence-algebra obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic coordinates are the two source sequence rows, two finite windows, two regular rational readbacks, dyadic operation ledger, pointwise operation row, and output seal. The structural coordinates are the componentwise transport, continuation replay, package provenance, and local naming rows.

Classifier stability is componentwise. The row H transports exactly the displayed coordinates of the carrier, so a classified packet cannot exchange one source sequence, window, readback, ledger, or output seal while keeping the same public sequence-algebra read.

Operation-row exactness is the role of D and O. The ledger stores the source and output tolerances, while the operation row records whether the read is a pointwise sum or a pointwise product under displayed bounds. Thus every arithmetic read is mediated by the finite dyadic budget before an output seal is exposed.

Finally, C, P, N replay, source, and name the same route. Since no carrier coordinate stores host sequence equality, quotient streams, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.RealSequenceAlgebraUp.RealSequenceAlgebraCarrier namecert obligations`

Theorem 1729.3 (Real sequence algebra limit consumer)**.** *Every* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *consumer that uses pointwise algebra on displayed* $\mathsf{Real}^{\uparrow}$ *sequences factors through an accepted* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *carrier. In the notation of Definition 1729.1, the consumer reads the finite route*

$$(S_X, S_Y) \longmapsto (W_X, W_Y) \longmapsto (R_X, R_Y) \longmapsto D \longmapsto O \longmapsto E \longmapsto H, C, P, N$$

before it invokes the limit-law handoff. The route exports no host sequence equality, quotient stream, selected limit, trichotomy, or ambient completeness coordinate.

Proof. Start with a limit-law consumer that asks for a pointwise algebra row. The source data visible to that consumer are the displayed sequence rows S_X, S_Y, not host functions on an ambient sequence type.

The finite windows and readbacks are opened next. The rows W_X, W_Y select the requested finite observations, while R_X, R_Y supply the regular rational readbacks used by the operation ledger.

The operation route then passes through D and O. These rows determine the tolerance accounting and the selected pointwise operation before the output seal E is available.

The remaining rows H, C, P, N transport, replay, source, and name this same finite packet. Thus the consumer reaches the $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ handoff only through the sequence-algebra carrier, with no coordinate from which to read host sequence equality, quotient streams, selected limits, trichotomy, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealSequenceAlgebraUp.RealSequenceAlgebraLimitConsumer`

Theorem 1729.4 (Real sequence algebra bounded consumer)**.** *Every* $\mathsf{BoundedRealSequence}^{\uparrow}$ *consumer of pointwise algebra reads bounds only through the displayed bounded-sequence surface and the regular Cauchy rows named by an accepted* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *carrier. In particular, a bounded pointwise product read must pass through the source sequence rows, finite windows, regular readbacks, dyadic bound ledger, operation row, output seal, and componentwise structural rows of Definition 1729.1.*

Proof. Begin with a bounded-sequence consumer of a pointwise algebra read. The boundedness information available to the consumer is the displayed $\mathsf{BoundedRealSequence}^{\uparrow}$ row and the regular rational readback data attached to the finite windows.

For a pointwise sum, the consumer reads the same source windows and regular readbacks before the dyadic ledger records the output tolerance. For a pointwise product, the consumer additionally reads the displayed bound entries through D and O before any output seal is exposed.

The output remains a $\mathsf{Real}^{\uparrow}$ seal named by E and transported through H, C, P, N. Since the carrier has no host sequence equality, quotient stream, selected limit, trichotomy, ambient completeness, Lean verification, or bridge coordinate, the bounded consumer can obtain bounds only from the displayed bounded-sequence and regular-Cauchy rows. □

Lean4 ✓ `BEDC.Derived.RealSequenceAlgebraUp.RealSequenceAlgebraBoundedConsumer`

Theorem 1729.5 (Real sequence algebra operation-row exactness)**.** *Every accepted* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *pointwise sum or bounded-product read factors through the two source* $\mathsf{Real}^{\uparrow}$ *sequence rows, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation and error ledger, the operation row, the output* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealSequenceAlgebra}^{\uparrow}}$ *row. Thus the operation row is*

exact: it records the selected pointwise sum or bounded product together with its dyadic budget before any output seal or limit-law handoff is available.

Proof. Project the accepted carrier $A = (S_X, S_Y, W_X, W_Y, R_X, R_Y, D, O, E, H, C, P, N)$ of Definition 1729.1. The two source sequence rows are S_X, S_Y, and the only finite observations of them are the windows W_X, W_Y with readbacks R_X, R_Y.

The dyadic operation and error ledger is D. For a pointwise sum it records the source and output tolerances; for a bounded product it also records the displayed bound data needed by the product budget.

The operation row O is downstream of those source and ledger rows. It therefore cannot expose a sum or bounded product read without first naming the two sources, their finite windows, their regular readbacks, and the dyadic tolerance accounting.

Apply Definition 1729.3 and Definition 1729.4. The first confines limit-law consumers to the same route, and the second confines bounded consumers to the displayed bound and regular-Cauchy rows.

Finally E, H, C, P, N seal, transport, replay, source, and locally name this same route. Since no carrier coordinate stores host sequence equality, quotient streams, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the operation-row read is exactly the displayed finite ledger. □

Lean4 ✓ `BEDC.Derived.RealSequenceAlgebraUp.RealSequenceAlgebraCarrier operation row exactness`

Theorem 1729.6 (Real sequence algebra pointwise zero unit)**.** *Let $A = (S_X, S_Y, W_X, W_Y, R_X, R_Y, D, O, E, H, C,$ be an accepted* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *carrier. Suppose the second source row S_Y is the displayed zero* $\mathsf{Real}^{\uparrow}$ *sequence row and the operation row O is the pointwise sum row. Then the public output read exports the first source sequence through the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget, output* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route identifies the zero source only by displayed* $\mathsf{Real}^{\uparrow}$ *zero rows, not by host sequence equality, and it exports no quotient stream, selected limit, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The first source route is S_X, W_X, R_X, while the second source route is S_Y, W_Y, R_Y.

Use the displayed zero hypothesis only on S_Y. It says that the second source is read through zero $\mathsf{Real}^{\uparrow}$ rows inside the carrier; it does not identify host sequences or supply an ambient equality of functions.

Apply operation-row exactness, Definition 1729.5. Since O is the pointwise sum row, the output seal can be opened only after the dyadic ledger D has compared the first source route with the displayed zero route.

The dyadic budget and output seal therefore replay the first source finite windows through the same W_X, R_X, D, E path, with H, C, P, N transporting, replaying, sourcing, and naming that path. The zero row contributes no additional quotient, limit, trichotomy, or completeness coordinate.

Thus every consumer of the pointwise zero-unit read sees the first source sequence through the original finite StreamName and RegSeqRat rows together with the same dyadic ledger and output seal. No host sequence equality or ambient completeness principle is introduced. □

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSequenceAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1729.1, Definition 1729.2, Definition 1729.3, and Definition 1729.4 seed the finite pointwise sequence-algebra surface over displayed $\mathsf{Real}^{\uparrow}$ sequence rows, finite windows, regular readbacks, dyadic operation ledgers, bounded operation rows, and output seals.

Formal verification: FormalStatus(NameCert$_{\text{RealSequenceAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host sequence equality, quotient streams, selected limits, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, operation-row exactness, seal handoff, nonescape, limit-law consumer factoring, and bounded-consumer bound routing for BEDC.Derived.RealSequenceAlgebraUp.

Constructive story: A RealSequenceAlgebra$^{\uparrow}$ packet is generated from two displayed Real$^{\uparrow}$ sequence rows, two finite StreamName$^{\uparrow}$ windows, two RegSeqRat$^{\uparrow}$ readbacks, a DyadicRatCore$^{\uparrow}$ operation and error ledger, a pointwise sum or bounded-product operation row, an output Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1730

A Concrete Naming Certificate for $\mathsf{LocatedRealComparison}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedRealComparison}^{\uparrow}$ packet records the finite comparison surface for two located real presentations. It sits between **??**, chapter 1381, chapter 1380, chapter 304, chapter 126, chapter 301, chapter 291, and chapter 38. The packet names the finite row surface by which a later order, density, or apartness consumer compares two displayed located-real endpoints without importing trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Definition 1730.1 (Located real comparison carrier)**.** *A* $\mathsf{LocatedRealComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, C, P, N)$$

with the following displayed rows:

1. *L_0 and L_1 are the two* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows. Each endpoint is read as a located real presentation before any comparison row is opened.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the common finite observation schedule used to inspect both endpoint presentations at the requested precision.*
3. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the windows of L_0 and L_1.*
4. *D_0 and D_1 are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance rows. They record the dyadic enclosures, slack budgets, and comparison tolerances used by the common window.*
5. *B is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *row. It records the finite comparison request, its rational bracket data, and the displayed sign or overlap evidence available at the chosen window.*
6. *A is the optional positive-gap handoff row. When the comparison exposes a positive separation, A routes the same gap through the* $\mathsf{LocatedApartness}^{\uparrow}$ *and* $\mathsf{ApartnessReal}^{\uparrow}$ *surfaces; when no positive gap is displayed, A records the absent handoff and exports no apartness witness.*
7. *H records componentwise* hsame *transport for both located-real endpoints, the shared window, both regular readbacks, both dyadic endpoint rows, the Bishop comparison row, the optional apartness handoff, continuation replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a comparison request through $L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparison}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet for two displayed located real endpoints. The classifier compares accepted packets only through $L_0, L_1, W, R_0, R_1, D_0, D_1, B, A,$ so it has no coordinate for trichotomy, total order of constructive reals, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonUp.LocatedRealComparisonUpTasteGate single carrier alignment`

Theorem 1730.2 (Located real comparison NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealComparison}^{\uparrow}$ *carrier*

$$K = (L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows, shared finite window, two regular readbacks, two dyadic endpoint and tolerance rows, Bishop comparison row, optional apartness handoff, transport, replay, provenance, and local naming rows;*
2. *shared-window discipline, requiring both endpoints to be inspected through the same W before the comparison row B is public;*
3. *readback exactness, requiring R_0, R_1, D_0, D_1 to supply the rational and dyadic data consumed by B without exposing host endpoint values;*
4. *classifier transport, requiring H to preserve componentwise sameness for the endpoint rows, window, readbacks, dyadic ledgers, comparison row, optional handoff row, and structural rows;*
5. *positive-gap handoff, requiring A to export a* $\mathsf{LocatedApartness}^{\uparrow}$ *or* $\mathsf{ApartnessReal}^{\uparrow}$ *witness only when the same displayed comparison data in B and dyadic budget in D_0, D_1 exhibit a positive gap;*
6. *non-escape, refusing trichotomy, total order of constructive reals, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No located-real comparison obligation is stored outside these six rows.

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonUp.LocatedRealComparisonCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1730.1. The projection exposes exactly the two located-real endpoints, the shared window, the two regular readbacks, the two dyadic ledgers, the Bishop comparison row, the optional apartness handoff, and the structural rows.

The shared-window obligation is read from W. Since both endpoint presentations are inspected through the same finite schedule before B is public, a comparison consumer cannot compare one endpoint at a hidden precision or through an unrecorded stream request.

Readback exactness is the role of R_0, R_1, D_0, D_1. The regular rational rows supply finite endpoint observations, while the dyadic rows store the slack budgets and endpoint enclosures consumed by the Bishop comparison row.

Classifier transport is componentwise. The row H preserves the endpoint, window, readback, dyadic, comparison, and optional handoff rows before C, P, N replay, source, and name the same packet.

Finally, the positive-gap handoff is governed by A. A handoff to $\mathsf{LocatedApartness}^{\uparrow}$ or $\mathsf{ApartnessReal}^{\uparrow}$ may occur only when the already displayed comparison and dyadic rows exhibit the gap; otherwise the row records absence. Thus trichotomy, total order, quotient real equality, selected representatives, countable choice, ambient completeness, Lean verification, and bridge checking never become local obligations. □

Theorem 1730.3 (Located real comparison shared-window stability)**.** *Every accepted* $\mathsf{LocatedRealComparison}^{\uparrow}$ *packet reads both endpoints through the same displayed* $\mathsf{StreamName}^{\uparrow}$ *window before it exposes the comparison row. Consequently two accepted carriers matched componentwise by* $L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H,$ *have the same finite comparison route and the same available positive-gap handoff status.*

Proof. Inspect an accepted carrier $K = (L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, C, P, N)$. The only window coordinate is W, and both endpoint readbacks cite this same finite observation schedule.

The comparison row B is downstream of the endpoint rows, readbacks, and dyadic ledgers. Therefore changing the public comparison route would require changing at least one displayed coordinate among $L_0, L_1, W, R_0, R_1, D_0, D_1, B$.

The transport row H moves these coordinates componentwise, while C, P, N replay, source, and name the transported packet. The optional handoff A is part of the same displayed route, so its present or absent status is stable under the same classifier match. □

Theorem 1730.4 (Located real comparison apartness handoff)**.** *If an accepted* $\mathsf{LocatedRealComparison}^{\uparrow}$ *carrier exposes a positive-gap handoff row, then every downstream* $\mathsf{LocatedApartness}^{\uparrow}$ *or* $\mathsf{ApartnessReal}^{\uparrow}$ *consumer of that gap factors through the displayed route*

$$(L_0, L_1) \longmapsto W \longmapsto (R_0, R_1) \longmapsto (D_0, D_1) \longmapsto B \longmapsto A \longmapsto H, C, P, N.$$

If the handoff row is absent, the packet exports no apartness witness.

Proof. Start with a downstream consumer asking for apartness evidence from the comparison packet. The endpoint data available to that consumer are the displayed located-real rows L_0 and L_1, not host endpoint values.

The consumer must next read the common window W, the two regular readbacks R_0, R_1, and the dyadic endpoint budgets D_0, D_1. These rows supply the finite observations consumed by the Bishop comparison row B.

When B and the dyadic budgets exhibit a positive gap, the handoff row A routes that same evidence to the $\mathsf{LocatedApartness}^{\uparrow}$ and $\mathsf{ApartnessReal}^{\uparrow}$ surfaces. When the row is absent, no consumer can project an apartness witness from the packet.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Hence the handoff exports exactly the displayed positive-gap evidence and no trichotomy, total order, quotient real equality, selected representative, countable-choice selector, ambient completeness witness, or bridge data. □

Theorem 1730.5 (Located real comparison Real seal factorization)**.** *Every accepted* $\mathsf{LocatedRealComparison}^{\uparrow}$ *carrier*

$$K = (L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, C, P, N)$$

first reads the two $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows* L_0, L_1 *and then factors their terminal* $\mathsf{Real}^{\uparrow}$ *seals through the shared finite readback route*

$$(L_0, L_1) \longmapsto W \longmapsto (R_0, R_1) \longmapsto (D_0, D_1)$$

before exposing either the $\mathsf{BishopRealComparison}^{\uparrow}$ *row* B *or the optional positive-gap handoff row* A*. Thus any downstream order, density, or apartness consumer of* B *or* A *reaches the two real seals only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonUp.LocatedRealComparisonCarrier real seal factorization`

Proof. Project the carrier definition. The only endpoint coordinates are L_0 and L_1, and the comparison packet contains no separate host endpoint row or quotient-real representative from which B or A could be opened directly.

Apply Definition 1730.3. The shared W coordinate is the common $\mathsf{StreamName}^{\uparrow}$ window for both endpoints, and the comparison route is stable only through the displayed coordinates $L_0, L_1, W, R_0, R_1, D_0, D_1, B, A, H, C, P, N$.

The two regular readbacks R_0, R_1 and the two dyadic ledgers D_0, D_1 are the finite rows that connect the endpoint presentations to the comparison row. Hence the terminal $\mathsf{Real}^{\uparrow}$ seals of the located endpoints are visible to B only after this common readback route has been traversed.

Apply Definition 1730.4 for the positive-gap branch. If A is present, it exports only the same displayed gap already routed through W, R_0, R_1, D_0, D_1 and B; if A is absent, it exports no apartness witness.

Consequently the factorization refuses host endpoint equality, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and bridge data. The public comparison and handoff surfaces are exactly the finite certified route named by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1730.1, Definition 1730.2, Definition 1730.3, Definition 1730.4, and Definition 1730.5 seed the finite comparison route over two $\mathsf{LocatedReal}^{\uparrow}$ endpoints, a shared $\mathsf{StreamName}^{\uparrow}$ window, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, a $\mathsf{BishopRealComparison}^{\uparrow}$ row, and an optional $\mathsf{LocatedApartness}^{\uparrow}$ or $\mathsf{ApartnessReal}^{\uparrow}$ positive-gap handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparison}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedRealComparisonUp.LocatedRealComparisonUpTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, total order of constructive reals, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, shared-window discipline, readback exactness, classifier transport, positive-gap handoff, non-escape, and downstream apartness routing for BEDC.Derived.LocatedRealComparisonUp.

Constructive story: A $\mathsf{LocatedRealComparison}^{\uparrow}$ packet is generated from two displayed $\mathsf{LocatedReal}^{\uparrow}$ endpoint rows, one shared $\mathsf{StreamName}^{\uparrow}$ window, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and tolerance ledgers, a $\mathsf{BishopRealComparison}^{\uparrow}$ row, an optional positive-gap handoff through $\mathsf{LocatedApartness}^{\uparrow}$ or $\mathsf{ApartnessReal}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1731

A Concrete Naming Certificate for $\mathsf{KuratowskiEmbedding}^{\uparrow}$

Following Bourbaki's and Kelley's metric-space treatment of distance functions, the $\mathsf{KuratowskiEmbedding}^{\uparrow}$ packet records the classical embedding of a metric space into a space of distance-to-point functions as finite BEDC data. It sits over the metric source of chapter 57, the real-distance rows of chapter 38, and the distance-preserving interface of chapter 439. The packet exposes a selected basepoint or displayed family row, distance-function target rows, and the isometric route; it does not import quotient completion, host function extensionality, or a detached real-valued function space.

Definition 1731.1 (Kuratowski embedding carrier)**.** *A* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, B, D, T, I, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose point and distance-witness data supply the domain of the embedding.*
2. *B is the selected basepoint or displayed point-family row used to normalize and compare distance functions.*
3. *D is the* $\mathsf{Real}^{\uparrow}$ *distance-witness row recording the finite reads $d(x, b)$ and $d(y, b)$ against the selected basepoint or family.*
4. *T is the distance-function target row naming the displayed family of* $\mathsf{Real}^{\uparrow}$ *distance observations rather than a host function space.*
5. *I is the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *route row witnessing that source distances are preserved by the displayed distance-function target.*
6. *H records componentwise* hsame *transport for M, B, D, T, I.*
7. *C records displayed* Cont *replay from metric-distance reads to target distance-function reads and then to the isometric route.*
8. *P is the* Pkg *provenance over* $\mathsf{KuratowskiEmbedding}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{IsometricEmbedding}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, host function extensionality, ambient Banach-space structure, or a selected completion representative.

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingTasteGate single carrier alignment`

Theorem 1731.2 (Kuratowski embedding NameCert obligations)**.** *For the carrier of Definition 7569.1, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$ *surface consists of six finite rows:*

1. *carrier admission: every accepted packet exposes* $K = (M, B, D, T, I, H, C, P, N)$ *and no hidden function-space coordinate;*
2. *metric-source exposure: every source point and source-distance read enters through the* $\mathsf{Met}^{\uparrow}$ *row* M*;*
3. *basepoint or family selection: the row* B *is the only displayed source for the normalizing point or comparison family;*
4. *real-distance target exposure: the rows* D *and* T *turn source-distance reads into* $\mathsf{Real}^{\uparrow}$ *distance-function observations before any target comparison is made;*
5. *isometric route: the row* I *is the only distance-preserving handoff, and it is read after* M, B, D, T*;*
6. *structural replay: the rows* H, C, P, N *preserve, replay, source, and name the same route without exporting quotient completion or host function extensionality.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 7569.1. The accepted packet displays the metric source, basepoint or family row, real-distance witness row, target row, isometric route, transport, continuation, provenance, and local naming row.

Read the dependency rows in order. The metric source row M supplies point and distance-witness data; the row B supplies the selected basepoint or displayed family; and the real-distance row D records the corresponding $\mathsf{Real}^{\uparrow}$ observations.

The target row T is therefore a displayed distance-function surface, not a host function space. The isometric row I can only be read after those source and target observations are visible, and H, C, P, N preserve that same finite route. □

The route consumes the metric source of chapter 57, the real-distance rows of chapter 38, and the distance-preserving handoff of chapter 439.

Theorem 1731.3 (Kuratowski embedding distance route)**.** *Every accepted* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *packet routes source-distance comparison through*

$$M \to B \to D \to T \to I \to H \to C \to P \to N.$$

Thus a consumer reaches the $\mathsf{IsometricEmbedding}^{\uparrow}$ *handoff only after reading the* $\mathsf{Met}^{\uparrow}$ *source, the selected basepoint or family row, and the* $\mathsf{Real}^{\uparrow}$ *distance-function target rows. No consumer receives quotient completion, host function extensionality, ambient Banach-space structure, or a selected completion representative from the packet.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingCarrier distance route`

Proof. Start with an accepted carrier $K = (M, B, D, T, I, H, C, P, N)$. A source-distance query must read M, and a distance-function query must next read the basepoint or family row B.

The real-valued observations are then stored in D and organized by T. Because T is part of the finite carrier, it supplies only displayed $\mathsf{Real}^{\uparrow}$ distance observations and not host-level function extensionality.

Finally apply the isometric route row I. The structural rows H, C, P, N keep the same route under transport and replay, so the only exported embedding data are the displayed metric, basepoint or family, real-distance, target, and isometric rows. □

Theorem 1731.4 (Kuratowski embedding distance readback exactness)**.** *Every accepted* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *packet reads source metric distance exactly through the displayed route*

$$M \to D \to T \to I.$$

The $\mathsf{Met}^{\uparrow}$ *row* M *supplies the source distance query, the* $\mathsf{Real}^{\uparrow}$ *row* D *supplies the distance witnesses used by the distance-function target* T*, and the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *row* I *is the first row from which a completion, hyperspace, or distance-function consumer may inspect the resulting target comparison. No consumer may read a distance-function target as exact before the metric source, real-distance witnesses, and isometric handoff have all been displayed.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbedding distance readback exactness`

Proof. Project the accepted carrier $K = (M, B, D, T, I, H, C, P, N)$ from Definition 7569.1. The source-distance query starts in M, while the basepoint or displayed family row B fixes the finite comparison context.

Apply the NameCert obligations of Definition 7569.2. They force every source-distance read through M and every real-valued distance observation through D before the target row T can be inspected.

Finally use the source-distance route of Definition 7569.3. The isometric handoff I is downstream of M, B, D, T, and the structural rows H, C, P, N only preserve that route. Thus completion, hyperspace, and distance-function consumers receive exactness through the displayed isometric readback rather than from an ambient function space. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KuratowskiEmbedding}^{\uparrow}$ packet is generated from a MetricUp source row, a selected basepoint or displayed family row, RealUp distance-witness rows, a distance-function target row, an IsometricEmbeddingUp route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7569.1, Definition 7569.2, and Definition 7569.3 seed the finite distance-function embedding surface over MetricUp, RealUp, and IsometricEmbeddingUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion, host function extensionality, ambient Banach-space structure, selected completion representatives, or bridge checking.

Upgrade path: Lean closure requires checked carrier admission, basepoint or family exposure, RealUp distance target exposure, isometric-route preservation, and structural replay proofs for BEDC.Derived.KuratowskiEmbeddingUp.

Chapter 1732

A Concrete Naming Certificate for $\mathsf{HellySelection}^{\uparrow}$

Following Helly's selection theorem in the Bishop–Bridges constructive reading, the $\mathsf{HellySelection}^{\uparrow}$ packet records the finite subsequence-selection surface available for bounded-variation real-sequence data. It consumes the partition ledger of chapter 398, the displayed sequence algebra of chapter 1729, the finite selector handoff of chapter 1641, and the regular rational stream names of chapter 301. The packet names only finite windows, variation budgets, selector rows, regular rational readbacks, transport, replay, provenance, and local naming; it does not import open-cover compactness, trichotomy, quotient stream equality, ambient completeness, or choice-selected subsequences.

Definition 1732.1 (Helly selection carrier)**.** *A* $\mathsf{HellySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, A, W, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *row, including the finite partition-variation ledger and the displayed uniform variation budget read by the selection request.*
2. *A is the* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *row that exposes the real-sequence source only through pointwise algebra windows, not through host equality of streams.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger recording the requested source indices, rational scales, and finite observation schedule.*
4. *S is the* $\mathsf{SequentialCompactness}^{\uparrow}$ *selector row whose selected indices and selected windows are displayed as data of the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected windows and rational tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the selected-window read after B, A, W, S, R have been displayed.*
7. *T records componentwise* hsame *transport for the bounded-variation ledger, sequence-algebra row, finite windows, selector row, regular readback, and terminal seal.*
8. *C records displayed* Cont *replay from a bounded-variation selection request through the sequence-algebra row, finite windows, selector row, regular readback, real seal, and transport data.*
9. *P is the* Pkg *provenance over* $\mathsf{HellySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RealSequenceAlgebra}^{\uparrow}$, $\mathsf{SequentialCompactness}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, W, S, R, E, T, C, P, N$. It has no coordinate for open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, or choice-selected subsequences.

Lean4 ✓ `BEDC.Derived.HellySelectionUp.HellySelectionTasteGate single carrier alignment`

Theorem 1732.2 (Helly selection NameCert obligations)**.** *For every accepted* $\mathsf{HellySelection}^{\uparrow}$ *carrier*

$$H = (B, A, W, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, sequence-algebra row, finite stream windows, displayed selector row, regular rational readback, real seal, transport, replay, provenance, and local naming;*
2. *bounded-variation exposure, requiring the variation budget read by the selection request to pass through B before any selected window is inspected;*
3. *sequence-window exposure, requiring every source observation to pass through A and W before the selector row S is read;*
4. *selector stability, requiring the selected indices and selected windows to be exactly the rows displayed in S and transported componentwise by T;*
5. *regular readback exactness, requiring every selected-window convergence read to pass from S to R before the terminal seal E is available;*
6. *nonescape, excluding open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, Lean verification, bridge checking, and choice-selected subsequences.*

No Helly-selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic coordinates are the bounded-variation row, the sequence-algebra row, the finite stream windows, the displayed selector row, the regular readback, and the terminal real seal. The structural coordinates are the componentwise transport, continuation replay, package provenance, and local naming rows.

The bounded-variation and window obligations are read in order. A consumer must first inspect the variation budget through B, then expose the real-sequence source through A and the finite observation schedule W.

Selector stability is internal to S and T. The selected indices and selected windows are named rows of the carrier, and the transport coordinate moves only those rows together with the visible source, window, readback, and seal data.

The regular readback and terminal seal are then forced by R and E. Since no carrier coordinate stores open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, Lean verification, bridge data, or choice-selected subsequences, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.HellySelectionUp.HellySelection namecert obligations`

Theorem 1732.3 (Helly selection bounded-variation window)**.** *Every accepted* $\mathsf{HellySelection}^{\uparrow}$ *packet reads its bounded-variation information through a finite window route*

$$B \longmapsto A \longmapsto W \longmapsto S.$$

The route exposes the source variation budget, sequence-algebra observations, requested stream windows, and displayed selector windows before any $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is available. It exports no open-cover compactness, trichotomy, quotient stream equality, ambient completeness, or choice-selected subsequence coordinate.*

Lean4 ✓ `BEDC.Derived.HellySelectionUp.HellySelection bounded variation window`

Proof. Begin with the bounded-variation source row B. Its visible data are finite partition ledgers and variation budgets, so the selection request starts from displayed bounded-variation information rather than an ambient compactness principle.

The sequence source is then opened through A and W. The row A supplies the pointwise real-sequence algebra surface, while W records the finite stream-name requests and rational scales used by the selector.

Only after these rows have been displayed can the selector row S be inspected. Thus the bounded-variation window route reaches the selected windows without introducing open-cover compactness, trichotomy, quotient stream equality, ambient completeness, or any choice-selected subsequence. □

Theorem 1732.4 (Helly selection finite-variation window handoff)**.** *Every accepted* $\mathsf{HellySelection}^{\uparrow}$ *packet must expose the* $\mathsf{BoundedVariation}^{\uparrow}$ *row, the* $\mathsf{RealSequenceAlgebra}^{\uparrow}$ *row, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any selected-subsequence consumer reads the route*

$$B, A, W \longmapsto S \longmapsto R, E.$$

The handoff is therefore a finite variation-window route: the consumer sees the displayed variation budget, source algebra observations, finite window schedule, selector row, regular rational tail budgets, and real seal in that order, not an ambient compactness principle or a choice-selected subsequence.

Lean4 ✓ `BEDC.Derived.HellySelectionUp.HellySelection finite variation window handoff`

Proof. Project the carrier of Definition 1732.1. The rows B, A, W are the only source-facing rows available before the selector is inspected, so a selected-subsequence consumer first reads the bounded-variation budget, sequence-algebra observations, and finite window schedule.

Apply Definition 1732.3. It forces the displayed route from B through A and W into S, and prevents a consumer from replacing the finite variation window by open-cover compactness, trichotomy, quotient stream equality, ambient completeness, or a choice-selected subsequence.

Finally apply Definition 1732.5. Once S has been displayed, every selected-window read passes through R and then E, with T, C, P, N preserving the same route. Thus the finite variation-window handoff is visible before any downstream subsequence read is exported. □

Theorem 1732.5 (Helly selection subsequence handoff)**.** *Every selected subsequence read exported by an accepted* $\mathsf{HellySelection}^{\uparrow}$ *carrier factors through the displayed selector row, regular rational handoff, terminal real seal, and structural rows*

$$S \longmapsto R \longmapsto E \longmapsto T, C, P, N.$$

The handoff names a finite selected-window route over $\mathsf{SequentialCompactness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *not a host-chosen subsequence or a quotient stream.*

Lean4 ✓ `BEDC.Derived.HellySelectionUp.HellySelection subsequence handoff`

Proof. Project the selector row S. Its selected indices and selected windows are part of the finite carrier, so a consumer cannot replace them by an external selection function.

The selected windows enter R together with the rational tail budgets. This is the only route by which the packet exposes a regular rational convergence read.

The terminal seal E is read after R, and the rows T, C, P, N transport, replay, source, and name the same route. Hence the subsequence handoff is finite and displayed, with no coordinate for a host-chosen subsequence or quotient stream equality. □

Theorem 1732.6 (Helly selection public export)**.** *The public boundary of* $\mathsf{HellySelection}^{\uparrow}$ *exports exactly the bounded-variation source row, real-sequence algebra row, finite stream windows, displayed selector row, regular rational readback, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}$ *row of Definition 1732.1. It exports no open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, or choice-selected subsequences.*

Proof. Inspect the carrier coordinates. The public rows are precisely $B, A, W, S, R, E, T, C, P, N$.

The NameCert obligation theorem shows that every local obligation is attached to those rows. The bounded-variation window theorem shows that the variation and window data are read before the selector is inspected, and the subsequence handoff theorem shows that every selected-window read passes through S, R, E, T, C, P, N.

No additional row remains from which open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, or a choice-selected subsequence could be exported. Therefore the public boundary is exactly the finite displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1732.1, Definition 1732.2, Definition 1732.3, Definition 1732.5, and Definition 1732.6 seed the finite bounded-variation subsequence-selection surface over displayed variation ledgers, sequence-algebra windows, selector rows, regular rational readbacks, and terminal real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient stream equality, ambient completeness, host sequence equality, Lean verification, bridge checking, or choice-selected subsequences.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation exposure, sequence-window exposure, selector stability, regular readback exactness, nonescape, handoff factoring, and public-export proofs for BEDC.Derived.HellySelection

Constructive story: A $\mathsf{HellySelection}^{\uparrow}$ packet is generated from a bounded-variation source row, real-sequence algebra row, finite StreamName windows, displayed SequentialCompactness selector row, RegSeqRat readback, Real seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1733

A Concrete Naming Certificate for $\mathsf{SequenceFilterBridge}^{\uparrow}$

Following Bishop–Bridges regular-sequence completions and Kelley-style filterbase completions, the $\mathsf{SequenceFilterBridge}^{\uparrow}$ packet records the finite bridge by which displayed regular sequence completion data and displayed Cauchy-filter completion data read the same completion surface. It sits between the sequence carrier of chapter 406, the finite filterbase surface of chapter 1601, the filter completion handoff of chapter 1569, the sequential completeness boundary of chapter 1515, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a human-origin L10 Real and Completion bridge, not a quotient filter construction, selected limit, countable-choice selector, host equality comparison, or ambient completeness assumption.

Definition 1733.1 (Sequence-filter bridge carrier)**.** *A* $\mathsf{SequenceFilterBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, F, Q, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *row, including the displayed sequence entries, Cauchy-modulus rows, tail-comparison rows, and provenance boundary.*
2. *F is the accepted* $\mathsf{FilterBase}^{\uparrow}$ *row generated from the same finite tail windows, with base packets indexed only by displayed precision requests and eventual-tail witnesses.*
3. *Q is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion handoff read from F after the filterbase directedness and Cauchy rows have been displayed.*
4. *T is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule common to the sequence side and the filterbase side.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the sequence windows and reused by the filterbase completion handoff.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, F, Q, T, R have been displayed.*
7. *H records componentwise* hsame *transport for the sequence row, filterbase row, completion handoff, stream schedule, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from sequence-completion reads to filter-completion reads and back along the same finite window schedule.*

9. *P is the* Pkg *provenance over* $\mathsf{SequenceFilterBridge}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}$ $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequenceFilterBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, Q, T, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable-choice selectors, host equality, or ambient completeness of the target metric or $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequenceFilterBridgeUp.SequenceFilterBridgeUpTasteGate single carrier alignment`

Theorem 1733.2 (Sequence-filter bridge NameCert obligations)**.** *For every accepted* $\mathsf{SequenceFilterBridge}^{\uparrow}$ *carrier $B = (S, F, Q, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequenceFilterBridge}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the displayed ten-row packet;*
2. *sequence exposure through S, including displayed entries, Cauchy-modulus rows, tail-comparison rows, and source provenance;*
3. *filterbase exposure through F, with base packets generated from the same finite tail windows and precision requests;*
4. *completion handoff through Q, requiring the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *read to cite the displayed filterbase rows of F;*
5. *shared-window readback through T and R, requiring both directions of the bridge to use the same* $\mathsf{StreamName}^{\uparrow}$ *schedule and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*
6. *Real and sequential-completeness compatibility through E and the* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *boundary, after the sequence, filterbase, completion, and readback rows have been displayed;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No NameCert obligation may be discharged by a quotient filter, selected limit, countable choice, host equality, or ambient completeness principle.

Proof. Project the carrier of Definition 1733.1. The rows $S, F, Q, T, R, E, H, C, P, N$ are the only coordinates available to the local classifier.

The sequence side is the row S. It exposes the finite Cauchy sequence data through chapter 406, while T and R make the inspected windows and regular rational readback visible before any completion-facing handoff is read.

The filter side is generated from the same windows. The row F records the $\mathsf{FilterBase}^{\uparrow}$ packets built from displayed tails, and Q reads the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ handoff only after those packets have been exposed.

The compatibility rows close the obligation surface. The row E seals the Real-facing read after the sequence, filterbase, completion, window, and readback rows have been displayed, while H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles have no coordinate in the carrier, the seven listed obligations exhaust the local NameCert surface. □

Theorem 1733.3 (Sequence-to-filter route)**.** *Every accepted sequence-completion read of a* $\mathsf{SequenceFilterBridge}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchySequenceSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{CauchyFilterCompletion}^{\uparrow}.$$

In the notation of Definition 1733.1, the consumer reads S, then the shared schedule T and readback R, then the filterbase row F, and only then the completion handoff Q with its structural rows.

Proof. Start with a sequence-completion read of the bridge packet. By Definition 1733.1, the only sequence source coordinate is S, and every completion-facing observation from that coordinate is routed through the finite schedule T and readback R.

The route then forms the filterbase row. The base packets in F are indexed by the same displayed tail windows and precision requests, so no independent filter selector or quotient-filter equality is introduced.

Finally the completion handoff Q reads chapter 1569. The structural rows H, C, P, N record that this is the same finite packet seen from the sequence side, so every accepted sequence-completion read reaches the filter completion surface through the displayed route. □

Lean4 ✓ `BEDC.Derived.SequenceFilterBridgeUp.SequenceFilterBridgeSequenceToFilterRoute`

Theorem 1733.4 (Filter-to-sequence route)**.** *Every accepted Cauchy-filter completion read of a* $\mathsf{SequenceFilterBridge}^{\uparrow}$ *carrier factors back through the displayed sequence route*

$$\mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchySequenceSpace}^{\uparrow} \longmapsto \mathsf{SequentiallyCompleteMetric}^{\uparrow}.$$

The filter-facing consumer reads F, then the shared window schedule T and readback R, then the sequence row S, and then the sequential-completeness boundary named in P.

Proof. Begin with a filter-completion read. The row F supplies only the displayed finite filterbase packets, and Q records the completion handoff attached to those packets.

The bridge exposes the same finite observations through T and R. These rows determine which sequence windows and regular rational readbacks are visible, so the filter-facing route cannot choose an unrelated sequence representative.

The row S then supplies the $\mathsf{CauchySequenceSpace}^{\uparrow}$ packet, and P records the $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ boundary used by the completion consumer. The replay row C makes the reverse traversal explicit, while H keeps the sequence, filterbase, completion, and readback rows componentwise transported together. □

Lean4 ✓ `BEDC.Derived.SequenceFilterBridgeUp.SequenceFilterBridgeFilterToSequenceRoute`

Theorem 1733.5 (Sequence-filter bridge nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, *or* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequenceFilterBridge}^{\uparrow}$ *carrier* $B = (S, F, Q, T, R, E, H, C, P$ *reads only the displayed sequence row, filterbase row, completion handoff, stream schedule, regular readback, Real seal, componentwise transport, continuation replay, provenance, and local NameCert row. The bridge exports no quotient filter, selected limit, countable-choice selector, host equality proof, or ambient completeness coordinate.*

Proof. Project the downstream rows from Definition 1733.1. The only rows exposed to Real, regular-rational, filter-completion, or sequential-completeness consumers are $S, F, Q, T, R, E, H, C, P, N$.

The sequence and filter presentations share their finite observations. The rows T and R attach the inspected windows and regular readbacks to both S and F, so neither side can escape to an unlisted representative, a quotient filter, or a selected limit.

The completion and Real-facing rows are downstream from the same finite route. The row Q is read only after F, and the row E is read only after S, F, Q, T, R have been displayed.

The structural rows do not add hidden analytic data. They only transport, replay, source, and name the displayed rows. Therefore countable choice, host equality, and ambient completeness have no carrier row, continuation edge, or provenance slot from which to enter the bridge. □

Falsifiable prediction: Every $\mathsf{SequenceFilterBridge}^{\uparrow}$ completion read factors through a displayed CauchySequenceSpace source row, shared StreamName schedule, RegSeqRat readback, FilterBase row, CauchyFilterCompletion handoff, Real seal, transport, replay, provenance, and local naming.

Independence witness: cauchysequencespace, filterbase, cauchyfiltercompletion, sequentially-completemetric, streamname, regseqrat, real: $\mathsf{SequenceFilterBridge}^{\uparrow}$ is not bijective to any listed sibling because it carries the two directed bridge routes between displayed sequence completion data and displayed Cauchy-filter completion data in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequenceFilterBridge}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequenceFilterBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1733.1, Definition 1733.2, Definition 1733.3, Definition 1733.4, and Definition 1733.5 seed the finite bridge between regular sequence completion data and Cauchy-filter completion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequenceFilterBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence exposure, filterbase exposure, completion handoff, shared-window readback, Real and sequential-completeness compatibility, transport and replay stability, and nonescape for BEDC.Derived.SequenceFilterBridgeUp.

Constructive story: A $\mathsf{SequenceFilterBridge}^{\uparrow}$ packet is generated from a CauchySequenceSpace row, a FilterBase row on the same finite tail windows, a CauchyFilterCompletion handoff, a StreamName schedule, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1734

A Concrete Naming Certificate for $\mathsf{CauchyFilterCluster}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyFilterCluster}^{\uparrow}$ packet records the finite bridge by which displayed Cauchy-filter evidence is read as sequence-cluster data before a Real-facing seal may be consumed. It sits after the filter route of chapter 333, the retained-support boundary of chapter 1688, the uniform-window route of chapter 1694, and the cluster-row surface of chapter 1580. Its readback route is the L10 spine through chapter 301, chapter 126, chapter 291, and chapter 38. The packet gives Phase Real and Completion consumers a named finite handoff from filter data to cluster-window data without asserting a selected limit, quotient stream equality, countable choice, host real equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 1734.1 (CauchyFilterCluster carrier)**.** *A* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (F, M, U, W, Q, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *filter-base source row, including displayed base packets, refinements, Cauchy-modulus rows, and source provenance.*
2. *M is the* $\mathsf{MinimalCauchyFilter}^{\uparrow}$ *exposure row, retaining exactly the source base packets that a downstream cluster or Real-facing consumer reads.*
3. *U is the* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *uniform-window row, naming the displayed uniform Cauchy windows attached to the retained support.*
4. *W is the cluster witness-window row. It lists the finite windows through which the same retained support is read as a* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *witness surface.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained support and witness windows.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by W and Q.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger on the same windows, with endpoints, radii, slack rows, comparison rows, and refinement budgets visible in the packet.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after F, M, U, W, Q, S, D have been displayed.*
9. *H records componentwise* hsame *transport for the filter source, retained support, uniform windows, cluster windows, regular readback, stream schedule, dyadic ledger, Real seal, and structural rows.*

10. *C records displayed* Cont *replay from filter refinements to retained support rows, from retained support rows to uniform and cluster windows, and from regular readback to the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MinimalCauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyFilter}^{\uparrow}$, RealSequenceClusterPoi RegSeqRat$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, M, U, W, Q, S, D, E, H, C, P, N$. It has no coordinate for selected limits, quotient stream equality, host real equality, countable choice, ambient completeness, open-cover compactness, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyFilterClusterUp.CauchyFilterClusterTasteGate single carrier alignment`

Theorem 1734.2 (CauchyFilterCluster NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *carrier $Z = (F, M, U, W, Q, S, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed filter source, retained support, uniform-window, cluster-window, regular-readback, stream-schedule, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*
2. *filter-source exposure through F, with no downstream read before the displayed Cauchy-filter base and refinement rows have been inspected;*
3. *minimal-filter exposure through M, requiring each cluster or Real-facing window to cite a retained support row rather than the whole ambient filter base;*
4. *uniform Cauchy-window admission through U, on the same retained support used by the cluster route;*
5. *cluster witness-window admission through W, requiring every cluster witness window to read the retained support, stream schedule, dyadic ledger, and regular readback rows;*
6. *RegSeqRat, StreamName, and DyadicRatCore readback through Q, S, D on the same finite windows;*
7. *Real-seal handoff through E, only after the filter, support, uniform-window, cluster-window, readback, schedule, and tolerance rows have been displayed;*
8. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No listed obligation may be discharged by selected limits, quotient stream equality, host real equality, countable choice, ambient completeness, open-cover compactness, or bridge checking.

Proof. Carrier admission is projection from Definition 1734.1. The rows $F, M, U, W, Q, S, D, E, H, C, P, N$ are the visible coordinates of one finite BHist packet, so the local certificate has no detached limit, quotient, choice, host-equality, compactness, or bridge coordinate.

The filter side is read first. The source row F supplies the Cauchy-filter base and refinement data, and the retained-support row M exposes exactly the base packets that later cluster or Real-facing consumers are allowed to inspect.

The window side is then fixed by U and W. Uniform Cauchy windows in U and cluster witness windows in W are attached to the same retained support, so the packet cannot route a cluster witness through a second ambient filter base.

The readback rows Q, S, D close the finite observation surface. They expose regular rational data, stream windows, and dyadic tolerance budgets on the same witness windows already listed by W.

Finally the Real-facing row E is downstream from those displayed rows, while H, C, P, N only transport, replay, package, and name the same route. Therefore the eight obligations exhaust the local $\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.CauchyFilterClusterUp.CauchyFilterCluster namecert obligations`

Theorem 1734.3 (CauchyFilterCluster cluster route)**.** *Every accepted* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *read exported by a* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *carrier* $Z = (F, M, U, W, Q, S, D, E, H, C, P, N)$ *factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MinimalCauchyFilter}^{\uparrow} \longmapsto \mathsf{UniformCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegS}$$

Concretely, the consumer reads F, then M, then the uniform windows U, then the cluster witness windows W, and only then the stream, dyadic, and regular-rational readback rows S, D, Q with their structural support.

Proof. Start from an accepted cluster read of Z. By Definition 1734.1, the only cluster witness coordinate is W, and it is placed after the Cauchy-filter source F, retained support M, and uniform-window row U.

The source route reads chapter 333, chapter 1688, and chapter 1694. These chapters supply the filter-base rows, retained-support boundary, and uniform Cauchy windows that the cluster witness is permitted to cite.

The observation route then reads the finite schedule and tolerance rows. The row S supplies $\mathsf{StreamName}^{\uparrow}$ windows, D supplies $\mathsf{DyadicRatCore}^{\uparrow}$ budgets on those windows, and Q supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback consumed by the cluster row.

The structural rows preserve the same factorization. Componentwise transport through H, replay through C, provenance through P, and local naming through N do not create a second cluster route, so every accepted $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ read factors through the displayed chain. □

Lean4 ✓ `BEDC.Derived.CauchyFilterClusterUp.CauchyFilterClusterClusterRoute`

Theorem 1734.4 (CauchyFilterCluster Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *carrier* $Z = (F, M, U, W, Q, S, D, E, H, C, P, N)$ *reads the terminal seal only through the displayed filter source, retained support, uniform Cauchy windows, cluster witness windows, stream schedule, dyadic tolerance ledger, regular rational readback, componentwise transport, continuation replay, provenance, and local NameCert row. The packet exports no selected limit, quotient stream equality, host real equality, countable choice, ambient completeness, open-cover compactness, or bridge-checked standard schema.*

Proof. Project the Real-facing row from Definition 1734.1. The only seal coordinate is E, and the carrier places it downstream from F, M, U, W, Q, S, D.

The route to E is finite. The filter source and retained support determine which base packets may be inspected; the uniform and cluster windows determine which finite observations are visible; and the stream, dyadic, and regular-rational rows determine the readback consumed before the seal.

The structural coordinates cannot enlarge the seal boundary. The rows H, C, P, N transport, replay, package, and name the displayed route, but they contain no coordinate for a selected limit,

quotient stream equality, host real equality, countable choice, ambient completeness, open-cover compactness, or checked standard bridge.

Thus every $\mathsf{Real}^{\uparrow}$ consumer reaches the seal through the displayed route and through no external completion principle. □

Falsifiable prediction: Every $\mathsf{CauchyFilterCluster}^{\uparrow}$ cluster or Real-facing read factors through a displayed CauchyFilter source, MinimalCauchyFilter retained support, UniformCauchyFilter window row, RealSequenceClusterPoint witness-window row, StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local naming.

Independence witness: cauchyfilter, minimal-cauchy-filter, uniform-cauchy-filter, real-sequence-cluster-point, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyFilterCluster}^{\uparrow}$ is not bijective to any listed sibling because it carries the finite bridge from retained Cauchy-filter support to cluster witness windows before the Real seal is read.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterCluster}^{\uparrow}$ packet is generated from a displayed CauchyFilter source row, MinimalCauchyFilter retained support row, UniformCauchyFilter window row, cluster witness-window row, RegSeqRat readback row, StreamName schedule, DyadicRatCore tolerance ledger, RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1734.1, Definition 1734.2, Definition 1734.3, and Definition 1734.4 seed the finite bridge from Cauchy-filter evidence to sequence-cluster and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterCluster}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-source exposure, retained-support exactness, uniform-window admission, cluster witness-window admission, StreamName, DyadicRatCore, and RegSeqRat readback, Real-seal boundary, transport and replay stability, provenance, and local naming for BEDC.Derived.CauchyFilterClusterUp.

Chapter 1735

A Concrete Naming Certificate for $\mathsf{CompleteSeparableMetric}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{CompleteSeparableMetric}^{\uparrow}$ packet records the traditional complete separable metric surface as one finite L10 NameCert route. It joins the separable metric data of chapter 1458, the completion route of chapter 1714, the complete-metric boundary of chapter 128, and the metric-completion interface of chapter 1506. When the underlying metric carrier is Real-facing, the dense schedule can also be read through the $\mathsf{RealSeparability}^{\uparrow}$ route of chapter 1809. Its observable route is read through the finite windows of chapter 126, the rational readback discipline of chapter 301, the real boundary of chapter 38, and the downstream complete-separable consumer surface of chapter 1490. The same finite complete-separable metric surface is the handoff consumed by chapter 1490 and by the effective dense-realizer route of chapter 1706.

Definition 1735.1 (Complete separable metric carrier)**.** *A* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, K, D, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row. It records the metric carrier, distance classifier, and the* $\mathsf{SeparableMetric}^{\uparrow}$ *countable-name surface over the same point histories.*
2. *K is the complete-metric seal. It records the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness handoff or the* $\mathsf{MetricCompletion}^{\uparrow}$ *admission route that supplies completion-facing convergence data.*
3. *D is the separable dense schedule. It stores the countable dense enumeration, the request indices, and the finite visibility evidence needed to use density.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It is the only route through which dense indices, Cauchy observations, and completion-facing name segments are inspected.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance ledger. It carries dyadic scales, Real distance boundaries, comparison budgets, and the finite tolerance rows attached to W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the dense schedule and tolerance ledger before the complete-metric seal is read.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *boundary row. It records terminal distance or limit-boundary readings and has no coordinate for ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

8. *H records componentwise* hsame *transport for the metric source, complete-metric seal, dense schedule, finite windows, tolerance ledger, regular readback, Real boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from metric admission through dense-window reads, tolerance checks, regular readback, and complete-metric seal inspection.*
10. *P is the* Pkg *provenance over* $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{SeparableCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteSeparableMetric}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite complete-separable metric packet. It does not store quotient completion equality, selected dense points, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteSeparableMetricUp.CompleteSeparableMetricTasteGate single carrier alignment`

Theorem 1735.2 (Complete separable metric NameCert obligations)**.** *For every accepted* CompleteSeparableMetric *carrier $Q = (M, K, D, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteSeparableMetric}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed metric source, complete-metric seal, dense schedule, finite windows, tolerance ledger, regular readback, Real boundary, transport, replay, provenance, and local naming rows;*
2. *complete-metric handoff, requiring the convergence or completion-facing seal K to be read from the same metric source that supplies M and never from a second host completion object;*
3. *countable-density visibility, requiring every density request to pass through the displayed schedule D and a finite* $\mathsf{StreamName}^{\uparrow}$ *window W;*
4. *tolerance discipline, requiring dyadic and Real comparison budgets in T before any completion-facing approximation is exposed;*
5. *regular readback, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to mediate finite rational observations before the complete-metric seal is inspected;*
6. *Real-seal nonescape, requiring the boundary row E to remain a terminal distance or limit reading rather than a proof of ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*
7. *ledger nonescape, excluding quotient completion equality, selected dense points, countable-choice selectors, open-cover compactness, and any hidden completion equality from the packet.*

No complete-separable metric obligation is stored outside these rows.

Proof. Project the carrier of Definition 1735.1. The projection exposes exactly the metric source M, complete-metric seal K, dense schedule D, finite window W, tolerance ledger T, regular readback R, Real boundary E, and structural rows H, C, P, N.

Carrier admission and complete-metric handoff are tied to the same metric source. The rows M and K are transported together by H, and the replay row C permits the completion-facing seal only after the source metric route has been displayed.

Density visibility is finite. A consumer reaches a dense candidate through the indexed schedule D and a displayed $\mathsf{StreamName}^{\uparrow}$ window W, then reads the tolerance ledger T and regular rational row R before consulting K or E.

The nonescape clauses follow from the carrier shape. None of the rows stores quotient completion equality, selected dense points, a countable-choice selector, open-cover compactness, hidden completion equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the listed obligations exhaust the local NameCert surface. □

Theorem 1735.3 (Complete separable metric density-completion handoff)**.** *Every* $\mathsf{PolishSpace}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *carrier* $Q = (M, K, D, W, T, R, E, H, C, P, N)$ *reads the finite route*

$$M, D \longmapsto W \longmapsto T \longmapsto R \longmapsto K \longmapsto E \longmapsto H, C, P, N$$

before it reads the public packet. Thus density, finite observation, tolerance, regular readback, and complete-metric seal data remain visible to the consumer, while quotient completion equality, selected dense points, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness remain outside the packet.*

Lean4 ✓ `BEDC.Derived.CompleteSeparableMetricUp.CompleteSeparableMetricCarrier density completion handoff`

Proof. Begin with a $\mathsf{PolishSpace}^{\uparrow}$ or completion-facing read of Q. Carrier admission gives the consumer the metric source and dense schedule only as the displayed pair M, D.

Replay the observation route. The request opens the finite $\mathsf{StreamName}^{\uparrow}$ window W, reads the dyadic or Real tolerance ledger T, and obtains the $\mathsf{RegSeqRat}^{\uparrow}$ readback R before the complete-metric seal K is available.

The Real boundary and public packaging are downstream. The row E records only terminal distance or limit-boundary data, while H, C, P, N transport, replay, source, and name the same finite route.

Therefore every downstream consumer reads the dense schedule, finite windows, tolerance ledger, regular readback, and complete-metric seal before the public packet. The excluded quotient, selected-point, choice, compactness, hidden-completion, and ambient-Real-completeness data have no coordinate in the carrier. □

Theorem 1735.4 (Complete separable metric finite-window density seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{PolishSpace}^{\uparrow}$*-facing read of an accepted* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *carrier* $Q = (M, K, D, W, T, R, E, H, C, P, N)$ *must expose the finite-window route*

$$M, D \longmapsto W \longmapsto T \longmapsto R \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

The row E *is only a terminal distance or limit-boundary row for the displayed route; it is not ambient* $\mathsf{Real}^{\uparrow}$ *completeness and cannot replace the complete-metric seal* K*.*

Lean4 ✓ `BEDC.Derived.CompleteSeparableMetricUp.CompleteSeparableMetricCarrier finite window density seal`

Proof. Project the carrier in Definition 1735.1. The projection exposes the metric source M, dense schedule D, finite window W, tolerance ledger T, regular readback R, complete-metric seal K, Real boundary row E, and structural rows H, C, P, N.

Apply Definition 1735.2. Density requests must pass through D and W, tolerance data must pass through T, and regular rational observations must pass through R before either completion-facing or Real-facing data are available.

Apply Definition 1735.3. The downstream consumer route already orders $M, D, W, T, R, K, E, H, C, P, N$, so every $\mathsf{Real}^{\uparrow}$ or $\mathsf{PolishSpace}^{\uparrow}$ read inherits the same finite-window density seal.

Finally inspect the role of E. The carrier assigns E only to terminal distance or limit-boundary readings, while K carries the complete-metric seal. Thus E cannot be read as ambient $\mathsf{Real}^{\uparrow}$ completeness or as a substitute for K. □

Theorem 1735.5 (Complete separable metric finite-density induction)**.** *For every accepted* CompleteSeparableMetr *carrier $Q = (M, K, D, W, T, R, E, H, C, P, N)$ and every displayed finite dense-prefix schedule inside the* $\mathsf{StreamName}^{\uparrow}$ *window row W, the prefix is consumed by induction through the same displayed rows. The empty prefix exposes only the metric source M, dense schedule D, and finite window W. If a prefix has already been consumed through M, D, W, T, R, then extending it by one dense index adds exactly that index from D, its dyadic or* $\mathsf{Real}^{\uparrow}$ *tolerance row in T, and its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in R before the same complete-metric seal K and terminal* $\mathsf{Real}^{\uparrow}$ *boundary row E are read. Thus every finite dense schedule prefix reaches completion-facing consumers through the route*

$$M, D, W \longmapsto T \longmapsto R \longmapsto K \longmapsto E$$

and not through quotient completion equality, selected dense points, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteSeparableMetricUp.CompleteSeparableMetricCarrier finite density induction`

Proof. Start with the carrier projection in Definition 1735.1. The displayed rows identify the only visible metric source, dense schedule, finite window, tolerance ledger, regular readback, complete-metric seal, and Real boundary rows.

The base case is the empty finite prefix. It makes no dense request, so Definition 1735.2 leaves visible only the source rows M, D and the finite window row W.

For the induction step, assume a finite prefix has already been consumed through M, D, W, T, R. Extending the prefix by one dense index opens one more displayed request in D through the same $\mathsf{StreamName}^{\uparrow}$ window W, then reads the attached dyadic or $\mathsf{Real}^{\uparrow}$ tolerance row in T and the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback in R.

The completion-facing part does not change with the prefix length. By Definition 1735.3, the extended prefix still reaches the complete-metric seal through K and the terminal Real boundary through E before any public packet is exposed.

Apply Definition 1735.4. Since every finite-window read already has the route $M, D, W, T, R, K, E, H, C, P, N$, the induction consumes each finite dense schedule prefix through those rows and through no quotient completion equality, selected dense point, countable-choice selector, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteSeparableMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteSeparableMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1735.1, Definition 1735.2, Definition 1735.3, and Definition 1735.5 seed the finite complete-separable route through metric source data, complete-metric seals, dense schedules, finite windows, tolerance ledgers, regular readbacks, finite-prefix induction, and Real boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteSeparableMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected dense points, countable choice, open-cover compactness, hidden completion equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric handoff, countable-density visibility, tolerance discipline, regular readback, Real-seal nonescape, ledger nonescape, and density-completion handoff for BEDC.Derived.CompleteSeparableMetricUp.

Constructive story: A CompleteSeparableMetric$^{\uparrow}$ packet is generated from a metric and separable source row, a complete-metric or metric-completion seal, a countable dense schedule, finite StreamName windows, DyadicRatCore or RealUp tolerance data, a RegSeqRat readback, a terminal RealUp boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1736

A Concrete Naming Certificate for $\mathsf{UniformCauchySeries}^{\uparrow}$

Bishop–Bridges constructive-analysis grounding treats convergence of a real series as effective Cauchy control on finite partial sums rather than as an ambient infinite-sum object. The $\mathsf{UniformCauchySeries}^{\uparrow}$ packet records that shared-uniform-tail route as finite BEDC data, sitting between the finite series surface of chapter 1581, the fast tail-budget schedule of chapter 367, and the shared-threshold criterion of chapter 435. It routes all endpoint-facing reads through selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ seal, with no host infinite sum, selected limit, quotient stream equality, countable choice, or ambient real completeness.

Definition 1736.1 (Uniform Cauchy series carrier)**.** *A* $\mathsf{UniformCauchySeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (T, S, W, Q, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the real-valued term stream, read only through selected finite observations and never as a completed host sequence.*
2. *S is the finite partial-sum window row, listing displayed initial segments, accumulated* $\mathsf{Real}^{\uparrow}$ *sum seals for those segments, and adjacent term contributions.*
3. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row for the terms, partial sums, and endpoint-facing observations used by the packet.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every selected term window and partial-sum window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording finite addition budgets, comparison radii, and requested tail tolerances.*
6. *M is the shared uniform Cauchy tail threshold row: one displayed threshold governs every accepted partial-sum comparison requested by the packet.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the term stream, partial-sum windows, selected stream names, regular readbacks, dyadic ledger, and shared threshold have been displayed.*
8. *H stores componentwise* hsame *transport for the term stream, partial-sum windows, selected stream windows, regular readbacks, dyadic ledger, tail threshold, endpoint seal, continuation, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from term reads to partial sums, from partial sums to regular readback, from readback to dyadic tolerance accounting, from the ledger to the shared uniform threshold, and from that threshold to the endpoint seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, W, Q, D, M, E, H, C, P, N$. It has no coordinate for a host infinite sum, a selected limit of partial sums, quotient equality of streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1736.2 (Uniform Cauchy series NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchySeries}^{\uparrow}$ *carrier $U = (T, S, W, Q, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed term-stream, partial-sum, stream-window, regular readback, dyadic ledger, shared-threshold, endpoint-seal, transport, replay, provenance, and naming rows;*

2. *classifier transport, requiring every accepted comparison to preserve $T, S, W, Q, D, M, E, H, C, P, N$ componentwise and to preserve no hidden summability datum;*

3. *uniform tail threshold, requiring the single row M to govern every displayed comparison of partial-sum windows beyond the requested tolerance;*

4. *partial-sum window exactness, requiring each finite endpoint-facing observation to pass through T, S, W, Q, and D before any tail or seal row is read;*

5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the endpoint row E to consume only the displayed finite route and never a host sum, chosen limit, quotient stream equality, countable choice, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.UniformCauchySeriesUp.TasteGate.UniformCauchySeriesTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1736.1. The packet displays exactly the rows $T, S, W, Q, D, M, E, H, C, P, N$, so the local certificate has no detached coordinate for a completed series or a choice-selected endpoint.

Classifier transport is componentwise. The row H stores the permitted hsame comparisons, while C replays only the displayed route from term reads through partial sums, readbacks, dyadic budgets, the shared tail threshold, and the endpoint seal.

The tail-threshold row is unique inside the packet. A tolerance request may ask for many finite partial-sum comparisons, but those comparisons all read the same displayed threshold row M before reaching the endpoint-facing seal.

Partial-sum exactness follows from the order of the carrier rows. The term stream T and partial-sum windows S are exposed through the selected windows W, then through the regular readback Q and dyadic ledger D.

Finally, the $\mathsf{Real}^{\uparrow}$ seal row E is downstream of the same finite route. Since no host infinite sum, selected limit, quotient stream equality, countable-choice selector, or ambient completeness theorem appears among the carrier coordinates, none can be exported by the local $\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}$ surface. □

Theorem 1736.3 (Uniform tail-threshold nonescape)**.** *Every endpoint-facing read from an accepted* UniformCauchySeries$^{\uparrow}$ *carrier factors through the displayed* RealSeries$^{\uparrow}$, FastConvergentSeries$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows named by the packet. Consequently the read cannot escape through a host infinite sum, selected limit, quotient stream equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchySeriesUp.TailThreshold.UniformCauchySeriesTailThresholdSemanticCertif`

Proof. Start with an endpoint-facing request. The carrier definition forces the request to read the real-valued term stream and finite partial-sum windows through the RealSeries$^{\uparrow}$ provenance row and the displayed rows T and S.

Next the request reads the fast tail-budget and shared criterion surfaces. The FastConvergentSeries$^{\uparrow}$ provenance supplies the finite tail-budget discipline, while the UniformCauchyCriterion$^{\uparrow}$ provenance supplies the single shared threshold row M for all accepted partial-sum comparisons.

The finite observations are then exposed only through W, Q, and D. These are respectively the selected StreamName$^{\uparrow}$ windows, the RegSeqRat$^{\uparrow}$ readbacks, and the DyadicRatCore$^{\uparrow}$ tolerance ledger.

The endpoint row E is a Real$^{\uparrow}$ seal for this already displayed route. The structural rows H, C, P, N transport, replay, source, and name the same route without adding any additional endpoint coordinate.

Because every stage of the read is one of the displayed sibling rows, the packet has no place from which to read a host infinite sum, selected limit, quotient stream equality, countable-choice selector, or ambient completeness theorem. □

Theorem 1736.4 (Uniform Cauchy series majorant sum handoff)**.** *Let* $U = (T, S, W, Q, D, M, E, H, C, P, N)$ *be an accepted* UniformCauchySeries$^{\uparrow}$ *carrier. Every endpoint-facing read whose term stream is supplied by the* RealSeries$^{\uparrow}$ *surface and whose tail control is supplied by a displayed* CauchyMajorantSeries$^{\uparrow}$ *or* FastConvergentSeries$^{\uparrow}$ *route factors through*

$$T \longmapsto S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

Here M is read as the shared tail threshold for the majorant-backed partial-sum comparisons, and E is read only after the selected StreamName$^{\uparrow}$ *windows, the* RegSeqRat$^{\uparrow}$ *readbacks, and the* DyadicRatCore$^{\uparrow}$ *ledger have already displayed the finite route to the endpoint* Real$^{\uparrow}$ *seal. Consequently the handoff exports the endpoint Real sum route without exporting a host infinite sum, selected limit, quotient stream equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $U = (T, S, W, Q, D, M, E, H, C, P, N)$. The RealSeries$^{\uparrow}$ surface supplies the visible term stream and partial-sum observations, so the endpoint request begins at T and S rather than at an external summability predicate.

The majorant-backed tail control is then read through the displayed sibling route. The CauchyMajorantSeries$^{\uparrow}$ surface contributes the finite majorant schedule, while the FastConvergentSeries$^{\uparrow}$ surface contributes the fast tail-budget discipline; both are consumed by the single shared threshold row M named in the UniformCauchySeries$^{\uparrow}$ carrier.

Before the endpoint row is visible, the request must pass through W, Q, and D. These rows open the selected StreamName$^{\uparrow}$ windows, read them as RegSeqRat$^{\uparrow}$ data, and account for the requested dyadic tolerances through DyadicRatCore$^{\uparrow}$.

Finally apply Definition 1736.3. Since the endpoint row E is downstream of the displayed threshold and ledger route, the structural rows H, C, P, N can only transport, replay, source, and

name the same finite handoff. No carrier row remains from which a host infinite sum, selected limit, quotient stream equality, countable-choice selector, or ambient completeness theorem could be read. □

Falsifiable prediction: Every $\mathsf{UniformCauchySeries}^{\uparrow}$ endpoint-facing read factors through finite partial-sum windows, one shared uniform Cauchy tail threshold, selected StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, fastconvergentseries, uniformcauchycriterion, regseqrat, streamname, dyadicratcore, real: $\mathsf{UniformCauchySeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a real-valued term stream, finite partial-sum windows, one shared uniform tail threshold, selected stream windows, regular readbacks, dyadic tolerance accounting, endpoint sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchySeries}^{\uparrow}$ packet is generated from a real-valued term stream, finite partial-sum windows, selected StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, one shared uniform Cauchy tail threshold, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1736.1, Definition 1736.2, Definition 1736.3, and Definition 1736.4 seed the finite shared-uniform-tail series route from real-valued term streams and displayed majorant control to RealUp endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchySeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, uniform tail thresholding, partial-sum window exactness, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.UniformCauchySeriesUp.

Chapter 1737

A Concrete Naming Certificate for $\mathsf{CauchyApproximationSequence}^{\uparrow}$

Bishop–Bridges constructive analysis treats a real name as a precision-indexed approximation practice: a requested tolerance is answered by displayed rational data and an explicit regularity route, not by a completed host value. The $\mathsf{CauchyApproximationSequence}^{\uparrow}$ packet records that finite request-to-seal surface between the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the regular completion boundary of chapter 1639. It gives later Real and Completion consumers one named route from precision requests to finite approximants, while refusing quotient stream equality, selected limits, countable choice, host real equality, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1737.1 (Cauchy approximation sequence carrier)**.** *A* $\mathsf{CauchyApproximationSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the requested-precision row, listing the finite tolerance questions currently being answered by the packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximant ledger, recording dyadic approximants, dyadic radius comparisons, and the finite error budgets attached to each requested precision.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *stream-window schedule opened for the requested precisions and no other hidden observations.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row obtained from the displayed stream windows and dyadic approximant ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, D, S, R have been exposed and replayed.*
6. *H records componentwise* hsame *transport for requested precisions, dyadic approximants, stream-window schedules, regular readbacks, the Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through D, then through S and R, and finally into the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, S, R, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1737.2 (Cauchy approximation sequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyApproximationSequence}^{\uparrow}$ *carrier $A = (Q, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the requested-precision row, dyadic approximant ledger, stream-window schedule, regular-rational readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *request exactness, requiring each precision question to be read from Q before any dyadic approximant in D is accepted;*

3. *dyadic ledger exactness, requiring D to record the approximant and tolerance comparison used for the displayed request, not an ambient real value;*

4. *window and readback exactness, requiring S and R to expose only the finite stream windows and regular rational data demanded by Q and justified by D;*

5. *Real-seal boundary, requiring E to remain downstream of Q, D, S, R and never to serve as a selected limit or host equality object;*

6. *componentwise transport and replay, requiring H and C to preserve exactly the displayed route from requested precision to Real seal;*

7. *provenance and local naming, requiring P and N to export the finite route over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *without adding quotient equality, choice, trichotomy, or ambient completeness.*

No approximation-sequence obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyApproximationSequenceUp.CauchyApproximationSequenceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1737.1. The accepted packet displays exactly the requested precisions Q, dyadic ledger D, stream windows S, regular readback R, Real seal E, and structural rows H, C, P, N.

Request exactness and dyadic ledger exactness follow from the route order. A consumer first reads a finite precision question from Q; only then may it consult D for the dyadic approximant and tolerance comparison attached to that question.

The window and readback rows are likewise downstream of the request and ledger. The schedule S opens only the finite windows demanded by Q, and R records the regular-rational data read through those windows under the displayed dyadic budget.

Finally, the Real seal row E is terminal for this finite route. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the same displayed packet, so no quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy principle, or ambient completeness theorem can become a local obligation. □

Theorem 1737.3 (Cauchy approximation sequence Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyApproximationSequence}^{\uparrow}$ *carrier reads only the displayed request-to-seal rows*

$$Q, D, S, R, E, H, C, P, N.$$

Consequently the consumer receives finite requested precisions, dyadic approximants, stream-window schedules, regular-rational readbacks, a Real seal, componentwise transport, displayed replay, provenance, and local naming data. It receives no quotient stream equality, selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a $\mathsf{Real}^{\uparrow}$ consumer read an accepted packet $A = (Q, D, S, R, E, H, C, P, N)$. Carrier projection gives access only to the rows named in Definition 1737.1.

The read begins with a requested precision in Q. The dyadic ledger D supplies the corresponding approximant and tolerance comparison; the stream schedule S opens the finite observation windows; and the regular readback R exposes the rational data that the Real seal may consume.

The terminal row E is therefore reached only after the finite route through Q, D, S, R has been displayed. The structural rows H, C, P, N transport, replay, source, and name the same route without adding any second equality or limit coordinate.

Since the packet has no carrier row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, a Real-facing consumer cannot read any of those objects from the local certificate. □

Falsifiable prediction: Every $\mathsf{CauchyApproximationSequence}^{\uparrow}$ Real-facing read factors through finite requested precisions, a DyadicRatCore approximant ledger, selected StreamName windows, RegSeqRat readbacks, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishopregularcauchycompletion: $\mathsf{CauchyApproximationSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries requested precisions, dyadic approximant rows, finite stream-window schedules, regular-rational readback, a terminal Real seal, transport, replay, provenance, and local naming in one request-indexed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyApproximationSequence}^{\uparrow}$ packet is generated from requested precision rows, a DyadicRatCore approximant ledger, selected StreamName windows, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1737.1, Definition 1737.2, and Definition 1737.3 seed the finite request-indexed route from dyadic precision questions to RealUp endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exactness, dyadic ledger exactness, window and readback exactness, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationSequenceUp.

Chapter 1738

A Concrete Naming Certificate for $\mathsf{CauchyTailEquivalence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyTailEquivalence}^{\uparrow}$ packet records equality of regular Cauchy real names by a shared finite tail route rather than by quotienting streams. It sits over the regular rational source rows of chapter 301, the selected-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the synchronized tail criterion of chapter 435, and the terminal real-name seal of chapter 38. The packet names the symmetric finite carrier consumed by the Real and Completion route: two regular Cauchy sources, one shared tail threshold, finite tolerance accounting, componentwise transport, and a Real-facing seal handoff with no quotient stream equality, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1738.1 (CauchyTailEquivalence carrier)**.** *A* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E_{\mathrm{tail}} = (X, Y, W, M, D, T, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational Cauchy observations are compared.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming exactly the finite source observations used on both sides of the comparison.*
3. *M is the shared* $\mathsf{StreamName}^{\uparrow}$ *tail threshold row; every accepted tolerance request for X and Y must read this one row before comparing tail windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested precision, the source radii, the tail slack, and the final comparison budget.*
5. *T is the finite tail-equivalence row asserting that beyond M the displayed X and Y observations meet the dyadic budget recorded in D.*
6. *H stores componentwise* hsame *transport for the two source rows, shared windows, shared tail threshold, dyadic ledger, tail-equivalence row, continuation, provenance, and local naming.*
7. *C stores displayed* Cont *replay from a Real-facing equality request through $X, Y, W, M, D, T, H, P, N$ before any seal is consumed.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, M, D, T, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyTailEquivalenceUp.CauchyTailEquivalenceUpTasteGate single carrier alignment`

Theorem 1738.2 (CauchyTailEquivalence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *carrier*

$$E_{\text{tail}} = (X, Y, W, M, D, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger, the shared tail-threshold row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the tail-equivalence row, and the structural rows;*
2. *symmetric source stability, requiring interchange of X and Y to preserve the same shared window, threshold, tolerance, tail-equivalence, transport, replay, provenance, and naming rows;*
3. *shared-threshold exactness, requiring every accepted comparison to read the single threshold row M before the dyadic budget D is discharged by T;*
4. *componentwise* hsame *transport, requiring H to preserve the two source rows, the shared windows, the threshold row, the tolerance ledger, and the tail-equivalence row without adding a quotient coordinate;*
5. *displayed* Cont *replay, requiring C to route each Real-facing request through $X, Y, W, M, D, T, H, P, N$ before the consumer reaches a* $\mathsf{Real}^{\uparrow}$ *seal;*
6. *refusal of quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No tail-equivalence obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.CauchyTailEquivalenceUp.TasteGate.CauchyTailEquivalenceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1738.1. The packet displays exactly the two regular Cauchy source rows, shared windows, one shared threshold, dyadic tolerance accounting, and structural naming rows.

Symmetry is finite because the carrier stores no oriented endpoint datum. Interchanging X and Y leaves W, M, D, T, H, C, P, N as the same displayed route, so the local classifier has no extra quotient or host-equality coordinate to transport.

Shared-threshold exactness follows from the order of reads in the carrier. A tolerance request must pass through W, then through the single row M, then through the dyadic ledger D before the tail-equivalence row T is available.

The transport and replay clauses are componentwise. The row H preserves the named source, window, threshold, tolerance, and tail rows, while C replays the same route for a Real-facing consumer.

Finally inspect the carrier inventory. Since quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from E_{tail}, none can appear in the local $\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}$ surface. □

Theorem 1738.3 (CauchyTailEquivalence tail transport)**.** *Let $E_{\text{tail}} = (X, Y, W, M, D, T, H, C, P, N)$ be an accepted* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *carrier. Any finite tail-equivalence read admitted for X and Y transports along componentwise* hsame *data exactly when the transported read preserves the shared* $\mathsf{StreamName}^{\uparrow}$ *windows W, the shared tail threshold M, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the tail-equivalence row T, the displayed* Cont *replay C, the* Pkg *provenance P, and the local naming row N.*

Consequently the transported read remains a finite tail comparison between the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows. It is not a quotient equality of streams, a selected limit, a countable-choice construction, a trichotomy comparison, or an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyTailEquivalenceUp.CauchyTailEquivalenceTailTransport`

Proof. For the forward direction, begin with an admitted tail-equivalence read. The NameCert obligations of Definition 1738.2 force the read through the carrier rows $X, Y, W, M, D, T, H, C, P, N$.

The componentwise transport row H can preserve only those displayed rows. Therefore an accepted transported read keeps the same selected windows, shared threshold, dyadic ledger, tail-equivalence row, continuation replay, provenance, and local naming.

For the reverse direction, suppose those rows are preserved by componentwise hsame data. Carrier admission and displayed replay then reconstruct the same finite tail route through W, M, D, T, C, P, N, so the local classifier admits the transported comparison.

The nonescape clause rules out stronger interpretations. Because the carrier contains no quotient coordinate, selected limit, choice selector, trichotomy row, or completeness theorem, transport cannot export any of them. □

Theorem 1738.4 (CauchyTailEquivalence Real seal handoff)**.** *Every Real-facing equality read exported by an accepted* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *carrier factors through the finite route*

$$(X, Y) \longmapsto W \longmapsto M \longmapsto D \longmapsto T \longmapsto H \longmapsto C \longmapsto P \longmapsto N \longmapsto \mathsf{Real}^{\uparrow}$$

before it may be consumed by a Real or Completion endpoint. Thus the consumer receives two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, one shared* $\mathsf{StreamName}^{\uparrow}$ *tail threshold, selected source windows, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data. It receives no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with a Real-facing equality request. The carrier definition requires the request to identify the two regular Cauchy source rows X and Y before any endpoint seal is available.

The request then reads the selected source windows W and the shared tail threshold M. Only after that shared threshold is displayed may the dyadic ledger D and tail-equivalence row T certify the requested comparison.

The structural rows do not add analytic data. They transport the finite route componentwise, replay it as a displayed continuation, record its provenance, and name it locally.

The final handoff to $\mathsf{Real}^{\uparrow}$ is therefore downstream of the finite route just listed. Since no quotient stream equality, selected limit, countable-choice selector, trichotomy principle, host real equality, or ambient completeness theorem appears among the rows, none is delivered to the Real or Completion consumer. □

Theorem 1738.5 (CauchyTailEquivalence Real-seal nonescape)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *packet must consume the terminal seal only after the finite route*

$$X, Y, W, M, D, T \longmapsto H, C, P, N.$$

The seal therefore cannot be reinterpreted as quotient stream equality, selected limit data, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the handoff theorem Definition 1738.4. It already routes every Real-facing equality read through the two regular rational source rows, selected windows, shared threshold, dyadic ledger, tail-equivalence row, transport, replay, provenance, and local naming before the Real endpoint is used.

Use the NameCert obligations of Definition 1738.2. They keep $X, Y, W, M, D, T, H, C, P, N$ as the complete local certificate surface and store no quotient, selector, trichotomy, host equality, or completeness coordinate.

Thus the Real seal is a terminal row of the displayed finite packet. Any consumer that treats it as an external equality or completion principle has left the accepted $\mathsf{CauchyTailEquivalence}^{\uparrow}$ route. □

Falsifiable prediction: Every $\mathsf{CauchyTailEquivalence}^{\uparrow}$ Real-facing equality read factors through two RegSeqRat source rows, selected StreamName windows, one shared StreamName tail threshold, a DyadicRatCore tolerance ledger, finite tail-equivalence data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, uniformcauchycriterion, real: $\mathsf{CauchyTailEquivalence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular Cauchy sources, one shared tail threshold, symmetric tail comparison, dyadic tolerance accounting, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailEquivalence}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, selected $\mathsf{StreamName}^{\uparrow}$ windows, one shared $\mathsf{StreamName}^{\uparrow}$ tail threshold, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite tail-equivalence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1738.1, Definition 1738.2, Definition 1738.3, and Definition 1738.4 seed the finite symmetric tail-equivalence carrier for the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailEquivalence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyTailEquivalenceUp.CauchyTailEquivalenceUpTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, symmetric source stability, shared-threshold exactness, componentwise transport, displayed replay, and Real seal handoff for BEDC.Derived.CauchyTailEquivalenceUp.

Chapter 1739

A Concrete Naming Certificate for $\mathsf{UniqueChoicePrinciple}^{\uparrow}$

Following Bishop–Bridges constructive analysis, unique relation readback is admitted only through displayed existence and uniqueness rows. The $\mathsf{UniqueChoicePrinciple}^{\uparrow}$ packet records that finite surface as a NameCert carrier: a source row and relation row are not turned into a selected representative or host function, but into a deterministic readback row whose use is justified by visible existence evidence and a uniqueness ledger. It sits beside the extension consumers of chapter 769 and chapter 1632, the completion interface of chapter 397, and the separated comparison boundary of chapter 1411.

The packet is a finite relation-to-readback certificate. It does not assert countable choice, selected representatives, host function equality, quotient completion, real trichotomy, or ambient completeness; it records only the displayed route by which an accepted source and relation row expose one deterministic readback.

Definition 1739.1 (UniqueChoicePrinciple carrier)**.** *A* $\mathsf{UniqueChoicePrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, R, E, U, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the source carrier row whose accepted elements may be queried.*
2. *R is the relation row over S and the readback surface, stored as finite classifier data rather than as a host function.*
3. *E is the existence witness row. For each accepted source read, it displays a relation output row before deterministic readback is visible.*
4. *U is the uniqueness ledger. It compares any two displayed relation outputs for the same accepted source by componentwise* hsame *transport and classifier agreement.*
5. *D is the deterministic readback row obtained only after E and U have been displayed.*
6. *H records componentwise* hsame *transport for source rows, relation rows, existence rows, uniqueness-ledger rows, deterministic readback rows, continuation routes, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a source query through S, R, E, U, D, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{UniqueChoicePrinciple}^{\uparrow}$, BHist, hsame, *classifier data,* Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniqueChoicePrinciple}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite unique-relation readback packet. It has no coordinate for countable choice, selected representatives, host function equality, quotient completion, real trichotomy, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.UniqueChoicePrincipleUp.UniqueChoicePrincipleTasteGate single carrier alignment`

Theorem 1739.2 (UniqueChoicePrinciple NameCert obligations)**.** *For every accepted* $\mathsf{UniqueChoicePrinciple}^{\uparrow}$ *carrier $Q = (S, R, E, U, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniqueChoicePrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source row S, relation row R, existence witness row E, uniqueness ledger U, deterministic readback row D, transport, continuation, provenance, and local naming rows;*

2. *existence visibility, requiring each accepted source query to display an E row before any deterministic readback row is consumed;*

3. *uniqueness-ledger determinacy, requiring two relation outputs over the same accepted source to be compared only through U by* hsame *transport and classifier agreement;*

4. *readback stability under* hsame *transport, requiring the deterministic row D to transport componentwise with S, R, E, U, H, C, P, N;*

5. *ledger non-escape, requiring every deterministic readback to factor through the displayed existence and uniqueness rows and forbidding countable choice, selected representatives, host function equality, quotient completion, real trichotomy, and ambient completeness from the local surface.*

No unique-choice obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.UniqueChoicePrincipleUp.UniqueChoicePrincipleCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1739.1. The packet displays the source, relation, existence witness, uniqueness ledger, deterministic readback, transport, continuation, provenance, and local naming rows before any readback can be consumed.

Existence visibility follows from the position of E in the carrier route. A source query can reach D only through the replay row C, and that replay passes through the relation row and the existence witness row first.

Uniqueness-ledger determinacy is the role of U. If two relation outputs are displayed for the same accepted source row, the packet compares them by the hsame and classifier data recorded in U, not by host equality or a hidden selector.

Readback stability is componentwise. The transport ledger H moves the source, relation, existence, uniqueness, deterministic readback, replay, provenance, and naming rows together, so the deterministic row has no independent equality principle.

Finally inspect the carrier inventory. Since no coordinate of Q is a countable-choice schedule, selected representative, host function equality proof, quotient-completion object, trichotomy decision, or ambient-completeness theorem, none can occur in the local NameCert surface. □

Theorem 1739.3 (UniqueChoicePrinciple deterministic readback)**.** *Let $Q = (S, R, E, U, D, H, C, P, N)$ be an accepted* UniqueChoicePrinciple$^{\uparrow}$ *carrier. Any two deterministic readbacks over the same accepted source row and relation row are compared only through the displayed uniqueness ledger U and the componentwise* hsame *transport recorded by H.*

Thus deterministic readback is a finite relation-ledger boundary. It is not countable choice, a selected representative, host function equality, quotient completion, real trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniqueChoicePrincipleUp.UniqueChoicePrincipleCarrier deterministic readback`

Proof. Start with two accepted deterministic readbacks over the same source row S and relation row R. By Definition 1739.1, each readback must be the row D reached through displayed existence evidence E and replay C inside the same packet.

The NameCert obligations of Definition 1739.2 force comparison of the corresponding relation outputs through the uniqueness ledger U. That ledger exposes only hsame transport and classifier agreement for the displayed rows.

The transport ledger H then carries this comparison componentwise across S, R, E, U, D, C, P, N. There is no separate host function equality or representative selector available to the readback.

The excluded principles have no coordinate in Q and no replay edge in C. Therefore any accepted comparison of deterministic readbacks is exactly the displayed uniqueness-ledger comparison transported by H. □

Closure status for NameCert$_{\text{UniqueChoicePrinciple}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{UniqueChoicePrinciple}^{\uparrow}}$, seed)

Scope closed: Definition 1739.1, Definition 1739.2, and Definition 1739.3 seed the finite unique-relation readback surface through source, relation, existence, uniqueness-ledger, deterministic readback, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{UniqueChoicePrinciple}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close countable choice, selected representatives, host function equality, quotient completion, real trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, existence visibility, uniqueness-ledger determinacy, readback stability under hsame transport, and ledger non-escape for BEDC.Derived.UniqueChoicePrincipleUp.

Constructive story: A UniqueChoicePrinciple$^{\uparrow}$ packet is generated from one source carrier row, one relation row, one existence witness row, one uniqueness ledger, one deterministic readback row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1740

A Concrete Naming Certificate for $\mathsf{RegularCauchyInterpolation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyInterpolation}^{\uparrow}$ packet records finite interpolation and reindexing of regular Cauchy rational names before a completed real-name consumer is allowed to read the interpolated row. It sits over the dyadic mesh discipline of chapter 291, the finite stream-window surface of chapter 126, the regular rational source rows of chapter 301, the terminal real-name seal of chapter 38, and the paired-row handoff discipline of chapter 414. The packet gives Real and completion consumers a finite BEDC route for interpolation and schedule change; it is not host interpolation, quotient-stream equality, a selected real, a host limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1740.1 (Regular Cauchy interpolation carrier)**.** *A* $\mathsf{RegularCauchyInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, D, M, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational observations are to be interpolated or reindexed.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row containing the dyadic interpolation nodes, endpoint tolerances, and local mesh-width bounds used by the displayed route.*
3. *M is the finite interpolation ledger, recording for each requested output precision the source indices, dyadic weights, endpoint observations, and tolerance split consumed by that request.*
4. *W is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window family exposing exactly the finite source observations read by M.*
5. *S is the regular readback schedule whose output row is obtained by replaying the finite interpolation ledger against R, D, M, W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source row, dyadic mesh row, interpolation ledger, window family, and readback schedule have been displayed.*
7. *H records componentwise* hsame *transport for the source row, mesh row, ledger, windows, readback schedule, Real seal, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from every interpolation-facing precision request through $R, D, M, W, S, E, H, P,$*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyInterpolation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterpolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, M, W, S, E, H, C, P, N$. The carrier has no coordinate for host interpolation algorithms, quotient-stream equality, selected reals, host limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterpolationUp.RegularCauchyInterpolationTasteGate single carrier alignment`

Theorem 1740.2 (Regular Cauchy interpolation NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyInterpolation}^{\uparrow}$ *carrier*

$$I = (R, D, M, W, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInterpolation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, finite interpolation ledger, displayed* $\mathsf{StreamName}^{\uparrow}$ *windows, regular readback schedule,* $\mathsf{Real}^{\uparrow}$ *seal row, and structural rows;*
2. *dyadic mesh exposure, requiring every interpolation node, endpoint tolerance, and mesh-width bound used by M to be read from D before an interpolated readback is available;*
3. *finite window exposure, requiring W to display exactly the source observations requested by the ledger and no completed stream equality;*
4. *regular readback accounting, requiring S to consume only the displayed rows R, D, M, W and the finite tolerance split stored in the ledger;*
5. *Real seal nonescape, requiring E to be exposed only after the source, mesh, ledger, window, and readback rows have been displayed;*
6. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite interpolation packet;*
7. *refusal of host interpolation theorems, quotient-stream equality, selected reals, host limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No interpolation obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyInterpolationUp.RegularCauchyInterpolationNameCertObligations`

Proof. Project the accepted carrier. The analytic rows are the source R, the dyadic mesh D, the finite interpolation ledger M, the displayed windows W, the readback schedule S, and the Real seal E.

Read the mesh and windows before forming any interpolated observation. The row D supplies the finite dyadic nodes, endpoint tolerances, and mesh-width bounds, while W exposes exactly the source observations named by the corresponding ledger entry of M.

Build the readback by replaying the ledger. Each requested output precision uses only the displayed source observations, dyadic weights, and tolerance split already present in R, D, M, W, so S is a regular readback schedule over finite data rather than an appeal to an ambient interpolation theorem.

Finally transport and package the packet through H, C, P, N. Since no carrier coordinate stores quotient-stream equality, host interpolation, selected reals, host limits, ambient completeness, Lean verification, or bridge data, none of those objects can become a local NameCert obligation. □

Theorem 1740.3 (Regular Cauchy interpolation dyadic-window handoff)**.** *Every readback exported by an accepted* $\mathsf{RegularCauchyInterpolation}^{\uparrow}$ *carrier factors through the finite route*

$$R \longmapsto D \longmapsto M \longmapsto W \longmapsto S$$

before it may be consumed as a regular Cauchy output row. Thus the consumer receives a regular rational source row, a dyadic mesh row, a finite interpolation ledger, displayed stream windows, and a regular readback schedule; it receives no quotient-stream equality, host interpolation theorem, selected real, host limit, or ambient completeness coordinate.

Proof. Begin with the accepted carrier and an interpolation-facing precision request. The request first projects the source row R and the mesh row D, so every endpoint and tolerance used downstream is already displayed.

The ledger row M then selects a finite set of source observations and dyadic weights. The window family W exposes precisely those observations, and componentwise replay through C preserves the same finite dependency order.

The row S is therefore downstream of the displayed mesh and windows. Because the carrier offers no coordinate for quotient-stream equality, host interpolation, selected reals, host limits, or ambient completeness, the handoff to the regular readback cannot escape this finite route. □

Theorem 1740.4 (Regular Cauchy interpolation Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{RegularCauchyInterpolation}^{\uparrow}$ *carrier factors through the finite route*

$$R \longmapsto D \longmapsto M \longmapsto W \longmapsto S \longmapsto E$$

before it may be consumed as a completed real-name boundary. Thus the Real-facing consumer receives the source row, dyadic mesh row, interpolation ledger, displayed windows, regular readback schedule, and seal row; it receives no host interpolation theorem, quotient-stream equality, selected real, host limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the terminal row E of the accepted packet. By carrier admission, E is not independent data; it is downstream of the displayed source row, dyadic mesh row, interpolation ledger, stream windows, and regular readback schedule.

The only route into E passes through S. The row S is itself read from R, D, M, W, so the Real-facing boundary inherits the same finite interpolation route and the same componentwise transport recorded by H.

No additional coordinate remains to supply host interpolation, quotient-stream equality, selected reals, host limits, or ambient completeness. The $\mathsf{Real}^{\uparrow}$ consumer therefore sees only the finite BEDC seal produced by the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInterpolation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1740.1, Definition 1740.2, Definition 1740.3, and Definition 1740.4 seed the finite interpolation route from a $\mathsf{RegSeqRat}^{\uparrow}$ source through $\mathsf{DyadicRatCore}^{\uparrow}$ mesh data, finite interpolation ledger, displayed $\mathsf{StreamName}^{\uparrow}$ windows, regular readback schedule, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real$^{\uparrow}$ completeness, host interpolation theorems, quotient-stream equality, selected reals, host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exposure, window handoff, regular readback accounting, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyInterpolationUp.

Constructive story: A RegularCauchyInterpolation$^{\uparrow}$ packet is generated from a RegSeqRat$^{\uparrow}$ source row, a DyadicRatCore$^{\uparrow}$ mesh row, a finite interpolation ledger, displayed StreamName$^{\uparrow}$ windows, a regular readback schedule, a Real$^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1741

A Concrete Naming Certificate for $\mathsf{UniformCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformCauchyModulus}^{\uparrow}$ packet records the finite shared Cauchy-window budget needed by the Real and completion route before any quotient stream, selected limit, or ambient completeness theorem is available. It sits between the selected-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the endpoint seal of chapter 38. It also reads the shared-bound interface of chapter 462 and the filter-side uniformity route of chapter 1694.

Definition 1741.1 (Uniform Cauchy modulus carrier)**.** *A* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, R, D, M, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row whose finite stream observations are visible to the packet;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected windows in S;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording every requested rational radius and comparison budget;*
4. *M is the shared Cauchy-window modulus row: one displayed budget assigns a finite tail window to each requested dyadic tolerance;*
5. *W is the finite witness row saying that all accepted pairs of selected windows beyond the budget in M are read inside the tolerance recorded in D;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row exposed only after S, R, D, M, W have been displayed;*
7. *H stores componentwise* hsame *transport for the stream windows, rational readbacks, dyadic ledgers, shared modulus, witness row, handoff, provenance, and local naming rows;*
8. *C stores displayed* Cont *replay from selected windows to regular readback, from regular readback to dyadic tolerance accounting, from the tolerance ledger to the shared modulus, and from the witness row to the* $\mathsf{Real}^{\uparrow}$ *handoff;*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{UniformCauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, M, W, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, open-cover compactness, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyModulusUp.UniformCauchyModulusUpTasteGate single carrier alignment`

Theorem 1741.2 (Uniform Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier $U = (S, R, D, M, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyModulus}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed selected-window, regular-readback, dyadic-ledger, shared-modulus, witness, handoff, transport, replay, provenance, and naming rows;*
2. *classifier transport, requiring accepted comparisons to preserve $S, R, D, M, W, E, H, C, P, N$ componentwise and to preserve no hidden completion datum;*
3. *shared-window budget exactness, requiring the single row M to govern every displayed Cauchy comparison requested by D;*
4. *finite witness replay, requiring each accepted comparison beyond the budget in M to pass through S, R, D, and W before any endpoint-facing handoff is read;*
5. $\mathsf{Real}^{\uparrow}$ *handoff nonescape, requiring E to consume only the displayed finite route and never quotient stream equality, selected limits, countable choice, open-cover compactness, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyModulusUp.UniformCauchyModulusTasteGate e0 row round trip`

Proof. Carrier admission is projection from Definition 1741.1. The displayed packet has exactly the rows $S, R, D, M, W, E, H, C, P, N$, so the local certificate has no detached limit selector, quotient stream coordinate, or ambient completeness witness.

Classifier transport is componentwise. The row H stores the permitted hsame comparisons, while C replays only the displayed route from selected windows through regular readback, dyadic budgets, the shared modulus row, the finite witness row, and the endpoint handoff.

The shared-window budget is unique inside the packet. A tolerance request may ask for many finite window comparisons, but those comparisons all read the same displayed modulus row M before the witness row W can be exported.

Finally, the $\mathsf{Real}^{\uparrow}$ handoff row E is downstream of the same finite route. Since none of the excluded principles is a coordinate of the carrier, none can be exported by the local $\mathsf{NameCert}_{\mathsf{UniformCauchyModulus}^{\uparrow}}$ surface. □

Theorem 1741.3 (Uniform Cauchy modulus Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier may read only the displayed selected-window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the shared modulus row M, the finite witness row W, and the structural rows H, C, P, N before reading the handoff row E. Such a consumer cannot read quotient stream equality, selected limits, countable choice, open-cover compactness, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Project the accepted carrier. The endpoint-facing row is E, but its admissible inputs are already fixed by the preceding rows: selected windows in S, rational readback in R, tolerance accounting in D, the shared budget in M, and finite comparison witnesses in W.

Transport, replay, provenance, and local naming do not add an endpoint object. They only preserve the same route through H, C, P, N.

Thus every $\mathsf{Real}^{\uparrow}$ or completion-facing read must pass through the finite carrier surface before reaching E. Since the carrier has no coordinate for the excluded principles, no such principle can be extracted from this handoff. □

Theorem 1741.4 (UniformCauchyModulus shared-window budget)**.** *For every accepted* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier* $U = (S, R, D, M, W, E, H, C, P, N)$*, a finite precision request must first read the selected* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the shared modulus row* M*, and the finite witness row* W*. If two endpoint-facing consumers share* M *and* W*, then their* $\mathsf{Real}^{\uparrow}$ *handoff row* E *is reached through the same displayed budget route*

$$S \longrightarrow R \longrightarrow D \longrightarrow M \longrightarrow W \longrightarrow E$$

as replayed by H *and* C*. No quotient stream, selected limit, countable choice, ambient completeness row, host real equality, open-cover compactness, or trichotomy coordinate can enter this budget.*

Lean4 ✓ `BEDC.Derived.UniformCauchyModulusUp.UniformCauchyModulusSharedWindowBudget`

Proof. Project the accepted carrier. The only rows available before the endpoint handoff are the selected-window row S, regular readback row R, dyadic tolerance row D, shared modulus row M, finite witness row W, transport row H, replay row C, provenance row P, and local naming row N.

Induct over the displayed witness row W. The empty witness route exposes no endpoint-facing read, so no consumer can reach E without the selected windows, readbacks, tolerance ledger, and shared modulus already displayed. In the step case, the next witness cell is read only after its selected windows have been transported through H and replayed through C along the route from S to R, from R to D, and from D to M.

Now take two endpoint-facing consumers that share M and W. The induction gives the same finite witness route for both consumers, and the carrier has only one handoff row E downstream of that route. Hence both consumers reach E through the displayed shared-window budget.

The excluded principles are not coordinates of U and are not produced by H or C. Therefore the finite budget cannot import quotient stream equality, a selected limit, countable choice, ambient completeness, host real equality, open-cover compactness, or trichotomy. □

Theorem 1741.5 (Uniform Cauchy modulus single-route exhaustion)**.** *For every accepted* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier* $U = (S, R, D, M, W, E, H, C, P, N)$*, any two* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumers that use the same precision request and the displayed witness row* W *factor through the same ordered route*

$$S \longrightarrow R \longrightarrow D \longrightarrow M \longrightarrow W \longrightarrow E.$$

The route is exhausted by the displayed rows of U*: no second modulus row, detached tail selector, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness can be inserted between the precision request and the endpoint handoff.*

Proof. Project the accepted carrier. By Definition 1741.1, the endpoint-facing order is already displayed as selected windows S, regular rational readbacks R, dyadic tolerance accounting D, one shared Cauchy-window modulus row M, finite witness replay W, and handoff row E.

The single-row obligation is fixed by Definition 1741.2: accepted comparisons must preserve the same row M for every displayed Cauchy comparison requested by D. Thus two consumers with the same precision request cannot split into distinct modulus rows or detached tail selectors before the witness row is read.

Apply Definition 1741.4 to the common witness row W. Its witness induction gives the same finite route through S, R, D, M, W for both consumers, with transport and replay supplied only by H and C.

Finally, Definition 1741.3 gives the nonescape boundary at E. Since the excluded principles are not coordinates of the carrier and are not produced by H or C, neither consumer can insert quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness into the route. □

Theorem 1741.6 (Uniform Cauchy modulus scoped kernel binding)**.** *For every accepted* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *carrier* $U = (S, R, D, M, W, E, H, C, P, N)$*, the selected windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, shared modulus row, witness replay, and* $\mathsf{Real}^{\uparrow}$ *handoff bind only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. No scoped kernel consumer of* U *can insert a second route between the finite precision request and the endpoint handoff.*

Proof. Start from the carrier definition. The rows $S, R, D, M, W, E, H, C, P, N$ are the only displayed coordinates, and the carrier contains no detached tail selector or hidden completion witness.

The NameCert obligations bind those coordinates componentwise. Carrier admission fixes the selected windows, regular readbacks, tolerance ledger, shared modulus, witness row, handoff, transport, replay, provenance, and local naming rows.

Apply the shared-window budget theorem to the middle of the route. It forces every precision request to pass through the same S, R, D, M, W budget before the endpoint row is visible.

Finally apply single-route exhaustion. The route from finite precision request to E is already exhausted by the displayed rows, so the scoped kernel surface is exactly the listed BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ binding surface. □

Theorem 1741.7 (Uniform Cauchy modulus compact-tail router)**.** *Any* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*, or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer reading a* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *endpoint must route through selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the shared modulus row* M*, finite witness replay* W*, and the* $\mathsf{Real}^{\uparrow}$ *handoff* E*. The route excludes selected subsequences, open-cover compactness, quotient stream equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1741.1. The endpoint-facing data are the selected windows, regular readbacks, dyadic tolerance ledger, shared modulus row, finite witness row, and handoff row.

Apply the shared-window budget theorem, Definition 1741.4. It forces every precision request to read the same route through S, R, D, M, W, E before a consumer receives endpoint data.

Use Definition 1741.5 and Definition 1741.6. They prevent a compact, complete, or continuous-map consumer from inserting a second route outside the displayed kernel rows.

Thus the compact-tail handoff remains a finite BEDC route. Since the carrier has no selected subsequence, open-cover compactness, quotient stream equality, countable-choice schedule, or ambient completeness coordinate, none can be exported. □

Falsifiable prediction: Every $\mathsf{UniformCauchyModulus}^{\uparrow}$ endpoint-facing read factors through selected StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, one shared Cauchy-window modulus row, finite witness replay, a RealUp handoff row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchymodulusmeet, uniformcauchyfilter, real: $\mathsf{UniformCauchyModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries selected windows, regular rational readbacks, dyadic tolerance accounting, one shared finite Cauchy-window budget, witness replay, endpoint handoff, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyModulus}^{\uparrow}$ packet is generated from selected StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, one shared finite Cauchy-window modulus row, finite witness replay, a RealUp handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert.

Upgrade path: Public closure requires a public-object surface and bridge alignment for BEDC.Derived.UniformCauchyModulusUp.

Chapter 1742

A Concrete Naming Certificate for $\mathsf{RegularCauchySquare}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySquare}^{\uparrow}$ packet records diagonal multiplication of a displayed regular rational Cauchy real name by itself as a finite bounded-window route. It sits over the regular rational source rows of chapter 301, the synchronized window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the binary product carrier of chapter 461, the product-budget ledger of chapter 676, and the terminal real-name seal of chapter 38. The packet is the diagonal square surface consumed by later real algebra routes; it is not host real multiplication, quotient stream equality, a selected limit, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1742.1 (Regular Cauchy square carrier)**.** *A* $\mathsf{RegularCauchySquare}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W_L, W_R, D_L, D_R, M, E, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *A is the single* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose diagonal square is being read.*
2. *W_L and W_R are duplicated aligned* $\mathsf{StreamName}^{\uparrow}$ *window rows opened from the same source row A at the same product-facing precision request and observation index.*
3. *D_L and D_R are identical* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from the duplicated windows; their equality is displayed as a diagonal source-lock row rather than inferred from quotient stream equality.*
4. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *diagonal product row obtained by feeding the two product source slots with the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row A and the two aligned endpoint rows D_L, D_R.*
5. *E is the* $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ *ledger row that records the paired source-window radii, dyadic square row, product rounding allowance, and remaining readback budget for the diagonal route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from M and E.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source row, duplicated windows, dyadic endpoint rows, diagonal product row, product-budget ledger, and regular readback have been displayed.*
8. *H records componentwise* hsame *transport for the source row, duplicated windows, dyadic endpoints, diagonal product row, product-budget ledger, readback, seal, continuation routes, package provenance, and local naming.*

9. *C records displayed* Cont *replay from any square-facing precision request through* $A, W_L, W_R, D_L, D_R, M, E, R, Z$
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySquare}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyProductBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySquare}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W_L, W_R, D_L, D_R, M, E, R, Z, H, C, P, N$. The carrier has no coordinate for host multiplication, quotient stream equality, selected limits, ambient completeness, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySquareUp.RegularCauchySquareTasteGate single carrier alignment`

Theorem 1742.2 (Regular Cauchy square NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySquare}^{\uparrow}$ *carrier*

$$S = (A, W_L, W_R, D_L, D_R, M, E, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySquare}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, duplicated aligned* $\mathsf{StreamName}^{\uparrow}$ *windows, identical* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, diagonal product row, product-budget ledger, regular readback,* $\mathsf{Real}^{\uparrow}$ *seal row, and structural rows;*
2. *diagonal source-lock, requiring both product source slots to read the same source row A before any square endpoint is available;*
3. *duplicated-window admission, requiring W_L and W_R to expose the same finite source window at the same product-facing precision request and observation index;*
4. *dyadic square row, requiring D_L and D_R to be identical endpoint rows read from the duplicated windows before the dyadic product observation is formed;*
5. *product-budget exactness, requiring E to be the finite* $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ *ledger for the diagonal product row M and the source-window radii already displayed;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the readback row R to consume only the diagonal product row and the displayed product-budget ledger;*
7. $\mathsf{Real}^{\uparrow}$ *seal boundary, requiring every real-facing read to pass through R and the visible square provenance before the seal row Z is exposed;*
8. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite square packet;*
9. *non-escape from host multiplication, quotient stream equality, selected limits, ambient completeness,* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No diagonal square obligation is stored outside these finite rows.

Theorem 1742.3 (Regular Cauchy square product handoff)**.** *Every accepted* $\mathsf{RegularCauchySquare}^{\uparrow}$ *packet factors through the existing* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route with both product source rows identified as the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row. More precisely, for*

$$S = (A, W_L, W_R, D_L, D_R, M, E, R, Z, H, C, P, N),$$

the product-facing component is the diagonal specialization of the product packet whose source rows are A, A, whose aligned windows are W_L, W_R, whose endpoint rows are D_L, D_R, whose product route is M, and whose product-budget handoff is E. The readback R and seal Z therefore consume the public product and budget boundary before any square-facing consumer can read the result.

Proof. Project the carrier rows of Definition 1742.1. The single source row A is copied into the two product source slots, and the duplicated windows W_L, W_R expose the same finite observation boundary before the dyadic endpoint rows D_L, D_R are available.

Apply the public product route of Definition 461.9. Its product carrier accepts two regular source rows, aligned windows, dyadic endpoint rows, a finite product ledger, a regular readback, transports, continuations, provenance, and local naming. In the square packet these product source rows are the displayed pair A, A, so the product component is the diagonal specialization of the same route.

Next apply the product-budget handoff rows of Definition 676.10 and Definition 676.11. They force the readback and real-facing seal to consume the finite product-budget ledger before any downstream consumer receives the result.

The remaining rows H, C, P, N are structural rows of the same finite packet. Since the carrier contains no coordinate for host multiplication, quotient stream equality, selected limits, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, the factorization cannot escape the displayed $\mathsf{RegularCauchyProduct}^{\uparrow}$ and $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ routes. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySquare}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySquare}^{\uparrow}$ packet is generated from one $\mathsf{RegSeqRat}^{\uparrow}$ source row, duplicated aligned $\mathsf{StreamName}^{\uparrow}$ windows, identical $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, a diagonal $\mathsf{RegularCauchyProduct}^{\uparrow}$ row, a $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySquare}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1742.1, Definition 1742.2, and Definition 1742.3 seed the finite diagonal square route through one $\mathsf{RegSeqRat}^{\uparrow}$ source row, duplicated aligned $\mathsf{StreamName}^{\uparrow}$ windows, identical $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, the existing $\mathsf{RegularCauchyProduct}^{\uparrow}$ route, the $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySquare}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchySquareUp.RegularCauchySquareTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host multiplication, quotient stream equality, selected limits, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal source-lock, product-budget exactness, RegSeqRat handoff, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySquareUp.

Chapter 1743

A Concrete Naming Certificate for $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$

Following Kreisel, Lacombe, and Shoenfield on effective continuity, and Bishop–Bridges on constructive real names, the $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ packet records the finite-prefix route by which a computable functional over choice-sequence data can hand a real-name consumer only inspected prefix evidence. It sits between the Baire-prefix surface of chapter 334, the observation discipline of chapter 1482, the finite-window carrier of chapter 126, the regular rational readback of chapter 301, and the endpoint seal of chapter 38. The chapter names the finite certificate boundary for prefix continuity; it does not complete a choice sequence, select a real limit, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1743.1 (Kreisel-Lacombe-Shoenfield carrier)**.** *A* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, O, S, R, E, M, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-context row naming the finite input prefix currently inspected by the functional;*
2. *O is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *observation row recording the choice-sequence queries whose answers are visible in that prefix context;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the output name is requested;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the output windows in S;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the prefix context, observations, window schedule, and regular readback have been displayed;*
6. *M is the finite modulus row assigning to each displayed output-window request the input-prefix length sufficient for replaying the read;*
7. *L is the finite continuity ledger recording every accepted pair of matching prefixes, their matching observations, and the common output-window readback justified by M;*
8. *H records componentwise* hsame *transport for the Baire prefix context, choice-sequence observations, stream-window schedule, regular readback, Real seal, finite modulus, continuity ledger, replay, provenance, and local naming rows;*

9. *C records displayed* Cont *replay from Baire prefixes to choice-sequence observations, from observations to the output window schedule, from the window schedule to regular rational readback, from the finite modulus to the ledger, and from the ledger to the* $\mathsf{Real}^{\uparrow}$ *seal;*
10. *P is the* Pkg *provenance over* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, O, S, R, E, M, L, H, C, P, N$. It has no coordinate for countable choice, completed host functions, quotient stream equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KreiselLacombeShoenfieldUp.KreiselLacombeShoenfieldUpTasteGate single carrier alignment`

Theorem 1743.2 (Kreisel-Lacombe-Shoenfield NameCert obligations)**.** *For every accepted* KreiselLacombeShoenfie *carrier $K = (B, O, S, R, E, M, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Baire prefix context, choice-sequence observations, StreamName window schedule, RegSeqRat readback, Real seal, finite modulus, continuity ledger, transport, replay, provenance, and local naming rows;*
2. *prefix-observation exactness, requiring every query in O to be read inside the displayed prefix context B;*
3. *output-window exactness, requiring every scheduled output request in S to be read back through R before the Real seal row E is available;*
4. *finite modulus exactness, requiring M to assign the input-prefix length used by each output-window request and by no hidden total function;*
5. *continuity-ledger replay, requiring L to compare accepted matching prefixes only through the observations, window schedule, readback row, and modulus row already displayed;*
6. *nonescape for countable choice, completed host functions, quotient stream equality, selected limits, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. The only computational rows are the Baire prefix context B, the choice-sequence observation row O, the output window schedule S, the regular rational readback R, the Real seal E, the finite modulus row M, and the continuity ledger L.

Carrier admission and classifier transport are componentwise. The row H moves exactly the listed coordinates, while the replay row C repeats the same route from prefixes to observations, output windows, rational readback, modulus entries, continuity ledger entries, and the endpoint seal.

The finite modulus obligation is local to displayed requests. A consumer can ask for an output window, but the packet answers by opening the corresponding prefix budget in M and then checking the ledger row L against visible observations.

The excluded principles are absent from the carrier. Since no row names countable choice, a completed host function, quotient stream equality, a selected limit, trichotomy, or ambient Real completeness, none of them can become a local $\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}$ obligation. □

Theorem 1743.3 (Kreisel-Lacombe-Shoenfield prefix continuity)**.** *Every output-window read from an accepted* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier factors through a finite prefix route*

$$B, O \longmapsto M \longmapsto S, R \longmapsto L \longmapsto E, H, C, P, N.$$

Thus two accepted carriers that agree on the displayed prefix context and choice-sequence observations up to the modulus row M have the same scheduled output-window readback through S and R for the ledger entry in L.

Proof. Start with an output-window read. The schedule row S is not available as a detached total output function; it is paired with the displayed prefix context B and observation row O.

Open the modulus row M. It assigns the finite input-prefix length required by the requested output window, so matching prefixes and matching observations are the only data the ledger may compare.

Replay the ledger row L. Its accepted entries bind the prefix agreement, observation agreement, scheduled output window, and regular rational readback into one finite route.

The structural rows H, C, P, N preserve this route and add no hidden input or output object. Therefore agreement on the displayed finite prefix data up to M determines the scheduled readback for the ledger entry under consideration. □

Theorem 1743.4 (Kreisel-Lacombe-Shoenfield StreamName modulus)**.** *Every displayed* $\mathsf{StreamName}^{\uparrow}$ *output-window request answered by an accepted* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier first opens the finite modulus row M. The answer then reads only the matching Baire prefix context B, choice-sequence observations O, regular rational readback R, and continuity ledger L before the* $\mathsf{Real}^{\uparrow}$ *seal row E is exposed. The handoff exports no completed host function, countable choice, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows from Definition 1743.1. The output-window request is represented by the schedule row S, while the only row assigning an input-prefix budget to that request is M.

Apply prefix continuity from Definition 1743.3. Once M is opened, the request is replayed through the displayed Baire prefix context B and the choice-sequence observations O, and the corresponding output data are read through S, R, L.

The Real seal row is downstream of that finite route. A consumer may inspect E only after the modulus entry, matching prefix context, observations, regular readback, and ledger entry have all been displayed.

The excluded principles are not carrier coordinates. The structural rows H, C, P, N preserve the same windowed handoff and cannot add a completed host function, countable-choice selector, quotient stream equality, selected limit, or ambient Real completeness theorem. □

Theorem 1743.5 (Kreisel-Lacombe-Shoenfield modulus-ledger exactness)**.** *For every accepted* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier $K = (B, O, S, R, E, M, L, H, C, P, N)$, each entry of the continuity ledger L is justified by exactly one displayed finite modulus row M, Baire prefix row B, choice-observation row O, StreamName window row S, and RegSeqRat readback row R. Componentwise transport and replay through H and C can preserve this displayed justification, but they cannot add countable choice, quotient stream equality, a completed host function, selected Real limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows. The ledger L is not a detached list of continuity assertions; by carrier admission it is downstream of the displayed prefix context B, observation row O, output-window schedule S, regular rational readback R, and finite modulus row M.

Apply Definition 1743.3. Matching prefixes and observations determine the scheduled output readback only after the relevant modulus entry has been opened.

Apply Definition 1743.4. Every StreamName request answered by the packet first reads M and then replays the route through B, O, S, R, L before the Real seal E is exposed.

It remains to rule out hidden support for the ledger. This is exactly the nonescape surface of Definition 1743.7: the transport, replay, provenance, and naming rows preserve displayed carrier coordinates and have no coordinate for countable choice, quotient stream equality, completed host functions, selected limits, or ambient Real completeness. □

Theorem 1743.6 (Kreisel-Lacombe-Shoenfield Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier must consume the displayed Baire prefix context, choice-sequence observation row, StreamName window schedule, RegSeqRat readback, finite modulus, and continuity ledger before reading the Real seal row. The handoff supplies finite real-name evidence only; it supplies no countable choice, completed host function, quotient stream equality, selected limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the endpoint-facing row E. By carrier admission it is downstream of B, O, S, R, M, L, so a Real consumer cannot read E without the prefix, observation, schedule, readback, modulus, and ledger rows.

The readback row R is the only rational-name information supplied to the endpoint. It is scheduled by S and justified by the ledger entries whose prefix budgets are recorded in M.

Transport and replay do not add a completion theorem. The rows H and C preserve the displayed route, while P and N source and name it as the local packet.

Consequently the Real handoff exports finite real-name evidence. The absent principles have no coordinate in the packet and cannot be extracted from the handoff. □

Theorem 1743.7 (Kreisel-Lacombe-Shoenfield nonescape)**.** *No accepted* $\mathsf{KreiselLacombeShoenfield}^{\uparrow}$ *carrier exports countable choice, a completed host function on Baire space, quotient stream equality, a selected real limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every consumer-visible datum is one of the displayed rows* $B, O, S, R, E, M, L, H, C, P, N$ *or a componentwise replay of those rows.*

Proof. List the carrier rows from Definition 1743.1. They are finite prefix, observation, window, readback, seal, modulus, ledger, transport, replay, provenance, and naming rows.

Now inspect each consumer route. Prefix-continuity reads pass through B, O, M, S, R, L, while Real handoff reads pass through B, O, S, R, M, L, E before the structural rows preserve the packet.

There is no remaining export surface. The classifier compares packets only through the displayed rows, and the structural rows H, C, P, N cannot introduce a principle absent from their inputs.

Thus the listed principles are refused by construction. Any consumer needing one of them must obtain it outside the local $\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1743.1, Definition 1743.2, Definition 1743.3, Definition 1743.6, and Definition 1743.7 seed the finite-prefix continuity certificate for computable functionals from Baire and choice-sequence observations into real-name data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KreiselLacombeShoenfield}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, completed host functions, quotient stream equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-observation exactness, output-window exactness, finite modulus exactness, continuity-ledger replay, Real handoff, and nonescape for BEDC.Derived.KreiselLacombeShoenfieldUp.

Constructive story: A KreiselLacombeShoenfield$^{\uparrow}$ packet is generated from Baire prefix context, choice-sequence observation, StreamName finite-window schedule, RegSeqRat readback, Real seal, finite modulus, continuity ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1744

Cauchy Modulus Monotone Normalization NameCert Construction

Following Bishop and Bridges on constructive analysis with explicit moduli, the CauchyModulusMonotoneNormalizat packet records the finite certificate by which an inspected Cauchy-modulus row is replaced by a displayed monotone threshold schedule without changing the tail-window claims already exposed to Real and Completion consumers. It sits on the explicit source route of chapter 1705, the separation boundary of chapter 1650, the finite completion route of chapter 1691, and the shared-budget surface of chapter 1741. The packet is a normalization certificate for later diagonal and tail-window arguments; it is not Real completeness, quotient completion, quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or a standard bridge.

Definition 1744.1 (Cauchy modulus monotone normalization carrier)**.** *A* $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, M, D, T, U, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row: a displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *surface whose Cauchy-window comparisons are being normalized.*
2. *M is the input* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row, assigning a finite tail budget to each requested dyadic tolerance in the source route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the finite precision requests, slack conversions, and comparison budgets consumed by M.*
4. *T is the finite prefix-maximum table. For each displayed tolerance request it records the largest threshold among the finitely many tighter requests visible in D.*
5. *U is the normalized monotone modulus row obtained by reading T as the replacement threshold schedule.*
6. *W is the tail-window witness row saying that every accepted pair of source observations beyond the threshold named by U is still admitted by the original row M at the requested tolerance.*
7. *E is the endpoint handoff row available to* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing consumers only after S, M, D, T, U, W have been displayed.*

8. *H records componentwise* hsame *transport for the source, input modulus, dyadic ledger, prefix-maximum table, normalized modulus, witness, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through D, M, T, U, W, and the endpoint handoff E.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, RegularCauchySeparation $\mathsf{FastCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, D, T, U, W, E, H, C, P, N$. It has no coordinate for Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyModulusMonotoneNormalizationUp.CauchyModulusMonotoneNormalizationUpTasteGate`
`single carrier alignment`

Theorem 1744.2 (Cauchy modulus monotone normalization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$ *carrier $Z = (S, M, D, T, U, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source, input modulus, dyadic tolerance ledger, prefix-maximum table, normalized modulus, tail-window witness, endpoint handoff, transport, replay, provenance, and local naming rows;*

2. *prefix-maximum exactness, requiring T to be read only from the finite tolerance requests displayed in D and the input thresholds displayed in M;*

3. *monotone schedule exposure, requiring U to expose the normalized threshold for each displayed tolerance request through T and no hidden cofinal tail;*

4. *tail-window preservation, requiring W to show that every comparison admitted beyond U is already a comparison admitted by M at the requested tolerance;*

5. *consumer handoff nonescape, requiring E to be downstream of S, M, D, T, U, W and to export no Real completeness, quotient completion, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or bridge datum;*

6. *componentwise transport, replay, provenance, and local naming stability for exactly the displayed rows.*

No monotone-normalization obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1744.1. The packet exposes the source row, input modulus, dyadic ledger, prefix-maximum table, normalized modulus, tail-window witness, endpoint handoff, and structural rows as one finite carrier.

Prefix-maximum exactness is finite. For each displayed tolerance request in D, the table T reads only the finitely many tighter requests already visible to the packet and the corresponding thresholds named by M.

The normalized modulus row U is therefore monotone by construction of the table T. Moving to a tighter displayed tolerance can only enlarge the inspected finite prefix, so the threshold exposed by U does not move backward.

Tail-window preservation is the witness row W. A consumer using U first reads the table entry in T, then reads the input threshold row M for the corresponding finite requests, and only then obtains the same tail-window comparison.

Finally, E, H, C, P, N hand off, transport, replay, source, and name the same finite route. Since Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and bridge data are absent from the carrier, none can become a local NameCert obligation. □

Theorem 1744.3 (Cauchy modulus monotone normalization tail-window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing read of an accepted* $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$ *carrier factors through*

$$S, M, D \longmapsto T \longmapsto U \longmapsto W \longmapsto E, H, C, P, N.$$

Thus later diagonal, separation, and tail-window consumers may read a monotone threshold schedule only through the displayed input modulus, dyadic tolerance ledger, prefix-maximum table, normalized row, and preservation witness. The route exports no Real completeness, quotient completion, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or standard bridge.

Proof. Start with a consumer read. The only normalized schedule coordinate is U, and Definition 1744.1 places U after the source, input modulus, dyadic ledger, and prefix-maximum table.

The consumer first reads S, M, D. This fixes the inspected source, the original Cauchy thresholds, and the finite tolerance requests whose prefix maximum is allowed to be formed.

The table T then supplies the displayed maximum for the relevant finite prefix, and U reads that table as the monotone schedule. The witness row W checks that using this threshold remains a valid tail-window read for the input modulus M.

Endpoint and structural rows do not add a completion object. They only pass the same normalized route to E and preserve it through H, C, P, N, so the excluded objects have no coordinate from which a consumer can read them. □

Falsifiable prediction: Every $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$ consumer read factors through a source row, an input CauchyModulus threshold row, a DyadicRatCore tolerance ledger, a finite prefix-maximum table, a normalized monotone modulus row, a tail-window preservation witness, an endpoint handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: effectivecauchysequence, regularcauchyseparation, fastcauchycompletion, uniformcauchymodulus: $\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the input modulus, dyadic tolerance ledger, prefix-maximum table, normalized monotone schedule, preservation witness, endpoint handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1744.1, Definition 1744.2, and Definition 1744.3 seed the finite normalization packet that turns displayed Cauchy-modulus threshold rows into monotone threshold schedules for later Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusMonotoneNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-maximum exactness, monotone schedule exposure, tail-window preservation, consumer handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusMonotoneNormalizationUp.

Constructive story: A CauchyModulusMonotoneNormalization$^{\uparrow}$ packet is generated from a displayed source row, an input CauchyModulus threshold row, a DyadicRatCore tolerance ledger, a finite prefix-maximum table, a normalized monotone modulus row, a tail-window witness, an endpoint handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1745

A Concrete Naming Certificate for $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ packet names the finite boundary where cut-shaped observations may be compared with regular Cauchy readback without constructing $\mathsf{Real}^{\uparrow}$ by Dedekind cuts. It sits beside the lower and upper real ledgers, the located-cut handoff of chapter 404, the comparison surface of chapter 1424, the stream and regular-rational readback route, the dyadic tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet supplies a boundary for Phase Real and Completion consumers: it allows cut evidence to be inspected, routed, and refused as finite BEDC data while keeping the regular Cauchy route as the only displayed Real-facing readback.

Definition 1745.1 (Dedekind cut Cauchy boundary carrier)**.** *A* $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, K, Q, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *row. It records exactly the lower cut observations admitted by the boundary and their finite downward-use discipline.*
2. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *row. It records exactly the upper cut observations admitted by the boundary and their finite upward-use discipline.*
3. *K is the* $\mathsf{LocatedCut}^{\uparrow}$ *row. It records the located separation and displayed gap witnesses tying the lower and upper observations together.*
4. *Q is the* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *row. It is the only comparison row through which cut-shaped observations may approach a Cauchy-facing read.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule. It names the inspected stream windows used by the regular readback branch.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational observations exposed after the finite windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the dyadic radii, comparison margins, and finite slack rows consumed by the comparison and readback branches.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal. It is visible only after the located-cut row, comparison row, stream windows, regular-rational readback, and dyadic tolerance ledger have all been displayed.*
9. *H records componentwise* hsame *transport for the lower row, upper row, located-cut row, comparison row, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a cut-shaped request through $L, U, K, Q, S, R, D, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutCauchyBoundary}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite cut-to-Cauchy boundary packet. It has no coordinate for quotient cuts, selected cuts, host suprema, a Dedekind construction of $\mathsf{Real}^{\uparrow}$*, ambient completeness, trichotomy, Classical choice, Quot.sound, or propext-dependent equality.*

Theorem 1745.2 (Dedekind cut Cauchy boundary NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ *carrier $B = (L, U, K, Q, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutCauchyBo}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed lower row, upper row, located-cut row, comparison row, stream schedule, regular readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming row;*
2. *cut-side discipline, requiring every lower-row read in L and every upper-row read in U to meet only through the located separation and gap witnesses displayed in K;*
3. *Cauchy-readback factorization, requiring every cut-shaped observation exposed by L, U, K to pass through Q and then through S, R, D before the* $\mathsf{Real}^{\uparrow}$ *seal E is visible;*
4. *Real seal non-escape, requiring E to remain a terminal seal for the regular Cauchy route and never to serve as a quotient cut, selected cut, host supremum, Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, ambient completeness, trichotomy, Classical choice, Quot.sound, or propext-dependent surface;*
5. *transport and replay stability, requiring H and C to preserve the displayed route $L, U, K, Q, S, R, D, E, P, N$ componentwise;*
6. *ledger exhaustion, requiring P and N to name exactly the displayed finite packet and no object outside it.*

No Dedekind cut Cauchy boundary obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1745.1. The accepted packet exposes only the lower row, upper row, located-cut row, comparison row, stream schedule, regular readback, dyadic ledger, Real seal, and structural rows H, C, P, N.

Cut-side discipline is finite. A lower request reads only L, an upper request reads only U, and the shared located evidence is the row K; there is no ambient cut object in which the two sides can be merged.

Cauchy-readback factorization is forced by the row order. The comparison row Q receives the cut-shaped observations, the rows S, R, D provide the regular stream, rational, and dyadic readback data, and only then is the $\mathsf{Real}^{\uparrow}$ seal E available.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, and Cont replay in C repeats the same route for every accepted cut-shaped request.

Finally, provenance and local naming are exhausted by P and N. Since none of the excluded surfaces is a coordinate of B, the local NameCert surface cannot export such a surface. □

Theorem 1745.3 (Dedekind cut Cauchy boundary nonescape)**.** *Let $B = (L, U, K, Q, S, R, D, E, H, C, P, N)$ be an accepted $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ carrier. Every Real/Completion consumer of B receives only the displayed lower-row evidence, upper-row evidence, located-cut witnesses, comparison row, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming row. It receives no quotient cut, selected cut, host supremum, Dedekind construction of $\mathsf{Real}^{\uparrow}$, ambient completeness, trichotomy, Classical choice, Quot.sound, or propext-dependent surface.*

Proof. Start with an accepted consumer read. The carrier presents the cut side only as L, U, K: lower observations, upper observations, and located witnesses. Because no quotient cut or selected cut is a coordinate, the consumer cannot recover such an object before entering the comparison row.

The comparison row is Q. It sends the cut-shaped evidence into the regular readback branch S, R, D, where finite stream windows, regular rational observations, and dyadic tolerance data are displayed before the Real seal is visible.

The Real-facing coordinate is only E. Its position downstream of Q, S, R, D prevents it from becoming a host supremum, Dedekind construction of $\mathsf{Real}^{\uparrow}$, ambient completeness principle, or trichotomy principle.

The structural rows H, C, P, N transport, replay, source, and name the same packet. They add no Classical choice, no Quot.sound, and no propext-dependent equality surface, so the listed exclusions cannot escape through the local NameCert. □

Theorem 1745.4 (Dedekind cut Cauchy boundary located refusal)**.** *Let $B = (L, U, K, Q, S, R, D, E, H, C, P, N)$ be an accepted $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ carrier. Any Real/Completion consumer that asks B for a located cut-side equality, interval boundary, or gap conclusion must first read the located-cut row K, then the comparison row Q, then the stream, regular-rational, and dyadic rows S, R, D, and only then the $\mathsf{Real}^{\uparrow}$ seal E.*

Conversely, any route that omits one of K, Q, S, R, D is refused as a located or equality-facing route to E. Such a route may still read the displayed lower and upper rows, transport row, replay row, provenance row, and local naming row, but those rows only transport, replay, source, and name the same finite boundary packet.

Proof. Project the accepted carrier along Definition 1745.1. The only cut-side coordinates are L, U, K, and the NameCert obligations of Definition 1745.2 require lower-row and upper-row reads to meet through the located separation and gap witnesses displayed in K.

The same obligation theorem gives the Cauchy-readback factorization. A cut-shaped observation that faces the $\mathsf{Real}^{\uparrow}$ seal must pass from K to the comparison row Q, then through the stream schedule S, the regular rational readback row R, and the dyadic tolerance ledger D, before E is visible.

For the converse, suppose a consumer omits one of K, Q, S, R, D. Then the factorization just described is incomplete, so the consumer has no displayed BEDC route from a located cut-side

question to E as an equality-facing conclusion. Apply Definition 1745.3: the missing route cannot be replaced by a quotient cut, selected cut, host supremum, Dedekind construction of $\mathsf{Real}^{\uparrow}$, ambient completeness, trichotomy, Classical choice, Quot.sound, or propext-dependent surface.

It remains only to account for the structural rows. The row H transports the displayed coordinates componentwise, C replays the same finite route, P records its provenance, and N names the local certificate. None of these rows adds a separate located or equality-facing route to E, so the refusal is exactly the refusal of every route that bypasses the regular Cauchy branch. □

Theorem 1745.5 (Dedekind cut Cauchy boundary regular readback dominance)**.** *Let $B = (L, U, K, Q, S, R, D, E,$ be an accepted* $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ *carrier. Every Real/Completion consumer of B that faces equality, located boundary, interval gap, or* $\mathsf{Real}^{\uparrow}$ *seal data must reach E through the finite route*

$$K, Q, S, R, D, E.$$

The lower and upper cut rows L, U remain visible cut observations, but they do not construct $\mathsf{Real}^{\uparrow}$ *by Dedekind cuts and they do not dominate equality-facing reads. The regular Cauchy branch through located evidence, comparison, stream windows, regular rational readback, and dyadic tolerance data dominates every equality-facing read of the boundary packet.*

Proof. Project the carrier of Definition 1745.1. The lower and upper rows L, U are observation rows, while K, Q, S, R, D, E are the displayed route from located cut evidence to a Real-facing seal.

Apply the NameCert obligations of Definition 1745.2. They require cut-side reads to meet through K and require every Cauchy-facing read to pass from K through Q, S, R, D before the seal E is available.

Use the nonescape theorem Definition 1745.3. Since quotient cuts, selected cuts, host suprema, and a Dedekind construction of $\mathsf{Real}^{\uparrow}$ are absent, no consumer can replace the regular branch by an unlisted cut construction.

Finally apply the located-refusal theorem Definition 1745.4. Any route omitting one of K, Q, S, R, D is refused as a located or equality-facing route to E, so the regular Cauchy branch is the dominant readback surface for every equality-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutCauchyBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutCauchyBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1745.1, Definition 1745.2, Definition 1745.3, and Definition 1745.4 seed the finite boundary comparing cut-shaped observations with regular Cauchy readback for Phase Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutCauchyBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient cuts, selected cuts, host suprema, Dedekind construction of $\mathsf{Real}^{\uparrow}$, ambient completeness, trichotomy, Classical choice, Quot.sound, propext-dependent equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cut-side discipline, Cauchy-readback factorization, Real seal non-escape, transport and replay stability, and ledger exhaustion for BEDC.Derived.DedekindCutCauchyBoundaryUp.

Constructive story: A $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ packet is generated from lower and upper real rows, a LocatedCut handoff, a DedekindCauchyComparison row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1746

A Concrete Naming Certificate for $\mathsf{CauchyTailDiameter}^{\uparrow}$

Following Bishop and Bridges regular Cauchy analysis, the $\mathsf{CauchyTailDiameter}^{\uparrow}$ packet records the finite witness that a displayed tail window has bounded diameter at a requested dyadic tolerance. It sits between the dyadic tolerance core of chapter 291, the stream-window source of chapter 126, the regular rational readback discipline of chapter 301, the terminal real-name seal of chapter 38, and the interval enclosure consumer of chapter 1625. The packet supplies the finite tail-diameter row later regular-sequence and real-completion arguments consume; it is not a completeness theorem, a quotient-real equality principle, or a point selector.

Definition 1746.1 (Cauchy tail diameter carrier)**.** *A* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, I, J, D, B, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the source stream or* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose tail is being inspected.*
2. *T is the finite tail threshold row, naming the displayed index after which the diameter claim is allowed to be read.*
3. *I and J are two visible tail-index rows, both certified to lie beyond the threshold T in the inspected window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row requested by the consumer.*
5. *B is the dyadic diameter-bound row, recording the displayed comparison that the two tail observations are within the bound attached to D.*
6. *W is the window-stability row asserting that every read of I, J, D, B uses the same finite* $\mathsf{StreamName}^{\uparrow}$ *window family and no hidden cofinal tail.*
7. *H records componentwise* hsame *transport for the source, threshold, two indices, tolerance, diameter bound, window-stability row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from the source row through the threshold, the two visible indices, the dyadic tolerance, the diameter bound, and the window-stability row.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailDiameter}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealIntervalEnclosure}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailDiameter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, I, J, D, B, W, H, C, P, N$. It has no coordinate for a completed real limit, quotient real equality, trichotomy, point selection, open-cover compactness, or a standard bridge.

Theorem 1746.2 (Cauchy tail diameter NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *carrier $K = (S, T, I, J, D, B, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailDiameter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source stream or* $\mathsf{RegSeqRat}^{\uparrow}$ *row, tail threshold, two visible tail indices, dyadic tolerance, diameter bound, window stability, transport, replay, provenance, and local naming rows;*
2. *threshold exactness, requiring both displayed indices I and J to be certified as tail indices beyond T before the diameter row is read;*
3. *dyadic bound exactness, requiring B to compare only the two observations exposed by I and J against the tolerance row D;*
4. *window stability, requiring all source and tail observations to use the same finite* $\mathsf{StreamName}^{\uparrow}$ *window family recorded by W;*
5. *componentwise transport and replay, requiring H and C to preserve the same source, threshold, indices, tolerance, bound, stability, provenance, and local naming rows;*
6. *refusal of completed real limits, quotient real equality, trichotomy, point selection, open-cover compactness, and standard-bridge data as local NameCert obligations.*

No Cauchy tail-diameter obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyTailDiameterUp.CauchyTailDiameterUpTasteGate single carrier alignment`

Proof. Project the accepted carrier. The only analytic rows are the source S, threshold T, visible indices I, J, tolerance D, diameter bound B, and window-stability row W.

Read the tail claim in dependency order. The threshold row is opened first, then the two indices are checked as visible tail indices in the same finite window family, and only then is the dyadic comparison row B available.

The structural rows preserve this route. Componentwise transport H can move only the listed coordinates, while the replay row C replays the same source-threshold-index-tolerance-bound-window sequence.

The provenance and local naming rows package the same finite data. Since the carrier contains no coordinate for a completed real limit, quotient real equality, trichotomy, point selection, open-cover compactness, or standard bridge, none of those objects can become a local obligation. □

Theorem 1746.3 (Cauchy tail diameter tail-window handoff)**.** *Every tail-diameter read from an accepted* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *carrier factors through the finite route*

$$S, T \longmapsto I, J \longmapsto D \longmapsto B \longmapsto W \longmapsto H, C, P, N.$$

Thus a consumer sees the source row, one threshold, two visible tail indices, a dyadic tolerance, a dyadic diameter bound, and the window-stability row before it can use the bound. The route exports no completed real limit, quotient real equality, trichotomy, point selection, open-cover compactness, or standard bridge.

Proof. Begin with a consumer read of the carrier. Carrier admission exposes $S, T, I, J, D, B, W, H, C, P, N$ as one finite packet, so the consumer cannot read a detached tail object.

Replay the continuation row C. The source row S supplies the finite observation family, T supplies the tail threshold, and I, J identify the two visible tail positions within that family.

The dyadic comparison is downstream. The tolerance row D fixes the requested radius, and the bound row B records the displayed diameter comparison for the two indexed observations.

Finally, W, H, P, N stabilize, transport, source, and name the same packet. No step in the route opens a completed real limit, quotient equality, trichotomy row, selected point, open-cover compactness witness, or standard bridge. □

Theorem 1746.4 (Cauchy tail diameter RegSeqRat consumption)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *consumer that uses a tail-diameter bound from an accepted* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *carrier must consume the displayed source row, tail threshold, two visible tail indices, dyadic tolerance, diameter bound, and window-stability row of Definition 1746.1. In particular, the consumer receives a finite diameter witness for the displayed tail window, not Real completeness, quotient real equality, trichotomy, point selection, open-cover compactness, or a standard bridge.*

Proof. Start with a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{RealIntervalEnclosure}^{\uparrow}$ consumer. The consumer-facing evidence is the displayed carrier $K = (S, T, I, J, D, B, W, H, C, P, N)$, so the source and tail threshold are the only rows from which the tail request can begin.

The visible tail indices then determine the readback. The consumer reads I and J as finite rows beyond T, consults the dyadic tolerance row D, and obtains the diameter comparison only from B.

Window stability prevents replacement of the route by a hidden cofinal tail. The row W keeps the source observations, two indices, and bound inside the same finite $\mathsf{StreamName}^{\uparrow}$ window family.

Transport, replay, provenance, and local naming finish the consumption route. They preserve the same rows for $\mathsf{RegSeqRat}^{\uparrow}$ and interval-enclosure consumers and add no coordinate for completeness, quotient equality, trichotomy, point selection, compactness, or a standard bridge. □

Theorem 1746.5 (Cauchy tail diameter fast-modulus consumption)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer that uses a* $\mathsf{FastCauchyModulus}^{\uparrow}$ *threshold to read a tail-diameter bound from an accepted* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *carrier must consume the displayed source row, threshold row, two visible tail indices, dyadic tolerance, diameter bound, and window-stability row of Definition 1746.1. The threshold route must pass through the fast or doubled threshold discipline of chapter 1781, so the selector is displayed in the finite packet and is not hidden in a completed Real limit, quotient stream equality, countable choice, trichotomy, point selection, open-cover compactness, or bridge datum.*

Proof. Project the accepted $\mathsf{CauchyTailDiameter}^{\uparrow}$ carrier. Its analytic rows are S, T, I, J, D, B, W, and no consumer can obtain the diameter bound without first reading the source, threshold, visible tail indices, tolerance, bound, and window-stability rows.

Apply the tail-window handoff and RegSeqRat consumption theorems above. Together they force every regular-rational or Real-facing read to pass through the same finite tail-window route before the bound can be used.

Now read the $\mathsf{FastCauchyModulus}^{\uparrow}$ route from chapter 1781. Its doubling-window theorem exposes the fast or doubled threshold discipline, and its NameCert obligations require that threshold selector to be part of the displayed carrier surface.

Thus a fast-modulus consumer supplies only a visible threshold discipline for the same tail-diameter rows. Since neither carrier contains a hidden selector, completed limit, quotient equality,

choice schedule, trichotomy row, point selector, compactness witness, or bridge datum, none is exported by the consumption route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailDiameter}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailDiameter}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1746.1, Definition 1746.2, Definition 1746.3, Definition 1746.4, and Definition 1746.5 seed the finite tail-diameter witness packet over source streams or $\mathsf{RegSeqRat}^{\uparrow}$ rows, displayed thresholds, visible tail indices, dyadic tolerances, diameter bounds, window-stability rows, and fast-modulus threshold discipline.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailDiameter}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient real equality, trichotomy, point selection, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, threshold exactness, dyadic bound exactness, window stability, transport, replay, provenance, local naming, tail-window handoff, and RegSeqRat consumption for BEDC.Derived.CauchyTailDiameterUp.

Constructive story: A $\mathsf{CauchyTailDiameter}^{\uparrow}$ packet is generated from a source stream or RegSeqRat row, a tail threshold, two visible tail indices, a DyadicRatCore tolerance row, a dyadic diameter-bound row, a StreamName window-stability row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1747

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailComposition}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ packet records the finite rule by which two displayed regular-Cauchy tail budgets are composed before a Real-facing consumer may read a seal. It sits over the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, the shared budget route of chapter 1741, the symmetric comparison surface of chapter 1738, and the diameter witness of chapter 1746. The packet gives Real and Completion consumers one finite tail-composition surface instead of a hidden cofinal tail, quotient stream, selected limit, or choice-like threshold selector.

Definition 1747.1 (Regular Cauchy tail composition carrier)**.** *A* $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T_1, T_2, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. T_1 *is the first regular-Cauchy tail threshold row, naming the displayed point after which the source observations may be read inside the first budget.*
2. T_2 *is the second regular-Cauchy tail threshold row, naming the displayed point after which the refinement observations may be read inside the second budget.*
3. B *is the composed tail-budget row; it records the finite threshold obtained by reading* T_1 *and* T_2 *in order and taking the displayed common tail region exposed by the packet.*
4. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row, requiring all source, intermediate, and refined reads to use the same finite window family.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested tolerance, the intermediate slack, and the final comparison budget.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that connects the window reads and dyadic tolerances to the regular rational sequence surface.*
7. E *is the tail-evidence row; it records that every accepted read beyond* B *is admitted through the two displayed tail refinements rather than through a quotient stream or a hidden limit.*

8. *H stores componentwise* hsame *transport for the two thresholds, composed budget, windows, dyadic ledger, regular-rational handoff, evidence, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from T_1 to T_2, from the two thresholds to B, from B to W, D, R, E, and then to the provenance and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailComposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T_1, T_2, B, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, countable choice, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCompositionUp.RegularCauchyTailCompositionTasteGate`
`single carrier alignment`

Theorem 1747.2 (Regular Cauchy tail composition NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *carrier*

$$Q = (T_1, T_2, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed tail thresholds, composed tail budget, shared window row, dyadic ledger, regular-rational handoff, tail-evidence row, transport, replay, provenance, and local naming rows;*
2. *threshold ordering, requiring T_1 to be read before T_2 and requiring the composed budget B to be downstream of both threshold rows;*
3. *dyadic budget exactness, requiring the tolerance ledger D to record the requested tolerance, the intermediate slack, and the final comparison budget used by B;*
4. *window stability, requiring W to keep the source, intermediate, and refined observations inside one finite* $\mathsf{StreamName}^{\uparrow}$ *window family;*
5. *regular-rational handoff, requiring R to expose the same readback route used by the* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer before any* $\mathsf{Real}^{\uparrow}$ *seal is read;*
6. *componentwise transport and replay, requiring H and C to preserve the two thresholds, composed budget, windows, dyadic ledger, handoff, evidence, provenance, and local naming rows;*
7. *refusal of quotient stream equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, countable choice, Lean verification, and bridge checking as local obligations.*

No tail-composition obligation is stored outside these displayed rows.

Proof. Project the accepted carrier. Its analytic rows are exactly the two thresholds T_1, T_2, composed budget B, shared windows W, dyadic ledger D, regular-rational handoff R, and tail evidence E.

The threshold obligations are read in order. A consumer first opens T_1, then opens the refinement threshold T_2, and only then may read the composed budget B as the displayed common tail region.

The numerical and window obligations are finite. The tolerance ledger D records the requested tolerance together with the intermediate slack, while W requires the source, intermediate, and refined observations to remain in one StreamName window family.

The structural rows preserve only this route. Componentwise transport H and displayed replay C carry the same coordinates through provenance P and local naming N. Since none of the excluded objects is a coordinate of Q, none can become a local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}$ obligation. □

Theorem 1747.3 (Regular Cauchy tail-budget associativity)**.** *Let*

$$Q = (T_1, T_2, B, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *carrier. Two successive finite tail refinements through* T_1 *and then* T_2 *compose into the single displayed threshold* B*. Consequently, any third finite tail read that consumes the result may read the composed budget either as the already displayed row* B *or as the replayed route*

$$T_1 \longrightarrow T_2 \longrightarrow B,$$

and the two readings preserve the same W, D, R, E, H, C, P, N *rows. The comparison is a finite threshold-composition statement; it is not a quotient equality of streams, a selected limit, a countable-choice schedule, trichotomy, or an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the successive refinement route. Carrier admission exposes T_1 and T_2 as two threshold rows in one packet, so the second refinement is not a detached cofinal tail.

Replay the continuation row C. Its threshold part reads T_1 before T_2 and then exposes the single composed budget row B. Thus a consumer that asks for the combined tail sees one displayed threshold after the two finite inputs have been read.

Now compare with the direct read of B. The transport row H preserves $T_1, T_2, B, W, D, R, E, P, N$ componentwise, and the dyadic ledger D and window row W are shared by both readings.

Therefore the two readings are the same local NameCert route through the carrier. Since the route never opens a quotient coordinate, selected limit, choice schedule, trichotomy row, or completeness theorem, associativity is only the finite composition of displayed tail thresholds. □

Theorem 1747.4 (Regular Cauchy tail composition Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read admitted by an accepted* $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *carrier factors through the finite route*

$$(T_1, T_2) \longmapsto B \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a Real or Completion consumer must first read the two displayed tail thresholds, the composed tail budget, the finite $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the tail-evidence row. No such read bypasses this route through quotient stream equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, countable choice, Lean verification, or bridge checking.*

Proof. Start with a Real-facing request. The carrier gives no immediate Real seal; the request must first identify the two threshold rows T_1, T_2 and the composed budget B.

The finite observation route then passes through W, D, R, E. The shared StreamName windows determine which source and refined observations are visible, the DyadicRatCore ledger fixes the tolerance budget, and the RegSeqRat handoff supplies the regular rational readback used by the tail-evidence row.

The structural rows finish the route. Componentwise transport and displayed replay preserve the same data into provenance and local naming before the terminal $\mathsf{Real}^{\uparrow}$ consumer may read the result.

The nonescape clause follows from the carrier inventory. Quotient equality, trichotomy, ambient completeness, selected limits, countable choice, Lean verification, and bridge checking are not coordinates of Q, so no Real-facing read can extract them from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1747.1, Definition 1747.2, Definition 1747.3, and Definition 1747.4 seed the finite composition carrier for regular-Cauchy tail budgets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold ordering, dyadic budget exactness, window stability, regular-rational handoff, componentwise transport, displayed replay, tail-budget associativity, and Real route nonescape for BEDC.Derived.RegularCauchyTailCompositionUp.

Constructive story: A $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ packet is generated from two regular-Cauchy tail thresholds, one composed tail-budget row, a shared StreamName window row, a DyadicRatCore tolerance ledger, a RegSeqRat handoff, tail evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1748

A Concrete Naming Certificate for $\mathsf{UniformLimitContinuous}^{\uparrow}$

Following Bishop–Bridges and Kelley-style uniform convergence of continuous maps, the $\mathsf{UniformLimitContinuous}^{\uparrow}$ packet records the standard constructive handoff from a uniformly convergent displayed family to a continuous displayed endpoint. It refines the uniform-limit certificate of chapter 463 by adding the continuity-modulus row that every endpoint consumer must read before it treats the sealed limit as a $\mathsf{ContinuousMap}^{\uparrow}$ object.

The chapter uses the $\mathsf{StreamName}^{\uparrow}$ finite-window surface, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ rational handoff, $\mathsf{Real}^{\uparrow}$ seal rows, and the $\mathsf{ContinuousMap}^{\uparrow}$ modulus discipline as anchors. It does not introduce quotient-function equality, selected host limits, open-cover compactness, countable choice, or ambient completeness.

Definition 1748.1 (Uniform-limit-continuous carrier)**.** *A* $\mathsf{UniformLimitContinuous}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, U, M, W, R, E, H, C, P, N)$$

with the following displayed coordinates:

1. *F is the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *family, read only through certified source-window, target-window, and modulus rows;*
2. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *row tying the family to one uniform-limit endpoint surface;*
3. *M is the shared continuity-modulus ledger used by the family and by the endpoint handoff;*
4. *W is the finite window schedule containing source requests, target tolerances, and the uniform threshold rows read from* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the same finite windows and uniform-limit comparisons;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal exposed by the uniform-limit route;*
7. *H stores componentwise* hsame *transport for the family, uniform-limit row, shared modulus, finite windows, regular-rational handoff, endpoint seal, continuation routes, provenance, and local naming row;*
8. *C stores the displayed* Cont *routes for reading the continuous-family modulus, entering the uniform-limit ledger, applying the shared window threshold, reaching the regular handoff, and exposing the endpoint as a continuous map read;*

9. *P is the* Pkg *provenance over* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLimitContinuous}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows, their transports, their continuation routes, package provenance, and local naming provenance.

Lean4 ✓ `BEDC.Derived.UniformLimitContinuousUp.UniformLimitContinuousTasteGate single carrier alignment`

Theorem 1748.2 (Uniform-limit-continuous NameCert obligations)**.** *For the carrier of Definition 1748.1, the local* $\mathsf{NameCert}_{\mathsf{UniformLimitContinuous}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the packet $Q = (F, U, M, W, R, E, H, C, P, N)$;*
2. *uniform-window stability, requiring every endpoint-facing read to use the same* $\mathsf{UniformLimit}^{\uparrow}$ *row U, finite window schedule W, and shared threshold rows;*
3. *continuity-modulus handoff, requiring the endpoint continuity read to factor through the displayed modulus ledger M before it is exported as a* $\mathsf{ContinuousMap}^{\uparrow}$ *read;*
4. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the regular-rational handoff R and endpoint seal E to be reached only through the uniform-limit row and the finite windows;*
5. *ledger refusal for quotient-function equality, selected limits, open-cover compactness, countable choice, ambient completeness, and any continuity proof not routed through F, U, M, W, R, E.*

Proof. Carrier admission is projection from Definition 1748.1. The packet lists the continuous family, uniform-limit row, shared modulus, finite windows, regular handoff, endpoint seal, transports, continuations, provenance, and local certificate.

Uniform-window stability follows because the only endpoint-facing route in C enters the uniform-limit row U and reads the same window schedule W. The transport rows in H move those coordinates componentwise, so the accepted classifier cannot switch to a pointwise or externally selected threshold.

The continuity-modulus handoff is the displayed route through M. The packet has no coordinate for an ambient open-cover proof, quotient of functions, selected host limit, countable-choice selector, or completeness theorem, so those objects cannot serve as NameCert obligations. □

Theorem 1748.3 (Uniform-limit-continuous continuity handoff)**.** *Every continuity read of the endpoint map exported by an accepted* $\mathsf{UniformLimitContinuous}^{\uparrow}$ *carrier factors through the finite route*

$$F, U, M, W \longmapsto R \longmapsto E.$$

Thus the endpoint is available as a $\mathsf{ContinuousMap}^{\uparrow}$ *read only after the displayed continuous-family row, uniform-limit row, shared continuity modulus, finite window schedule, regular-rational handoff,* $\mathsf{Real}^{\uparrow}$ *seal, and visible* hsame, Cont, Pkg, *and* NameCert *provenance have been consumed. No quotient-function equality, selected limit, open-cover compactness, countable choice, or ambient completeness is exported by the packet.*

Proof. Begin with a consumer asking for continuity of the endpoint. By Definition 1748.1, the only continuity-facing entrance is the displayed family row F together with the shared modulus ledger M.

Next the request enters the uniform-limit row U and the finite window schedule W. These rows supply the uniform threshold and finite comparisons needed before the regular-rational handoff R can be read.

Finally the endpoint seal E is exposed through the same continuation and provenance rows. Applying Definition 1748.2, there is no exported coordinate for quotient-function equality, selected host limits, open-cover compactness, countable choice, or ambient completeness, so every continuity read has the stated finite factorization. □

Theorem 1748.4 (Uniform-limit-continuous public export)**.** *Let $Q = (F, U, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{UniformLimitContinuous}^{\uparrow}$ *carrier. The public endpoint-continuity export of Q is exactly the* $\mathsf{ContinuousMap}^{\uparrow}$ *endpoint read obtained through the rows*

$$F, U, M, W, R, E, H, C, P, N.$$

Every consumer first reads the displayed continuous-family row F, the uniform-limit row U, the shared modulus row M, the finite window schedule W, the regular-rational handoff R, and the endpoint seal E, and then transports and replays that endpoint through H, C, P, N. The export refuses quotient-function equality, selected limits, countable choice, ambient completeness, and any continuity coordinate not routed through these rows.

Proof. Apply Definition 1748.2. It identifies the accepted packet rows as the whole local NameCert surface and makes the shared modulus, finite windows, regular handoff, endpoint seal, transport, replay, provenance, and naming rows visible.

Next apply Definition 1748.3. The endpoint continuity read factors through F, U, M, W, then through R, and finally through E, with H, C, P, N preserving the same route.

The two statements have the same carrier rows. Since neither statement supplies quotient-function equality, selected host limits, countable-choice selectors, ambient completeness, or an external continuity proof coordinate, the public export is precisely the displayed $\mathsf{ContinuousMap}^{\uparrow}$ endpoint read. □

Theorem 1748.5 (Uniform-limit-continuous obligation-closure package)**.** *The carrier admission of Definition 1748.1, the NameCert obligation row of Definition 1748.2, the continuity handoff of Definition 1748.3, and the public export of Definition 1748.4 give the full local obligation surface for* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformLimit}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *reads inside an accepted* $\mathsf{UniformLimitContinuous}^{\uparrow}$ *packet. The package excludes quotient-function equality, selected host limits, open-cover compactness, countable choice, and ambient completeness.*

Proof. Project the accepted carrier. The definition exposes only the rows $F, U, M, W, R, E, H, C, P, N$, so every local obligation must be read through the displayed continuous-family, uniform-limit, modulus, window, handoff, endpoint, transport, replay, provenance, and naming coordinates.

Apply Definition 1748.2. It identifies the carrier-admission and refusal duties attached to those rows, including the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance.

Next apply Definition 1748.3 and Definition 1748.4. The first theorem routes endpoint continuity through F, U, M, W, R, E, and the second theorem exports that route as the public $\mathsf{ContinuousMap}^{\uparrow}$ read. Since neither route adds quotient-function equality, selected host limits, open-cover compactness, countable choice, or ambient completeness, the four displayed rows form exactly the stated obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitContinuous}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformLimitContinuous}^{\uparrow}$ packet is generated from a displayed ContinuousMap family, a UniformLimit row, a shared continuity modulus, finite StreamName and DyadicRatCore windows, a RegSeqRat handoff, a RealUp endpoint seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitContinuous}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 1748.1, Definition 1748.2, Definition 1748.3, Definition 1748.4, and Definition 1748.5 form the finite obligation surface for uniform limits of continuous maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLimitContinuous}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient-function equality, selected host limits, open-cover compactness, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-window stability, continuity-modulus handoff, RealUp seal nonescape, and ledger refusal for the same finite packet.

Chapter 1749

A Concrete Naming Certificate for $\mathsf{UniformLimitInterchange}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{UniformLimitInterchange}^{\uparrow}$ packet records the finite handoff by which continuity data for a finite family of displayed real-valued maps is preserved when the family is consumed through a uniform-limit route. It consumes the uniform-limit endpoint packet of chapter 463, the continuous-map rows of chapter 130, the shared-window modulus service of chapter 1741, the regular rational readback discipline of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes the Real and Completion handoff for finite uniform-limit continuity consumers; it does not claim host function-space completeness, quotient equality of maps, selected limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1749.1 (UniformLimitInterchange carrier)**.** *A* $\mathsf{UniformLimitInterchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, L, M, R, S, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows whose source and target Real windows are visible to the packet.*
2. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *row that reads the same finite family through its shared uniform-tail route.*
3. *M is the* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *evidence row, recording the single modulus ledger used by the continuity rows and by the uniform-limit route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite window observations after the shared modulus row has been displayed.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed from the regular readback and made available to Real and Completion consumers.*
6. *T is the interchange transport row, asserting that continuity-facing reads of F and endpoint-facing reads of L use the same M, R, S route.*
7. *H records componentwise* hsame *transport for the continuous-map ledger, uniform-limit row, shared modulus evidence, regular readback, Real seal, interchange transport, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from F to L, from both rows to M, from M to R, from R to S, and from this route to the transport row T.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformLimitInterchange}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformCauchyModulus}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLimitInterchange}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, L, M, R, S, T, H, C, P, N$. It has no coordinate for host function-space completeness, quotient equality of maps, selected host limits, open-cover compactness, pointwise-only convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformLimitInterchangeUp.UniformLimitInterchangeTasteGate single carrier alignment`

Theorem 1749.2 (UniformLimitInterchange NameCert obligations)**.** *For every accepted* $\mathsf{UniformLimitInterchange}^{\uparrow}$ *carrier $I = (F, L, M, R, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformLimitInterchange}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family ledger,* $\mathsf{UniformLimit}^{\uparrow}$ *route, shared* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *evidence,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, interchange transport, replay, provenance, and local naming rows;*
2. *continuity-route exactness, requiring every continuity-facing read of F to use the same displayed family rows consumed by L;*
3. *shared-modulus exactness, requiring the continuity rows and the uniform-limit row to consult the single modulus evidence row M before a readback is exposed;*
4. *RegSeqRat readback exactness, requiring R to be obtained only after F, L, M have been displayed;*
5. *Real-seal handoff, requiring S to be consumed only after R and only along the route replayed by C;*
6. *componentwise transport and displayed replay for F, L, M, R, S, T, P, N through H and C;*
7. *refusal of host function-space completeness, quotient equality of maps, selected host limits, open-cover compactness, pointwise-only convergence, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No uniform-limit interchange obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 1749.1. The only analytic rows are the finite continuous-map ledger F, the uniform-limit route L, the shared modulus row M, the regular readback R, the Real seal S, and the transport row T.

The continuity and limit routes meet at the shared modulus. A continuity-facing read cannot bypass M, because the carrier contains no second modulus row, and a uniform-limit read cannot expose a readback before F, L, M have been displayed.

The Real-facing boundary is downstream. The replay row C places R after F, L, M and places S after R, while the transport row H moves only the listed coordinates.

The provenance and local naming rows package the same finite route. Since no coordinate names host function-space completeness, quotient map equality, selected limits, open-cover compactness, pointwise-only convergence, or ambient Real completeness, none of those objects is a local NameCert obligation. □

Theorem 1749.3 (UniformLimitInterchange Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read exported by an accepted* $\mathsf{UniformLimitInterchange}^{\uparrow}$ *carrier factors through the finite route*

$$F, L \longmapsto M \longmapsto R \longmapsto S \longmapsto T, H, C, P, N.$$

Thus the consumer receives a finite uniform-limit continuity handoff from continuous-map rows to a Real seal through the shared modulus evidence, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the displayed transport and replay rows. The route exports no host function-space completeness, quotient equality of maps, selected host limits, open-cover compactness, pointwise-only convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real or Completion consumer of the accepted packet. The endpoint seal S is not an entrance row; the carrier first exposes the finite continuous-map ledger F and the $\mathsf{UniformLimit}^{\uparrow}$ route L.

The shared modulus row is then forced. By the shared-modulus obligation in Definition 1749.2, both the continuity rows and the limit row consult the same M before the regular readback row R is available.

After R is displayed, the Real seal S can be consumed. The interchange transport row T states that the continuity-facing and endpoint-facing requests follow this same route, and the structural rows H, C, P, N preserve and name it.

Composing these route projections gives the displayed factorization. Because every step is a row of the finite packet and the packet has no coordinate for the excluded analytic objects, the handoff cannot export any stronger host-level principle. □

Theorem 1749.4 (UniformLimitInterchange shared modulus determinacy)**.** *Let* $I = (F, L, M, R, S, T, H, C, P, N)$ *be an accepted* $\mathsf{UniformLimitInterchange}^{\uparrow}$ *carrier. Every consumer route from the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *rows of* F *and the* $\mathsf{UniformLimit}^{\uparrow}$ *route* L *to* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the* $\mathsf{Real}^{\uparrow}$ *seal factors through the same displayed shared-modulus row* M *before it reaches* R *and* S*.*

Equivalently, the finite gate for the interchange is determined by the carrier rows $F, L, M, R, S, T, H, C, P, N$*: no host function-space completeness, quotient equality of maps, selected limit, open-cover compactness, pointwise-only convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness can replace the row* M *in a certified readback route.*

Proof. Project the accepted carrier through Definition 1749.1. Its analytic surface contains the continuous-map ledger F, the uniform-limit row L, the shared modulus evidence M, the regular readback R, the Real seal S, and the transport row T.

Apply Definition 1749.2. The shared-modulus exactness row identifies M as the single row consulted by both the continuity-facing reads of F and the limit-facing read of L before any $\mathsf{RegSeqRat}^{\uparrow}$ readback is exposed.

Apply Definition 1749.3. Since every Real or Completion consumer reaches S only through the displayed route

$$F, L \longmapsto M \longmapsto R \longmapsto S \longmapsto T, H, C, P, N,$$

both R and S are downstream of that same M.

The remaining excluded objects are absent from the classifier coordinates. They therefore cannot supply an alternate gate for the finite readback route or replace the shared modulus row inside the local $\mathsf{NameCert}_{\mathsf{UniformLimitInterchange}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitInterchange}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitInterchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1749.1, Definition 1749.2, Definition 1749.3, and Definition 1749.4 seed the finite continuity handoff from continuous-map rows and a uniform-limit route to RegSeqRat readback and a Real seal.

Formal verification: FormalStatus(NameCert$_{\text{UniformLimitInterchange}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function-space completeness, quotient equality of maps, selected host limits, open-cover compactness, pointwise-only convergence, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuity-route exactness, shared-modulus exactness, RegSeqRat readback exactness, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformLimitInte

Constructive story: A UniformLimitInterchange$^{\uparrow}$ packet is generated from a finite ContinuousMap family ledger, a UniformLimit route, shared UniformCauchyModulus evidence, RegSeqRat readback, a RealUp seal, an interchange transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1750

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$

Following Bishop–Bridges regular Cauchy sequence discipline, the $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ packet records the finite fact that once a regular rational name is accepted at an earlier tail window, later tail windows may reuse the same tolerance ledger without opening a new completion object. It sits between the selected-window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the finite equality route of chapter 1738, the tail-threshold determinacy surface of chapter 1423, and the terminal real-name seal of chapter 38. The packet supplies the monotone tail-extension certificate consumed by the Real and Completion route; it is not quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1750.1 (Regular Cauchy tail monotonicity carrier)**.** *A* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{tail}} = (E, L, R, D, T, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the earlier* $\mathsf{StreamName}^{\uparrow}$ *tail-window row whose accepted regular Cauchy read is already visible.*
2. *L is the later* $\mathsf{StreamName}^{\uparrow}$ *tail-window row, displayed as an extension of the same source schedule beyond E.*
3. *R is the single* $\mathsf{RegSeqRat}^{\uparrow}$ *source row read through both E and L.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the earlier and later reads.*
5. *T is the monotone tail-extension row, asserting that the accepted tail comparison at E remains accepted when the later window L is substituted under the same source row R and tolerance ledger D.*
6. *A is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold-determinacy row used to confirm that later windows do not change the chosen tail threshold for the displayed tolerance.*
7. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row available only after E, L, R, D, T, A have been displayed.*
8. *H records componentwise* hsame *transport for the earlier and later windows, source row, tolerance ledger, monotone extension row, threshold-determinacy row, seal handoff, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from the earlier window to the later window, from both windows to the shared regular source, from the source to the dyadic tolerance ledger, from the ledger to the monotone extension row, and from the extension row through threshold determinacy to the* $\mathsf{Real}^{\uparrow}$ *handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, R, D, T, A, Q, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, hidden cofinal tails, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailMonotonicityUp.RegularCauchyTailMonotonicityUpTasteGate`
`single carrier alignment`

Definition 1750.2 (Regular Cauchy tail monotonicity obligation surface)**.** *For an accepted* RegularCauchyTailMono *carrier*

$$M_{\text{tail}} = (E, L, R, D, T, A, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the earlier* $\mathsf{StreamName}^{\uparrow}$ *window, later* $\mathsf{StreamName}^{\uparrow}$ *window, one* $\mathsf{RegSeqRat}^{\uparrow}$ *source, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, monotone tail-extension row,* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold-determinacy row,* $\mathsf{Real}^{\uparrow}$ *seal handoff, transport, replay, provenance, and local naming rows;*

2. *common-source exactness, requiring E and L to read the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*

3. *tolerance-ledger exactness, requiring the earlier and later tail reads to consult the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*

4. *monotone extension exactness, requiring T to be read only after E, L, R, D are visible and only as the later-window extension of the earlier accepted read;*

5. *threshold-determinacy replay, requiring A to reuse the displayed tolerance and source data rather than choosing a new threshold outside the packet;*

6. *componentwise transport and displayed replay for $E, L, R, D, T, A, Q, P, N$ through H and C;*

7. *refusal of quotient stream equality, selected limits, countable choice, trichotomy, host real equality, hidden cofinal tails, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No monotone tail-extension obligation is stored outside these rows.

Theorem 1750.3 (Regular Cauchy tail monotone window extension)**.** *Let $M_{\text{tail}} = (E, L, R, D, T, A, Q, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ *carrier. Any accepted regular Cauchy tail read at the earlier window E extends to the later window L exactly through the displayed route*

$$E \longmapsto L \longmapsto R \longmapsto D \longmapsto T \longmapsto A \longmapsto H, C, P, N.$$

Thus the later-window read remains a finite $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *computation over the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It does not introduce quotient stream equality, selected limits, countable choice, trichotomy, host real equality, hidden cofinal tails, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier of Definition 1750.1. Carrier admission exposes the earlier window E, later window L, shared source R, tolerance ledger D, monotone extension row T, threshold-determinacy row A, and structural rows.

The earlier read cannot move to L by changing source data. Common-source exactness in Definition 1750.2 forces both windows to consult R, while tolerance-ledger exactness forces both reads to consult D.

The monotone extension is the only analytic transition row. It is read as T after E, L, R, D are already visible, and the threshold-determinacy row A confirms that the later window has not introduced a second tail threshold for the same displayed tolerance.

Transport and replay preserve this finite route. The rows H, C, P, N move, replay, source, and name the same packet, so no excluded quotient, limit, choice, order-comparison, hidden-tail, or completeness coordinate is available. □

Theorem 1750.4 (Regular Cauchy tail monotonicity Real seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read exported by an accepted* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ *carrier factors through the earlier window E, the later window L, the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the monotone tail-extension row T, the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold-determinacy row A, and the structural rows H, C, P, N before the seal handoff row Q may be consumed. The consumer therefore receives a finite monotone-tail certificate, not quotient stream equality, selected limits, countable choice, trichotomy, host real equality, hidden cofinal tails, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ or completion-facing request. The handoff row Q is downstream of the displayed carrier, so the request first reads the earlier and later $\mathsf{StreamName}^{\uparrow}$ windows E, L and the shared $\mathsf{RegSeqRat}^{\uparrow}$ source R.

The tolerance accounting is then fixed by D. The monotone tail-extension row T uses that same ledger to pass from the accepted earlier tail read to the later-window read, while A records that the tail threshold is determined by the displayed source and tolerance data.

The structural rows do not create a new endpoint. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same route through E, L, R, D, T, A.

Only after this route has been displayed may the consumer read Q. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, trichotomy, host equality, hidden cofinal tails, or ambient completeness, the seal handoff cannot export any of them. □

Falsifiable prediction: Every $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ Real-facing read factors through earlier and later StreamName windows, one RegSeqRat source row, a DyadicRatCore tolerance ledger, a monotone tail-extension row, RealCauchyModulus threshold determinacy, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchytailequivalence, realcauchymodulus, real: $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an earlier tail window, a later tail window, one regular rational source, one tolerance ledger, a monotone extension row, threshold determinacy, Real seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1750.1, Definition 1750.2, Definition 1750.3, and Definition 1750.4 seed the finite monotone-tail extension certificate between regular Cauchy names and Real seals.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailMonotonicity}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularCauchyTailMonotonicityUp.RegularCauchyTailMonotonicityUpTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, hidden cofinal tails, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-source exactness, tolerance-ledger exactness, monotone extension exactness, threshold-determinacy replay, Real seal factorization, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyTailMonotonicityUp.

Constructive story: A RegularCauchyTailMonotonicity$^{\uparrow}$ packet is generated from earlier and later StreamName tail windows, one RegSeqRat source row, a DyadicRatCore tolerance ledger, a monotone tail-extension row, RealCauchyModulus threshold determinacy, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Chapter 1751

A Concrete Naming Certificate for $\mathsf{UniformLimitContinuity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformLimitContinuity}^{\uparrow}$ packet records the finite BEDC surface for the theorem that a uniform limit of continuous real-valued maps is continuous. It reads the $\mathsf{UniformLimit}^{\uparrow}$ route of chapter 463, the $\mathsf{ContinuousMap}^{\uparrow}$ rows of chapter 130, the $\mathsf{UniformModulus}^{\uparrow}$ consumer surface, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, and the terminal $\mathsf{Real}^{\uparrow}$ seal rows. The packet claims no pointwise-only convergence theorem, selected host limit, quotient function space, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1751.1 (UniformLimitContinuity carrier)**.** *A* $\mathsf{UniformLimitContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, M, T, R, E, G, U, H, C, P, N)$$

with the following displayed coordinates:

1. *F is the* $\mathsf{UniformLimit}^{\uparrow}$ *family row naming the uniformly convergent real-valued map family and its limiting endpoint route.*
2. *M is the shared modulus row that every continuity request and every uniform-tail request reads before a tolerance is consumed.*
3. *T is the tail ledger row inherited from the uniform-limit packet, exposing only the accepted shared-threshold comparisons.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular handoff row reached from the same family, modulus, and tail rows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the limiting endpoint after the regular handoff has been displayed.*
6. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the approximating maps and the limiting graph surface visible to downstream consumers.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *or uniform-continuity consumer row that receives the shared modulus data before reading continuity evidence.*
8. *H stores componentwise* hsame *transports for F, M, T, R, E, G, U, package provenance, and the local naming row.*
9. *C stores the displayed* Cont *replay route from uniform-tail exposure through regular handoff, real seal, continuous-map graph, and uniform-continuity consumption.*

10. *P is the* Pkg *provenance over* UniformLimitContinuity$^\uparrow$, UniformLimit$^\uparrow$, ContinuousMap$^\uparrow$, UniformModulus$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformLimitContinuity}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these displayed rows, their componentwise transports, their continuation replay routes, package provenance, and local naming provenance.

Theorem 1751.2 (UniformLimitContinuity NameCert obligations)**.** *For the carrier of Definition 1751.1, the local* NameCert$_{\text{UniformLimitContinuity}^\uparrow}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the packet $K = (F, M, T, R, E, G, U, H, C, P, N)$;*
2. *uniform-tail exposure, requiring continuity-facing reads to pass through the shared modulus row M and tail ledger row T before any limiting endpoint is exposed;*
3. *continuity handoff, requiring every* ContinuousMap$^\uparrow$ *consumer to read the graph row G only after the uniform-limit route has exposed R and E;*
4. *transport, replay, and provenance stability through the displayed H, C, P, N rows;*
5. *nonescape from pointwise-only convergence, host-selected limits, quotient function equality, open-cover compactness, and ambient* Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformLimitContinuityUp.UniformLimitContinuityUpTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1751.1. The displayed tuple names the uniform-limit family, shared modulus, tail ledger, regular handoff, real seal, continuous-map graph, uniform-continuity consumer row, transports, continuations, provenance, and local certificate.

For the route obligations, read an endpoint-facing continuity request through C. The route first exposes F, M, T, then reaches R and E, and only then allows the continuous-map graph row G and uniform-continuity consumer row U to be used.

The transport and provenance clauses are componentwise in H and P, with replay recorded by C and local naming by N. Since the carrier contains no coordinate for the excluded analytic structures, those structures cannot be exported by the local certificate. □

Theorem 1751.3 (UniformLimitContinuity continuous-map handoff)**.** *Every* ContinuousMap$^\uparrow$ *consumer of the limiting endpoint of an accepted* UniformLimitContinuity$^\uparrow$ *carrier factors through the* UniformLimit$^\uparrow$ *shared threshold and seal route*

$$F \longmapsto M \longmapsto T \longmapsto R \longmapsto E$$

before reading the continuous-map graph row G or the uniform-continuity consumer row U. Thus the limiting continuity data are consumed only after the shared modulus, uniform tail ledger, regular handoff, and real seal have been displayed.

Proof. Start with a ContinuousMap$^\uparrow$ consumer of the limiting endpoint. By the carrier definition, the only limiting endpoint row is E, and the only route to it is the displayed replay path through F, M, T, R.

Apply the uniform-tail exposure and continuity handoff clauses of Definition 1751.2. They force the consumer to read the shared threshold row and tail ledger before the regular handoff and seal are available, and they place the graph row G after that route.

The remaining rows H, C, P, N record transport, replay, package provenance, and naming provenance for the same path. Hence a continuous-map consumer factors through the uniform-limit threshold and seal route before it reads continuity data. □

Theorem 1751.4 (UniformLimitContinuity modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or uniform-continuity consumer of an accepted* $\mathsf{UniformLimitContinuity}^{\uparrow}$ *carrier* $K = (F, M, T, R, E, G, U, H, C, P, N)$ *must read the shared modulus row* M *before using the tail ledger* T*, regular handoff* R*, real seal* E*, continuous-map graph* G*, or consumer row* U*. Thus all uniform-continuity consumption in the packet factors through the same displayed modulus row before it reaches any endpoint, graph, or downstream consumer surface.*

Proof. Project the accepted carrier along Definition 1751.1. The only modulus-bearing coordinate available to a uniform-continuity request is the shared row M, while T, R, E, G, U occur later in the displayed carrier route.

Apply the uniform-tail exposure clause of Definition 1751.2. It requires continuity-facing reads to pass through M and the tail ledger before the limiting endpoint route is exposed.

Apply Definition 1751.3 to the endpoint-facing part of the same consumer. That theorem places the route through F, M, T, R, E before G or U can be read, so a $\mathsf{UniformModulus}^{\uparrow}$ or uniform-continuity consumer cannot reach the later rows without first passing through M.

The remaining rows H, C, P, N do not introduce a second route. They transport, replay, package, and name the same carrier path, so they preserve the modulus handoff rather than bypassing it. □

Theorem 1751.5 (UniformLimitContinuity Cauchy criterion handoff)**.** *Every accepted* $\mathsf{UniformLimitContinuity}^{\uparrow}$ *carrier* $K = (F, M, T, R, E, G, U, H, C, P, N)$ *sends its shared modulus row* M *and tail ledger* T *through the* $\mathsf{UniformLimit}^{\uparrow}$ *row, the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *or* $\mathsf{CauchyCriterion}^{\uparrow}$ *surface, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before any* $\mathsf{ContinuousMap}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer reads continuity. The route exports no pointwise-only convergence theorem and no selected host limit.*

Proof. Project the accepted carrier through Definition 1751.1. The rows F, M, T, R, E are the only uniform-limit, shared-modulus, tail-ledger, regular-readback, and Real-seal coordinates available before the continuity-facing rows G and U.

Apply Definition 1751.4. It forces every $\mathsf{UniformModulus}^{\uparrow}$ or uniform-continuity consumer to read M before T, R, E, G, U can be used.

Apply Definition 1751.3. That handoff places the endpoint-facing continuity read after the route through F, M, T, R, E, so a $\mathsf{ContinuousMap}^{\uparrow}$ consumer also waits for the shared modulus, tail ledger, regular readback, and Real seal.

The $\mathsf{UniformCauchyCriterion}^{\uparrow}$ or $\mathsf{CauchyCriterion}^{\uparrow}$ surface reads the same tail ledger and regular-seal route rather than a second limit object. Since the carrier has no coordinate for pointwise-only convergence or a selected host limit, those excluded objects cannot mediate the continuity read. □

Theorem 1751.6 (UniformLimitContinuity nonescape boundary)**.** *An accepted* $\mathsf{UniformLimitContinuity}^{\uparrow}$ *carrier exports only the displayed uniform-limit family row, shared modulus row, tail ledger, regular handoff, real seal, continuous-map graph, uniform-continuity consumer row, componentwise transports, continuation replay, package provenance, and local naming row of Definition 1751.1. It exports no pointwise-only convergence theorem, no host limit selector, no quotient function equality, no open-cover compactness principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Inspect the carrier tuple. Its visible rows are precisely $F, M, T, R, E, G, U, H, C, P, N$, and its consumer order is the replay route recorded by C.

Use Definition 1751.3. Any continuity-facing endpoint read passes through the shared threshold, tail ledger, regular handoff, and real seal before the continuous-map graph is read.

The excluded objects would require an additional carrier coordinate or a replay route outside C. Neither is present in the packet, so the public surface is exhausted by the displayed finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformLimitContinuity}^{\uparrow}$ packet is generated from a uniform-limit family row, a shared modulus row, a uniform tail ledger, a regular handoff, a real seal, continuous-map graph rows, a uniform-continuity consumer row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1751.1, Definition 1751.2, Definition 1751.3, and Definition 1751.6 bind the seed carrier, obligation surface, continuous-map handoff, and nonescape boundary for the finite uniform-limit-continuity packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLimitContinuity}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.UniformLimitContinuityUp`

Bridge status: none

Not claimed: This chapter does not close pointwise-only convergence, selected host limits, quotient function equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a checked Lean certificate.

Upgrade path: A formal carrier theorem and bridge theorem remain verification-axis work over the same finite uniform-limit-continuity surface.

Chapter 1752

A Concrete Naming Certificate for $\mathsf{CantorCompleteness}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Cantor's nested-interval principle, the $\mathsf{CantorCompleteness}^{\uparrow}$ packet records the finite naming boundary for a descending sequence of closed located intervals whose displayed diameters tend to zero and whose regular-rational readback reaches a terminal $\mathsf{Real}^{\uparrow}$ seal. It sits between the nested interval surfaces of chapter 320, the located endpoint discipline of chapter 394, the tail-diameter witness of chapter 1746, the window and readback route of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The completion-facing consumer route is shared with chapter 1421, which packages the same nested-interval width-window, RegSeqRat handoff, and RealUp seal as an explicit intersection consumer. The chapter isolates the constructive Cantor-completeness interface as NameCert data; it does not assert Heine–Borel compactness, open-cover compactness, choice-selected points, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1752.1 (Cantor completeness carrier)**.** *A* $\mathsf{CantorCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{Cantor}} = (I, L, R, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{NestedInterval}^{\uparrow}$ *row listing the nested closed interval spine, with each later interval displayed as a subinterval of the earlier row.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row for the left and right endpoints of every displayed interval in the inspected finite window.*
3. *R is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *ledger asserting that the visible interval diameters are eventually bounded by each requested dyadic tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the diameter ledger and by the regular-rational readback route.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row identifying which finite prefix of the nested interval spine is inspected at the requested tolerance.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracting the compatible regular rational name from the endpoint and diameter rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, R, D, W, Q have been displayed.*

8. *H records componentwise* hsame *transport for the nested intervals, located endpoints, diameter ledger, dyadic tolerances, window row, regular readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the nested interval spine through located endpoints, diameter-to-zero evidence, dyadic tolerances, StreamName windows, RegSeqRat readback, and the terminal Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorCompleteness}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, R, D, W, Q, E, H, C, P, N$. It has no coordinate for an open cover, a Heine–Borel subcover, a choice-selected point, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorCompletenessUp.CantorCompletenessTasteGate single carrier alignment`

Theorem 1752.2 (Cantor completeness NameCert obligations)**.** *For every accepted* $\mathsf{CantorCompleteness}^{\uparrow}$ *carrier*

$$K_{\mathrm{Cantor}} = (I, L, R, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the nested closed interval spine, located endpoint rows, diameter-to-zero ledger, dyadic tolerance row, StreamName window row, RegSeqRat readback row, Real seal, transport, replay, provenance, and local naming rows;*

2. *nesting exactness, requiring each visible later interval in I to be read as a closed subinterval of the preceding visible interval;*

3. *endpoint locatedness, requiring L to display the left and right endpoint rows used by every visible interval comparison;*

4. *diameter-tail exactness, requiring R to answer each requested tolerance only through the dyadic row D and the finite window row W;*

5. *readback exactness, requiring Q to extract a regular rational name only from the compatible endpoint and diameter rows exposed by I, L, R, D, W;*

6. *seal exactness, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to be downstream of the displayed RegSeqRat readback rather than an ambient completeness assumption;*

7. *componentwise transport, displayed replay, package provenance, and local naming for the same rows through H, C, P, N;*

8. *refusal of open-cover compactness, Heine–Borel subcovers, choice-selected points, quotient real equality, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No Cantor-completeness obligation is stored outside these rows.

Proof. Project the accepted carrier. Carrier admission exposes the nested interval spine I, located endpoint rows L, diameter ledger R, dyadic tolerance row D, StreamName window row W, RegSeqRat readback Q, Real seal E, and structural rows H, C, P, N.

The interval information is read first. Nesting exactness keeps each visible later interval inside the preceding closed interval, and endpoint locatedness ensures that the comparisons are made only through the displayed endpoint rows.

The diameter and window rows control the limiting read. For each requested dyadic tolerance, the ledger R consults D and the finite StreamName window W before any readback can be produced.

The regular-rational and Real rows are downstream. The row Q repacks the compatible endpoint and diameter data as a regular rational name, and E seals that name as the displayed $\mathsf{Real}^{\uparrow}$ output.

Transport, replay, provenance, and local naming preserve this same route. Since no coordinate carries an open cover, Heine–Borel subcover, choice-selected point, quotient equality, trichotomy, or ambient completeness principle, none of those objects can become a local NameCert obligation. □

Theorem 1752.3 (Cantor completeness nested diameter handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{CantorCompleteness}^{\uparrow}$ *carrier factors through the finite route*

$$I, L \longmapsto R, D, W \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives the nested closed interval rows, located endpoint rows, diameter-to-zero ledger, dyadic tolerances, finite StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, package provenance, and local NameCert. The route exports no open-cover compactness, Heine–Borel subcover, choice-selected point, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer request for the Real-facing output. The request can enter the packet only through the accepted carrier, so the first visible data are the nested interval spine I and the located endpoint row L.

Next read the diameter route. The ledger R answers the requested tolerance by consulting the dyadic row D and the finite window row W, keeping the argument inside the displayed tail of the interval spine.

The readback row then supplies the candidate name. Because Q is downstream of I, L, R, D, W, the regular rational name is produced from the same compatible endpoint and diameter data rather than from an external point selector.

Finally, the Real seal E and structural rows H, C, P, N package the same finite route for consumers. No step in the route opens an open cover, invokes a subcover theorem, chooses a point from the nested family, quotients real names, decides trichotomy, or assumes ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorCompleteness}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1752.1, Definition 1752.2, and Definition 1752.3 seed the finite nested closed interval, diameter-tail, regular-rational readback, and Real-seal packet for Cantor-style completeness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, Heine–Borel compactness, choice-selected points, quotient real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nesting exactness, endpoint locatedness, diameter-tail exactness, readback exactness, seal exactness, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.CantorCompletenessUp.

Constructive story: A $\mathsf{CantorCompleteness}^{\uparrow}$ packet is generated from nested closed interval rows, located endpoint rows, a diameter-to-zero ledger, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1753

A Concrete Naming Certificate for $\mathsf{BishopModulusReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopModulusReal}^{\uparrow}$ packet records the explicit-modulus real-name carrier used when a constructive real name is read through finite precision data rather than through a detached equality principle. It sits over the dyadic tolerance arithmetic of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the fast real-name route of chapter 1589, and the completion-facing modulus route of chapter 1691. The packet makes the Bishop modulus visible as finite BEDC data before any FastCauchyReal or FastCauchyCompletion consumer treats the name as Real-facing data.

Definition 1753.1 (BishopModulusReal carrier)**.** *A* $\mathsf{BishopModulusReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the explicit Bishop modulus row. It records, for each finite precision request, the displayed index bound and the local tail discipline that every downstream read must consume.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened only at the windows named by M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for those windows, including dyadic radii, endpoint comparisons, rounding rows, and tolerance arithmetic.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S and D under the modulus budget exposed by M.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, S, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the modulus row, stream windows, dyadic ledger, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each finite Real-facing precision request through M, S, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopModulusReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FastCauchyReal}^{\uparrow}$, $\mathsf{FastCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopModulusReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopModulusRealUp.BishopModulusRealTasteGate single carrier alignment`

Theorem 1753.2 (BishopModulusReal NameCert obligations)**.** *For every accepted* $\mathsf{BishopModulusReal}^{\uparrow}$ *carrier $B = (M, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopModulusReal}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed Bishop modulus, finite stream-window row, dyadic tolerance ledger, regular rational readback, terminal Real seal, and structural rows H, C, P, N;*
2. *modulus exactness, requiring every finite precision request to read the row M before any stream window, dyadic tolerance, regular readback, or Real seal is exposed;*
3. *window and readback compatibility, requiring S and D to be consumed under the same displayed modulus budget before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R may be read;*
4. *Real-seal nonescape, requiring E to remain terminal with respect to M, S, D, R and to expose no detached Real object, selected limit, host equality, or ambient completeness theorem;*
5. *componentwise transport and provenance, requiring H, C, P, N to preserve and name only the displayed route under* hsame *transport,* Cont *replay, package provenance, and local certification.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1753.1. The visible packet consists of the Bishop modulus row M, finite stream window S, dyadic tolerance ledger D, regular readback R, Real seal E, and structural rows H, C, P, N.

Modulus exactness follows from the placement of M at the front of the route. A Real-facing precision request first fixes the displayed bound, and every later observation is read inside the finite budget named by that bound.

Window and readback compatibility read chapter 126, chapter 291, and chapter 301 in order. The window S and ledger D are consumed before R is available, so regular rational data cannot be detached from the displayed Bishop modulus.

The Real-seal nonescape clause reads chapter 38. The row E is terminal and downstream of M, S, D, R, while H, C, P, N transport, replay, package, and name exactly that route.

Since quotient stream equality, selected limits, countable choice, host real equality, trichotomy, and ambient Real completeness are absent from the carrier, no local NameCert obligation can export them. □

Theorem 1753.3 (BishopModulusReal fast-Cauchy handoff)**.** *Let $B = (M, S, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopModulusReal}^{\uparrow}$ *carrier. Every* $\mathsf{FastCauchyReal}^{\uparrow}$ *or* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *consumer reads the packet only through the displayed modulus route*

$$M \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently those consumers receive an explicit Bishop modulus, finite stream windows, dyadic tolerance arithmetic, regular rational readback, the terminal $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming before any Real-facing datum is available. The route cannot use quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a FastCauchyReal or FastCauchyCompletion read of B. By Definition 1753.1, the only Real-facing coordinate is E, and the definition places it downstream of the modulus row M, stream window S, dyadic ledger D, and regular readback row R.

The first part of the route is fixed by the modulus and finite-window rows. The row M supplies the explicit finite bound, S exposes only the corresponding stream observations, and D supplies the dyadic tolerances and endpoint comparisons for those observations.

The second part of the route is fixed by regular readback and the Real seal. The row R is consumed only after S and D, and E seals the Real-facing datum only after the regular row has been displayed.

Finally, H, C, P, N preserve and name the same dependency order. Because the excluded objects have no coordinate in the carrier and no replay edge in the displayed route, every FastCauchyReal or FastCauchyCompletion read factors through the modulus route shown in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopModulusReal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopModulusReal}^{\uparrow}$ packet is generated from an explicit Bishop modulus row, StreamName finite windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopModulusReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1753.1, Definition 1753.2, and Definition 1753.3 seed the finite explicit-modulus Real-name route consumed by FastCauchyReal and FastCauchyCompletion packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopModulusReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, window and readback compatibility, Real-seal nonescape, componentwise transport, provenance, and local naming for the same displayed packet.

Chapter 1754

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ packet records the finite precision-to-tail threshold service used by regular Cauchy real names before any completed limit, quotient stream equality, or choice-selected modulus is available. It reads the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational source route of chapter 301, the terminal real-name seal of chapter 38, the displayed tail-diameter witness of chapter 1746, and the shared-window budget of chapter 1741. The packet names the one-source threshold row that later $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, and $\mathsf{UniformCauchyModulus}^{\uparrow}$ consumers may cite when a requested precision must be turned into a visible finite tail service.

Definition 1754.1 (Regular Cauchy tail modulus carrier)**.** *A* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, T, W, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular Cauchy tail service is being queried.*
2. *Q is the precision-request row, recording the requested dyadic tolerance as a visible consumer input.*
3. *T is the displayed tail-threshold row returned for the request Q on the source S.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window service showing which source observations are visible once the threshold T has been read.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row against which the displayed request and tail observations are compared.*
6. *H records componentwise* hsame *transport for the source, request, threshold, window service, dyadic tolerance, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the source and precision request through the threshold, the finite window service, and the dyadic tolerance row.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, T, W, D, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1754.2 (Regular Cauchy tail modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *carrier $K = (S, Q, T, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular source, precision request, displayed threshold, finite window service, dyadic tolerance, transport, replay, provenance, and local naming rows;*
2. *request exactness, requiring Q to be the precision request consumed by the source row S and by no detached schedule;*
3. *tail-threshold exactness, requiring T to be the displayed tail threshold returned for the pair (S, Q);*
4. *window handoff, requiring W to expose only finite* $\mathsf{StreamName}^{\uparrow}$ *observations available after the threshold T is read;*
5. *dyadic tolerance compatibility, requiring the request row Q and all tail-window comparisons exported through W to be checked against the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
6. *transport and replay stability, requiring H and C to preserve the same source-request-threshold-window-tolerance route;*
7. *provenance and local naming, requiring P and N to package exactly the displayed rows S, Q, T, W, D, H, C;*
8. *refusal of quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert obligations.*

No regular Cauchy tail-modulus obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailModulusUp.RegularCauchyTailModulusTasteGate single carrier alignment`

Theorem 1754.3 (Regular Cauchy tail modulus window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that uses a tail threshold from an accepted* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *carrier must read the rows in the order*

$$S, Q, T, W, D, H, C, P, N.$$

Thus the consumer sees the regular source, the requested precision, the displayed threshold, the finite window service, the dyadic tolerance row, transport, replay, provenance, and local naming before using the threshold. The route exports no quotient stream equality, selected limit, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailModulusUp.RegularCauchyTailModulusWindowHandoff`

Definition 1754.4 (Regular Cauchy tail modulus diameter-control carrier)**.** *A diameter-control* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K^{\diamondsuit} = (S, Q, T, W, D, B, U, H, C, P, N)$$

whose first five rows are the regular source S, precision request Q, displayed threshold T, finite window W, and $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance D of Definition 1754.1. The row B is a* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *certificate row over the same S, Q, T, W, D route, and the row U is a* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *consumer row over the same source, request, threshold, window, tolerance, and diameter-control row. The remaining rows H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}$ *packaging for exactly these displayed rows.*

The classifier compares accepted packets only through $S, Q, T, W, D, B, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1754.5 (Regular Cauchy tail modulus diameter control)**.** *If a diameter-control* RegularCauchyTailModulu *carrier*

$$K^{\diamondsuit} = (S, Q, T, W, D, B, U, H, C, P, N)$$

is accepted, then every two displayed tail indices beyond the threshold row T read their diameter bound through the $\mathsf{CauchyTailDiameter}^{\uparrow}$ *row B after the shared route S, Q, T, W, D and before the structural rows H, C, P, N. Thus the threshold is a concrete finite diameter-control service: the same source, precision request, threshold, finite window, and dyadic tolerance that admit the tail handoff also admit the displayed tail-diameter bound.*

The conclusion uses no quotient stream equality, selected limit, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge data.*

Proof. Read the accepted packet by projection. The first five projections recover the route S, Q, T, W, D, and Definition 1754.3 forces any consumer of the threshold to pass through that route before the structural rows are available.

Apply the finite-window reading of chapter 1746 to the displayed row B. Since B is part of the same accepted packet and its carrier coordinates are exactly S, Q, T, W, D, every pair of visible tail indices beyond T obtains its bound from the same finite window and the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row.

The remaining rows H, C, P, N only transport, replay, package, and name the displayed data. They add no equality of quotient streams, no selected limit, no choice principle, no trichotomy, no compactness principle, no ambient completeness claim, and no bridge datum. □

Theorem 1754.6 (Regular Cauchy tail modulus uniform window consumption)**.** *Every* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *consumer using the threshold T of an accepted diameter-control* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *carrier must first consume the same route*

$$S, Q, T, W, D, B$$

before reading its local uniform-modulus row U or the structural rows H, C, P, N. Consequently the uniform modulus is not a detached schedule: it is a finite-window consumer of the displayed source, request, threshold, window, dyadic tolerance, and $\mathsf{CauchyTailDiameter}^{\uparrow}$ *diameter-control row.*

Proof. Project the accepted packet to the threshold route and then to the diameter-control row. The preceding theorem supplies the finite tail-diameter service through B, so any consumer that claims to use the same threshold already has the route S, Q, T, W, D, B in view.

Apply the shared-window budget described by chapter 1741. The $\mathsf{UniformCauchyModulus}^{\uparrow}$ row U is admitted only as a consumer over the displayed route, so its scheduling data is read after the diameter-control row and cannot be separated from the finite window that witnesses the tail bound.

The structural rows preserve this dependency by transport, replay, provenance, and local naming. They do not introduce quotient stream equality, selected limits, choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 1754.7 (Regular Cauchy tail modulus RegSeqRat consumer)**.** *Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read that consumes a* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *threshold from an accepted diameter-control carrier*

$$K^{\diamondsuit} = (S, Q, T, W, D, B, U, H, C, P, N)$$

must first expose the same $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*,* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *diameter row* B*, and* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *budget row* U *already named by the packet. Consequently the threshold is consumed only as the finite route*

$$S, Q, T, W, D, B, U, H, C, P, N,$$

and not as quotient stream equality, a selected limit, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge data.*

Proof. Start with Definition 1754.3. It forces any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ threshold consumer to read the regular source, precision request, displayed threshold, finite window, and dyadic tolerance rows before the structural rows.

Apply Definition 1754.5. Once the same threshold route is visible, the tail-diameter row B supplies the finite diameter-control service over S, Q, T, W, D.

Then use Definition 1754.6. The uniform Cauchy modulus row U is downstream of S, Q, T, W, D, B, so a RegSeqRat or Real consumer cannot detach the budget from the visible window or from the dyadic tolerance ledger.

The remaining rows H, C, P, N only transport, replay, package, and name this route. Since the carrier contains no excluded host-side coordinate, the displayed rows exhaust the consumer service. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1754.1, Definition 1754.2, Definition 1754.3, Definition 1754.4, Definition 1754.5, and Definition 1754.6 seed the finite precision-to-tail threshold packet over RegSeqRat source rows, dyadic precision requests, displayed thresholds, finite StreamName window services, DyadicRatCore tolerances, CauchyTailDiameter rows, UniformCauchyModulus rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exactness, tail-threshold exactness, window handoff, dyadic tolerance compatibility, transport, replay, provenance, and local naming for future BEDC.Derived.RegularCauchyTailModul obligations.

Constructive story: A $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ packet is generated from a RegSeqRat source row, a precision request, a displayed tail threshold, a finite StreamName window service, a DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1755

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$

Bishop–Bridges constructive regular Cauchy analysis treats a modulus as reusable finite evidence: once a displayed precision has produced a tail threshold, later consumers may cite that threshold through monotone window data rather than choose another modulus. The $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ packet records this threshold-reuse service over the precision-to-tail carrier of chapter 1754, the later-window discipline of chapter 1750, the finite observation surface of chapter 126, the regular rational source route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The certificate gives Real and uniform-limit consumers one displayed handoff for reusing a tail threshold; it is not quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1755.1 (Regular Cauchy tail modulus reuse carrier)**.** *A* $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R_{\text{reuse}} = (S, Q, T, E, L, W, D, M, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular Cauchy tail service is being reused.*
2. *Q is the displayed precision-request row already consumed by the source.*
3. *T is the* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *threshold row returned for (S, Q).*
4. *E is the earlier* $\mathsf{StreamName}^{\uparrow}$ *tail window on which the threshold T was first read.*
5. *L is the later* $\mathsf{StreamName}^{\uparrow}$ *tail window that asks to reuse the same threshold and precision request.*
6. *W is the shared window-family row, requiring E and L to expose observations from the same finite stream-name service.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by both the original tail request and the reused later-window comparison.*
8. *M is the* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ *handoff row, showing that the later window may read the earlier tail evidence without changing S, Q, T, D.*
9. *U is the reuse row; it records that a downstream Real or uniform-limit consumer cites T through M rather than selecting a fresh threshold.*

10. *H records componentwise* hsame *transport for the source, request, threshold, earlier window, later window, shared window family, dyadic tolerance, monotone handoff, reuse row, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from S, Q to T, from T to E, L, W, D, M, U, and then through provenance and local naming.*
12. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$, $\mathsf{RegularCauchyTailModulus}^{\uparrow}$, $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, T, E, L, W, D, M, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, hidden cofinal tails, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailModulusReuseUp.RegularCauchyTailModulusReuseTasteGate`
`single carrier alignment`

Theorem 1755.2 (Regular Cauchy tail modulus reuse NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ *carrier*

$$R_{\text{reuse}} = (S, Q, T, E, L, W, D, M, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational source, precision request, reused threshold, earlier and later stream windows, shared window family, dyadic tolerance, monotone handoff, reuse row, transport, replay, provenance, and local naming rows;*
2. *threshold provenance, requiring T to be the displayed* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *row returned from the same (S, Q) pair stored in the carrier;*
3. *window compatibility, requiring E and L to belong to the shared finite* $\mathsf{StreamName}^{\uparrow}$ *window family W;*
4. *tolerance reuse, requiring the original threshold read and the later-window read to consult the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
5. *monotone handoff admission, requiring M to witness that L extends the accepted tail read from E without changing S, Q, T, D;*
6. *reuse exactness, requiring U to cite the displayed threshold T through M rather than produce a new threshold row;*
7. *componentwise transport and displayed replay for $S, Q, T, E, L, W, D, M, U, P, N$ through H and C;*
8. *refusal of quotient stream equality, selected limits, countable choice, trichotomy, hidden cofinal tails, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No tail-modulus reuse obligation is stored outside these rows.

Theorem 1755.3 (Regular Cauchy tail modulus reuse monotone handoff)**.** *Let*

$$R_{\text{reuse}} = (S, Q, T, E, L, W, D, M, U, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ *carrier. Any Real-facing or uniform-limit-facing read that reuses the threshold* T *must factor through the finite route*

$$S, Q \longmapsto T \longmapsto E, L, W, D \longmapsto M \longmapsto U \longmapsto H, C, P, N.$$

Consequently the consumer receives the same source row, precision request, tail threshold, window family, and dyadic tolerance that generated the original modulus row. The handoff is monotone threshold reuse; it is not a quotient equality of streams, a selected limit, a countable-choice schedule, trichotomy, a hidden cofinal tail, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Falsifiable prediction: Every $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ Real-facing or uniform-limit-facing read factors through one RegSeqRat source row, one precision request, one displayed RegularCauchyTailModulus threshold, earlier and later StreamName windows, one shared window family, one DyadicRatCore tolerance row, a RegularCauchyTailMonotonicity handoff, a reuse row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-tail-modulus, regular-cauchy-tail-monotonicity, stream-name, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the original threshold row and the later-window monotone handoff that authorizes reuse by downstream consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1755.1, Definition 1755.2, and Definition 1755.3 seed the finite threshold-reuse certificate over a regular rational source, displayed precision request, reused tail threshold, earlier and later finite windows, dyadic tolerance, monotone handoff, reuse row, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, hidden cofinal tails, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold provenance, window compatibility, tolerance reuse, monotone handoff admission, reuse exactness, componentwise transport, displayed replay, and consumer route nonescape for BEDC.Derived.RegularCauchyTailModulusReuseUp.

Constructive story: A $\mathsf{RegularCauchyTailModulusReuse}^{\uparrow}$ packet is generated from one RegSeqRat source row, one precision request, one displayed RegularCauchyTailModulus threshold, earlier and later StreamName windows, one shared window family, one DyadicRatCore tolerance row, a RegularCauchyTailMonotonicity handoff, a reuse row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1756

A Concrete Naming Certificate for $\mathsf{RegularCauchySquareRoot}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ packet records the finite square-root readback service available for a displayed nonnegative regular Cauchy rational name before any completed real quotient, trichotomy principle, or host real square-root theorem is invoked. It sits beside the regular rational source discipline of chapter 301, the finite stream-window service of chapter 126, the dyadic arithmetic ledger of chapter 291, the monotone and modulus tail services of chapter 1750 and chapter 1754, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a visible route for a constructive square-root approximation while keeping total square root on arbitrary reals, quotient real equality, selected limits, and ambient completeness outside the local certificate.

Definition 1756.1 (Regular Cauchy square-root carrier)**.** *A* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, N, W, D, B, T, M, S, E, H, C, P, A)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose observations form the regular rational name to be square-rooted.*
2. *N is the nonnegativity witness row, recording finite lower-bound data sufficient for the displayed square-root route and no trichotomy coordinate.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window service exposing exactly the source observations used by the square-root ledger.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row containing dyadic interval endpoints, midpoint arithmetic, squaring comparisons, tolerance splits, and rational order certificates used by the ledger.*
5. *B is the dyadic bisection or Newton ledger, recording for each requested precision the finite interval or Newton step, the squared-endpoint check, and the selected dyadic output approximation.*
6. *T is the* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *request-to-threshold row used to determine which source tail must be visible for the requested square-root precision.*
7. *M is the* $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$ *row showing that later source windows preserve the accepted tail and tolerance ledger.*

8. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by replaying B against R, N, W, D, T, M.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the source, nonnegativity witness, windows, dyadic ledger, square-root ledger, tail rows, and readback row have been displayed.*
10. *H records componentwise* hsame *transport for the source, nonnegativity witness, windows, dyadic ledger, square-root ledger, tail rows, readback, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from every square-root precision request through $R, N, W, D, B, T, M, S, E, H, P,$*
12. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyTailModulus}^{\uparrow}$, $\mathsf{RegularCauchyTailMonotonicity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySquareRoot}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, N, W, D, B, T, M, S, E, H, C, P, A$. It has no coordinate for full $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, total square root on arbitrary reals, quotient real equality, selected limits, host real square-root functions, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySquareRootUp.TasteGate.RegularCauchySquareRootTasteGate single carrier alignment`

Theorem 1756.2 (Regular Cauchy square-root NameCert obligations)**.** *For every accepted* RegularCauchySquareRo *carrier*

$$Q = (R, N, W, D, B, T, M, S, E, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySquareRoot}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational source, nonnegativity witness, finite StreamName windows, DyadicRatCore arithmetic ledger, square-root ledger, tail modulus row, tail monotonicity row, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *nonnegativity exactness, requiring N to certify the displayed source row R rather than an external representative or completed real;*
3. *window exactness, requiring W to expose precisely the source observations read by the square-root ledger and no quotient stream equality;*
4. *dyadic square-root accounting, requiring B to use only dyadic interval bisection or Newton steps whose endpoint squares, midpoint arithmetic, and tolerance splits are stored in D;*
5. *tail-modulus compatibility, requiring T to supply the visible threshold for each requested square-root precision;*
6. *monotone-tail stability, requiring M to preserve the accepted source and tolerance ledger when later windows are read;*
7. *regular readback exactness, requiring S to be obtained by replaying the displayed ledger rows R, N, W, D, B, T, M;*
8. *Real seal nonescape, requiring E to be downstream of the regular readback and not a host square-root value;*
9. *componentwise transport, displayed replay, provenance, and local naming, requiring H, C, P, A to preserve exactly the same square-root packet;*

10. *refusal of full* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, total square root on arbitrary reals, quotient real equality, selected limits, host real square-root functions, Lean verification, and bridge checking as local certificate data.*

No regular Cauchy square-root obligation is stored outside these rows.

Theorem 1756.3 (Regular Cauchy square-root Newton handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads a square-root approximation from an accepted* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *carrier must factor through the displayed route*

$$R \longmapsto N \longmapsto W \longmapsto D \longmapsto B \longmapsto T \longmapsto M \longmapsto S \longmapsto E.$$

Thus the consumer sees the nonnegative source row, finite observation windows, dyadic bisection or Newton ledger, tail modulus threshold, monotone tail stability row, regular readback, and Real seal before using the square-root output. The handoff exports no full $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, total square root on arbitrary reals, quotient real equality, selected limit, or host real square-root function.*

Falsifiable prediction: Every $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ Real-facing read factors through a nonnegative RegSeqRat source row, StreamName finite windows, a DyadicRatCore bisection or Newton ledger, RegularCauchyTailModulus threshold service, RegularCauchyTailMonotonicity stability, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regularcauchytailmodulus, regularcauchytailmonotonicity, real: $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries nonnegative-source data, finite source windows, a dyadic square-root ledger, tail threshold and monotonicity rows, regular readback, Real seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySquareRoot}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySquareRoot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1756.1, Definition 1756.2, and Definition 1756.3 seed the finite square-root packet over a nonnegative regular rational source, finite StreamName windows, DyadicRatCore bisection or Newton data, tail modulus and monotonicity rows, regular readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySquareRoot}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, total square root on arbitrary reals, quotient real equality, selected limits, host real square-root functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nonnegativity exactness, window exactness, dyadic square-root accounting, tail-modulus compatibility, monotone-tail stability, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySquareRootUp.

Constructive story: A $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ packet is generated from a nonnegative RegSeqRat source row, StreamName finite windows, a DyadicRatCore bisection or Newton ledger, RegularCauchyTailModulus threshold service, RegularCauchyTailMonotonicity stability, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1757

A Concrete Naming Certificate for $\mathsf{BoundedSet}^{\uparrow}$

Following Hausdorff–Kelley metric-space practice and Bishop–Bridges constructive analysis, the $\mathsf{BoundedSet}^{\uparrow}$ packet records bounded subset data as a finite NameCert surface rather than as an ambient host-set fact. It sits over the metric carrier of chapter 57, the algebraic and order-facing real rows of chapter 766 and chapter 38, the ball-containment ledger of chapter 1450, and the consumer routes of chapter 1503 and chapter 339. The packet exposes exactly the center, radius, subset classifier, and ball-containment evidence needed by diameter, finite-net, precompactness, and completion-facing arguments.

Definition 1757.1 (BoundedSet carrier)**.** *A* $\mathsf{BoundedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, S, c, r, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier whose distance rows are the only metric data available to the packet.*
2. *S is the bounded subset classifier row. It records accepted membership reads as finite classifier entries over X.*
3. *c is the displayed center row, or the displayed witness row naming the local center used by the boundedness certificate.*
4. *r is the* $\mathsf{Real}^{\uparrow}$ *or rational bound row read through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface.*
5. *B is the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger asserting that every accepted membership read of S is routed through the displayed ball with center c and bound r.*
6. *H records componentwise* hsame *transport for the metric carrier, subset classifier, center or witness, real or rational bound, ball-containment ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a membership request through X, S, c, r, B, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{MetricDiameter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, c, r, B, H, C, P, N$. It has no coordinate for an ambient host set, a supremum row, compactness, open-cover compactness, a selected maximum, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier semantic name certificate`

Theorem 1757.2 (BoundedSet NameCert obligations)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{Met}^{\uparrow}$ *carrier, bounded subset classifier, displayed center or witness,* $\mathsf{Real}^{\uparrow}$ *or rational bound read through* $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger, transport, replay, provenance, and local naming rows;*
2. *subset classifier stability, requiring membership reads of S to be preserved componentwise by the displayed transport row H;*
3. *ball containment, requiring each accepted membership read to pass through the* $\mathsf{MetricBall}^{\uparrow}$ *ledger B with center c and bound r;*
4. *real-bound nonescape, requiring the bound row r to be read only through the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface and not as a host supremum, selected maximum, trichotomy proof, or completeness theorem;*
5. *transport and replay stability for the same X, S, c, r, B, P, N route under* hsame *transport and* Cont *replay.*

No BoundedSet NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 1757.1. The only analytic rows are the metric carrier X, subset classifier S, displayed center or witness c, bound row r, and ball-containment ledger B.

Carrier admission is therefore rowwise. A membership request first names the metric carrier and classifier, then reads the center or witness and the bound comparison row before any containment claim is available.

Subset classifier stability and transport stability are forced by the single transport row H. Since H moves only the listed coordinates, it cannot replace the displayed classifier by a host subset or by an unrecorded predicate.

Ball containment is forced by B. The continuation row C replays membership reads through X, S, c, r, B, so a downstream consumer sees the $\mathsf{MetricBall}^{\uparrow}$ containment route before it can use boundedness.

Finally, r is a displayed $\mathsf{Real}^{\uparrow}$ or rational bound read through $\mathsf{RealAlgOrder}^{\uparrow}$. Because the carrier contains no coordinate for a supremum, selected maximum, trichotomy proof, compactness principle, open-cover argument, or ambient Real completeness, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetTasteGate single carrier alignment`

Theorem 1757.3 (BoundedSet ball-containment route)**.** *Every accepted subset membership read from a* $\mathsf{BoundedSet}^{\uparrow}$ *carrier factors through the displayed route*

$$X, S \longmapsto c, r \longmapsto B \longmapsto H, C, P, N.$$

Consequently every MetricDiameter$^{\uparrow}$ *or* UniformSpace$^{\uparrow}$ *consumer receives the* MetricBall$^{\uparrow}$ *containment ledger before it can read bounded-subset data. The route exports no host set, supremum, compactness, open-cover compactness, selected maximum, trichotomy, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Begin with an accepted membership read. By Definition 1757.1, the read is a classifier row of S over the metric carrier X and is not an ambient host-set membership fact.

The center and bound rows are opened next. The row c supplies the displayed center or witness, and r supplies the real or rational radius through the order-facing comparison surface.

The containment claim is downstream of those rows. The ledger B is the only coordinate that relates the membership read to a MetricBall$^{\uparrow}$ packet, so every boundedness read passes through B before diameter or uniform-space data can be consumed.

The structural rows preserve the same order. Componentwise transport, replay, provenance, and local naming add no coordinate for any stronger analytic principle, so the displayed factorization is the only exported route. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier ball containment route`

Theorem 1757.4 (BoundedSet real-bound nonescape)**.** *An accepted* BoundedSet$^{\uparrow}$ *carrier exports the displayed bound row r only as a* Real$^{\uparrow}$ *or rational comparison read through* RealAlgOrder$^{\uparrow}$ *and the* MetricBall$^{\uparrow}$ *containment ledger. It exports no host set, supremum, compactness, open-cover compactness, selected maximum, trichotomy, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Inspect the carrier rows. The bound coordinate r is paired with the center or witness c and the containment ledger B; it is not paired with a host-order supremum row, a selected maximal point, a cover family, or a completeness witness.

Every replay of r is governed by C. The replay starts at a membership request, opens X, S, c, r, and then reads the ball-containment ledger B before the structural rows H, P, N package the result.

Thus r is available only as part of the displayed comparison-and-containment route. Since the excluded objects have no carrier coordinate and no replay edge, they cannot escape through the bound row. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier real bound nonescape`

Theorem 1757.5 (BoundedSet obligation closure rows)**.** *For every accepted* BoundedSet$^{\uparrow}$ *carrier $Q = (X, S, c, r, B, H, C, P, N)$ of Definition 1757.1, the obligation-facing surface is exhausted by the concrete rows $X, S, c, r, B, H, C, P, N$. In particular, every* MetricDiameter$^{\uparrow}$ *or* UniformSpace$^{\uparrow}$ *consumer that reads boundedness must pass through the* MetricBall$^{\uparrow}$ *containment ledger B and the* RealAlgOrder$^{\uparrow}$ *comparison read of r before it can consume the bounded-subset claim.*

Proof. Project the carrier named in Definition 1757.1. The subset classifier is S, the displayed center or witness is c, the bound is r, and the containment evidence is B.

The only route from membership to boundedness passes through these rows. The consumer first reads X, S, c, r, then reads B as the MetricBall containment ledger, and only then reaches the replay and naming rows H, C, P, N.

Since no other analytic coordinate occurs in the carrier, diameter and uniform-space consumers cannot bypass either the ball-containment row or the real-order comparison row. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier obligation closure rows`

Theorem 1757.6 (BoundedSet MetricBall carrier obligation)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, each membership read of* S *must pass through the displayed* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B *over the same metric carrier* X*, center row* c*, and bound row* r *before it can be consumed as bounded-set data. The carrier exports no host set, subset comprehension oracle, selected maximal point, supremum row, trichotomy proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier metric ball carrier obligation`

Proof. Project the carrier of Definition 1757.1. The subset classifier S is paired with the metric carrier X, center row c, bound row r, and containment ledger B inside the same finite tuple.

Apply Definition 1757.3. It forces every accepted membership read to follow the route from X, S through c, r and then through B before the structural rows are available.

Use Definition 1757.4. The excluded host set, supremum, selected maximum, trichotomy, and ambient completeness rows have no coordinate in the packet, so the $\mathsf{MetricBall}^{\uparrow}$ ledger is the only boundedness carrier obligation. □

Theorem 1757.7 (BoundedSet RealAlgOrder radius obligation)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the radius or bound row* r *is readable only through the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface before the* $\mathsf{MetricBall}^{\uparrow}$ *containment row* B *can witness membership containment. A diameter, uniform-space, finite-net, or completion-facing consumer cannot replace* r *by a host supremum, selected maximum, trichotomy decision, compactness proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the bound row in Definition 1757.1. It is explicitly a $\mathsf{Real}^{\uparrow}$ or rational bound read through $\mathsf{RealAlgOrder}^{\uparrow}$, and it is paired with c and B rather than with a host-order extremum.

Apply Definition 1757.4. That theorem confines every replay of r to the displayed comparison-and-containment route.

Then use Definition 1757.11. Downstream consumers receive boundedness only after the $\mathsf{MetricBall}^{\uparrow}$ containment and real-order comparison rows are displayed, so no stronger analytic principle can replace the radius obligation. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier real order radius obligation`

Theorem 1757.8 (BoundedSet RealSeparability forward link)**.** *When an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *packet over a* $\mathsf{Real}^{\uparrow}$ *metric carrier is consumed by a* $\mathsf{RealSeparability}^{\uparrow}$ *route, the consumer may read only the displayed center row* c*, radius row* r*,* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B*, and countable dense witness rows from chapter 1809. The handoff cannot infer compactness, a supremum, a selected maximum, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $Q = (X, S, c, r, B, H, C, P, N)$ using Definition 1757.1. The bounded-set side exposes the metric carrier X, membership classifier S, center row c, radius row r, containment ledger B, and structural rows H, C, P, N.

Route membership through the containment ledger as in Definition 1757.6. A separability consumer therefore receives bounded membership only after the $\mathsf{MetricBall}^{\uparrow}$ row B has paired the membership classifier with the displayed center and radius rows.

Use the radius obligation Definition 1757.7. The radius remains a displayed $\mathsf{RealAlgOrder}^{\uparrow}$ comparison input, so it cannot become a host supremum, selected maximum, trichotomy decision, compactness witness, or ambient completeness theorem.

Finally pass the finite ball-cover request to the countable dense witness surface of chapter 1809. The $\mathsf{RealSeparability}^{\uparrow}$ route may consume the displayed ball data and dense rows, but the structural rows H, C, P, N preserve only that finite handoff. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier real separability forward link`

Theorem 1757.9 (BoundedSet NameCert ledger nonescape)**.** *Let $Q = (X, S, c, r, B, H, C, P, N)$ be an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier. The local* $\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}$ *ledger consumes exactly the membership classifier S,* $\mathsf{MetricBall}^{\uparrow}$ *containment row B,* $\mathsf{RealAlgOrder}^{\uparrow}$ *radius comparison row r, and structural rows H, C, P, N over the metric carrier X and center row c. No accepted ledger read can escape into host sets, suprema, selected maxima, trichotomy, compactness, finite-net existence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier namecert ledger nonescape`

Proof. Begin with Definition 1757.2. It identifies carrier admission, subset classifier stability, ball containment, real-bound nonescape, and transport-replay stability as the whole local certificate surface.

Use Definition 1757.6 for the membership side. Every accepted member of S must pass through the displayed $\mathsf{MetricBall}^{\uparrow}$ ledger B over X, c, r.

Use Definition 1757.7 for the radius side. The bound row r remains a $\mathsf{RealAlgOrder}^{\uparrow}$ comparison input and not a host extremal object or completeness theorem.

The structural rows H, C, P, N only transport, replay, source, and name this same route. Since the carrier has no coordinate for the excluded analytic objects, the NameCert ledger cannot export them. □

Theorem 1757.10 (BoundedSet subset-ball replay stability)**.** *For an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier $Q = (X, S, c, r, B, H, C, P, N)$ of Definition 1757.1, componentwise replay preserves the order*

$$X, S \longmapsto c, r \longmapsto B \longmapsto H, C, P, N.$$

Thus a transported $\mathsf{MetricDiameter}^{\uparrow}$ *or* $\mathsf{UniformSpace}^{\uparrow}$ *consumer still reads boundedness only after the subset membership row has passed through* $\mathsf{MetricBall}^{\uparrow}$ *containment and the bound row has passed through* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier subset ball replay stability`

Proof. The transport row H is componentwise, so it can move the metric carrier, subset classifier, center or witness, bound, containment ledger, replay, provenance, and local name only along their displayed coordinates.

The continuation row C replays the same dependency order. A transported membership request starts at X, S, opens c, r, reads B, and then packages the result through H, P, N.

Therefore replay stability does not create a new boundedness route. The consumer boundary remains the MetricBall containment and RealAlgOrder comparison route recorded in the carrier. □

Theorem 1757.11 (BoundedSet diameter consumer boundary)**.** *Every* $\mathsf{MetricDiameter}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier $Q = (X, S, c, r, B, H, C, P, N)$ from Definition 1757.1 receives only the finite rows $X, S, c, r, B, H, C, P, N$. Its diameter read must factor through* $\mathsf{MetricBall}^{\uparrow}$ *containment for S around c and through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface for r before any boundedness datum is available. The same boundary applies to* $\mathsf{UniformSpace}^{\uparrow}$ *consumers that use boundedness as a uniform-control input.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier diameter consumer boundary`

Proof. Start with the diameter-facing read. The carrier offers the metric row X and the classifier row S, but neither row by itself contains a diameter bound.

The center and bound rows supply the displayed comparison data. The row c names the center or witness, while r is available only through the order-facing comparison surface.

The containment ledger B is then required before the consumer can treat membership as bounded. The remaining rows H, C, P, N transport, replay, package, and name the same finite route, so no supremum, selected maximum, compactness theorem, or ambient completeness row can be read by a diameter or uniform-space consumer. □

Theorem 1757.12 (BoundedSet ball-radius ledger factorization)**.** *Every boundedness read from an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier*

$$Q = (X, S, c, r, B, H, C, P, N)$$

factors through the displayed ball-radius ledger

$$S \longmapsto c, r \longmapsto B \longmapsto H, C, P, N.$$

Here r is read only through the $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface, and B is read only as the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger. Thus no finite-net, diameter, or uniform-space consumer can use a bounded-subset claim before receiving the displayed center, radius, ball-containment, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier ball radius ledger factorization`

Proof. Project the carrier of Definition 1757.1. The subset classifier is S, the displayed center or witness is c, the radius row is r, and the containment ledger is B.

Apply Definition 1757.2. It places carrier admission, subset classifier stability, ball containment, real-bound nonescape, transport, replay, provenance, and local naming in the same finite obligation surface.

Now use Definition 1757.11. A consumer can treat the subset as bounded only after the $\mathsf{MetricBall}^{\uparrow}$ containment row and the $\mathsf{RealAlgOrder}^{\uparrow}$ comparison read have been displayed. The structural rows H, C, P, N preserve that order, so the factorization is exactly the route shown above. □

Theorem 1757.13 (BoundedSet radius ledger)**.** *Every accepted bounded-set read from a* $\mathsf{BoundedSet}^{\uparrow}$ *carrier $Q = (X, S, c, r, B, H, C, P, N)$ exposes a finite radius ledger over the displayed* $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, *and metric rows before boundedness is exported. The ledger consists of the metric carrier X, subset classifier S, center or witness row c, radius row r, and* $\mathsf{MetricBall}^{\uparrow}$ *containment row B, with transport, replay, provenance, and naming through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier radius ledger`

Proof. Project the carrier of Definition 1757.1. The radius coordinate is r, and it is paired with the metric row X, subset classifier S, center or witness row c, and containment ledger B.

Apply Definition 1757.2 and Definition 1757.4. They force every radius read through the displayed Real or rational comparison surface and exclude suprema, selected maxima, trichotomy, compactness, and ambient completeness.

Use Definition 1757.12. The resulting ledger is finite and rowwise: S leads to c, r, then to B, and finally to H, C, P, N before any boundedness datum is exported. □

Theorem 1757.14 (BoundedSet MetricBall handoff)**.** *Every membership or boundedness consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$ *must pass through the* $\mathsf{MetricBall}^{\uparrow}$ *row* B *and the* $\mathsf{MetricDiameter}^{\uparrow}$ *consumer boundary before a bound is exported. The handoff names the finite ball-radius route over* $X, S, c, r, B, H, C, P, N$ *and not a host set, selected center family, supremum, compactness theorem, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier metric ball handoff`

Proof. Start with Definition 1757.3. It sends every accepted membership read through X, S, then c, r, and then the $\mathsf{MetricBall}^{\uparrow}$ containment ledger B.

Apply Definition 1757.11 and Definition 1757.16. These theorems require a diameter-facing consumer to read the same displayed ball and radius rows before any $\mathsf{MetricDiameter}^{\uparrow}$ bound is public.

Finally use Definition 1757.20. The envelope contains only the metric, classifier, center, radius, ball, and structural rows, so the handoff cannot export the excluded host-level objects. □

Theorem 1757.15 (BoundedSet uniform-space boundary)**.** *Every* $\mathsf{UniformSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier receives only the displayed finite bound and entourage or metric rows routed through* $X, S, c, r, B, H, C, P, N$*. The carrier does not provide total boundedness, compactness, selected centers, open-cover data, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier uniform space boundary`

Proof. Project the carrier and read Definition 1757.2. The available analytic coordinates are X, S, c, r, B, while H, C, P, N only transport, replay, source, and name those rows.

Use Definition 1757.3 and Definition 1757.11. A uniform-space consumer receives boundedness only after the membership row has passed through $\mathsf{MetricBall}^{\uparrow}$ containment and the bound row has passed through the displayed Real or rational comparison surface.

Apply Definition 1757.17. Finite nets, compactness, selected centers, and completeness are downstream obligations not stored in the bounded-set packet, so the uniform-space boundary stops at the displayed finite rows. □

Theorem 1757.16 (BoundedSet diameter consumer handoff)**.** *Every diameter-facing consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$ *must receive the rows* $X, S, c, r, B, H, C, P, N$ *before it can read bounded-subset data. In particular, the consumer must pass through the* $\mathsf{Met}^{\uparrow}$ *carrier* X*, the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B*, and the* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison row* r *before any* $\mathsf{MetricDiameter}^{\uparrow}$ *bound is public.*

The handoff exports no supremum, selected maximum, compactness theorem, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier diameter consumer handoff`

Proof. Project the carrier of Definition 1757.1. The only subset data is S, and the only bounding data is the displayed center or witness c, bound row r, and containment ledger B.

Apply Definition 1757.3. It places every membership read behind the route from X, S through c, r and then through B.

Apply Definition 1757.4. The bound row is read only through the displayed Real or rational comparison surface, so a diameter consumer cannot replace it by a supremum or selected maximum.

The rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since compactness, trichotomy, and ambient Real completeness have no carrier coordinate, the handoff stops at the displayed bounded-set rows. □

Theorem 1757.17 (BoundedSet finite-net consumer boundary)**.** *Every finite-net or precompactness consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$ *must read boundedness through* $X, S, c, r, B, H, C, P, N$*, with* X *supplying the* $\mathsf{Met}^{\uparrow}$ *carrier,* B *supplying the* $\mathsf{MetricBall}^{\uparrow}$ *boundary, and* r *supplying the* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison data. The consumer receives a bounded-subset boundary for later finite-net construction; it does not receive compactness, an open-cover subcover, a selected finite net, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier finite net consumer boundary`

Proof. Start from a finite-net request. The carrier does not contain a finite-net row, so the request can only consume boundedness through the subset classifier S and the displayed ball data c, r, B.

Use Definition 1757.3. It requires each accepted member of S to pass through the $\mathsf{MetricBall}^{\uparrow}$ ledger before bounded-subset data is available.

Use Definition 1757.4. It keeps the radius row within the Real or rational comparison route and refuses selected maxima, suprema, and trichotomy.

The structural rows H, C, P, N export only this bounded boundary. Since a finite net, compactness theorem, open-cover subcover, and ambient completeness principle are absent from Q, the consumer must obtain those obligations elsewhere. □

Theorem 1757.18 (BoundedSet total-bounded consumer boundary)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$ *must receive, in addition to* Q*, a separate finite-net or located-net row. The bounded-set packet contributes the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger, the* $\mathsf{MetricDiameter}^{\uparrow}$ *radius or diameter boundary, and the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison read for* r*; it does not contribute the finite cover, center family, located membership rows, compactness theorem, open-cover subcover, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness required by total boundedness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier totally bounded consumer`

Proof. Project the bounded-set carrier. Its analytic rows are the metric source X, membership classifier S, center or witness c, radius row r, and ball-containment ledger B.

Use chapter 1450, chapter 1503, and chapter 766 to read those rows as a radius or diameter ledger: membership passes through $\mathsf{MetricBall}^{\uparrow}$, while the bound is read through $\mathsf{RealAlgOrder}^{\uparrow}$ before any downstream consumer sees it.

Now compare with chapter 127. A total-boundedness consumer needs finite centers and coverage witnesses for each displayed tolerance, or a located-net row that supplies the same finite coverage data. No such row occurs among $X, S, c, r, B, H, C, P, N$.

The structural rows H, C, P, N preserve the bounded route, but they cannot synthesize finite cover data. Therefore a $\mathsf{TotallyBounded}^{\uparrow}$ consumer may use the bounded packet only after an independent finite-net or located-net row is supplied, and it receives no compactness or finite-net existence from boundedness alone. □

Theorem 1757.19 (BoundedSet completion nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$ *must pass through* $X, S, c, r, B, H, C, P, N$*, the* $\mathsf{Met}^{\uparrow}$ *carrier, the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger, and the* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison row before it can use bounded-subset data. The carrier supplies a boundedness boundary for completion arguments, not a completed subset, not a selected completion point, not compactness, not trichotomy, and not ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the bounded-set carrier. Its analytic rows are the metric carrier X, subset classifier S, displayed center or witness c, comparison row r, and containment ledger B.

Apply Definition 1757.3. A completion-facing consumer must see membership routed through the displayed ball before it may consume boundedness.

Apply Definition 1757.4. The comparison row remains a Real or rational bound read through $\mathsf{RealAlgOrder}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$, not a completeness assertion.

Finally transport and replay through H, C, P, N. Since the carrier has no completed-subset row, selected completion point, compactness proof, trichotomy row, or ambient Real-completeness theorem, boundedness cannot escape into those stronger completion claims. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier completion nonescape`

Theorem 1757.20 (BoundedSet closure obligation envelope)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the bounded-set obligation envelope is exactly the displayed* $\mathsf{Met}^{\uparrow}$ *carrier row* X*, subset classifier row* S*, center or witness row* c*, radius row* r *read through* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B*, and the* $\mathsf{MetricDiameter}^{\uparrow}$ *and* $\mathsf{UniformSpace}^{\uparrow}$ *consumer boundaries routed through those same rows. The structural rows* H, C, P, N *transport, replay, source, and name this envelope; they do not add compactness, a selected finite net, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1757.1. The analytic data are precisely X, S, c, r, B, while H, C, P, N are structural rows for transport, replay, provenance, and local naming.

Use Definition 1757.3 and Definition 1757.4. They force each membership and bound read through the $\mathsf{MetricBall}^{\uparrow}$ ledger and the $\mathsf{RealAlgOrder}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ comparison surface before any consumer can use boundedness.

Finally apply Definition 1757.16 and Definition 1757.19. Diameter, uniform, and completion-facing consumers receive only that displayed envelope, so the stronger compactness and completeness claims remain outside the packet. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier closure obligation envelope`

Theorem 1757.21 (BoundedSet radius classifier stability)**.** *If an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier transports its radius data to a consumer, the transported radius classifier is stable exactly along the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison row* r *and the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B*. No consumer may replace this transport by a selected maximum, supremum, host-order comparison, trichotomy decision, or ambient completeness argument.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier radius classifier stability`

Proof. Start with the radius row in Definition 1757.1. The carrier pairs r with the displayed center or witness c and containment ledger B, not with a host extremum or selected maximum.

Apply Definition 1757.4. It confines every read of r to the Real or rational comparison route and excludes suprema, selected maxima, trichotomy, and ambient completeness.

Use Definition 1757.3. The comparison row becomes a bounded-set classifier only through the metric-ball ledger B, and componentwise transport through H can replay only that same classifier. □

Theorem 1757.22 (BoundedSet located diameter readback)**.** *Every located-diameter consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier must read diameter control through the displayed ledger*

$$X, S, c, r, B \longmapsto H, C, P, N.$$

In particular, the consumer may use the located ball and radius rows as bounded-diameter input for $\mathsf{MetricDiameter}^{\uparrow}$ *or* $\mathsf{UniformSpace}^{\uparrow}$*, but it cannot infer a selected diameter, a least upper bound, compactness, finite-net existence, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier located diameter readback`

Proof. Begin with Definition 1757.16. A diameter consumer receives boundedness only through the metric carrier, subset classifier, center or witness, bound, containment ledger, and structural rows.

Use Definition 1757.20. It identifies the same rows as the full obligation envelope for metric, ball, diameter, real-order, and uniform consumers.

Finally apply Definition 1757.21. The located ball and radius data remain classifier reads through r and B, so selected diameters, suprema, compactness, finite nets, trichotomy, and ambient completeness have no carrier coordinate. □

Theorem 1757.23 (BoundedSet MetricBall containment dependency)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the* $\mathsf{MetricBall}^{\uparrow}$ *containment dependency is an explicit L10 row: each accepted membership read of* S *must pass through the displayed carrier coordinates* X, c, r*, the radius row* r*, and the subset-ball replay ledger* B, H, C, P, N *before any boundedness claim is exported. Thus the packet supplies a dependency row for* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{MetricDiameter}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*, and* $\mathsf{UniformSpace}^{\uparrow}$ *consumers, not a host-set containment fact.*

Proof. Project the displayed carrier of Definition 1757.1. The only rows available to a membership read are the metric carrier X, classifier S, center or witness c, radius row r, containment ledger B, and structural rows H, C, P, N.

Apply Definition 1757.3 and Definition 1757.6. These force every accepted member of S through the same $\mathsf{MetricBall}^{\uparrow}$ containment route before the read can be consumed as bounded-set data.

Use Definition 1757.13 and Definition 1757.10. The radius row and replay row preserve the order from X, S through c, r, B and then through H, C, P, N.

Finally invoke Definition 1757.22. Located diameter and uniform-space consumers receive only that displayed ledger, so the containment dependency is an L10 row rather than an ambient host predicate. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier metric ball containment dependency`

Theorem 1757.24 (BoundedSet Real radius ledger dependency)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the radius read* r *is ledger-controlled: it is read through the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *comparison surface and the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger before boundedness reaches a consumer. No consumer may replace* r *by host real order, a selected supremum, trichotomy, compactness, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier real radius ledger`

Proof. Start with the radius coordinate in Definition 1757.1. The row r is paired with the displayed center or witness c and with the ball-containment ledger B, not with a host-order extremum.

Apply Definition 1757.7. It requires the radius or bound row to be read through the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ comparison surface before containment is available.

Use Definition 1757.13 and Definition 1757.21. They keep the radius classifier on the finite ledger $X, S, c, r, B, H, C, P, N$ and prevent replacement by a selected maximum, supremum, host-order comparison, trichotomy decision, or ambient completeness argument.

Finally apply Definition 1757.22. A located-diameter or uniform-space consumer may use the ledger as bounded-diameter input, but it cannot read any stronger real-order object from the packet. □

Theorem 1757.25 (BoundedSet real-clamping stability)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, a bounded-set radius read clamped to a located interval must pass through the displayed* $\mathsf{RealClamping}^{\uparrow}$ *clamp row, the* $\mathsf{LocatedUpperBound}^{\uparrow}$ *upper-bound witness, the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger* B*, and the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison surface before boundedness reaches finite-net, precompactness, diameter, or completion consumers. The resulting route is a finite bounded-radius handoff through* $X, S, c, r, B, H, C, P, N$*, not a selected supremum, host interval order, compactness assertion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier real clamping stability`

Proof. Start with the radius coordinate of Definition 1757.1. The row r is readable only together with X, S, c and the ball-containment ledger B.

Apply Definition 1757.24. It places every radius read behind the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ comparison surface and the $\mathsf{MetricBall}^{\uparrow}$ containment route before boundedness is public.

The clamped interval read is therefore an additional consumer of that same radius ledger. It may pass through $\mathsf{RealClamping}^{\uparrow}$ and $\mathsf{LocatedUpperBound}^{\uparrow}$ to present a located bounded interval, but those rows consume the already displayed comparison and ball-containment data rather than replacing them.

Finally use Definition 1757.17 and Definition 1757.19. Finite-net, precompactness, diameter, and completion consumers receive only the routed bounded-radius handoff, so selected suprema, host interval order, compactness, and ambient completeness remain outside the packet. □

Theorem 1757.26 (BoundedSet obligation carrier admission)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *packet* $Q = (X, S, c, r, B, H, C, P, N)$*, obligation-level carrier admission is rowwise over the displayed metric carrier* X*, subset classifier* S*, center or witness* c*, real or rational bound row* r*, ball-containment ledger* B*, componentwise transport* H*, replay row* C*, package provenance* P*, and local name* N*. No obligation consumer may admit the packet from an ambient host subset, a hidden supremum, a selected finite net, compactness, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1757.1. The displayed rows $X, S, c, r, B, H, C, P, N$ are the whole packet, so carrier admission is obtained by checking those coordinates and no external host-set predicate.

Use Definition 1757.2. Its carrier-admission clause already lists the metric, classifier, center or witness, bound, containment, transport, replay, provenance, and local naming rows as the local $\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}$ surface.

Finally apply Definition 1757.20. The envelope sends diameter, uniform, and completion-facing consumers through the same rows. Since compactness, finite-net selection, trichotomy, suprema, and ambient Real completeness do not occur in the carrier, they cannot be added at the obligation-admission boundary. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier obligation carrier admission`

Theorem 1757.27 (BoundedSet obligation classifier transport)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, subset-classifier transport at obligation level is exactly the componentwise* hsame *movement of* S *along the same* X, c, r, B *rows. A transported membership*

read remains a bounded-subset read only when it replays through H and C to the displayed ball-containment ledger; it cannot be replaced by an unrecorded host predicate, a new radius classifier, a selected maximum, or a completion-side subset equality.

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier obligation classifier transport`

Proof. Start with the subset classifier row S in Definition 1757.1. The row classifies accepted membership reads over the displayed metric carrier X, not over an ambient host set.

Apply Definition 1757.3. Any membership read must pass from X, S to c, r and then to the ledger B before the structural rows are used.

Use Definition 1757.21. It fixes the radius classifier along the comparison row r and containment ledger B. Therefore H and C may transport and replay only the same classifier route, and no selected maximum, replacement predicate, or completion equality can enter the transported obligation. □

Theorem 1757.28 (BoundedSet obligation ledger nonescape)**.** *For every accepted* $\mathsf{BoundedSet}^{\uparrow}$ *carrier* $Q = (X, S, c, r, B, H, C, P, N)$*, the obligation ledger for ball containment and real bounds is the finite route*

$$X, S, c, r, B \longmapsto H, C, P, N.$$

The row B records containment in the displayed metric ball and the row r records the real or rational bound through $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*; together they supply boundedness to* $\mathsf{MetricDiameter}^{\uparrow}$*, finite-net, precompactness, and completion-facing consumers without exporting least bounds, compactness, open-cover compactness, trichotomy, quotient equality, or host Real completeness.*

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier obligation ledger`

Proof. First read the containment side. By Definition 1757.3, membership data must pass through X, S, c, r, B before boundedness is available to a consumer.

Next read the bound side. The real-bound nonescape theorem confines r to the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ comparison route and prevents a supremum, selected maximum, trichotomy proof, or completeness theorem from being inferred.

Finally combine the consumer handoff theorems. The diameter handoff, completion nonescape, closure-obligation envelope, and located-diameter readback all reuse the same H, C, P, N structural rows. Thus metric diameter, finite-net, precompactness, and completion consumers receive the ball-containment and bound ledger only as finite boundedness evidence, not as stronger compactness or completeness data. □

Theorem 1757.29 (BoundedSet obligation consumer package)**.** *Every finite-net, precompactness,* $\mathsf{MetricDiameter}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *packet* $Q = (X, S, c, r, B, H, C, P, N)$ *receives boundedness only through the displayed carrier route*

$$X, S, c, r, B \longmapsto H, C, P, N.$$

The consumer may project metric membership, the subset classifier, the center or witness, the bound row, and the ball-containment ledger, and may then replay the same rows through componentwise transport, continuation, provenance, and local naming. It cannot replace the route by host-set boundedness, hidden compactness, a finite-net selection, a supremum, trichotomy, quotient equality, or ambient completion data.

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier obligation consumer package`

Proof. Start with carrier admission, Definition 1757.26. It admits the packet only from $X, S, c, r, B, H, C, P, N$, so a downstream consumer has no independent host-set boundedness coordinate to inspect.

Next use classifier transport, Definition 1757.27. Membership and subset movement remain tied to S over the same X, c, r, B rows and are replayed only through H and C.

Finally apply ledger nonescape, Definition 1757.28. The boundedness evidence delivered to finite-net, precompactness, diameter, uniform-space, and completion-facing consumers is exactly the displayed ball-containment and real-bound ledger followed by H, C, P, N. Since the packet contains no compactness, supremum, trichotomy, quotient, or completion coordinate, no consumer can obtain one from the obligation package. □

Theorem 1757.30 (BoundedSet metric-bornology consumer)**.** *Let $Q = (X, S, c, r, B, H, C, P, N)$ be an accepted* $\mathsf{BoundedSet}^{\uparrow}$ *packet. Every ?? consumer of Q reads exactly the route*

$$X, S, c, r, B \longmapsto H, C, P, N$$

before hereditary or finite-union bornology rows can consume the bounded-set data. The radius row r is read through $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$*, the containment row B is read through the* $\mathsf{MetricBall}^{\uparrow}$ *center-radius ledger, and the downstream metric-bornology packet is the bounded-family surface of chapter 4091.*

Consequently the consumer receives metric carrier data, subset-classifier data, a displayed center or witness, a real or rational radius comparison, ball containment, transport, replay, provenance, and local naming, but no host set, supremum, selected maximum, compactness proof, open-cover compactness, trichotomy, quotient equality, or ambient completion datum.

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier metric bornology consumer`

Proof. Project the bounded-set carrier of Definition 1757.1. Its analytic rows are exactly X, S, c, r, B, and its support rows are H, C, P, N.

Use Definition 1757.3. It forces every membership read through the center-radius path before boundedness reaches any downstream consumer. The radius component is the same $\mathsf{Real}^{\uparrow}$ or rational comparison read through $\mathsf{RealAlgOrder}^{\uparrow}$, and the containment component is the same $\mathsf{MetricBall}^{\uparrow}$ ledger.

Finally apply the metric-bornology surface of chapter 4091. Hereditary and finite-union bornology rows may consume bounded-set data only after the displayed route has been opened, so the consumer obtains exactly the finite bounded-family handoff and none of the excluded host principles. □

Theorem 1757.31 (BoundedSet standard-interface bridge)**.** *The public bounded-set consumer package over* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *??*, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *is exactly the bridge input for the bounded-set standard interface. An accepted carrier*

$$Q = (X, S, c, r, B, H, C, P, N)$$

exports metric carrier data, subset classification, a displayed center or witness, a real or rational bound, ball containment, metric-bornology handoff, transport, replay, provenance, and local naming. It exports no compactness proof, supremum, trichotomy, quotient equality, or completion coordinate.

Proof. Start with Definition 1757.29. It identifies the public consumer route as the displayed carrier path $X, S, c, r, B \longmapsto H, C, P, N$ and excludes hidden host-set boundedness.

Apply Definition 1757.30. This places the public route against the **??** consumer surface while preserving the $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows used by the carrier.

Finally use Definition 1757.28. The ledger supplies only ball containment and real-bound data followed by transport, replay, provenance, and naming. These rows are precisely the standard-interface bridge input, and no excluded compactness, supremum, trichotomy, quotient, or completion coordinate is present. □

Lean4 ✓ `BEDC.Derived.BoundedSetUp.BoundedSetCarrier standard interface bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1757.1, Definition 1757.2, Definition 1757.3, Definition 1757.4, Definition 1757.11, Definition 1757.15, Definition 1757.30, and Definition 1757.31 bind the mature public consumer surface and standard-interface bridge over $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, **??**, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Not claimed: This chapter does not close compactness, Heine–Borel, open-cover compactness, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Mature closure requires worked examples and completeness-facing cross-chapter treatment for the bounded-set interface.

Constructive story: A $\mathsf{BoundedSet}^{\uparrow}$ packet is generated from a MetricUp carrier, a bounded subset classifier row, a displayed center or witness, a RealUp or rational bound read through RealAlgOrderUp, a MetricBallUp containment ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1758

A Concrete Naming Certificate for $\mathsf{CauchyNullDifference}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyNullDifference}^{\uparrow}$ packet records the finite route by which two regular Cauchy rational names expose equality of their $\mathsf{Real}^{\uparrow}$ endpoints: first form the displayed regular-Cauchy difference, then certify that displayed difference as a $\mathsf{NullSequence}^{\uparrow}$, and only then allow the terminal real-name equality seal to be read. It sits between the regular rational source rows of chapter 301, the pointwise difference route of chapter 429, the zero-tail classifier of chapter 380, the finite stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, and the endpoint surface of chapter 38.

Definition 1758.1 (Cauchy null-difference carrier)**.** *A* $\mathsf{CauchyNullDifference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (X, Y, D, Z, W, T, E, H, K, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are compared.*
2. *D is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row displaying the aligned pointwise difference stream $X - Y$.*
3. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-shrinkage row that consumes the displayed difference stream.*
4. *W stores the finite* $\mathsf{StreamName}^{\uparrow}$ *windows used by the source rows, the difference row, and the null-sequence consumer.*
5. *T stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance requests, slack rows, and comparison budgets used by D and Z.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *equality-seal row, readable only after the displayed difference has passed through Z.*
7. *H records componentwise* hsame *transport for source rows, difference rows, null-sequence rows, windows, tolerance ledgers, the equality seal, continuation, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from the two source rows through D, then through Z, and finally into the seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyNullDifference}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNullDifference}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, D, Z, W, T, E, H, K, P, N$. It has no coordinate for quotient stream equality, host equality of reals, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyNullDifferenceUp.CauchyNullDifferenceTasteGate single carrier alignment`

Theorem 1758.2 (Cauchy null-difference NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNullDifference}^{\uparrow}$ *carrier* $C = (X, Y, D, Z, W, T, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyNullDifference}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *displayed difference row, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-shrinkage row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal, transport, continuation, provenance, and local naming rows;*
2. *source stability, requiring accepted comparisons to preserve the two regular Cauchy source rows componentwise;*
3. *difference handoff exactness, requiring D to be the displayed pointwise difference route generated from X and Y through the finite windows W;*
4. *null-sequence consumption, requiring Z to consume precisely the displayed difference row D with the tolerance ledger T before any equality seal is read;*
5. *real-seal nonescape, requiring E to read only the null-difference route $X, Y, D, Z, W, T, H, K, P, N$ and never a quotient stream equality, host real equality, selected limit, countable-choice schedule, trichotomy principle, ambient completeness theorem, or bridge certificate.*

No Cauchy null-difference obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1758.1. The accepted packet displays exactly the two source rows, the difference row, the null-sequence row, windows, tolerance ledger, equality seal, transport, continuation, provenance, and local naming rows.

The source and difference clauses are then forced by the order of the displayed route. The two $\mathsf{RegSeqRat}^{\uparrow}$ rows X, Y are read first; the $\mathsf{RegularCauchyDifference}^{\uparrow}$ row D is the only coordinate that can display their pointwise difference; and the windows W are the finite observations shared by the source and difference reads.

The null-sequence clause is the next step. The row Z consumes D together with the dyadic tolerance ledger T, so the zero-shrinkage evidence is visible before the endpoint row E is inspected.

Finally inspect the carrier inventory. Since quotient stream equality, host equality of reals, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, and bridge data are not coordinates of C, none can become local NameCert obligations. □

Theorem 1758.3 (Cauchy null-difference Real seal boundary)**.** *Let* $C = (X, Y, D, Z, W, T, E, H, K, P, N)$ *be an accepted* $\mathsf{CauchyNullDifference}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *equality-facing consumer of the two regular Cauchy source rows must first read the finite route*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow E$$

as replayed by W, T, H, K, P, N. Thus the endpoint seal is exposed only after the regular-Cauchy difference has been displayed and certified as a null sequence; it is not a quotient equality of streams, a host equality proof, a selected limit, a countable-choice construction, a trichotomy comparison, or an ambient completeness assertion.

Proof. Start with an equality-facing consumer. By Definition 1758.2, the consumer can read the source data only through the accepted carrier C.

The RegularCauchyDifference handoff is the first major step. The rows X, Y provide the regular rational observations, while D displays their aligned difference through the finite windows W and the dyadic tolerance ledger T.

The NullSequence classifier is then consumed before the endpoint is available. The row Z reads the same displayed difference route, and the transport and continuation rows H, K preserve that route under componentwise comparison and replay.

Only after this null-difference package has been displayed may the consumer reach E. The provenance and local naming rows P, N record the same finite route and add no analytic coordinate.

The non-escape statement follows from the carrier inventory. No quotient stream equality, host equality proof, selected limit, countable-choice row, trichotomy comparison, or ambient completeness theorem is present, so the $\mathsf{Real}^{\uparrow}$ equality seal is exactly the stated finite boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNullDifference}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNullDifference}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1758.1, Definition 1758.2, and Definition 1758.3 seed the finite route from two regular Cauchy source rows through displayed difference, NullSequence zero-shrinkage, StreamName windows, DyadicRatCore tolerance rows, and a terminal Real equality seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNullDifference}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host equality of reals, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source stability, difference handoff exactness, NullSequence consumption, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.CauchyNullDifferenceUp.

Constructive story: A $\mathsf{CauchyNullDifference}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one RegularCauchyDifference route, one NullSequence zero-shrinkage row, finite StreamName windows, DyadicRatCore tolerances, a terminal Real equality-seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1759

A Concrete Naming Certificate for $\mathsf{FareySequence}^{\uparrow}$

Following Hardy–Wright's standard treatment of Farey sequences and the Stern–Brocot rational tree, the $\mathsf{FareySequence}^{\uparrow}$ packet records finite ordered rational boundary sequences whose adjacent rows are determinant-one neighbors. It sits between the tree-facing $\mathsf{SternBrocot}^{\uparrow}$ ledger of chapter 1704, the rational sources $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ of chapter 37 and chapter 291, the finite observation route $\mathsf{StreamName}^{\uparrow}$ of chapter 126, the regular readback $\mathsf{RegSeqRat}^{\uparrow}$ of chapter 301, the approximation window $\mathsf{RealRationalApproximation}^{\uparrow}$ of chapter 1668, and the terminal real-name seal $\mathsf{Real}^{\uparrow}$ of chapter 38; the packet stores only finite rational rows, denominator bounds, dyadic tolerances, adjacency ledgers, stream windows, approximation handoffs, transport, replay, provenance, and naming.

Definition 1759.1 (Farey sequence carrier)**.** *A* $\mathsf{FareySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite ordered boundary row, listing rational endpoints as displayed* $\mathsf{Rat}^{\uparrow}$ *rows.*
2. *A is the adjacent determinant-one ledger, recording that each consecutive pair of boundary rows is a Farey-neighbor pair.*
3. *M is the mediant and refinement row, recording the displayed numerator-denominator sum inserted between adjacent boundary rows when a refinement step is requested.*
4. *L is the denominator-bound row, recording the finite Farey level or displayed denominator cap that bounds every rational row inspected by the packet.*
5. *T is the dyadic tolerance row, read by* $\mathsf{DyadicRatCore}^{\uparrow}$ *when a downstream approximation request asks for a finite error budget.*
6. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *handoff row, sending each adjacent-pair inspection to the finite tree address and Farey-neighbor ledger used by the Stern–Brocot packet.*
7. *D is the rational-density and approximation handoff row, exposing the finite sequence as a rational bracket source for L10 approximation routes.*
8. *Q is the sibling rational-source row read by* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, *and* $\mathsf{ContinuedFraction}^{\uparrow}$ *consumers when those consumers are present in the surrounding route.*

9. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which sequence entries are requested and replayed.*
10. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same ordered boundary and refinement data.*
11. *G is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff row, packaging the displayed rational bracket, denominator bound, dyadic tolerance, stream window, and regular rational readback for real-facing consumers.*
12. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the rational-source, stream-window, and regular-rational rows have been displayed.*
13. *H records componentwise* hsame *transport for boundary sequence, adjacency ledger, mediant row, denominator bound, dyadic tolerance, Stern–Brocot handoff, density handoff, rational-source row, stream window, regular-rational readback, RealRationalApproximation handoff, real seal, replay, provenance, and local naming rows.*
14. *C records displayed* Cont *replay from a finite observation request through boundary inspection, determinant-one adjacency checking, mediant refinement, denominator-bound inspection, dyadic tolerance readback, Stern–Brocot handoff, rational-source handoff, stream-window readback, regular-rational readback, RealRationalApproximation handoff, and the real seal.*
15. *P is the* Pkg *provenance over* $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
16. *N is the local* $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$. The carrier has no coordinate for host real order, quotient real equality, selected best approximants, trichotomy, countable choice, ambient completeness, or a completed real representative.

Lean4 ✓ `BEDC.Derived.FareySequenceUp.TasteGate.FareySequenceTasteGate single carrier alignment`

Theorem 1759.2 (Farey sequence NameCert obligations)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the ordered boundary sequence, adjacent determinant-one ledger, mediant refinement row, denominator-bound row, dyadic tolerance row, Stern–Brocot handoff, density handoff, rational-source row, stream-window row, regular-rational readback, RealRationalApproximation handoff, real seal, transport, replay, provenance, and naming rows;*
2. *adjacency stability, requiring A to record determinant-one adjacency for every consecutive pair before and after each displayed refinement step;*
3. *monotone finite sequence order, requiring the displayed row B to keep the finite boundary sequence in the same rational order after a mediant row is inserted;*
4. *finite level control, requiring L and T to record the displayed denominator cap and dyadic tolerance consumed by the approximation route;*
5. *mediant handoff, requiring M and S to send each refinement to the corresponding* $\mathsf{SternBrocot}^{\uparrow}$ *finite tree address and Farey-neighbor ledger;*

6. *approximation handoff, requiring G to expose the bracket, denominator-bound, dyadic-tolerance, stream-window, and regular-rational rows to* $\mathsf{RealRationalApproximation}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read;*
7. *ledger non-escape, requiring every* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer to read through Q, W, R, G, E rather than through a host real order, quotient real equality, selected best approximant, trichotomy, countable choice, or ambient completeness field.*

No Farey-sequence obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceNameCertObligations`

Proof. Carrier admission is projection from Definition 1759.1. The accepted tuple exposes exactly the ordered boundary sequence, adjacency ledger, mediant refinement, denominator-bound, dyadic-tolerance, Stern–Brocot handoff, density handoff, rational-source, stream-window, regular-rational, RealRationalApproximation, real-seal, transport, replay, provenance, and local naming rows listed in the statement.

Adjacency stability is local to A. Each consecutive pair of rows in B has its determinant-one check recorded before it can be used as a Farey-neighbor pair, and each refinement inserts only the mediant row M between the inspected adjacent pair.

The order and level obligations are finite. The sequence row B names the displayed left-to-right rational boundary order, the mediant row is inserted between the two rows that generated it, and L, T record the denominator cap and dyadic tolerance without invoking a host trichotomy or quotient-real comparison.

The handoff obligation is read from S. It translates the same adjacent-pair inspection to the $\mathsf{SternBrocot}^{\uparrow}$ address and Farey-neighbor ledger, while D and Q expose the resulting finite rational data to approximation consumers.

Finally, W, R, G, E, H, C, P, N keep the real-facing route downstream of finite rational rows. Since the carrier has no coordinate for host real order, quotient real equality, selected best approximants, trichotomy, countable choice, ambient completeness, or completed representatives, the listed rows exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier namecert obligations`

Theorem 1759.3 (Farey sequence Stern–Brocot adjacency obligations)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each determinant-one adjacency read from A is routed through the $\mathsf{SternBrocot}^{\uparrow}$ *row S before any mediant refinement row M, approximation handoff row G, or terminal* $\mathsf{Real}^{\uparrow}$ *seal E can be consumed. The route is preserved by the NameCert obligations of Definition 1759.2, the approximation-window factorization of Definition 1759.6, and the mediant refinement stability of Definition 1759.9.*

Proof. Project the accepted carrier. The adjacent determinant-one ledger is A, and the only tree-facing handoff coordinate attached to that ledger is S.

Apply the local NameCert obligations of Definition 1759.2. They require each adjacent-pair inspection to be recorded in A and then sent through the $\mathsf{SternBrocot}^{\uparrow}$ handoff before the packet treats the pair as a Farey-neighbor route.

Next apply approximation-window factorization. The rows G and E are downstream of the finite ordered boundary, adjacency ledger, mediant row, denominator and tolerance rows, Stern–Brocot handoff, stream window, and regular readback rows, so an approximation consumer cannot inspect G or E before the A, S route is visible.

Finally apply mediant refinement stability. The inserted mediant is read only between the two boundary rows already inspected by A, and the same finite tree address is carried by S. Thus every mediant or real-approximation read remains behind the determinant-one Stern–Brocot adjacency obligation, with no host order, selected best approximant, quotient-real equality, trichotomy, choice, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier stern brocot adjacency obligations`

Theorem 1759.4 (Farey sequence carrier admission)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

carrier admission exposes exactly the finite ordered boundary row B, adjacent determinant-one ledger A, mediant refinement row M, denominator-bound row L, dyadic tolerance row T, Stern–Brocot handoff S, density handoff D, rational-source row Q, stream window W, regular rational readback R, RealRationalApproximation handoff G, terminal $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance P, and local naming row N.*

Proof. Project the accepted tuple through Definition 1759.1. The carrier definition lists the rows $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$ and no additional coordinates.

The analytic rows are read first. The ordered boundary sequence, determinant-one adjacency ledger, mediant refinement row, denominator-bound row, dyadic tolerance row, Stern–Brocot handoff, density handoff, rational-source row, stream window, regular rational readback, approximation handoff, and real seal are exactly $B, A, M, L, T, S, D, Q, W, R, G, E$.

The structural rows are H, C, P, N. They transport, replay, source, and name the same displayed packet, so carrier admission cannot expose host real order, quotient real equality, selected best approximants, trichotomy, countable choice, ambient completeness, or a completed real representative. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier admission`

Theorem 1759.5 (Farey sequence classifier transport)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

componentwise classifier transport through H, C, P, N preserves the displayed rows $B, A, M, L, T, S, D, Q, W, R, G, E$. Any transported Farey-sequence packet therefore has the same boundary-sequence classifier, adjacency classifier, mediant classifier, denominator and tolerance classifiers, rational-source classifier, stream-window classifier, regular-readback classifier, approximation classifier, and real-seal classifier, read through the same local $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *route.*

Proof. Start with the componentwise transport row H. Its coordinates compare the boundary sequence, adjacency ledger, mediant row, denominator bound, dyadic tolerance, handoff rows, stream window, regular readback, approximation row, and real seal one field at a time.

The displayed replay row C then preserves the observation route through the same fields. A request transported from one accepted packet to another still reads $B, A, M, L, T, S, D, Q, W, R, G, E$ in the same order before it reaches the local naming row.

Finally P and N package and name the transported route. Because the classifier has no extra coordinate beyond the carrier rows, transport through H, C, P, N preserves the stated componentwise classifiers without adding a selected approximant, host comparison, or ambient completion witness. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequence classifier transport`

Theorem 1759.6 (Farey sequence approximation-window factorization)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every $\mathsf{RealRationalApproximation}^{\uparrow}$ *read from* F *factors through the ordered boundary row* B*, determinant-one adjacency ledger* A*, mediant refinement row* M*, denominator-bound row* L*, dyadic tolerance row* T*, Stern–Brocot handoff* S*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, approximation handoff* G*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, with* H, C, P, N *preserving the same route under transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceApproximationWindowFactorization`

Proof. Project the carrier through Definition 1759.1. The approximation-facing rows are displayed in the tuple, and carrier admission from Definition 1759.4 exposes exactly those rows before any Real-facing read is available.

Apply the NameCert obligations of Definition 1759.2. They force adjacency stability through A, mediant refinement through M, finite denominator and tolerance control through L, T, and the Stern–Brocot handoff through S before the approximation handoff can be consumed.

Use classifier transport from Definition 1759.5. The rows H, C, P, N preserve the boundary, adjacency, refinement, denominator, tolerance, window, readback, approximation, and Real-seal classifiers componentwise, so the transported packet keeps the same ordered route.

Finally read the approximation side through W, R, G, E. The finite stream window supplies the displayed observations, the regular-rational row repackages the same window, the $\mathsf{RealRationalApproximation}^{\uparrow}$ row receives the bracket with its denominator and dyadic budget, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after those rows. Thus no quotient Real equality, selected best approximant, trichotomy, countable choice, or ambient completeness coordinate enters the factorization. □

Theorem 1759.7 (Farey sequence denominator-bound window)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, the denominator cap* L *and dyadic tolerance* T *must be displayed before any mediant refinement row* M *or approximation consumer reads* G, E*. The route through* L, T *is a finite* BHist *budget, not a host real order, choice principle, selected best approximant, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier denominator bound window`

Proof. Read the approximation-window factorization theorem. It places L, T before W, R, G, E in every Real-facing route.

The mediant refinement stability theorem keeps M attached to the same finite denominator and tolerance rows. Thus refinement and approximation consumers receive the displayed budget before they inspect either the inserted mediant or the terminal Real-facing handoff. □

Theorem 1759.8 (Farey sequence stream-window stability)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *preserve the boundary row* B *and adjacency row* A *under classifier*

transport before the Real-facing seal E is read. The stream window therefore cannot introduce a host sequence, selected subsequence, quotient Real equality, choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use classifier transport. The rows H, C, P, N preserve the boundary, adjacency, stream-window, and regular-rational classifiers componentwise.

Then read approximation-window factorization. It routes every Real-facing approximation through W, R, G before E, so the transported stream window and regular readback remain attached to the original Farey boundary and adjacency rows. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier stream window stability`

Theorem 1759.9 (Farey sequence mediant refinement stability)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the mediant row M preserves adjacent determinant-one boundary exposure through A, S, L, T: the inserted mediant is read between the two displayed adjacent boundary rows named by B, the adjacency ledger A records the determinant-one checks for the neighboring pairs created by the insertion, the Stern–Brocot handoff S reads the same finite tree address, and L, T keep the denominator and dyadic tolerance budgets finite. The refinement exports no selected best approximant, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the adjacent pair selected from B. The determinant-one exposure for that pair is the row A, and the mediant row M is admitted only as the displayed numerator-denominator sum inserted between those two boundary rows.

After insertion, the two new neighboring pairs are still checked by A. The Stern–Brocot handoff S reads the same finite tree address route, so the refinement remains a finite Farey-neighbor exposure rather than a host-order comparison.

The rows L and T keep the denominator cap and dyadic tolerance budget attached to the refinement. Since Definition 1759.1 contains no coordinate for selected best approximants, trichotomy, countable choice, ambient completeness, or a completed real representative, mediant refinement cannot export any of those principles. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceMediantRefinementStability`

Theorem 1759.10 (Farey sequence denominator-refinement induction)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the finite refinement route induced by the denominator-bound row L is obtained by induction over the displayed level budget and the mediant row M. The base level reads the boundary row B unchanged; each successor level inspects adjacent entries through A, inserts exactly the mediant row admitted by M when L permits the denominator, and transports the resulting boundary through T, S, H, C, P, N before any D, Q, W, R, G, E consumer is available.

Proof. Use the carrier of Definition 1759.1 to expose the finite rows $B, A, M, L, T, S, H, C, P, N$. The denominator-bound window of Definition 1759.7 makes L visible before a refinement or approximation consumer can read the route.

The induction is a sibling-consuming route through chapter 1704 for adjacent mediants and through chapter 291 for the dyadic tolerance budget before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can read the bracket.

The base level is the displayed boundary row B. No adjacent insertion is required, so carrier admission and the NameCert obligations of Definition 1759.2 supply the whole packet at that level.

For the successor level, inspect one adjacent pair through A. The mediant refinement stability theorem Definition 1759.9 identifies M as the inserted numerator-denominator row, while denominator and tolerance control from Definition 1759.21 keeps the insertion under L, T.

Apply the induction hypothesis to the remaining displayed boundary. Approximation-window factorization from Definition 1759.6 keeps D, Q, W, R, G, E downstream of the finite route, so the induction never imports host order, selected approximants, quotient Real equality, trichotomy, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceDenominatorRefinementInduction`
Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier denominator refinement induction`

Theorem 1759.11 (Farey sequence finite mediant coverage)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, each boundary inserted by a displayed mediant refinement remains routed through* A, S, L, T*. Consequently every inserted rational boundary is covered by the same determinant-one adjacency ledger, Stern–Brocot handoff, denominator cap, and dyadic tolerance rows before it can be read by* D, Q, W, R, G, E*.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceFiniteMediantCoverage`

Proof. Start with an inserted boundary row. By mediant refinement stability, the row is produced from an adjacent pair already named by B and checked by A.

The finite tree-facing route is supplied by S. The Stern–Brocot handoff lock of Definition 1759.14 keeps every successor or approximation read that consumes M behind A, L, T, S.

The budget rows are L, T. Denominator and tolerance control says that no second host bound or selected modulus can enter any read of M, S, D, Q, W, R, G, E.

Finally apply approximation-window factorization. The downstream rational, stream, regular-readback, approximation, and Real-seal rows remain after A, S, L, T, so each inserted boundary has finite mediant coverage through the displayed packet rows. □

Theorem 1759.12 (Farey sequence Real-bracket consumer lock)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

any Real-facing bracket consumer must read $B, A, M, L, T, S, Q, W, R, G, E$ *before the terminal seal is consumed. In particular, no* $\mathsf{RealRationalApproximation}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer can bypass the displayed boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, rational-source, stream-window, regular-readback, approximation, and seal rows.*

Proof. Begin with the approximation-window factorization theorem. It places each Real-facing read behind the ordered boundary, determinant-one adjacency ledger, mediant row, denominator and tolerance rows, Stern–Brocot handoff, stream window, regular readback, approximation handoff, and terminal seal.

Use finite mediant coverage above for inserted boundaries. Every boundary created by refinement remains under A, S, L, T, so the bracket read cannot detach a refined endpoint from its finite denominator and tolerance budget.

The rational-source and readback rows are then Q, W, R, G, E. The Real readback root obligation of Definition 1759.15 and the approximation ledger non-escape theorem of Definition 1759.26 keep those rows inside the same displayed Farey packet.

Thus every Real-bracket consumer reads $B, A, M, L, T, S, Q, W, R, G, E$ before the seal. The carrier contains no quotient Real equality, selected best approximant, host order, trichotomy, countable choice, or ambient completeness coordinate that could supply an alternate bracket route. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier real bracket consumer lock`

Theorem 1759.13 (Farey sequence finite-density root package)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each finite-density read exported to an L10 approximation or completion consumer factors through one displayed root package: the boundary row B, adjacency ledger A, mediant row M, denominator and tolerance rows L, T, $\mathsf{SternBrocot}^{\uparrow}$ *handoff S,* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{RealRationalApproximation}^{\uparrow}$ *row G, and terminal* $\mathsf{Real}^{\uparrow}$ *seal E, with H, C, P, N preserving the same route. The package exports no selected best approximant, host order, quotient real equality, trichotomy, countable choice, or ambient completeness principle.*

Proof. Start with the Farey carrier and NameCert obligations. The carrier of Definition 1759.1 and the obligations of Definition 1759.2 expose exactly the finite boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, rational-source, stream, readback, approximation, Real-seal, transport, replay, provenance, and naming rows.

The density route is then locked to finite denominator data. The denominator-bound window theorem Definition 1759.7 and the denominator refinement induction of Definition 1759.10 place each inspected density window behind B, A, M, L, T before any real-facing row can be read.

Next apply the Stern–Brocot handoff lock of Definition 1759.14. It keeps each mediant or successor-level read attached to A, L, T, S rather than to a host-order branch choice.

Finally use the approximation-window factorization theorem Definition 1759.6. It sends the resulting finite bracket through W, R, G, E, while H, C, P, N transport, replay, source, and name the same packet. Hence every finite-density read factors through the displayed root package and cannot export any of the refused ambient objects. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceFiniteDensityRootPackage`

Theorem 1759.14 (Farey sequence Stern–Brocot handoff lock)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every denominator-level successor or approximation read that consumes a mediant row M must pass through the adjacent determinant-one ledger A, the denominator cap L, the dyadic tolerance T, and the $\mathsf{SternBrocot}^{\uparrow}$ *handoff S before the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *row G or terminal* $\mathsf{Real}^{\uparrow}$ *row E is read. The locked route exports no selected best approximant, host order, quotient real equality, trichotomy, countable choice, or ambient completeness principle.*

Proof. Start with a successor or approximation read that consumes M. Carrier admission exposes M only as the mediant row for an adjacent pair already displayed in B, so the determinant-one ledger A is the first required witness for that read.

Apply mediant refinement stability from Definition 1759.9. The inserted row remains tied to the same adjacent-pair inspection, and the Stern–Brocot handoff S records the corresponding finite tree route rather than a host-order branch choice.

Next use denominator and tolerance control from Definition 1759.21. The denominator cap L and dyadic tolerance T are the only budget rows available to the mediant and approximation route, so no second host bound or selected modulus can enter before the read reaches G or E.

Finally apply approximation-window factorization from Definition 1759.6. The real-facing rows G, E are downstream of A, M, L, T, S, W, R and the structural rows H, C, P, N. Since the carrier has no coordinate for selected best approximants, host order, quotient real equality, trichotomy, countable choice, or ambient completeness, the handoff is locked to the finite Stern–Brocot route. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceSternBrocotHandoffLock`

Theorem 1759.15 (Farey sequence Real readback root obligation)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-facing Farey read factors through the finite route*

$$B, A, M, L, T, S, Q, W, R, G, H, C, P, N \longmapsto E.$$

Thus the ordered boundary, adjacent determinant-one ledger, mediant row, denominator cap, dyadic tolerance, Stern–Brocot handoff, rational-source row, StreamName window, RegSeqRat readback, approximation handoff, transport, replay, provenance, and local naming rows are all visible before the terminal Real seal is consumed. The route supplies no selected best approximant, host order, quotient real equality, trichotomy, countable choice, or ambient completeness principle.

Proof. Start from a Real-facing Farey read. Carrier admission exposes the only Real seal as E, and the approximation-window factorization theorem places E after the finite boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, window, readback, and approximation rows.

The rational and stream stages are read before the seal. The rational-source row Q, StreamName window W, RegSeqRat readback R, and approximation handoff G give the displayed route to the terminal Real boundary.

Finally transport, replay, provenance, and local naming are carried by H, C, P, N. Since no row of the carrier stores a selected approximant, host order, quotient Real equality, trichotomy, choice schedule, or ambient completeness datum, the listed route exhausts the Real-facing readback obligation. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRealReadbackRootObligation`

Theorem 1759.16 (Farey sequence RegSeqRat density root obligation)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every $\mathsf{RegSeqRat}^{\uparrow}$ *consumer and rational-density consumer receives only the displayed boundary row* B*, adjacent determinant-one ledger* A*, mediant row* M*, denominator cap* L*, dyadic tolerance row* T*, density handoff* D*, rational-source row* Q*, StreamName window* W*, and regular readback row* R*, with* H, C, P, N *preserving that same finite route. No such consumer receives a host order, selected best approximant, quotient real equality, trichotomy, countable choice, or ambient completeness coordinate.*

Proof. Read the density side of the carrier. The finite rational data available before any regular readback are B, A, M, L, T, D, Q, namely the displayed boundary, adjacency, mediant, denominator, tolerance, density, and rational-source rows.

The window and regular readback are then W, R. The StreamName row fixes the finite observation window, and the RegSeqRat row replays that window as a regular rational readback without adding a second rational-density witness.

Transport and replay preserve the same finite route through H, C, P, N. Because the carrier has no coordinate for host order, selected approximants, quotient real equality, trichotomy, choice, or ambient completeness, the RegSeqRat and rational-density consumers can receive only the displayed rows listed in the statement. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRegSeqRatDensityRootObligation`

Theorem 1759.17 (Farey sequence level-successor induction)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the successor from one displayed denominator level to the next is generated by induction on the finite boundary row B. The base boundary is admitted unchanged, and each successor step reads one adjacent pair through A, inserts the permitted mediant through M when the denominator cap in L admits it, and carries the resulting row through T, S, H, C, P, N. The construction uses no parameter-transport equivalence, selected best approximant, host order, quotient real equality, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceLevelSuccessorInduction`

Proof. Induct on the displayed boundary row B. For the empty and singleton boundaries there is no adjacent pair to inspect, so carrier admission supplies the whole next-level row and no mediant insertion is performed.

For the successor step, expose the first adjacent pair through the determinant-one ledger A. The mediant row M supplies exactly the numerator-denominator sum for that pair, while the denominator cap L decides whether that finite row belongs to the next displayed level.

Apply the induction hypothesis to the remaining boundary suffix. The tolerance row T and Stern–Brocot handoff S keep the inserted row on the same finite route, and H, C, P, N transport, replay, source, and name the resulting level.

Since each step consumes only $B, A, M, L, T, S, H, C, P, N$, the construction is an induction over the displayed finite row. The excluded host-order, quotient, trichotomy, choice, selected-approximant, and ambient-completeness data never become available. □

Theorem 1759.18 (Farey sequence mediant density window)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each density window opened by a $\mathsf{RegSeqRat}^{\uparrow}$ *or rational approximation consumer is refined by finite mediant insertion through A, M, L, T, S before it is handed to D, Q, W, R, G, E. In particular, a requested window between adjacent displayed rationals is covered by the boundary row already present in B or by the inserted mediant row admitted by M under the denominator cap L and tolerance row T.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceMediantDensityWindow`

Proof. Begin with a density-window request. Carrier admission exposes the boundary row B and the adjacent determinant-one ledger A before any rational-source, stream, or regular-readback row can be consumed.

If the requested window is already covered by an adjacent boundary endpoint, the route stays inside B, A and proceeds to the density handoff D. No mediant is inserted in this case.

If the window lies strictly between an adjacent pair, use the level-successor induction of Definition 1759.17. The induction step inserts the unique displayed mediant row through M and keeps it under the denominator and tolerance rows L, T.

The Stern–Brocot row S records the same adjacent-pair route, after which D, Q, W, R, G, E read the density, rational-source, stream-window, RegSeqRat, approximation, and Real-seal data. Thus the window is refined by finite mediant insertion rather than by trichotomy, selected approximants, host order, quotient equality, choice, or ambient completeness. □

Theorem 1759.19 (Farey sequence RegSeqRat density induction)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *density route is obtained by induction over the displayed denominator-level successor rows. At each level the finite boundary row is refined by* A, M, L, T, S*, the density handoff is read through* D, Q, W*, and the regular rational readback* R *is produced before* G, E *are available. The route preserves the no-trichotomy, no-choice, no-host-order, no-quotient-equality, and no-ambient-completeness exclusions.*

Proof. Induct on the displayed denominator-level successor row supplied by Definition 1759.17. The base level supplies only the boundary data already admitted by the carrier, so the RegSeqRat density read is the finite readback through D, Q, W, R for that boundary.

For the successor level, apply the mediant density window theorem Definition 1759.18. Each new gap is either already covered by the boundary or refined by the mediant row generated through A, M, L, T, S.

After the finite refinement step, read D, Q, W as the density, rational-source, and StreamName window rows. The regular rational row R packages exactly that windowed data, and the approximation and Real rows G, E remain downstream.

The structural rows H, C, P, N preserve the same induction route under transport, replay, provenance, and local naming. Since the carrier contains no coordinate for trichotomy, countable choice, host order, quotient real equality, selected best approximants, or ambient completeness, the RegSeqRat density derivation is internal to the displayed Farey packet. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRegSeqRatDensityInduction`

Theorem 1759.20 (Farey sequence root-unblock package)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the root-facing Farey package is the conjunction of carrier admission, the local NameCert obligations, approximation-window factorization, the Stern–Brocot handoff lock, the Real readback root obligation, and the RegSeqRat density root obligation. Consequently downstream $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers read the same finite Farey packet through* $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$*, with no selected best approximant, host order, quotient real equality, trichotomy, countable choice, or ambient completeness principle.*

Proof. Begin with carrier admission and the local NameCert obligations. These expose exactly the boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, density, rational-source, stream-window, readback, approximation, Real-seal, transport, replay, provenance, and naming rows.

Next combine approximation-window factorization with the Stern–Brocot handoff lock. The first routes the windowed approximation read through W, R, G, E, while the second keeps mediant and denominator-level reads on the finite A, M, L, T, S route.

Apply the two root obligations above. The Real readback obligation keeps terminal Real consumers behind the same finite route, and the RegSeqRat density obligation restricts rational-density consumers to the displayed boundary, mediant, tolerance, stream-window, and readback rows.

The structural rows H, C, P, N preserve that package under transport, replay, provenance, and local naming. Since the accepted carrier stores none of the excluded host-order, selection, quotient, choice, or completeness data, the package is a finite root-facing unblock certificate rather than an analytic completion principle. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier root unblock package`

Theorem 1759.21 (Farey sequence denominator and tolerance control)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the denominator-bound row L and the dyadic-tolerance row T are the only finite denominator and tolerance rows consumed by the mediant refinement and approximation route. In particular, every read of M, S, D, Q, W, R, G, E that depends on a denominator cap or tolerance budget factors through L, T and through no additional host bound, selected modulus, quotient-real comparison, or ambient completeness coordinate.

Proof. Project the carrier of Definition 1759.1. The displayed packet contains exactly one denominator-bound coordinate L and exactly one dyadic-tolerance coordinate T.

The mediant row M reads denominator data only through the displayed boundary and adjacent-pair inspection together with L. The Stern–Brocot and rational-source rows S, D, Q inherit the same finite cap, so they cannot introduce a second denominator witness.

The approximation side is then forced through W, R, G, E. The finite stream window and regular rational readback use the tolerance row T before the $\mathsf{RealRationalApproximation}^{\uparrow}$ handoff G and the terminal $\mathsf{Real}^{\uparrow}$ seal E are available.

The componentwise transport and replay rows H, C preserve the same two coordinates. Since the carrier has no coordinate for a host bound, selected modulus, quotient-real comparison, or ambient completeness principle, L, T exhaust the denominator and tolerance control consumed by the route. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceDenominatorToleranceControl`

Theorem 1759.22 (Farey sequence level successor)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the denominator-bound row L and mediant row M produce the next finite Farey level by induction on the displayed boundary row B. Each successor step inspects one adjacent pair recorded by

A, inserts exactly the mediant row admitted by M when the denominator cap in L permits it, and transports the resulting boundary through S, H, C, P, N without invoking selected best approximants, host order, quotient real equality, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceLevelSuccessor`

Proof. Induct on the finite boundary row B. The empty and singleton boundaries have no adjacent pair, so the next level is the displayed row already admitted by carrier admission and no mediant insertion is available.

For the inductive step, expose the first adjacent pair through A. The mediant refinement stability theorem Definition 1759.9 identifies the only permitted insertion as the numerator-denominator sum stored in M, and the denominator and tolerance control theorem Definition 1759.21 keeps that insertion under the cap recorded by L.

Apply the induction hypothesis to the remaining boundary suffix. The Stern–Brocot handoff S records the same adjacent-pair route, while H, C, P, N transport, replay, source, and name the resulting finite level. Since every step reads only $B, A, M, L, S, H, C, P, N$, no excluded order, quotient, selection, choice, or completeness object enters the successor construction. □

Theorem 1759.23 (Farey sequence adjacency density)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each requested adjacent gap in the displayed boundary row is refined through A, M, S and then handed to the density and approximation rows D, Q, W, R, G, E. The refinement is a finite adjacent-pair inspection and not a selected best approximant, host real-order comparison, quotient-real equality, trichotomy, countable-choice selector, or ambient completeness principle.

Proof. Begin with a requested adjacent gap. Carrier admission and the NameCert obligations identify the gap by its two boundary entries in B and by the determinant-one ledger entry in A.

Apply mediant refinement stability. The row M supplies the displayed mediant for that adjacent pair, and the handoff row S records the same finite Stern–Brocot route without selecting a branch outside the packet.

Finally read the density and approximation surface. The rows D, Q expose the finite rational source, W, R expose the stream window and regular-rational readback, and G, E expose the RealRationalApproximation handoff and terminal Real seal. The classifier transport theorem keeps this route under H, C, P, N, so the density claim remains finite and cannot import a best-approximant selector, trichotomy, choice, quotient equality, host order, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier adjacency density`

Theorem 1759.24 (Farey sequence refinement coverage)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every $\mathsf{RealRationalApproximation}^{\uparrow}$ *consumer reads each Farey refinement through the finite route $B, A, M, L, T, S, W, R, G, E$ together with transport, replay, provenance, and local naming through H, C, P, N. Thus refinement coverage is exhaustive over the displayed packet and contains no quotient real equality, selected approximant, trichotomy, countable choice, host sequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start from an accepted approximation-window request. The approximation-window factorization theorem routes the request through the ordered boundary B, adjacency ledger A, mediant row M, denominator and tolerance rows L, T, Stern–Brocot handoff S, stream window W, regular readback R, approximation handoff G, and Real seal E.

Use adjacency density for the local refinement step. It shows that each requested adjacent gap is refined by the finite A, M, S route before D, Q, W, R, G, E are consumed by rational-window or Real-facing readers.

The real approximation ledger non-escape theorem then confines the consumer to the same displayed packet. Transport through H, replay through C, provenance through P, and local naming through N preserve the coverage route, so every refinement visible to a $\mathsf{RealRationalApproximation}^{\uparrow}$ consumer is accounted for by $B, A, M, L, T, S, W, R, G, E, H, C, P, N$ and by no excluded ambient object. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRefinementCoverage`

Theorem 1759.25 (Farey sequence stream-window denominator lock)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every stream-window read W consumed by R, G, E carries the denominator-bound row L and the dyadic-tolerance row T from the same accepted carrier. Consequently, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *consumers cannot replace the displayed Farey denominator cap by a host denominator bound, an external modulus, a quotient-real comparison, or an ambient completeness coordinate.*

Proof. Project the accepted carrier through Definition 1759.1. The rows L, T, W, R, G, E are coordinates of the same finite packet, so a window read cannot be detached from the denominator and tolerance rows that classify the packet.

Apply the denominator and tolerance control of Definition 1759.21. It identifies L, T as the only finite bound and tolerance rows available to any read of W, R, G, E that depends on such data.

Finally use the approximation ledger non-escape theorem Definition 1759.26. Since real-facing reads remain inside $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$, no downstream consumer can substitute a host cap, external modulus, quotient-real comparison, or ambient completeness witness for the displayed rows L, T. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier stream window denominator lock`

Theorem 1759.26 (Farey sequence approximation ledger non-escape)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each $\mathsf{RealRationalApproximation}^{\uparrow}$ *read and each terminal* $\mathsf{Real}^{\uparrow}$ *read factors through the finite ledger $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$. The exported surface contains no quotient real equality, no selected best approximant, no trichotomy, no countable-choice selector, and no ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier real approximation ledger nonescape`

Proof. Begin with a real-facing read of the accepted carrier. By the handoff clause in Definition 1759.2, the read must pass through the rational bracket, denominator-bound row, dyadic-tolerance row, stream window, regular rational readback, and $\mathsf{RealRationalApproximation}^{\uparrow}$ handoff before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

The finite rational data are exactly B, A, M, L, T, S, D, Q. These rows display the boundary sequence, determinant-one adjacency ledger, mediant refinement, denominator cap, tolerance budget, Stern–Brocot handoff, density handoff, and sibling rational-source handoff.

The real-facing route is exactly W, R, G, E. The finite stream window reads entries, the regular rational readback packages the sequence row, the approximation handoff exposes the displayed bracket and budget, and the real seal records only the downstream endpoint allowed by the preceding rows.

Transport, replay, provenance, and naming are supplied by H, C, P, N. They preserve the same finite inventory and do not add a coordinate whose classifier could select a best approximant or compare quotient real names.

Therefore every $\mathsf{RealRationalApproximation}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read factors through the listed packet coordinates. The absence of host real order, quotient real equality, selected best approximants, trichotomy, countable choice, ambient completeness, and completed representatives in Definition 1759.1 gives the stated non-escape boundary. □

Theorem 1759.27 (Farey sequence RealRationalApproximation handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing approximation read of an accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FareySequence}^{\uparrow},\ \mathsf{SternBrocot}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{RationalStream}^{\uparrow},\ \mathsf{ContinuedFraction}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeq}$$

with the optional siblings omitted only when the surrounding packet does not expose them. The route uses the ordered boundary sequence, adjacent determinant-one ledger, denominator-bound row, dyadic tolerance row, mediant refinement row, Stern–Brocot handoff, rational-source row, stream window, regular-rational readback, RealRationalApproximation handoff, and real seal. It supplies no host real order, quotient real equality, selected best approximant, trichotomy, countable choice, ambient completeness, or independent completed-real representative.

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRealApproximationHandoff`

Proof. Start with an accepted carrier $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$. The Farey-facing data are exactly the finite boundary sequence B, the determinant-one ledger A, the mediant refinement row M, the denominator-bound row L, and the dyadic tolerance row T.

The Stern–Brocot handoff is the row S. It reads each adjacent pair and refinement through the same finite tree address and Farey-neighbor ledger used by chapter 1704.

The rational-source handoff is then carried by D and Q. Dyadic, rational, rational-stream, and continued-fraction consumers can inspect the displayed finite rational rows together with the tolerance and denominator-bound rows, but they receive no additional real-order field.

The approximation route is carried by W, R, G, E. A finite $\mathsf{StreamName}^{\uparrow}$ window requests entries from the sequence, $\mathsf{RegSeqRat}^{\uparrow}$ reads the resulting regular rational row, $\mathsf{RealRationalApproximation}^{\uparrow}$ receives the bracket with its dyadic tolerance and denominator bound, and $\mathsf{Real}^{\uparrow}$ receives only the downstream seal row.

Componentwise transport and replay preserve the same factorization for classified packets. The provenance and local naming rows name the same finite inventory, so no quotient real equality, selected limit, ambient completeness, or independent representative can enter the route. □

Theorem 1759.28 (Farey sequence regular-readback approximation bridge)**.** *For every accepted* FareySequence$^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the RegSeqRat$^{\uparrow}$ *readback row* R *and the* RealRationalApproximation$^{\uparrow}$ *handoff row* G *are forced through the same ordered boundary row* B*, adjacency ledger* A*, denominator-bound row* L*, dyadic-tolerance row* T*, and stream-window row* W*. The bridge exports a regular rational readback and a real-approximation handoff only along this common finite boundary, not through a host sequence, selected approximant, quotient-real equality, countable choice, or ambient completion.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRegularReadbackApproximationBridge`

Proof. Start from the carrier of Definition 1759.1. The regular readback R and approximation handoff G are not independent rows; they are read after the same boundary, adjacency, denominator, tolerance, and stream-window rows B, A, L, T, W are displayed.

Apply the approximation-window factorization of Definition 1759.6. It routes each RealRationalApproximation$^{\uparrow}$ read through the ordered boundary, determinant-one adjacency ledger, denominator and tolerance rows, stream window, regular readback, and approximation handoff before the terminal real seal is available.

Use the RealRationalApproximation handoff theorem Definition 1759.27. The handoff keeps R and G downstream of the same finite Farey packet, so the bridge cannot introduce a host sequence, selected approximant, quotient-real equality, countable-choice selector, or ambient completion coordinate. □

Theorem 1759.29 (Farey sequence continued-fraction window)**.** *Every* ContinuedFraction$^{\uparrow}$ *consumer of an accepted* FareySequence$^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$$

must read the rational-source row Q*, the finite* StreamName$^{\uparrow}$ *window* W*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the denominator-bound row* L*, and the dyadic tolerance row* T *before any continued-fraction comparison is exported. The comparison route therefore exposes only displayed finite rational-source and window rows, with no selected tail, host real order, quotient real equality, trichotomy, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the accepted carrier through Definition 1759.1. A continued-fraction consumer can find its rational-source row only at Q, and that row is already tied to the displayed boundary, mediant, denominator, and tolerance data.

The next visible access is the finite window row W. It requests only displayed entries of the Farey packet, so a comparison cannot bypass the packet through a host rational sequence.

The regular readback row R packages the same windowed data before any continued-fraction comparison leaves the packet. The rows L and T keep the denominator cap and dyadic tolerance attached to that read.

Transport, replay, provenance, and naming through H, C, P, N preserve this route. Since the carrier has no selected continued-fraction tail, host real order, quotient equality, trichotomy, choice selector, or ambient completeness coordinate, every exported continued-fraction comparison is confined to Q, W, R, L, T and the displayed support rows. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceContinuedFractionWindow`

Theorem 1759.30 (Farey sequence Stern–Brocot mediant density route)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the mediant refinement row M and the Stern–Brocot handoff row S jointly preserve determinant-one adjacency through A and keep the denominator and tolerance data attached through L, T. The resulting density route is finite and exports no selected best approximant, branch selector, host real order, quotient real equality, trichotomy, choice selector, or ambient completeness coordinate.

Proof. Begin with an adjacent pair from the ordered boundary row B. The determinant-one check for that pair is the ledger row A, and the mediant row M inserts only the displayed numerator-denominator sum between those two boundary entries.

The Stern–Brocot handoff S reads the same adjacent-pair inspection. It therefore sends the refinement to the finite tree-facing ledger without selecting an independent branch or importing a host-order comparison.

The denominator and tolerance side is locked by L, T. Every density read that uses the mediant or the Stern–Brocot handoff keeps the displayed denominator cap and dyadic error budget attached to the same finite refinement step.

The downstream rows $D, Q, W, R, G, E, H, C, P, N$ can only consume the resulting finite route. Because none of the carrier rows stores a best-approximant selector, branch selector, host real order, quotient equality, trichotomy, choice, or completeness witness, the mediant density route remains the finite one stated above. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceSternBrocotMediantDensityRoute`

Theorem 1759.31 (Farey sequence Real approximation density route)**.** *Every* $\mathsf{RealRationalApproximation}^{\uparrow}$ *density read of an accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier factors through the full finite inventory*

$$B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N.$$

In particular, the read first uses the ordered boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, and density rows B, A, M, L, T, S, D, then the rational-source, window, regular-readback, approximation, and Real-seal rows Q, W, R, G, E, and finally transport, replay, provenance, and naming through H, C, P, N. It has no host order, quotient Real equality, trichotomy, choice selector, selected best approximant, or ambient completeness coordinate.

Proof. Start with a density read aimed at $\mathsf{RealRationalApproximation}^{\uparrow}$. The Farey-side part of the carrier is B, A, M, L, T, S, D: the boundary row, adjacency ledger, mediant refinement, denominator cap, tolerance budget, Stern–Brocot handoff, and density handoff.

The rational-source and windowed-readback part is Q, W, R. These rows ensure that the density read reaches rational and regular rational consumers through displayed finite windows rather than through a host rational or real sequence.

The real-facing endpoint is then G, E. The handoff row G supplies the $\mathsf{RealRationalApproximation}^{\uparrow}$ packet, and E exposes only the terminal $\mathsf{Real}^{\uparrow}$ seal reached from the preceding finite rows.

Finally H, C, P, N transport, replay, source, and name the same inventory. Since Definition 1759.1 contains no coordinate for host order, quotient Real equality, trichotomy, choice, selected best approximants, or ambient completeness, every Real approximation density read factors through exactly the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier real approximation density route`

Theorem 1759.32 (Farey sequence stream-window adjacency scope)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the $\mathsf{StreamName}^{\uparrow}$ *window* W *reads only the displayed ordered boundary row* B *and the adjacency ledger* A *when it exports a finite Farey window. In particular, every windowed entry request is classified by the displayed rational boundary row, every neighboring-pair request is classified by the determinant-one rows in* A*, and no host real order, quotient real comparison, selected branch, or ambient completion datum is available to the window classifier.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceStreamWindowAdjacencyScope`

Proof. Project the accepted packet to B, A, W, H, C, P, N. The row W is a finite stream window whose entries are requested from the displayed boundary sequence B, so the entry classifier is already bounded by the ordered rational rows of B.

Neighboring-pair reads then use A. Each adjacent request in the window points to the determinant-one ledger row for the displayed consecutive pair, not to a host-order comparison or to an external real representative.

The rows H, C, P, N transport, replay, package, and name the same finite data. Since the carrier has no coordinate for host real order, quotient real comparison, selected branches, or ambient completion, the stream-window classifier cannot escape B, A, W, H, C, P, N. □

Theorem 1759.33 (Farey sequence rational-source handoff scope)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RationalStream}^{\uparrow}$*, and* $\mathsf{ContinuedFraction}^{\uparrow}$ *consumer factors through the rational-source row* Q*, the stream-window row* W*, the regular-rational readback* R*, the approximation handoff* G*, and the real seal* E *whenever those sibling consumers are present. The handoff exposes only finite rational rows, dyadic tolerance data, windowed sequence requests, regular readback, and the named approximation route.*

Proof. Start with a sibling rational consumer. The accepted carrier exposes rational-source data through Q, which packages the displayed rational boundary, dyadic tolerance, and denominator information already recorded by B, L, T.

The consumer then reads finite sequence access through W and regular rational replay through R. These rows keep the request inside the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces before any real-facing approximation row is visible.

The rows G and E provide the only approximation and real-seal endpoints. Thus $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, and $\mathsf{ContinuedFraction}^{\uparrow}$ consumers factor through Q, W, R, G, E and receive no independent host rational carrier, selected continued-fraction tail, quotient real comparison, or ambient completion witness. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRationalSourceHandoffScope`

Theorem 1759.34 (Farey sequence local naming replay scope)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the componentwise transport H*, displayed replay* C*, package provenance* P*, and local naming row* N *preserve the same finite packet* $B, A, M, L, T, S, D, Q, W, R, G, E$*. They do not add host real order,*

quotient real equality, selected approximants, trichotomy, countable choice, ambient completeness, or a completed real representative to the Farey sequence route.

Proof. Project the accepted carrier to the transport and replay rows. The row H compares packets componentwise across the displayed boundary, adjacency, mediant, bound, tolerance, handoff, window, readback, approximation, and real-seal rows.

The row C replays observation requests through the same components. It has no separate source from which a host order, quotient equality, or selected approximant could be read.

Finally, P and N package and name the already displayed packet. Because the listed carrier coordinates exhaust the local certificate, transport, replay, provenance, and naming preserve the finite Farey packet without adding trichotomy, countable choice, ambient completeness, or a completed real representative. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceLocalNamingReplayScope`

Theorem 1759.35 (Farey sequence mediant window coverage)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each displayed denominator-bounded mediant window is covered by a finite adjacent-row inspection of B, A, M, L*. The coverage row names the two adjacent rational boundary entries, the inserted mediant, and the level cap before any* $\mathsf{RealRationalApproximation}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer may read the window. It exports no host real order, quotient real equality, selected best approximant, trichotomy, countable choice, or ambient completeness coordinate.*

Proof. Project the accepted carrier to the boundary, adjacency, mediant, and level rows. The ordered row B supplies the finite list of rational boundary entries, A supplies the determinant-one neighboring checks, M supplies the displayed numerator-denominator sum, and L supplies the finite denominator cap.

For an inspected adjacent pair, the only admitted refinement is the mediant row placed between the two named endpoints. Thus the displayed window is bounded by the same adjacent-row inspection that created it, and every denominator-bounded request is accounted for by a finite segment of B, A, M, L.

The downstream rows $T, S, D, Q, W, R, G, E, H, C, P, N$ preserve that finite coverage route. Since none of those rows contains a host-order comparison, quotient equality, selected best approximant, trichotomy, choice selector, or completeness witness, the mediant window cannot escape the displayed adjacent-row coverage. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceMediantWindowCoverage`

Theorem 1759.36 (Farey sequence stream approximation totality)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every accepted approximation request that reaches the $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff first routes through the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*. The handoff then reads* G *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *from the same displayed packet; it does not choose a best approximant or identify quotient real names.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceStreamApproximationTotality`

Proof. Start with an accepted approximation request. The finite rational data available to it are the boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, density, and rational-source rows B, A, M, L, T, S, D, Q.

The request must next pass through the window row W. That row supplies only finite $\mathsf{StreamName}^{\uparrow}$ access to displayed sequence entries, so the approximation cannot bypass the stream window to a host rational sequence.

After the window is displayed, the readback row R packages the same data as a $\mathsf{RegSeqRat}^{\uparrow}$ surface. Only then can G expose the $\mathsf{RealRationalApproximation}^{\uparrow}$ handoff and E expose the terminal $\mathsf{Real}^{\uparrow}$ seal.

Because the route is $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N$ and the carrier has no selected-best-approximant or quotient-real coordinate, the accepted approximation request is total only along this finite stream and regular-rational route. □

Theorem 1759.37 (Farey sequence adjacent dyadic window)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

an adjacent Farey window inspected through B, A, M, L *gives a dyadic tolerance route only through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *rows in* Q *together with the tolerance row* T*. The route may feed* $\mathsf{RationalStream}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *consumers through* W*, but it cannot introduce a host real-order comparison, selected best approximant, or quotient-real equality witness.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceAdjacentDyadicWindow`

Proof. Start with an adjacent-pair inspection. The finite boundary row B names the rational endpoints, the adjacency ledger A records determinant-one neighboring, the mediant row M supplies the displayed refinement, and L bounds the denominators.

The dyadic tolerance read is then forced through T and Q. These rows are the only coordinates that expose $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ data to downstream rational consumers.

The stream-facing part of the same request uses W for the $\mathsf{StreamName}^{\uparrow}$ window and may expose $\mathsf{RationalStream}^{\uparrow}$ through the rational-source handoff. Since no host-order, selected-approximant, or quotient-equality coordinate appears in Definition 1759.1, the adjacent window remains a finite dyadic-tolerance route. □

Theorem 1759.38 (Farey sequence rational stream readback)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the $\mathsf{RationalStream}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *readback of an adjacent Farey window preserves the same classifier rows* B, A, M, L, T, Q, W*. When the readback is repackaged as a* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, it still records the same finite window classifier and does not add a new rational sequence, choice selector, or ambient completion coordinate.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRationalStreamReadback`

Proof. Read the stream-facing route from Q, W. The rational-source row Q exposes only the displayed rational data already controlled by B, A, M, L, T, and the finite stream window W requests entries from that displayed sequence.

The regular rational readback row R repackages the same window for $\mathsf{RegSeqRat}^{\uparrow}$. It is downstream of Q, W, so it cannot replace the classifier by a hidden rational stream or by a selected subsequence.

Transport and replay through H, C preserve the same rows before provenance and local naming are read. Thus the classifier remains B, A, M, L, T, Q, W, R throughout the rational-stream readback. □

Theorem 1759.39 (Farey sequence real approximation boundary)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the Real-facing approximation boundary is the route from adjacent Farey rows through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and then* G, E *for* $\mathsf{RealRationalApproximation}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$. *The boundary exports finite approximation data only; it cannot export quotient equality of real names, a selected limit, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the adjacent window and dyadic tolerance route of Definition 1759.37. It confines the approximation request to B, A, M, L, T, Q, W before the regular readback is available.

Apply the readback scope of Definition 1759.38. The row R gives the $\mathsf{RegSeqRat}^{\uparrow}$ surface for the same displayed window, preserving the rational and stream classifiers.

Only after those rows are displayed can G expose the $\mathsf{RealRationalApproximation}^{\uparrow}$ handoff and E expose the terminal $\mathsf{Real}^{\uparrow}$ seal. The carrier contains no quotient-real equality, selected-limit, trichotomy, choice, or ambient-completeness coordinate, so the real-facing boundary is finite approximation data and nothing stronger. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRealApproximationBoundary`

Theorem 1759.40 (Farey sequence Stern–Brocot refinement scope)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the Stern–Brocot-facing scope of the packet is exactly the refinement handoff through S *from an adjacent-row inspection of* B, A, M, L. *No other row exports a tree address, branch selector, or refinement path to a tree-facing consumer.*

Proof. Read the tree-facing data from the carrier. The only row named as a Stern–Brocot handoff is S, and its input is the same finite adjacent-pair inspection supplied by B, A, M, L.

The rational-source and approximation rows D, Q, W, R, G, E are downstream of that handoff. They can consume the finite rational and window data, but they do not contain a separate tree address or branch-selection coordinate.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the carrier stores no hidden branch selector or independent refinement path, every tree-facing use of $\mathsf{FareySequence}^{\uparrow}$ is scoped by the single Stern–Brocot handoff S. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceSternBrocotRefinementScope`

Theorem 1759.41 (Farey sequence neighbor determinacy)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

an adjacent determinant-one inspection in A *determines a unique displayed Stern–Brocot refinement route inside the carrier: the boundary rows are read from* B, *the mediant insertion is read from* M, *the tree-facing address is read from* S, *and every transported or replayed use of that route remains under* H, C, P, N. *The determinacy is internal to the displayed rows and does not assert quotient-real equality, a selected best approximant, trichotomy, choice, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier neighbor determinacy`

Proof. Start with the finite adjacent-pair data. Theorems 1759.4, 1759.2, and 1759.9 identify B, A, M as the boundary, determinant-one, and mediant rows for a displayed refinement.

The tree-facing route is then forced by S. Theorems 1759.30 and 1759.40 say that the Stern–Brocot consumer reads only the handoff row attached to that adjacent-pair inspection, with no separate branch selector or refinement path.

Finally transport and replay through H, C, P, N preserve the same route by Theorems 1759.5 and 1759.34. Since the carrier has no coordinate for quotient-real equality, selected approximants, trichotomy, choice, or ambient completeness, the displayed Stern–Brocot route is unique at the level of the packet rows. □

Theorem 1759.42 (Farey sequence denominator ledger exactness)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the denominator bounds and dyadic tolerances consumed by any $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff are read from the same finite ledger rows* L, T *before the handoff reaches* W, R, G, E*. No consumer may replace* L, T *by a host denominator bound, selected modulus, quotient-real comparison, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier denominator ledger`

Proof. Read the ledger rows first. Theorems 1759.21 and 1759.37 identify L, T as the displayed denominator and dyadic-tolerance source for adjacent Farey windows.

Next pass to stream and regular-rational consumers. Theorems 1759.32, 1759.38, and 1759.36 route W and R through the same adjacent-window data rather than through an independent bound.

The real-facing handoff is downstream of that route. By Theorems 1759.6, 1759.39, and 1759.26, G, E receive only the displayed ledger, window, and readback rows, so no host bound, selected modulus, quotient comparison, or ambient completeness coordinate can enter. □

Theorem 1759.43 (Farey sequence dyadic mediant bracket)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

each adjacent determinant-one packet displayed by B, A *determines a dyadic bracket row whose mediant refinement remains inside the displayed rational stream route* Q, W, R*. The same denominator and tolerance ledger* L, T *is the budget consumed by* $\mathsf{RealRationalApproximation}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *through* G, R*, with no selected best approximant, trichotomy, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier dyadic mediant bracket`

Proof. Read the adjacent Farey packet first. Theorems 1759.2, 1759.9, and 1759.42 place the boundary row, determinant-one ledger, mediant row, denominator cap, and dyadic tolerance in B, A, M, L, T.

Next pass to the rational stream route. Theorems 1759.38 and 1759.44 keep the displayed bracket inside Q, W, R, so the mediant row cannot be replaced by a hidden stream element or selected best approximant.

Finally hand the same budget to real-approximation consumers. Theorems 1759.39 and 1759.26 route G, E from the displayed denominator and tolerance rows, while the carrier has no coordinate for trichotomy, quotient real equality, countable choice, or ambient completeness. □

Theorem 1759.44 (Farey sequence rational coverage)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

every rational-window approximation consumer factors through the rows already present in the carrier: $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *are read through* Q, T*,* $\mathsf{RationalStream}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *through* Q, W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *through* R*,* $\mathsf{RealRationalApproximation}^{\uparrow}$ *through* G*, and* $\mathsf{Real}^{\uparrow}$ *through* E*, with* $B, A, M, L, S, H, C, P, N$ *preserving the finite Farey-neighbor context. The coverage statement adds no quotient-real equality, selected best approximant, trichotomy, choice, or Real-completeness claim.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceRationalCoverage`

Proof. Begin with the rational-source rows. Theorems 1759.33, 1759.37, and 1759.35 place $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ reads inside Q, T, W over the same finite boundary and adjacency rows.

The regular and approximation rows are then read in order. Theorems 1759.38, 1759.27, and 1759.39 route R, G, E from the rational window to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The context rows $B, A, M, L, S, H, C, P, N$ are preserved by carrier admission, classifier transport, and local naming replay. Thus every rational-window approximation consumer factors through the displayed Farey packet rows, and the excluded quotient, selection, trichotomy, choice, and completeness objects remain absent from the carrier. □

Theorem 1759.45 (Farey sequence denominator-monotone coverage)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, the displayed denominator row* L *covers each boundary entry of* B *monotonically along the finite row order before any* W, R, G, E *approximation consumer is read. The coverage is a* BHist *and* $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *fact over* $B, A, M, L, T, H, C, P, N$*, transported only by the displayed* hsame *rows and replayed only through the displayed* Cont *rows.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceDenominatorMonotoneCoverage`

Proof. Induct over the displayed boundary row B. The first and last rows are read from carrier admission, while each adjacent step is checked by the determinant-one row A and the denominator budget row L.

At a mediant insertion, the row M supplies the inserted numerator-denominator data and T keeps the dyadic tolerance request attached to the same budget. Componentwise transport through H and replay through C preserve that finite budget row, so downstream W, R, G, E reads cannot introduce a larger hidden denominator source. □

Theorem 1759.46 (Farey sequence Stern–Brocot cofinal bracket)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, every displayed Stern–Brocot bracket consumed through* S *is cofinal with a finite adjacent bracket already present in* B, A, M, L, T*. The cofinality certificate is the carried* BHist *route through* S, H, C, P, N*, not a host order-completeness or infinite-branch selector.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceSternBrocotCofinalBracket`

Proof. Induct over the finite Stern–Brocot handoff row S. The base bracket is one of the adjacent pairs in B checked by A, with its denominator budget read from L.

For a refinement step, the mediant row M inserts the next bracket inside the previous adjacent pair and the tolerance row T records the requested depth. Since H, C, P, N transport, replay, source, and name only those rows, the bracket exported to a consumer is cofinal inside the displayed finite Farey context. □

Theorem 1759.47 (Farey sequence real rational-approximation unblock)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier* $F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N)$*, a* $\mathsf{RealRationalApproximation}^{\uparrow}$ *consumer may read an approximation route only after the finite coverage rows* $B, A, M, L, T, S, D, Q, W, R, G$ *have been displayed. The terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is therefore reached through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *rows, with no selected best approximant, quotient real equality, trichotomy, choice, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier real rational approximation unblock`

Proof. Start with the rational-source rows. The boundary row B, adjacency row A, mediant row M, denominator row L, tolerance row T, Stern–Brocot row S, density row D, and rational source row Q form the finite rational bracket inventory.

The approximation route then passes through W, R, G in order: stream window, regular readback, and real-rational handoff. Transport through H, replay through C, and provenance through P, N keep the terminal seal E attached to that inventory, so a Real or Completion consumer receives a finite rational-approximation route and no hidden selector. □

Theorem 1759.48 (Farey sequence adjacency obligation)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the determinant-one adjacency obligation of $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *is bound exactly by the rows* A *and* S*. The row* A *records the adjacent determinant-one checks for consecutive entries of* B*, and the row* S *carries the same adjacent-pair inspection to the* $\mathsf{SternBrocot}^{\uparrow}$ *handoff before any* W, R, G, E *approximation read is available.*

Proof. Carrier admission from Definition 1759.4 exposes B, A, S as displayed rows of the same accepted packet. The classifier transport theorem Definition 1759.5 keeps these rows componentwise fixed under H, C, P, N.

The local adjacency content is supplied by A. The adjacent dyadic window theorem Definition 1759.37 starts each approximation window with the displayed boundary row and the determinant-one ledger before tolerance or stream data can be consumed.

The tree-facing continuation is supplied by S. The Stern–Brocot refinement scope theorem Definition 1759.40 and the neighbor determinacy theorem Definition 1759.41 route the same adjacent inspection through the Stern–Brocot handoff without adding a branch selector, host order, quotient real equality, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier adjacency obligation`

Theorem 1759.49 (Farey sequence refinement obligation)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the mediant refinement obligation of $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *is bound exactly by the rows* M, L, T *together with the adjacency and Stern–Brocot rows* A, S*. The inserted mediant is read from* M*, its finite denominator and tolerance budgets are read from* L, T*, and its refinement route remains attached to the adjacent-pair handoff through* A, S*.*

Proof. Start with the mediant row exposed by carrier admission. The theorem Definition 1759.9 identifies M as the displayed numerator-denominator sum inserted between the two boundary rows named by B and checked by A.

The finite budget is supplied by L, T. The denominator and tolerance control theorem Definition 1759.21 says that every mediant, Stern–Brocot, rational-source, stream, readback, and approximation read that depends on such data factors through those two rows.

The refinement handoff is then routed through S. Theorems 1759.14, 1759.30, and 1759.24 keep the inserted row on the finite A, M, L, T, S route before any downstream approximation consumer can read W, R, G, E. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier refinement obligation`

Theorem 1759.50 (Farey sequence approximation obligation)**.** *For every accepted* $\mathsf{FareySequence}^{\uparrow}$ *carrier*

$$F = (B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P, N),$$

the $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff obligation of* $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$ *is bound exactly by the rows* W, R, G, E *over the finite Farey context* B, A, M, L, T, S, D, Q*. A real-facing approximation read must pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the handoff row* G*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

Proof. Begin with the windowed approximation route. The approximation-window factorization theorem Definition 1759.6 routes every $\mathsf{RealRationalApproximation}^{\uparrow}$ read through the ordered boundary, adjacency, mediant, denominator, tolerance, Stern–Brocot, stream, readback, handoff, and real-seal rows.

The stream and rational readback stages are finite. The adjacent dyadic window theorem Definition 1759.37 supplies Q, T, W from the same adjacent Farey window, and the rational stream readback theorem Definition 1759.38 repackages that window as the row R without adding a new rational sequence or choice selector.

The real-facing boundary is then G, E. The theorem Definition 1759.39 and the real approximation ledger non-escape theorem Definition 1759.26 keep the handoff inside $B, A, M, L, T, S, D, Q, W, R, G, E, H, C, P$ with no quotient real equality, selected limit, trichotomy, countable choice, host sequence, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FareySequenceUp.FareySequenceCarrier approximation obligation`

Closure status for $\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FareySequence}^{\uparrow}$ packet is generated from a finite ordered rational boundary sequence, an adjacent determinant-one ledger, a mediant refinement row, a denominator-bound row, a dyadic tolerance row, a Stern–Brocot handoff, rational-source and density handoffs, a finite StreamName window, a RegSeqRat readback, a RealRationalApproximation handoff, a RealUp seal, componentwise transports, displayed continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1759.44, Definition 1759.46, and Definition 1759.47 bind the bridge scope through finite Farey approximation, Stern–Brocot refinement, RegSeqRat density readback, and the Real-rational approximation route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FareySequence}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not close quotient real equality, selected best approximants, trichotomy, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: No theory-axis upgrade remains; bridge checking and Lean verification are separate obligations.

Chapter 1760

A Concrete Naming Certificate for $\mathsf{AdmissibleRepresentation}^{\uparrow}$

Following Weihrauch and the represented-spaces tradition in computable analysis, the $\mathsf{AdmissibleRepresentation}^{\uparrow}$ packet records the finite finality interface by which Cauchy names become sufficient for represented-space consumers. It sits over the represented-space surface of chapter 1494, the Cauchy-representation handoff of chapter 1680, the finite stream windows of chapter 126, the regular rational readback boundary of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet expresses admissibility as a local NameCert surface: a consumer may use the displayed Cauchy route, but receives no quotient stream, selected limit, host real equality, countable-choice row, metric-completeness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Definition 1760.1 (AdmissibleRepresentation carrier)**.** *An* $\mathsf{AdmissibleRepresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, K, W, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *source row whose consumers read only the finite represented-space interface.*
2. *K is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *source row supplying the admissible Cauchy route for the same represented-space observations.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened by both X and K.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the displayed stream windows become regular rational observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare those observations at the displayed precisions.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, W, R, D have been replayed.*
7. *F is the continuous-consumer finality row: every represented-space consumer displayed in the packet factors through the same K, W, R, D, E route before reading its output.*
8. *H records componentwise* hsame *transport for the represented-space row, Cauchy source row, stream-window schedule, regular readback row, dyadic tolerance ledger, real seal, finality row, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from represented-space access through the Cauchy source, finite windows, regular readback, dyadic tolerance comparison, real seal, and consumer-finality handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{AdmissibleRepresentation}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AdmissibleRepresentation}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite admissible-representation packet. Its classifier compares accepted carriers only after transporting the displayed rows to a common finite surface, and it contains no coordinate for quotient streams, selected limits, host real equality, countable choice, metric completeness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.AdmissibleRepresentationUp.AdmissibleRepresentationTasteGate single carrier alignment`

Theorem 1760.2 (AdmissibleRepresentation NameCert obligations)**.** *For every accepted* $\mathsf{AdmissibleRepresentation}^{\uparrow}$ *carrier $A = (X, K, W, R, D, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AdmissibleRepresentation}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the represented-space source, Cauchy source, finite stream windows, regular readback, dyadic tolerance ledger, real seal, consumer-finality row, transport, replay, provenance, and local naming rows;*

2. *represented-space compatibility, requiring X to expose only the represented-space interface already admitted by the packet;*

3. *Cauchy handoff, requiring K, W, R, D, E to be the only displayed route from names to the real-facing seal;*

4. *consumer finality, requiring every displayed represented-space consumer to factor through K, W, R, D, E before reading output data;*

5. *transport, replay, and provenance, requiring H, C, P to preserve and source exactly the displayed packet;*

6. *local naming, requiring N to certify precisely those rows and no quotient stream, selected limit, host real equality, countable-choice row, metric-completeness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

No admissible-representation obligation is stored outside these rows.

Proof. Project the accepted carrier. Carrier admission exposes $X, K, W, R, D, E, F, H, C, P, N$ and no further row.

Represented-space compatibility is the X projection. It is read only as the represented-space source already present in the packet, so it cannot introduce a second representation relation or host-level equality.

The Cauchy handoff is the ordered route K, W, R, D, E. The source row supplies the Cauchy representation, the stream schedule supplies the finite observations, the regular readback exposes rational data, the dyadic ledger compares tolerances, and the real seal is reached only at the end of that replay.

Consumer finality is the F projection. Any displayed represented-space consumer must pass through the same handoff route before it reads output data, so its computation has no independent access to a quotient stream, selected limit, or completeness principle.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same packet, and therefore add no extra analytic coordinate. The listed rows exhaust the local NameCert surface. □

Theorem 1760.3 (AdmissibleRepresentation real-Cauchy handoff)**.** *Let $A = (X, K, W, R, D, E, F, H, C, P, N)$ be an accepted* $\mathsf{AdmissibleRepresentation}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing represented-space consumer displayed by A factors through the route*

$$X \longmapsto K \longmapsto W \longmapsto R \longmapsto D \longmapsto E \longmapsto F, H, C, P, N.$$

Thus the consumer receives the displayed $\mathsf{CauchyRepresentation}^{\uparrow}$ *route and no quotient stream, selected limit, host real equality, countable-choice row, metric-completeness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with a $\mathsf{Real}^{\uparrow}$-facing represented-space consumer of A. The represented-space source is X, but the only real-facing access row attached to X inside the packet is the Cauchy source K.

Replay the Cauchy route. The consumer opens the finite $\mathsf{StreamName}^{\uparrow}$ schedule W, reads the $\mathsf{RegSeqRat}^{\uparrow}$ row R, consults the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, and reaches the $\mathsf{Real}^{\uparrow}$ seal E only after those rows have been consumed.

Now apply finality. The row F states that every displayed consumer factors through this same route, while H, C, P, N merely transport, replay, source, and name it. Since the carrier has no coordinate for quotient streams, selected limits, host real equality, countable choice, metric completeness, or ambient real completeness, none of those data can be delivered to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{AdmissibleRepresentation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AdmissibleRepresentation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1760.1, Definition 1760.2, and Definition 1760.3 seed the finite represented-space finality interface from $\mathsf{CauchyRepresentation}^{\uparrow}$ names to $\mathsf{Real}^{\uparrow}$-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AdmissibleRepresentation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representations, selected limits, host real equality, countable choice, metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, represented-space compatibility, Cauchy handoff, consumer finality, transport, replay, provenance, and local naming for BEDC.Derived.AdmissibleRepresentationUp.

Constructive story: An $\mathsf{AdmissibleRepresentation}^{\uparrow}$ packet is generated from a $\mathsf{RepresentedSpace}^{\uparrow}$ source, a $\mathsf{CauchyRepresentation}^{\uparrow}$ source, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal, a consumer-finality row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1761

A Concrete Naming Certificate for DyadicErrorBudget$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicErrorBudget$^{\uparrow}$ packet records the finite epsilon-budget split used when two visible dyadic approximation errors must be joined before any quotient stream equality, selected limit, or ambient Real$^{\uparrow}$ completeness principle is available. It sits on the dyadic arithmetic core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the tail-radius ledger of chapter 757. The packet gives RealCompletionExactBoundaryUp and RealCauchyCompletion$^{\uparrow}$ consumers a named finite cross-route triangle-budget carrier instead of forcing each consumer to restate the same dyadic slack accounting.

Definition 1761.1 (Dyadic error-budget carrier)**.** *A* DyadicErrorBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, T, H, C, P, N)$$

with the following displayed rows:

1. *Q is the requested dyadic tolerance for the downstream comparison.*
2. *A and B are the two displayed sub-budget rows whose dyadic sum is required to fit inside Q.*
3. *S is the split certificate saying that the two sub-budgets are the only local epsilon pieces consumed by the packet.*
4. *W_X and W_Y are the two finite* StreamName$^{\uparrow}$ *windows opened for the compared approximation routes.*
5. *D_X and D_Y are the two* DyadicRatCore$^{\uparrow}$ *error rows read from the visible windows.*
6. *D_Z is the* DyadicRatCore$^{\uparrow}$ *triangle row recording the displayed dyadic sum of the two error rows against Q.*
7. *R_X and R_Y are the* RegSeqRat$^{\uparrow}$ *readback rows attached to the two windows.*
8. *T is the* DyadicTailRadiusLedger$^{\uparrow}$ *handoff row that records the same request and split inside the tail-radius accounting route.*
9. *H records componentwise* hsame *transport for the request, split, windows, dyadic rows, readbacks, tail-radius handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the request through the split, the two windows, the two dyadic error rows, the triangle row, the regular readbacks, and the tail-radius handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{DyadicErrorBudget}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicErrorBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, T, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicErrorBudgetUp.DyadicErrorBudgetUpTasteGate single carrier alignment`

Theorem 1761.2 (Dyadic error-budget triangle accounting)**.** *For every accepted* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *carrier*

$$E = (Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, T, H, C, P, N),$$

any downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBoundaryUp, *or* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *consumer that uses the packet's error bound must read the finite route*

$$Q, A, B, S \longmapsto W_X, W_Y \longmapsto D_X, D_Y, D_Z \longmapsto R_X, R_Y, T, H, C, P, N.$$

Thus the requested tolerance Q is split only through A, B, S, the two visible approximation errors are read only through the finite windows and dyadic rows W_X, W_Y, D_X, D_Y, and the exported triangle budget is exactly the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *row D_Z together with the tail-radius handoff T.*

Lean4 ✓ `BEDC.Derived.DyadicErrorBudgetUp.DyadicErrorBudgetCarrier triangle accounting`

Proof. Project the carrier of Definition 1761.1. The request row, the two sub-budget rows, and the split row are the only coordinates that can supply an epsilon split.

Read the two approximation routes through the displayed windows. The rows W_X, W_Y open the finite StreamName observations, D_X, D_Y record the two dyadic error contributions, and R_X, R_Y attach the corresponding RegSeqRat readbacks.

The triangle step is the row D_Z. It reads the same request and the same two sub-budgets, so a consumer obtains a bound only by passing through the displayed dyadic sum row and not through a hidden stream quotient or selected limit.

Finally the tail-radius handoff T and the structural rows H, C, P, N preserve the same finite route. Since no other coordinate is present, every listed downstream consumer receives exactly the displayed triangle-budget packet. □

Theorem 1761.3 (Dyadic error-budget NameCert obligations)**.** *For every accepted* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *carrier $E = (Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicErrorBudget}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the request, two sub-budgets, split certificate, two StreamName windows, three DyadicRatCore rows, two RegSeqRat readbacks, tail-radius handoff, transport, replay, provenance, and local naming rows;*

2. *request exactness, requiring Q to be the downstream tolerance consumed by the packet;*

3. *split exhaustion, requiring A and B to be the only local epsilon pieces and S to bind them to Q;*

4. *window exactness, requiring W_X and W_Y to be the finite windows from which the two error rows are read;*

5. *dyadic triangle exactness, requiring D_Z to record the displayed dyadic sum of D_X and D_Y against Q;*
6. *regular readback and tail-radius handoff, requiring R_X, R_Y, T to consume the same windows, dyadic rows, request, and split;*
7. *transport and replay stability, requiring H and C to preserve the same finite route;*
8. *provenance and local naming, requiring P and N to package exactly the displayed rows $Q, A, B, S, W_X, W_Y, D_X,$*
9. *refusal of quotient streams, selected limits, host equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert obligations.*

No dyadic error-budget obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1761.1. The carrier lists the full request, split, window, dyadic, readback, handoff, transport, replay, provenance, and local naming inventory.

Request exactness and split exhaustion follow from the rows Q, A, B, S. The packet gives the downstream tolerance one split certificate, and the carrier has no third sub-budget coordinate.

Window exactness and dyadic triangle exactness follow from W_X, W_Y, D_X, D_Y, D_Z. The two error rows are visible only through their finite windows, and the exported triangle bound is the displayed dyadic row D_Z.

The rows R_X, R_Y, T, H, C, P, N then carry the same route to regular readback, tail-radius accounting, transport, replay, provenance, and naming. Since quotient streams, selected limits, host equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge data are absent from the carrier, they cannot become local obligations. □

Theorem 1761.4 (Dyadic error-budget ladder composition)**.** *Composing two accepted* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *packets whose downstream and upstream tolerance rows match yields a single displayed ladder route. The exported tolerance is still read through the two split certificates, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *triangle rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoffs, tail-radius rows, and structural support of the original packets; no quotient stream, selected limit, host equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate is introduced.*

Proof. Project the two carriers of Definition 1761.1. Each carrier supplies its own request row, two sub-budget rows, split certificate, finite windows, dyadic error rows, triangle row, regular readbacks, tail-radius handoff, transport, replay, provenance, and local name.

Identify the shared tolerance request where the downstream row of the first packet is the upstream row of the second. The composition has no new request source; it reads that shared row through the two displayed split certificates.

Apply triangle accounting from Definition 1761.2 to each packet. The first packet exports its bound through its finite windows, dyadic rows, regular readbacks, and tail-radius handoff, and the second packet reads the matching tolerance through the same kind of displayed route.

Concatenate the displayed rows and use the NameCert obligations of Definition 1761.3 for both packets. The resulting ladder route is sourced and named by the two original structural supports, and the excluded host, quotient, choice, order, and completeness principles remain absent. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicErrorBudget}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicErrorBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1761.1, Definition 1761.2, and Definition 1761.3 seed the finite epsilon-split packet over a dyadic request, two displayed sub-budgets, two StreamName windows, three DyadicRatCore rows, two RegSeqRat readbacks, tail-radius handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{DyadicErrorBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host equality, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exactness, split exhaustion, window exactness, dyadic triangle exactness, regular readback, tail-radius handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicErrorBudgetUp.

Constructive story: A DyadicErrorBudget$^{\uparrow}$ packet is generated from a downstream dyadic request, two displayed sub-budgets, a split certificate, two finite StreamName windows, two dyadic error rows, one dyadic triangle row, two RegSeqRat readbacks, a DyadicTailRadiusLedger handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1762

A Concrete Naming Certificate for BishopModulusProductClosure$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopModulusProductClosure$^{\uparrow}$ packet records the explicit-modulus product closure route for two constructive real names before the result is sealed as a Real-facing product. It binds the source-modulus surface of chapter 1753, the dyadic split of chapter 1761, the regular-Cauchy multiplication route of chapter 1702, the Cauchy product sibling of chapter 464, and the terminal Real seal of chapter 38. The packet is a finite certificate that product reads consume displayed moduli, displayed dyadic budgets, and displayed regular-Cauchy product rows rather than quotient stream equality, selected limits, host real multiplication, countable choice, trichotomy, or ambient completeness.

Definition 1762.1 (Bishop modulus product-closure carrier)**.** *A* BishopModulusProductClosure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, U, V, E, H, C, P, N)$$

with the following displayed rows:

1. *M_X and M_Y are the two* BishopModulusReal$^{\uparrow}$ *source routes. Each row exposes one explicit Bishop modulus, its StreamName window discipline, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.*
2. *Q is the requested dyadic tolerance for the product read.*
3. *A and B are the two sub-budget rows assigned to the two source-modulus error contributions.*
4. *S is the* DyadicErrorBudget$^{\uparrow}$ *split row certifying that A and B exhaust the local error split for Q.*
5. *W_X and W_Y are the finite* StreamName$^{\uparrow}$ *factor-window rows opened through the source moduli M_X and M_Y.*
6. *D_X and D_Y are the two* DyadicRatCore$^{\uparrow}$ *factor-error rows read from the displayed windows.*
7. *D_Z is the* DyadicRatCore$^{\uparrow}$ *product-error row that combines D_X, D_Y under the split Q, A, B, S.*
8. *R_X and R_Y are the two* RegSeqRat$^{\uparrow}$ *source readbacks exposed by the source-modulus rows before multiplication.*
9. *U is the* RegularCauchyMultiplication$^{\uparrow}$ *row consuming $R_X, R_Y, W_X, W_Y, D_X, D_Y, D_Z$ under the displayed budget split.*

10. *V is the* $\mathsf{CauchyProduct}^{\uparrow}$ *sibling row that presents the same product read as the Cauchy-product NameCert surface.*

11. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *product seal reached only after $M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, U, V$ have been displayed.*

12. *H records componentwise* hsame *transport for the two source moduli, the error-budget split, windows, dyadic rows, regular readbacks, product rows, Real seal, replay, provenance, and local naming.*

13. *C records displayed* Cont *replay from each Real-facing product request through the same finite route.*

14. *P is the* Pkg *provenance over* $\mathsf{BishopModulusProductClosure}^{\uparrow}$, $\mathsf{BishopModulusReal}^{\uparrow}$, $\mathsf{DyadicErrorBudget}^{\uparrow}$, $\mathsf{RegularCauchyMultiplication}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

15. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopModulusProductClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, U, V, E,$ It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, host real multiplication, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1762.2 (Bishop modulus product-closure NameCert obligations)**.** *For every accepted* $\mathsf{BishopModulusProductClosure}^{\uparrow}$ *carrier*

$$Z = (M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, U, V, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopModulusProductClosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{BishopModulusReal}^{\uparrow}$ *source routes, requested tolerance, two sub-budgets, split certificate, StreamName windows, DyadicRatCore factor and product rows, RegSeqRat source readbacks, RegularCauchyMultiplication row, CauchyProduct row, Real seal, transport, replay, provenance, and local naming;*

2. *source-modulus exactness, requiring M_X and M_Y to be read before any factor window, dyadic factor row, regular readback, multiplication row, CauchyProduct row, or Real product seal is exposed;*

3. *error-budget split exhaustion, requiring Q, A, B, S to be the only local product-error budget route and to factor through the* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *split surface;*

4. *product-row compatibility, requiring $W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y$ to be the common rows consumed by both U and V;*

5. *Real-seal nonescape, requiring E to remain terminal with respect to the displayed source-modulus, budget, window, dyadic, regular-readback, and product rows;*

6. *transport and replay stability, requiring H and C to preserve the same finite route under* hsame *transport and* Cont *replay;*

7. *provenance and local naming, requiring P and N to package exactly the displayed rows and no additional quotient, selected-limit, choice, trichotomy, host-equality, host-multiplication, completeness, Lean, or bridge data.*

No Bishop modulus product-closure obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1762.1. The packet displays the two source-modulus rows, the product tolerance and split, the two factor windows, the dyadic factor and product ledgers, the regular readbacks, the two product rows, the Real seal, and the structural rows.

Source-modulus exactness follows by reading chapter 1753 twice. The rows M_X and M_Y expose the two Bishop modulus routes before $W_X, W_Y, D_X, D_Y, R_X, R_Y$ can be consumed.

The error-budget clause is the sibling route through chapter 1761. The request Q, sub-budgets A, B, and split row S are the only budget coordinates in the carrier, so the split is exhausted by those displayed rows.

Product-row compatibility reads chapter 1702 and chapter 464 over the same source data. Both product rows consume the displayed StreamName windows, DyadicRatCore rows, and RegSeqRat readbacks, so neither row can introduce a second product source.

Finally apply the Real seal discipline from chapter 38. The row E is terminal and downstream of the two source-modulus routes, the budget split, the finite windows, the dyadic rows, the regular readbacks, and the product rows, while H, C, P, N transport, replay, package, and name exactly that route. □

Lean4 ✓ `BEDC.Derived.BishopModulusProductClosureUp.BishopModulusProductClosureTasteGate single carrier alignment`

Theorem 1762.3 (Bishop modulus product-closure Real product seal)**.** *For every accepted* BishopModulusProductC *carrier*

$$Z = (M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D_Y, D_Z, R_X, R_Y, U, V, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-facing product read factors through the finite route*

$$M_X, M_Y \longmapsto Q, A, B, S \longmapsto W_X, W_Y \longmapsto D_X, D_Y, D_Z \longmapsto R_X, R_Y \longmapsto U, V \longmapsto E, H, C, P, N.$$

Consequently the read factors through $\mathsf{BishopModulusReal}^{\uparrow}$*,* $\mathsf{DyadicErrorBudget}^{\uparrow}$*,* $\mathsf{RegularCauchyMultiplication}^{\uparrow}$*,* $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before the Real product seal is available.*

Proof. Begin with a Real-facing product read of Z. By Definition 1762.1, the only Real-facing coordinate is the terminal row E.

The source part of the route is forced by the two $\mathsf{BishopModulusReal}^{\uparrow}$ rows of chapter 1753. A consumer reaches factor windows, dyadic factor rows, and regular readbacks only after M_X and M_Y have displayed the corresponding modulus routes.

The product-budget part is forced by chapter 1761. The rows Q, A, B, S expose the finite budget split before D_Z can be used as the product-error row.

The multiplication part is forced by chapter 1702 and chapter 464. The rows U and V consume the same windows, dyadic rows, and RegSeqRat readbacks, and neither row precedes the source-modulus or error-budget routes.

The final seal is the Real boundary of chapter 38. Since E is downstream of $M_X, M_Y, Q, A, B, S, W_X, W_Y, D_X, D$ every Real-facing product read factors through the route in the statement and through the structural rows H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopModulusProductClosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopModulusProductClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1762.1, Definition 1762.2, and Definition 1762.3 seed the finite explicit-modulus product route over two BishopModulusReal source rows, a DyadicErrorBudget split, RegularCauchyMultiplication, CauchyProduct, and a Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopModulusProductClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-modulus exactness, error-budget split exhaustion, product-row compatibility, Real-seal nonescape, transport and replay stability, provenance, and local naming for BEDC.Derived.BishopModulusProductClosureUp.

Constructive story: A $\mathsf{BishopModulusProductClosure}^{\uparrow}$ packet is generated from two BishopModulusReal source routes, one dyadic product request, two displayed sub-budgets, a DyadicErrorBudget split, two StreamName factor windows, DyadicRatCore factor and product ledgers, RegSeqRat readbacks, RegularCauchyMultiplication and CauchyProduct rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1763

A Concrete Naming Certificate for $\mathsf{AbelSummation}^{\uparrow}$

Following Abel and Dirichlet summation by parts in Bishop–Bridges constructive analysis, the $\mathsf{AbelSummation}^{\uparrow}$ packet isolates the finite identity consumed by the Abel-test route of chapter 1496 and the Dirichlet-test route of chapter 1497. Its source rows sit over the finite series windows of chapter 121; its regular handoff and dyadic estimates use chapter 301 and chapter 291; and its seal-facing boundary is the $\mathsf{Real}^{\uparrow}$ route of chapter 38. The certificate records a displayed finite transform and the handoff rows that downstream convergence tests may read; it does not choose an infinite sum or appeal to host completeness.

Definition 1763.1 (AbelSummation carrier)**.** *An* $\mathsf{AbelSummation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, A, D, B, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite partial-sum row, displaying the inspected source values and their cumulative sums on the admitted interval.*
2. *A is the coefficient-window row, displaying the scalar coefficients read at the same finite endpoints.*
3. *D is the finite-difference row, displaying the adjacent coefficient differences used by the summation-by-parts calculation.*
4. *B is the boundary-term row, displaying the two endpoint products and the finite interior products determined by S, A, D.*
5. *T is the tail-estimate row, assigning a requested dyadic tolerance to a finite source window, coefficient window, and difference window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed boundary and tail rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to that regular rational handoff.*
8. *H records componentwise* hsame *transport for partial sums, coefficient windows, finite differences, boundary terms, tail estimates, regular handoff, real seal, continuation replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a precision request through T to the rows S, A, D, B, then through R to the seal row E.*

10. *P is the* Pkg *provenance over* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelSummation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven displayed rows. It has no coordinate for a selected infinite sum, quotient series equality, host real completeness, countable choice, trichotomy, open-cover compactness, or an ambient summation operator.

Lean4 (definition) `BEDC.Derived.AbelSummationUp.AbelSummationUp`
Lean4 ✓ `BEDC.Derived.AbelSummationUp.AbelSummationTasteGate single carrier alignment`

Theorem 1763.2 (AbelSummation NameCert obligations)**.** *For every accepted* $\mathsf{AbelSummation}^{\uparrow}$ *carrier* $Q = (S, A, D, B, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AbelSummation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *partial-sum exposure for S, preserving the inspected source values and cumulative sums along componentwise* hsame *transport;*
3. *coefficient-window exposure for A, preserving the endpoint coefficients read by the finite identity;*
4. *finite-difference exposure for D, preserving the adjacent coefficient differences used by the interior products;*
5. *boundary exactness for B, stating that the displayed endpoint and interior terms are the finite summation-by-parts row determined by S, A, D;*
6. *tail-handoff exactness for T, R, E, forcing every completion-facing consumer through the displayed boundary row and regular rational handoff;*
7. *transport stability, continuation replay, provenance, and local naming for exactly the route recorded by H, C, P, N.*

These are obligations over displayed finite rows, not obligations over a host summation operator or a selected completed series.

Proof. Project the accepted packet $Q = (S, A, D, B, T, R, E, H, C, P, N)$. The projection exposes exactly the partial-sum row, coefficient-window row, finite-difference row, boundary-term row, tail-estimate row, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

Read the finite identity through S, A, D, B. The row S supplies cumulative sums on the inspected interval, A supplies the endpoint coefficients, and D supplies the adjacent coefficient differences. The boundary row B records the endpoint products and interior products obtained from those rows.

Now read a precision request through T. The schedule names only finite windows, so the handoff row R receives a regular rational estimate whose data are already displayed in S, A, D, B, T.

Finally apply the structural rows. Componentwise transport in H preserves the analytic rows together, while C, P, N replay, source, and name that same route. Since the carrier has no further coordinate, the seven listed clauses exhaust the local $\mathsf{NameCert}_{\mathsf{AbelSummation}^{\uparrow}}$ surface. □

Theorem 1763.3 (AbelSummation partial-sum handoff)**.** *Every accepted* $\mathsf{AbelSummation}^{\uparrow}$ *carrier sends a displayed coefficient-weighted finite sum to a completion-facing consumer only through*

$$S, A, D, B, T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer may read the summation-by-parts calculation only after reading the finite partial sums, coefficient windows, adjacent differences, boundary terms, and tail estimate that determine the handoff.*

Proof. Begin with an accepted carrier and a completion-facing read. By the carrier definition, the only rows visible to such a read are the regular handoff row R, the seal row E, and the structural rows H, C, P, N.

Trace R backward through the packet. Its input is the tail-estimate row T, and the estimate row is defined over the displayed finite rows S, A, D, B.

The partial sums, coefficient values, finite differences, and boundary terms are therefore read before any regular rational or real seal row can be consumed. No separate coordinate supplies a host sum, a quotient series equality, or a choice-selected limit.

Transport and replay preserve this route componentwise. Hence every completion-facing read factors through the displayed chain and cannot bypass the finite summation-by-parts packet. □

Lean4 ✓ `BEDC.Derived.AbelSummationUp.AbelSummationPartialSumHandoff`

Theorem 1763.4 (AbelSummation Dirichlet-test route)**.** *Any* $\mathsf{DirichletTest}^{\uparrow}$ *or* $\mathsf{AbelTest}^{\uparrow}$ *consumer that uses a summation-by-parts row from an accepted* $\mathsf{AbelSummation}^{\uparrow}$ *carrier factors through the same finite identity rows* S, A, D, B, T*. The consumer may combine those rows with its own bounded-partial-sum or monotone-null ledger, but it cannot import selected infinite sums, quotient series equality, host real completeness, countable choice, trichotomy, or open-cover compactness from the* $\mathsf{AbelSummation}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.AbelSummationUp.AbelSummationDirichletTestRoute`

Proof. Project the shared summation-by-parts input used by the convergence-test consumer. The $\mathsf{AbelSummation}^{\uparrow}$ carrier exports only the rows S, A, D, B, T to an analytic handoff, followed by R, E, H, C, P, N for regular readback, seal, transport, replay, provenance, and local naming.

For an $\mathsf{AbelTest}^{\uparrow}$ read, the downstream packet may add its monotone null coefficient ledger and uniform-limit row. For a $\mathsf{DirichletTest}^{\uparrow}$ read, the downstream packet may add its bounded partial-sum and null-tail schedule rows. In both cases the summation-by-parts input itself remains the displayed finite row B determined by S, A, D.

Because the source carrier contains no prohibited coordinate, neither consumer can receive such data through hsame transport or Cont replay. The route is exactly the finite BEDC identity plus the consumer's own convergence-test rows. □

Falsifiable prediction: An accepted $\mathsf{AbelSummation}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal, $\mathsf{AbelTest}^{\uparrow}$ row, or $\mathsf{DirichletTest}^{\uparrow}$ row without reading the partial-sum row, coefficient-window row, finite-difference row, boundary-term row, and tail-estimate row refutes the carrier surface.

Independence witness: series, abel-test, dirichlet-test, regseqrat, dyadicratcore, real: no listed sibling supplies the whole eleven-row packet $Q = (S, A, D, B, T, R, E, H, C, P, N)$, because each sibling contributes only a source, convergence-test consumer, regular readback, dyadic estimate, or seal face while this chapter binds the finite summation-by-parts identity with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelSummation}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelSummation}^{\uparrow}$ packet is generated from finite partial-sum rows, displayed coefficient windows, adjacent finite-difference rows, boundary-term rows, a finite tail-estimate row, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{AbelSummation}^{\uparrow}}$, seed)

Scope closed: Definition 1763.1, Definition 1763.2, Definition 1763.3, and Definition 1763.4 seed the finite summation-by-parts boundary over Series$^{\uparrow}$, AbelTest$^{\uparrow}$, DirichletTest$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{AbelSummation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected infinite sums, quotient series equality, host real completeness, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite NameCert obligation surface, partial-sum handoff theorem, and Dirichlet-test route theorem.

Chapter 1764

A Concrete Naming Certificate for $\mathsf{UniformLimitMetric}^{\uparrow}$

Following Bourbaki and Bishop–Bridges, the $\mathsf{UniformLimitMetric}^{\uparrow}$ packet records the traditional metric-valued uniform-limit handoff as a finite L10 NameCert route. It sits between the uniform-limit continuity boundary of chapter 1748, the interchange route of chapter 1749, the complete-metric consumer surface of chapter 128, and the displayed metric source of chapter 57. Its distance rows are read through the rational and real route of chapter 301, chapter 38, and chapter 291.

The packet exposes the finite metric data needed by a complete-metric consumer of a uniformly convergent metric-valued family. It does not introduce host completeness, quotient streams, selected limits, open-cover compactness, countable choice, or a second metric completion object.

Definition 1764.1 (Uniform-limit-metric carrier)**.** *A* $\mathsf{UniformLimitMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, F, U, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier, distance classifier, metric-law ledger, and the finite distance observations available to the packet.*
2. *F is the metric-valued family row. It records the displayed family entries whose pairwise distances are inspected only through M and through finite windows.*
3. *U is the uniform modulus row, giving one shared threshold schedule for the family and for the endpoint-facing read.*
4. *B is the finite dyadic distance-budget row. It stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, request indices, late-window bounds, and distance comparison budgets consumed by U.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-comparison row obtained after the metric distance observations and dyadic budgets have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for terminal distance readings reached from the regular tail comparison.*
7. *H records componentwise* hsame *transport for the metric source, family row, uniform modulus, dyadic budgets, regular tail comparison, Real seal, continuation routes, package provenance, and local naming row.*
8. *C records displayed* Cont *replay from the metric source through the family row, uniform modulus, dyadic budget, regular tail comparison, Real seal, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* UniformLimitMetric$^{\uparrow}$, UniformLimitContinuous$^{\uparrow}$, UniformLimitInterchange$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{UniformLimitMetric}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, F, U, B, R, E, H, C, P, N$. It has no coordinate for host completeness, quotient streams, selected limits, open-cover compactness, countable-choice selectors, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 1764.2 (Uniform-limit-metric NameCert obligations)**.** *For every accepted* UniformLimitMetric$^{\uparrow}$ *carrier $Q = (M, F, U, B, R, E, H, C, P, N)$, the local* NameCert$_{\text{UniformLimitMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, metric-valued family, uniform modulus, dyadic distance budgets, regular tail comparison, Real seal, transport, replay, provenance, and local naming rows;*
2. *classifier exactness, requiring every metric-valued family read to use the point and distance classifiers displayed by M;*
3. *uniform-modulus stability, requiring endpoint-facing reads and family-facing reads to consult the same threshold schedule U before any tail comparison is exported;*
4. *dyadic budget exactness, requiring every distance estimate to pass through the finite* DyadicRatCore$^{\uparrow}$ *budget row B;*
5. *RegSeqRat tail comparison, requiring R to be obtained only after the metric distance observations and dyadic budgets have been displayed;*
6. *Real seal handoff, requiring E to be consumed only after R and only along the route replayed by C;*
7. *ledger nonescape, excluding host completeness, quotient streams, selected limits, open-cover compactness, countable-choice selectors, hidden completion objects, and ambient* Real$^{\uparrow}$ *completeness as local certificate data.*

No uniform-limit metric obligation is stored outside these rows.

Proof. Project the carrier of Definition 1764.1. The analytic rows are exactly the metric source M, the metric-valued family row F, the uniform modulus U, the dyadic budget row B, the regular tail comparison R, and the Real seal E.

Classifier exactness follows from the shape of M and F. The family row contains no independent point equality or distance relation, so every family-facing read must return to the displayed point and distance classifiers carried by M.

The modulus and budget rows then determine the tail comparison route. The replay row C places U before B, places B before R, and places R before E, while H transports only the same listed coordinates.

The refusal clauses are forced by absence of coordinates. Since the carrier has no host completeness, quotient stream, selected limit, open-cover compactness, choice selector, hidden completion object, or ambient Real-completeness row, those objects cannot become local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.UniformLimitMetricUp.UniformLimitMetricTasteGate single carrier alignment`

Theorem 1764.3 (Uniform-limit-metric complete handoff)**.** *Every complete-metric consumer of an accepted* $\mathsf{UniformLimitMetric}^{\uparrow}$ *carrier reads the finite route*

$$M, F \longmapsto U \longmapsto B \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives the displayed metric classifier, uniform modulus, finite dyadic distance budgets, $\mathsf{RegSeqRat}^{\uparrow}$ *tail comparison,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it reads the packet. The route never exports host completeness, quotient streams, selected limits, open-cover compactness, countable choice, hidden completion objects, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a complete-metric consumer of Q. By Definition 1764.1, the consumer can enter the packet only through the displayed metric source M and the metric-valued family row F.

The uniform threshold route is visible before any completion-facing read. The row U supplies the shared modulus, and the dyadic budget row B supplies the finite distance tolerances attached to the inspected windows.

After those rows have been displayed, the regular tail comparison R and the Real seal E become available. The structural rows H, C, P, N transport, replay, source, and name that same finite route.

Composing these projections gives the displayed factorization. Applying Definition 1764.2, a complete-metric consumer cannot replace the route by host completeness, quotient streams, selected limits, open-cover compactness, countable choice, hidden completion data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1764.1, Definition 1764.2, and Definition 1764.3 seed the finite metric-valued uniform-limit route through displayed metric classifiers, uniform modulus rows, dyadic distance budgets, RegSeqRat tail comparisons, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLimitMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full metric completeness, open-cover compactness, host completeness, quotient streams, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, uniform-modulus stability, dyadic budget exactness, RegSeqRat tail comparison, Real seal handoff, ledger nonescape, and complete-metric consumer handoff for BEDC.Derived.UniformLimitMetricUp.

Constructive story: A $\mathsf{UniformLimitMetric}^{\uparrow}$ packet is generated from a displayed MetricUp source, a metric-valued family row, a shared uniform modulus, finite DyadicRatCore distance budgets, a RegSeqRat tail comparison, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1765

A Concrete Naming Certificate for $\mathsf{HardyCesaroMean}^{\uparrow}$

Following Hardy on divergent series and Bishop–Bridges constructive analysis, the $\mathsf{HardyCesaroMean}^{\uparrow}$ packet records finite Cesaro averaging of a displayed real-name sequence before any Real-completion consumer reads a transformed endpoint. It sits between the summability-transform route of chapter 1682, the shared finite-tail context of chapter 1736, the finite sequence windows of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names a finite averaging route; it does not import a host summability theorem, a selected limit, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1765.1 (Hardy–Cesaro mean carrier)**.** *A* $\mathsf{HardyCesaroMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, P, U, D, R, E, T, C, Q, N)$$

with the following displayed rows:

1. *S is the source real-name sequence window, listing only the finite* $\mathsf{StreamName}^{\uparrow}$ *observations of the input sequence requested by the current Cesaro prefix.*
2. *P stores finite prefix sums, each obtained from the displayed source rows in S and never from a completed host sequence.*
3. *U stores the unary denominator and prefix-length rows, including the visible length used to divide each prefix sum by its Cesaro denominator.*
4. *D stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *division rows and tolerance budgets for prefix summation, denominator inversion, averaging, and endpoint-facing error accounting.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite Cesaro means exposed by P, U, D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source windows, prefix sums, denominator rows, dyadic budgets, and regular readback have been displayed.*
7. *T stores componentwise* hsame *transport for source windows, prefix sums, denominator rows, dyadic budgets, regular readback, real seal, continuation, provenance, and local naming.*
8. *C stores displayed* Cont *replay from source-window reads to prefix sums, from prefix sums and denominator rows to dyadic division, from dyadic division to regular readback, and from regular readback to the real seal.*

9. *Q is the* Pkg *provenance over* $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{Seq}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HardyCesaroMean}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, P, U, D, R, E, T, C, Q, N$. It has no coordinate for a host summability method, selected limit, quotient equality of real-name streams, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.HardyCesaroMeanUp.HardyCesaroMeanUp`
Lean4 ✓ `BEDC.Derived.HardyCesaroMeanUp.HardyCesaroMeanTasteGate single carrier alignment`

Theorem 1765.2 (Hardy–Cesaro mean NameCert obligations)**.** *For every accepted* $\mathsf{HardyCesaroMean}^{\uparrow}$ *carrier $H = (S, P, U, D, R, E, T, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HardyCesaroMean}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the displayed source-window, prefix-sum, denominator, dyadic-division, regular-readback, real-seal, transport, continuation, provenance, and naming rows;*
2. *finite Cesaro averaging exactness, requiring each exposed mean to be computed from the displayed prefix sum P, visible prefix length U, and dyadic division ledger D;*
3. *transformed regular-readback handoff, requiring every transformed sequence read to pass through R after the source, prefix, denominator, and dyadic rows have been displayed;*
4. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the endpoint row E to consume only the displayed finite averaging route;*
5. *transport and provenance, requiring T, C, Q, N to preserve, replay, source, and name the same packet without adding a hidden host limit or summability coordinate.*

Proof. Project the carrier of Definition 1765.1. Carrier admission is the finite inventory $S, P, U, D, R, E, T, C, Q, N$, so the local certificate has no detached coordinate for an infinite source sequence or a completed mean sequence.

Finite Cesaro averaging exactness is read from the order of the displayed rows. The source window S feeds the finite prefix sums P; the visible denominator row U supplies the prefix length; and the dyadic ledger D records the finite division and tolerance budget used by the exposed mean.

The transformed readback is then forced through R. A $\mathsf{Real}^{\uparrow}$ endpoint can only continue from R to the seal row E, with no second route through a host summability theorem, selected limit, quotient equality, countable choice, trichotomy, or ambient completeness principle.

Finally, T, C, Q, N transport, replay, source, and name exactly the displayed route. They are structural rows over the same finite packet and therefore cannot contribute an additional analytic principle. □

Theorem 1765.3 (Hardy–Cesaro regular transform handoff)**.** *Every Real-completion-facing read from an accepted* $\mathsf{HardyCesaroMean}^{\uparrow}$ *carrier factors through the displayed source route in* $\mathsf{Series}^{\uparrow}$ *or* $\mathsf{Seq}^{\uparrow}$*, the summability-transform context of* $\mathsf{ToeplitzLemma}^{\uparrow}$ *and* $\mathsf{UniformCauchySeries}^{\uparrow}$*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets, the* $\mathsf{FastConvergentSeries}^{\uparrow}$ *tail discipline where present, and the* $\mathsf{Real}^{\uparrow}$ *seal. Consequently the read exposes only*

$$S, P, U, D, R, E, T, C, Q, N$$

before it reaches a completion-facing consumer.

Proof. Start with a completion-facing request for the Cesaro-transformed sequence. By Definition 1765.1, the request first sees the source rows through S and the provenance row Q, so the source is available only as displayed $\mathsf{Series}^{\uparrow}$ or $\mathsf{Seq}^{\uparrow}$ data.

The averaging route is the finite matrix-row instance of the summability-transform surface named by chapter 1682. When a uniform tail or summable-series context is present, chapter 1736 supplies the sibling route that keeps all tail information inside finite partial-sum and threshold rows.

The actual Cesaro mean is then read through P, U, D. The selected source windows are the $\mathsf{StreamName}^{\uparrow}$ observations in S, the finite divisions and tolerance budgets are the $\mathsf{DyadicRatCore}^{\uparrow}$ rows in D, and the transformed regular sequence reaches consumers only through the $\mathsf{RegSeqRat}^{\uparrow}$ row R.

If a fast tail discipline is part of the displayed provenance, it is consumed only through the $\mathsf{FastConvergentSeries}^{\uparrow}$ rows named by Q before the endpoint reaches E. The endpoint is therefore a $\mathsf{Real}^{\uparrow}$ seal for the already displayed route, not a selected limit or an ambient completeness witness.

The rows T, C, Q, N preserve the same route under transport, continuation replay, package provenance, and local naming. Since every completion-facing read has already passed through those finite rows, no host summability principle, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can be recovered from the packet. □

Lean4 ✓ `BEDC.Derived.HardyCesaroMeanUp.HardyCesaroMeanRegularTransformHandoff`

Falsifiable prediction: Every $\mathsf{HardyCesaroMean}^{\uparrow}$ completion-facing read factors through finite source windows, prefix sums, unary denominator rows, DyadicRatCore division budgets, RegSeqRat readback, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: series, seq, toeplitzlemma, uniformcauchyseries, streamname, regseqrat, dyadicratcore, fastconvergentseries, real: $\mathsf{HardyCesaroMean}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source sequence windows, finite prefix sums, unary denominator rows, dyadic averaging budgets, regular transformed readback, optional tail-discipline provenance, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HardyCesaroMean}^{\uparrow}}$.

Constructive story: A $\mathsf{HardyCesaroMean}^{\uparrow}$ packet is generated from source real-name sequence windows, finite prefix sums, unary denominator and prefix-length rows, dyadic division and tolerance budgets, RegSeqRat readback for Cesaro means, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HardyCesaroMean}^{\uparrow}}$, seed)

Scope closed: Definition 1765.1, Definition 1765.2, and Definition 1765.3 seed the finite Cesaro averaging route from real-name sequence windows to Real-completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HardyCesaroMean}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host summability, selected limits, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite Cesaro averaging exactness, transformed regular-readback handoff, Real seal nonescape, transport and provenance, and TasteGate field faithfulness for BEDC.Derived.HardyCesaroMeanUp.

Chapter 1766

A Concrete Naming Certificate for $\mathsf{HolderContinuity}^{\uparrow}$

Following Holder and Bishop–Bridges constructive analysis, the $\mathsf{HolderContinuity}^{\uparrow}$ packet records the classical power-law continuity surface as finite BEDC data. It sits between the displayed metric source of chapter 57, the terminal real coefficient route of chapter 38, the graph-facing map surface of chapter 130, the exponent-one boundary of chapter 410, and the explicit modulus routes of chapter 1631 and chapter 369. The packet gives later Real and Completion consumers a finite power-law modulus layer without forcing all continuity data to be either Lipschitz or arbitrary-modulus data.

Definition 1766.1 (Holder continuity carrier)**.** *A* $\mathsf{HolderContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, G, \alpha, K, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, carrying the source point classifier, source distance classifier, and the finite source-distance observations inspected by the packet.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, carrying the target point classifier, target distance classifier, and the finite target-distance observations exposed by the graph row.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from X to Y, including only those finite source and target observations consumed by the continuity read.*
4. *α is the rational exponent row. It records a positive rational exponent, its displayed comparison data, and the finite power-law read discipline used by the packet.*
5. *K is the* $\mathsf{Real}^{\uparrow}$ *coefficient ledger for the displayed Holder constant and the real-valued distance estimates used by the power-law bound.*
6. *M is the induced* $\mathsf{ModulusContinuity}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *row obtained from X, Y, G, α, K by reading the power-law budget as a displayed modulus.*
7. *H records componentwise* hsame *transport for the two metric rows, graph row, rational exponent, coefficient ledger, induced modulus row, continuation route, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite source-distance request through G, α, K, M, H, P, N to the target-distance estimate.*

9. *P is the* Pkg *provenance over* HolderContinuity$^\uparrow$, Met$^\uparrow$, Real$^\uparrow$, ContinuousMap$^\uparrow$, ModulusContinuity$^\uparrow$, UniformModulus$^\uparrow$, LipschitzMap$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{HolderContinuity}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, Y, G, \alpha, K, M, H, C, P, N$. It has no coordinate for a host real power function, unrestricted exponent calculus, ambient metric completion, quotient metric equality, selected limit, choice sequence, or a continuity principle detached from the displayed graph.

Lean4 ✓ `BEDC.Derived.HolderContinuityUp.HolderContinuityTasteGate single carrier alignment`

Theorem 1766.2 (Holder continuity NameCert obligations)**.** *For every accepted* HolderContinuity$^\uparrow$ *carrier $Q = (X, Y, G, \alpha, K, M, H, C, P, N)$, the local* NameCert$_{\text{HolderContinuity}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source and target* Met$^\uparrow$ *rows,* ContinuousMap$^\uparrow$ *graph row, rational exponent row,* Real$^\uparrow$ *coefficient ledger, induced modulus row, transport, replay, provenance, and local naming rows;*
2. *exponent and coefficient stability, requiring α and K to be transported only componentwise and to remain attached to the same graph row G;*
3. *power-law metric-bound read, requiring every accepted source-distance request to read the target-distance estimate through X, Y, G, α, K before any modulus row is exported;*
4. *induced modulus handoff, requiring M to be consumed as the displayed* ModulusContinuity$^\uparrow$ *or* UniformModulus$^\uparrow$ *row generated by the power-law budget;*
5. *transport and replay, requiring H and C to preserve the same displayed dependency order under* hsame *transport and* Cont *replay;*
6. *ledger nonescape, excluding host real power functions, unrestricted exponent calculus, ambient metric completion, quotient metric equality, selected limits, choice sequences, and detached continuity principles as local certificate data.*

No Holder continuity obligation is stored outside these rows.

Proof. Project the carrier of Definition 1766.1. Carrier admission exposes exactly the two metric rows X, Y, the continuous graph row G, the exponent row α, the coefficient ledger K, the induced modulus row M, and the structural rows H, C, P, N.

Exponent and coefficient stability are componentwise clauses. The row α is read only as the displayed rational exponent, while K is read only as the Real coefficient ledger attached to the same graph row G.

The power-law metric-bound read is forced by the order of the rows. A source-distance request first reads the metric source X, then the graph row G, then the target metric row Y, and only then consults α and K for the displayed power-law estimate.

The modulus handoff is the row M. Since M is downstream of X, Y, G, α, K, every ModulusContinuity$^\uparrow$ or UniformModulus$^\uparrow$ consumer receives the displayed power-law budget rather than an arbitrary continuity witness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. The excluded objects have no coordinate in the carrier, so they cannot become local NameCert obligations. □

Theorem 1766.3 (Holder continuity modulus handoff)**.** *Every* ModulusContinuity$^\uparrow$ *or* UniformModulus$^\uparrow$ *consumer of an accepted* HolderContinuity$^\uparrow$ *carrier reads the Holder packet only through* Met$^\uparrow$, Real$^\uparrow$,

ContinuousMap$^{\uparrow}$, ModulusContinuity$^{\uparrow}$, UniformModulus$^{\uparrow}$, LipschitzMap$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. Equivalently, the consumer factors through the displayed route*

$$X, Y, G, \alpha, K \longmapsto M \longmapsto H, C, P, N.$$

The handoff exports no host real power function, unrestricted exponent calculus, ambient metric completion, quotient metric equality, selected limit, choice sequence, or detached continuity principle.

Proof. Begin with a modulus consumer of Q. By Definition 1766.1, the only modulus-facing coordinate is M, and M is displayed only after the two metric rows, graph row, exponent row, and coefficient ledger have been read.

The first part of the route is analytic. The source and target distance classifiers come from X and Y, the graph-facing continuity data come from G, the rational exponent comes from α, and the Real coefficient and distance estimates come from K.

The second part of the route is the continuity handoff. The row M is read as a ModulusContinuity$^{\uparrow}$ or UniformModulus$^{\uparrow}$ row, while the LipschitzMap$^{\uparrow}$ dependency is visible only as the exponent-one boundary named in provenance, not as an independent replacement for the Holder packet.

The structural rows H, C, P, N preserve the same factorization under transport, replay, provenance, and local naming. Since every consumer-facing read has already passed through those rows, none of the excluded host-level or choice-level objects can be recovered from the packet. □

Closure status for NameCert$_{\text{HolderContinuity}^{\uparrow}}$.

Constructive story: A HolderContinuity$^{\uparrow}$ packet is generated from source and target MetricUp rows, a ContinuousMap graph row, a positive rational exponent row, a RealUp coefficient ledger, an induced ModulusContinuity or UniformModulus row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HolderContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 1766.1, Definition 1766.2, and Definition 1766.3 seed the finite power-law continuity route from displayed metric and graph data to modulus consumers.

Formal verification: FormalStatus(NameCert$_{\text{HolderContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted exponent calculus, host real power functions, ambient metric completion, quotient metric equality, selected limits, choice sequences, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exponent and coefficient stability, power-law metric-bound read, induced modulus handoff, transport, replay, ledger nonescape, and modulus-consumer handoff for BEDC.Derived.HolderContinuityUp.

Chapter 1767

A Concrete Naming Certificate for $\mathsf{FiniteEpsilonNet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ packet records the finite epsilon-net witness used before total-bounded, compact-metric, and continuous-map consumers read a metric handoff. It sits over the displayed metric source of chapter 57, the tolerance-indexed total-boundedness surface of chapter 127, the compact-metric consumer row of chapter 129, and the finite rational tolerance route supplied by $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$. The packet keeps centers, coverage witnesses, and transport ledgers as finite BEDC rows rather than as a host-level finite subset or an open-cover compactness assertion.

Definition 1767.1 (Finite epsilon-net carrier)**.** *A* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, \varepsilon, P, C, D, H, R, S, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier, distance classifier, and metric-law ledger read by the packet.*
2. *ε is the positive tolerance row, read as a* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cell together with the displayed positivity witness used by downstream coverage claims.*
3. *P is the closed* $\mathsf{ProbeBundle}$ *of centers. Its membership rows are the only center-admission data exported by the packet.*
4. *C is the center-carrier ledger, recording for each accepted center of P the corresponding point-classifier admission in X.*
5. *D is the distance and coverage ledger. For each accepted source point inspected by the packet it displays an admitted center of P and a metric-distance row in X bounded by ε.*
6. *H records componentwise* hsame *transport for the metric source, tolerance row, center bundle, center-carrier ledger, distance and coverage ledger, replay row, provenance row, and local naming row.*
7. *R records displayed* Cont *replay from a coverage request through $X, \varepsilon, P, C, D, H, S, N$.*
8. *S is the* Pkg *provenance over* $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, \varepsilon, P, C, D, H, R, S, N$. It has no coordinate for an ambient finite subset, a host enumeration, an open cover, a selected compactness proof, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1767.2 (Finite epsilon-net NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier $Q = (X, \varepsilon, P, C, D, H, R, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, positive tolerance, closed center bundle, center-carrier ledger, coverage-distance ledger, transport, replay, provenance, and local naming rows;*
2. *center visibility, requiring every center used by a coverage witness to enter through the displayed* $\mathsf{ProbeBundle}$ *row P and the center-carrier ledger C;*
3. *finite coverage, requiring each inspected source point to be paired by D with an admitted center and a displayed distance row bounded by ε;*
4. *tolerance transport, requiring the same* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row to be preserved by H before any coverage conclusion is exported;*
5. *metric-distance handoff, requiring every coverage distance to be read through the point and distance classifiers carried by X;*
6. *ledger nonescape, excluding ambient finite subsets, host enumerations, open covers, selected compactness proofs, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No finite epsilon-net obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 1767.1. The analytic rows are exactly the metric source X, positive tolerance ε, closed center bundle P, center-carrier ledger C, and coverage-distance ledger D.

Carrier admission and center visibility are rowwise. A center can be used only after it is visible in P and admitted by C as a point of the metric source X.

The coverage claim is then forced by D. Each inspected source point is paired with one displayed center and one distance comparison, and that distance comparison is read through the metric classifiers of X before it is bounded by ε.

The transport and replay rows preserve the same route. The row H moves no coordinate beyond $X, \varepsilon, P, C, D, R, S, N$, and R replays coverage requests through the same ordered data.

The refusal clauses follow from absence of coordinates. Since the carrier has no host finite subset, host enumeration, open-cover family, compactness selector, choice schedule, or ambient Real-completeness row, none of those objects can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.FiniteEpsilonNetUp.FiniteEpsilonNetTasteGate single carrier alignment`

Theorem 1767.3 (Finite epsilon-net coverage obligation)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier $Q = (X, \varepsilon, P, C, D, H, R, S, N)$ must read the metric source row X, the positive tolerance row ε, the center bundle P, the center-carrier ledger C, and the coverage-distance ledger D before it may use the net as a covering witness. The consumer receives no ambient finite subset, host enumeration, open-cover family, selected compactness proof, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows. The only coverage data are the metric source X, positive tolerance ε, center bundle P, center-carrier ledger C, and coverage-distance ledger D.

The center rows are prerequisite data. A consumer cannot use a proposed center before the bundle P displays it and the ledger C admits it as a point of the metric source X.

The coverage row is then read through D. Each inspected source point is paired with an admitted center and a displayed distance comparison bounded by ε.

Apply Definition 1767.5. That handoff places every total-bounded or compact-metric read downstream of the same finite center and distance rows, so the covering witness cannot be replaced by a host finite subset or open-cover argument. □

Theorem 1767.4 (Finite epsilon-net center-transport obligation)**.** *For every accepted* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier* $Q = (X, \varepsilon, P, C, D, H, R, S, N)$*, componentwise* hsame *transport preserves exactly the same center rows of* P*, the same center-carrier admissions of* C*, and the same coverage-distance ledger* D*. A transported finite-net read may replay the route through* H *and* R*, but it may not introduce a new center, tolerance, coverage comparison, host enumeration, open-cover proof, or ambient completeness row.*

Proof. Project the transport row H. It acts componentwise on $X, \varepsilon, P, C, D, R, S, N$ and has no coordinate for additional centers or detached coverage witnesses.

The center data are therefore unchanged. Transport can move the displayed bundle row P and the admission ledger C, but it cannot add a center outside the bundle or drop the metric-source admission attached to that center.

The coverage-distance ledger is transported in the same way. Each row of D keeps the inspected source point, admitted center, and distance comparison bounded by ε.

Apply Definition 1767.5. Downstream total-bounded and compact-metric consumers still read the same X, ε, P, C, D route after transport, so no host enumeration, open-cover proof, selected compactness witness, or ambient completeness row is exported. □

Theorem 1767.5 (Finite epsilon-net totally-bounded handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier reads the finite route*

$$X, \varepsilon \longmapsto P, C, D \longmapsto H, R, S, N.$$

Thus the consumer receives the finite center bundle, positive tolerance row, coverage witnesses, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *before any total-bounded conclusion is available. The handoff exports no ambient finite subset, host enumeration, open cover, selected compactness proof, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a total-bounded or compact-metric consumer of Q. By Definition 1767.1, the consumer can enter the packet only through the metric source X and the displayed tolerance row ε.

The finite center data are opened next. The closed bundle P names the centers, C admits those centers as points of X, and D supplies the corresponding distance and coverage witnesses.

The structural rows then package exactly that finite route. Componentwise transport H preserves the same tolerance and center data, replay R exposes the route to downstream consumers, provenance S records the package lineage, and N names the local certificate.

Therefore the total-bounded handoff factors through the displayed finite-net route before any consumer can use total boundedness. Applying Definition 1767.2, the consumer cannot replace the route by a host finite subset, host enumeration, open-cover argument, selected compactness proof, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1767.6 (Finite epsilon-net Lebesgue-number handoff)**.** *Every* $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *carrier reads the finite route*

$$X, \varepsilon, P, C, D \longmapsto H, R, S, N$$

before it may inspect a cover-stability tolerance. Thus the consumer receives center rows, membership rows, dyadic or rational tolerance rows, the $\mathsf{TotallyBounded}^{\uparrow}$ *refinement surface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The handoff exports no selected subcover, open-cover compactness theorem, host* $\mathsf{Real}^{\uparrow}$ *equality, countable-choice schedule, or ambient completeness assertion.*

Proof. Project the carrier of Definition 1767.1. The only tolerance-facing rows available to a Lebesgue-number finite-net consumer are the metric source X, the positive tolerance row ε, the closed center bundle P, the center-carrier ledger C, and the coverage-distance ledger D.

Use Definition 1767.2. Center visibility and finite coverage force every center and membership read through P, C, D, while tolerance transport keeps the same rational or dyadic tolerance row visible under H.

Apply Definition 1767.5 for the refinement surface consumed by $\mathsf{TotallyBounded}^{\uparrow}$ and compact-metric routes. The Lebesgue-number finite-net handoff may read that finite refinement surface before a cover-stability tolerance, but it cannot replace the finite route by an open-cover compactness proof.

The nonescape clauses are inherited from the same rows. Since the packet has no coordinate for a selected subcover, host Real equality, countable-choice schedule, or ambient completeness principle, no $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ consumer can obtain one from this handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNet}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1767.1, Definition 1767.2, and Definition 1767.5 seed the finite epsilon-net packet over displayed metric sources, positive rational or dyadic tolerances, closed center bundles, coverage ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full total boundedness, compact metric completeness, uniform continuity, open-cover compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, center visibility, finite coverage, tolerance transport, metric-distance handoff, ledger nonescape, and total-bounded consumer handoff for BEDC.Derived.FiniteEpsilonNetUp.

Constructive story: A $\mathsf{FiniteEpsilonNet}^{\uparrow}$ packet is generated from a MetricUp source row, a positive RatUp or DyadicRatCoreUp tolerance, a closed ProbeBundle of centers, a center-carrier ledger, distance and coverage rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1768

A Concrete Naming Certificate for $\mathsf{DyadicToleranceScale}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicToleranceScale}^{\uparrow}$ packet records the single dyadic precision scale row that a regular rational or real-name consumer must read before turning finite stream observations into endpoint-facing data. It sits over the dyadic tolerance arithmetic of chapter 291, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the Cauchy threshold discipline of chapter 292, and the terminal real-name seal of chapter 38. The packet gives Real and Completion routes one visible scale certificate instead of spreading the same precision ledger across adjacent dyadic, modulus, and readback chapters.

Definition 1768.1 (Dyadic tolerance scale carrier)**.** *A* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (s, d, w, r, m, e, h, c, p, n)$$

with the following displayed rows:

1. *s is the scale row. It records the finite dyadic precision index, the displayed tolerance requested at that index, and the monotone relation from coarser requests to finer requests.*
2. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to s, including the dyadic radius, rounding, comparison, and containment rows used by the scale.*
3. *w is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the precision named by s and budgeted by d.*
4. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the scale row, dyadic ledger, and stream window have been displayed.*
5. *m is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row saying that the same scale controls the finite tail bound consumed by regular readback.*
6. *e is the terminal* $\mathsf{Real}^{\uparrow}$ *handoff row exposed only after s, d, w, r, m have been read.*
7. *h records componentwise* hsame *transport for the scale row, dyadic ledger, stream window, regular readback, Cauchy threshold, Real handoff, replay, provenance, and local naming rows.*
8. *c records displayed* Cont *replay from the scale request through the dyadic ledger, stream window, regular readback, Cauchy threshold, Real handoff, transport, provenance, and local naming rows.*
9. *p is the* Pkg *provenance over* $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *n is the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, d, w, r, m, e, h, c, p, n$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 (definition) `BEDC.Derived.DyadicToleranceScaleUp.DyadicToleranceScaleUp`

Theorem 1768.2 (Dyadic tolerance scale NameCert obligations)**.** *For every accepted* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier $T = (s, d, w, r, m, e, h, c, p, n)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed scale row, DyadicRatCore tolerance ledger, StreamName window, RegSeqRat readback, CauchyModulus threshold, Real handoff, transport, replay, provenance, and local naming rows;*
2. *scale monotonicity, requiring the row s to order coarser and finer dyadic precision requests before any ledger, window, readback, threshold, or seal row can be consumed;*
3. *classifier transport, requiring accepted comparisons to preserve $s, d, w, r, m, e, h, c, p, n$ componentwise and to expose no hidden precision coordinate;*
4. *RegSeqRat handoff, requiring the readback row r to consume the displayed scale, dyadic ledger, and stream window rather than a detached stream quotient or selected limit;*
5. *Real-seal non-escape, requiring the row e to remain terminal with respect to s, d, w, r, m and to export no host equality, countable choice, trichotomy, ambient completeness theorem, Lean verification, or bridge data;*
6. *provenance and local naming, requiring p and n to package exactly the displayed rows and no additional completion datum.*

No dyadic tolerance-scale obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1768.1. The visible packet consists exactly of the scale row s, dyadic ledger d, stream window w, regular readback r, Cauchy threshold m, Real handoff e, and structural rows h, c, p, n.

Scale monotonicity is the local content of s. Since s is the only row carrying the precision index and the coarser-to-finer relation, every downstream precision comparison must read it before any ledger, window, readback, threshold, or seal can be named.

Classifier transport is componentwise through h and replayed through c. These rows preserve the displayed route from s to d, from d to w, from w to r, from r to m, and from m to e.

The RegSeqRat handoff and Real-seal clauses follow from the placement of r and e. The readback row is downstream of the displayed scale, ledger, and window, while the Real handoff is terminal after the same route and the Cauchy threshold row.

The excluded objects are absent from the carrier and are not produced by transport, replay, provenance, or local naming. Hence no local NameCert obligation can be stored outside the displayed rows. □

Theorem 1768.3 (Dyadic tolerance scale RegSeqRat handoff)**.** *Let $T = (s, d, w, r, m, e, h, c, p, n)$ be an accepted* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of T must read the finite route*

$$s \longmapsto d \longmapsto w \longmapsto r \longmapsto m \longmapsto e \longmapsto h, c, p, n$$

before the regular readback and before the Real seal are available. Consequently the dyadic scale row is the unique precision gate for those consumers, and no consumer can bypass it through quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicToleranceScaleUp.DyadicToleranceScaleRegSeqRatHandoff`

Proof. Project the accepted carrier. The only readback coordinate is r, and the only Real-facing coordinate is e.

The readback coordinate is not free-standing. By Definition 1768.1, r is obtained after the scale row s, the DyadicRatCore ledger d, and the StreamName window w have been displayed.

The Real-facing coordinate is also not free-standing. The row e is downstream of r and the CauchyModulus threshold row m, so a Real consumer reaches it only after the same scale, ledger, window, and regular readback route has already been read.

Finally, h, c, p, n preserve and name that route without adding a second precision coordinate. Since the carrier has no excluded coordinate, every RegSeqRat or Real consumer must pass through the dyadic scale row before readback and seal. □

Theorem 1768.4 (Dyadic tolerance scale precision-gate exhaustion)**.** *Let* $T = (s, d, w, r, m, e, h, c, p, n)$ *be an accepted* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of* T *must pass through the scale row* s*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* d*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* w*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* m*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* r*, the* $\mathsf{Real}^{\uparrow}$ *seal* e*, and the structural rows* h, c, p, n*. No quotient stream equality, selected limit, host equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate is available to such a consumer.*

Proof. Project the carrier of Definition 1768.1. The visible rows are exactly the scale, dyadic ledger, finite window, regular readback, Cauchy threshold, Real seal, and structural rows $s, d, w, r, m, e, h, c, p, n$.

Apply Definition 1768.2. The scale monotonicity row must be read before any ledger, window, readback, threshold, or seal row, and the classifier transport exposes no hidden precision coordinate.

Now apply Definition 1768.3. It forces each RegSeqRat or Real consumer through the route from s to d, then w, r, m, e, and finally h, c, p, n.

Because the carrier and the handoff route contain no quotient, selected-limit, host-equality, choice, trichotomy, or completeness row, the scale row exhausts the precision gate for every accepted consumer. □

Theorem 1768.5 (Dyadic tolerance scale obligation-closure scope)**.** *Let* $T = (s, d, w, r, m, e, h, c, p, n)$ *be an accepted* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier. Every accepted obligation read of* T *is exhausted by the scale row* s*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* d*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* w*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* m*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* r*, the* $\mathsf{Real}^{\uparrow}$ *seal* e*, componentwise* hsame *transport* h*, displayed* Cont *replay* c*,* Pkg *provenance* p*, and the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$ *row* n*. The obligation surface exports no quotient stream equality, selected limit, countable choice, trichotomy, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Proof. Project the accepted carrier through Definition 1768.1. Its visible coordinates are exactly $s, d, w, r, m, e, h, c, p, n$, with s naming the dyadic precision scale and d, w, m, r, e forming the finite route toward regular readback and the Real seal.

Apply Definition 1768.2. The obligation rows are carrier admission, scale monotonicity, classifier transport, RegSeqRat handoff, Real-seal non-escape, provenance, and local naming, and each of those rows is stored on the displayed coordinates of the carrier.

Use Definition 1768.3 together with Definition 1768.4. They force every RegSeqRat or Real consumer through the same scale, DyadicRatCore ledger, StreamName window, CauchyModulus threshold, RegSeqRat readback, Real seal, transport, replay, package, and naming route.

It remains only to identify the boundary. The carrier has no coordinate for quotient stream equality, a selected limit, countable choice, trichotomy, host equality, ambient Real completeness, or bridge data, and the obligation rows do not construct such a coordinate. Therefore the displayed rows exhaust the obligation-closure surface. □

Theorem 1768.6 (Dyadic tolerance scale Real regular readback)**.** *Let $T = (s, d, w, r, m, e, h, c, p, n)$ be an accepted* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read from T factors through the dyadic scale row s, the* $\mathsf{StreamName}^{\uparrow}$ *finite window w, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row m, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row r, the terminal* $\mathsf{Real}^{\uparrow}$ *seal e, componentwise* hsame *transport h, displayed* Cont *replay c,* Pkg *provenance p, and the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$ *row n. Consequently a Real-facing consumer receives a regular rational readback only through the displayed dyadic scale route, not through quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Proof. Start with Definition 1768.3. It places every RegSeqRat and Real consumer downstream of the route from the scale row s through the dyadic ledger d, the finite stream window w, the regular readback r, the Cauchy threshold m, the Real seal e, and the structural rows h, c, p, n.

Apply Definition 1768.4. The scale row is the unique precision gate for those consumers, and the displayed dyadic ledger, StreamName window, Cauchy threshold, RegSeqRat readback, Real seal, transport, replay, provenance, and naming rows are the only rows available for the read.

Finally use Definition 1768.5. Its closure scope says that the same rows exhaust every accepted obligation read of the packet. Therefore a Real-facing read factors through the regular readback and Real seal exactly along the local NameCert route, with no bypass through an excluded quotient, selected limit, host-equality, choice, completeness, or bridge coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$, obligation)

Scope closed: Definition 1768.1, Definition 1768.2, Definition 1768.3, Definition 1768.4, and Definition 1768.5 close the finite dyadic precision-scale obligation surface from a scale row through dyadic ledger, StreamName window, Cauchy threshold, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicToleranceScale}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: The next step is Lean verification of the displayed obligation-closure surface for BEDC.Derived.DyadicToleranceScaleUp.

Constructive story: A $\mathsf{DyadicToleranceScale}^{\uparrow}$ packet is generated from one dyadic scale row, a DyadicRatCore tolerance ledger, a StreamName finite window, RegSeqRat readback, a CauchyModulus threshold, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1769

A Concrete Naming Certificate for $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ packet records the finite located-tail envelope by which a regular located Cauchy source becomes visible to $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumers. It sits over the regular located source boundary of chapter 1454, the paired tail-agreement seal of chapter 699, the limit handoff surface of chapter 386, and the nested interval compactness boundary of chapter 1584. The envelope keeps the tail window, dyadic tolerance, agreement seal, limit seal, and terminal Real seal in one finite NameCert route before any consumer treats the route as completed real data.

Definition 1769.1 (LocatedRealTailEnvelope carrier)**.** *A* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, W, D, A, L, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *source row, including the regular rational source, located enclosure, and visible convergence-rate data.*
2. *W is the finite tail-window row naming the source indices inspected by the consumer.*
3. *D is the dyadic tolerance ledger for W, including the requested radii, endpoint comparisons, and readback bounds.*
4. *A is the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row certifying that the displayed tail window agrees with the Real-facing read at the named tolerance.*
5. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row consuming the same finite tail window and dyadic ledger as the limit-seal handoff.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after R, W, D, A, L have been displayed.*
7. *H records componentwise* hsame *transport for the source, tail window, dyadic ledger, agreement seal, limit seal, terminal Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *precision request through $R, W, D, A, L, S, H, P, N$*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealTailEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted envelopes only through $R, W, D, A, L, S, H, C, P, N$. It has no coordinate for quotient streams, selected host limits, countable choice, open-cover compactness, host real equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.LocatedRealTailEnvelopeUp.LocatedRealTailEnvelopeTasteGate single carrier alignment`

Theorem 1769.2 (LocatedRealTailEnvelope NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ *carrier $E = (R, W, D, A, L, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealTailEnvelope}^{\uparrow}}$ *surface consists exactly of the following six obligation rows:*

1. *carrier exposure for the displayed located Cauchy source, finite tail window, dyadic tolerance ledger, agreement seal, limit seal, terminal Real seal, and structural rows H, C, P, N;*
2. *located-tail route stability, requiring every consumer precision request to read the source row R, the finite window W, and the dyadic ledger D in the same displayed order;*
3. *agreement-seal compatibility, requiring the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row A to consume the same W, D route as the located source;*
4. *CauchyLimitSeal handoff, requiring the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row L to read no tail data outside R, W, D, A;*
5. *Real-seal routing, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *row S to be downstream of the source, window, tolerance, agreement, and limit-seal rows;*
6. *ledger non-escape, requiring H, C, P, N to preserve and name only the displayed route and to export no quotient stream, selected host limit, countable-choice selector, open-cover compactness object, or ambient Real completeness principle.*

No NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1769.1. The admitted packet contains the located Cauchy source R, the finite tail window W, the dyadic ledger D, the agreement row A, the Cauchy limit seal L, the terminal Real seal S, and the structural rows H, C, P, N.

Located-tail route stability follows from the order of the displayed rows. A consumer precision request first fixes the located source, then reads only the finite window named for that source, and then reads the dyadic tolerance ledger attached to that window.

Agreement-seal compatibility is forced because A has no window or tolerance coordinate other than W and D. The same route is therefore used for the located source and for the tail-agreement read.

The CauchyLimitSeal handoff is the next row in the packet. The row L consumes the already displayed R, W, D, A route and has no separate source for an unbounded tail, selected limit, or host convergence predicate.

Finally S is terminal, and the rows H, C, P, N only transport, replay, source, and name the same finite route. Since the excluded objects are absent from the carrier inventory, no local obligation can export them. □

Theorem 1769.3 (LocatedRealTailEnvelope Real-seal factorization)**.** *Let $E = (R, W, D, A, L, S, H, C, P, N)$ be an accepted* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer read of E factors through the displayed located tail route*

$$R \longmapsto W \longmapsto D \longmapsto A \longmapsto L \longmapsto S \longmapsto H, C, P, N$$

before reading the terminal Real seal.

Consequently the consumer receives a regular located Cauchy source, finite tail window, dyadic tolerance ledger, RealTailAgreementSeal row, CauchyLimitSeal row, terminal $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. The route cannot use quotient streams, selected host limits, countable choice, open-cover compactness, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier by Definition 1769.1. The only Real-facing endpoint is S, and the carrier places S after the located source, tail window, dyadic ledger, agreement seal, and limit seal.

The first part of the route is the located-tail read. The row R supplies the regular located Cauchy source, W selects the finite tail window inspected for the request, and D supplies the dyadic tolerance ledger for that window.

The second part of the route is the seal read. The row A certifies agreement on the same window and ledger, and L packages the CauchyLimitSeal handoff before S can be exposed.

The structural rows preserve the route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming do not add a second route to $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$. Hence every consumer read factors through the displayed located tail route, and the excluded quotient, selector, compactness, host-equality, and ambient-completeness coordinates remain unavailable. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealTailEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ packet is generated from a RegularLocatedCauchyReal source row, a finite tail-window row, a dyadic tolerance ledger, a RealTailAgreementSeal row, a CauchyLimitSeal row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealTailEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1769.1, Definition 1769.2, and Definition 1769.3 seed the finite located-tail envelope for RealUp and CompletionUp consumers over displayed agreement and limit-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealTailEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, located-tail route stability, agreement-seal compatibility, CauchyLimitSeal handoff, Real-seal routing, and ledger non-escape for the same displayed packet.

Chapter 1770

A Concrete Naming Certificate for $\mathsf{RegularCauchyDistance}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RegularCauchyDistance}^{\uparrow}$ packet records the finite distance ledger between two regular Cauchy names before any $\mathsf{Real}^{\uparrow}$ metric handoff treats the distance as a completed real. It sits over the regular rational readback of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance rows of chapter 291, and the terminal real-name seal of chapter 38. The chapter supplies the distance-account row consumed by Real and metric-facing packets; it does not identify quotient streams, compare host reals by trichotomy, select limits, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1770.1 (Regular Cauchy distance carrier)**.** *A* $\mathsf{RegularCauchyDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_{\mathrm{dist}} = (X, Y, S, T, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are compared.*
2. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *window row exposing aligned finite observations of X and Y.*
3. *T is the tolerance-window row, recording the displayed tail threshold at which the two names are read for a requested distance precision.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *distance ledger, containing the dyadic absolute-difference bounds and slack rows used by the finite comparison.*
5. *Q is the precision-query row consumed jointly by S, T, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *distance seal row, read only after the finite ledger has displayed the distance account.*
7. *H records componentwise* hsame *transport for the two source rows, paired windows, threshold row, dyadic ledger, precision query, distance seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the two source rows through S, T, D, Q and then into E, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDistance}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, T, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDistanceUp.RegularCauchyDistanceUpTasteGate single carrier alignment`

Theorem 1770.2 (Regular Cauchy distance NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDistance}^{\uparrow}$ *carrier*

$$L_{\mathrm{dist}} = (X, Y, S, T, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDistance}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, tolerance-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *distance ledger, precision query, terminal* $\mathsf{Real}^{\uparrow}$ *distance seal, transport, replay, provenance, and local naming rows;*
2. *source alignment, requiring the windows in S to expose observations from the same two source rows X, Y named by the carrier;*
3. *query exactness, requiring Q to be the displayed precision request consumed by the threshold row T and the dyadic ledger D;*
4. *dyadic distance exactness, requiring D to store precisely the absolute-difference bounds and slack rows read through S, T, Q;*
5. *Real metric handoff, requiring E to consume the finite dyadic distance ledger as a* $\mathsf{Real}^{\uparrow}$ *distance seal after X, Y, S, T, D, Q are visible;*
6. *componentwise transport and displayed replay for $X, Y, S, T, D, Q, E, P, N$ through H and C;*
7. *refusal of quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No regular Cauchy distance obligation is stored outside these rows.

Theorem 1770.3 (Regular Cauchy distance classifier stability)**.** *Let*

$$L_{\mathrm{dist}} = (X, Y, S, T, D, Q, E, H, C, P, N)$$

and

$$L'_{\mathrm{dist}} = (X', Y', S', T', D', Q', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyDistance}^{\uparrow}$ *carriers. If their source rows, paired windows, threshold rows, dyadic distance ledgers, precision queries, terminal seals, transport rows, replay rows, provenance rows, and local naming rows are componentwise* hsame*, then the local classifier gives the same distance certificate verdict to L_{dist} and L'_{dist}.*

Consequently classifier stability is ledgerwise: it follows only from the displayed source-window-threshold-ledger-query-seal route and not from quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1770.4 (Regular Cauchy distance Real metric handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *metric consumer that reads a distance between the two source rows of an accepted* $\mathsf{RegularCauchyDistance}^{\uparrow}$ *carrier must factor through the finite route*

$$X, Y \longmapsto S, T, Q \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

The consumer therefore receives the two regular rational source rows, aligned finite observation windows, the requested tolerance threshold, the dyadic absolute-difference ledger, and the terminal real-name distance seal before using the distance as metric data. This handoff is a finite distance account between regular Cauchy names; it is not a quotient equality of streams, host real trichotomy, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Falsifiable prediction: Every $\mathsf{RegularCauchyDistance}^{\uparrow}$ metric-facing read factors through two RegSeqRat source rows, paired StreamName windows, one tolerance-window row, one DyadicRatCore distance ledger, one precision query, one terminal RealUp distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchyDistance}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular Cauchy source rows, aligned finite windows, dyadic absolute-difference bounds, and the terminal RealUp distance seal that metric consumers read as one ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDistance}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1770.1, Definition 1770.2, Definition 1770.3, and Definition 1770.4 seed the finite distance ledger over two regular Cauchy names, paired StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readbacks, a terminal RealUp distance seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDistance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source alignment, query exactness, dyadic distance exactness, Real metric handoff, componentwise transport, displayed replay, classifier stability, and metric-consumer nonescape for BEDC.Derived.RegularCauchyDistanceUp.

Constructive story: A $\mathsf{RegularCauchyDistance}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName windows, one tolerance-window row, one DyadicRatCore distance ledger, one precision query, one terminal RealUp distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1771

A Concrete Naming Certificate for $\mathsf{CauchyRealizer}^{\uparrow}$

Following Weihrauch and Bishop–Bridges, the $\mathsf{CauchyRealizer}^{\uparrow}$ packet records the explicit finite route by which effective Cauchy data is decoded, inspected through stream windows, read back as regular rational data, budgeted by dyadic tolerances, and sealed for the current Real and Completion route. It sits over the effective source surface of chapter 1705, the representation decoding boundary of chapter 1680, the represented-space naming interface of chapter 1494, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is the finite NameCert route for explicit Cauchy realization; it is not Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or a standard bridge.

Definition 1771.1 (Cauchy realizer carrier)**.** *A* $\mathsf{CauchyRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (E, R, V, W, Q, D, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source row, naming the effective Cauchy input, its visible request schedule, and the finite source evidence used by the realizer.*
2. *R is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *decoding row, read together with the* $\mathsf{RepresentedSpace}^{\uparrow}$ *row V so that the source name is interpreted through the displayed representation interface.*
3. *V is the represented-space row that fixes the admissible naming surface consumed by R and exported to downstream Real and Completion consumers.*
4. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the realizer for the displayed precision requests.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the regular rational observations that the Real route may consume.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the requested radii, slack rows, and finite comparison evidence used to certify the readback.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after the source, representation, represented-space, stream-window, regular-readback, and dyadic-ledger rows have been displayed.*

8. *H records componentwise* hsame *transport for the effective source, representation decoder, represented-space row, stream windows, regular readback, dyadic ledger, terminal Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each Real or Completion precision request through $E, R, V, W, Q, D, S, H, P,$*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyRealizer}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted realizers only through $E, R, V, W, Q, D, S, H, C, P, N$. It has no coordinate for Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or a standard bridge.

Lean4 ✓ `BEDC.Derived.CauchyRealizerUp.CauchyRealizerUpTasteGate single carrier alignment`

Theorem 1771.2 (Cauchy realizer NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealizer}^{\uparrow}$ *carrier*

$$Z = (E, R, V, W, Q, D, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source,* $\mathsf{CauchyRepresentation}^{\uparrow}$ *decoder,* $\mathsf{RepresentedSpace}^{\uparrow}$ *naming surface,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows H, C, P, N;*
2. *source-decoder compatibility, requiring the effective Cauchy source E to be read through the representation row R and the represented-space row V before any stream window is exposed;*
3. *finite-window exactness, requiring every precision request to inspect only the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows W attached to E, R, V;*
4. *regular-readback exactness, requiring Q to consume exactly the displayed windows W and to export no second rational-name route;*
5. *dyadic tolerance accounting, requiring D to store precisely the visible tolerance radii, slack rows, and comparison evidence consumed by Q and S;*
6. *Real-seal routing, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *row S to be downstream of E, R, V, W, Q, D;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *non-escape for Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, and standard-bridge data.*

No Cauchy realizer obligation is stored outside these rows.

Proof. Project the carrier of Definition 1771.1. Its visible computational source is E, and the only interpretation rows available for that source are the decoder R and represented-space row V.

The finite observation route is then forced by the displayed order. A precision request reaches W only after E, R, V are fixed, reaches the regular readback Q only through those windows, and reaches the dyadic ledger D only as the tolerance account for that readback.

The terminal seal is downstream. The row S has no entrance other than E, R, V, W, Q, D, while H, C, P, N transport, replay, source, and name the same route. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 1771.3 (Cauchy realizer representation handoff)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{CauchyRealizer}^{\uparrow}$ *carrier factors its source request through the displayed representation route*

$$E \longmapsto R \longmapsto V \longmapsto W \longmapsto Q \longmapsto D \longmapsto S \longmapsto H, C, P, N.$$

Consequently the consumer receives an effective Cauchy source, a CauchyRepresentation decoder, a RepresentedSpace naming row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal Real seal, transport, replay, provenance, and local naming. The handoff does not supply quotient stream equality, selected limits, countable choice, host real equality, trichotomy, Real completeness, Lean verification, or a standard bridge.

Proof. Begin with the accepted carrier and read its first three rows. The source row E is not consumed directly by Real or Completion; it is interpreted through the Cauchy representation row R and the represented-space row V.

Next inspect the finite data available after decoding. The only observation surface is the displayed family of stream windows W, and the only regular rational output attached to those windows is Q.

Finally read the tolerance and seal rows. The dyadic ledger D accounts for the requested precision before the terminal Real seal S is exposed, and H, C, P, N preserve that same route. This proves the stated factorization and leaves the excluded quotient, selector, choice, equality, trichotomy, completeness, verification, and bridge objects outside the handoff. □

Theorem 1771.4 (Cauchy realizer Real seal non-escape)**.** *Let* $Z = (E, R, V, W, Q, D, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchyRealizer}^{\uparrow}$ *carrier. Any downstream use of the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S *must pass through the finite source-decoder-window-readback-ledger route*

$$E, R, V, W, Q, D$$

and the structural rows H, C, P, N*. Thus the Real seal cannot be used as a hidden endpoint for Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or a standard bridge.*

Proof. The only $\mathsf{Real}^{\uparrow}$ row in the carrier is S. By Definition 1771.1, S is placed after the effective Cauchy source, the representation decoder, the represented-space row, stream windows, regular readback, and dyadic tolerance ledger.

A downstream consumer therefore reaches S only by replaying the displayed route through C and transporting it componentwise through H. The package row P and local name N record the same route and do not add another endpoint.

Because no carrier coordinate stores completeness, quotient equality, a selected limit, a choice schedule, trichotomy, host real equality, Lean evidence, or bridge data, the Real seal cannot escape the finite route named above. □

Falsifiable prediction: Every $\mathsf{CauchyRealizer}^{\uparrow}$ Real or Completion read factors through an EffectiveCauchySequence source, a CauchyRepresentation decoder, a RepresentedSpace row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: effective-cauchy-sequence, cauchy-representation, representedspace, streamname, regseqrat: $\mathsf{CauchyRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an

effective Cauchy source, representation decoding, represented-space naming, finite stream windows, regular rational readback, dyadic tolerance accounting, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealizer}\uparrow}$.

Constructive story: A $\mathsf{CauchyRealizer}^{\uparrow}$ packet is generated from an EffectiveCauchySequence source row, a CauchyRepresentation decoder row, a RepresentedSpace naming row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealizer}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1771.1, Definition 1771.2, Definition 1771.3, and Definition 1771.4 seed the finite explicit-Cauchy realizer route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealizer}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-decoder compatibility, finite-window exactness, regular-readback exactness, dyadic tolerance accounting, Real-seal routing, representation handoff, and Real-seal non-escape for BEDC.Derived.CauchyRealizerUp.

Chapter 1772

A Concrete Naming Certificate for $\mathsf{RegularCauchySqueeze}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{RegularCauchySqueeze}^{\uparrow}$ packet records the finite squeeze route by which a middle regular Cauchy real name is enclosed between lower and upper regular Cauchy names before any $\mathsf{Real}^{\uparrow}$ consumer treats the enclosure as completed real data. It sits over the regular rational readback of chapter 301, the finite window interface of chapter 126, the shared tail handoff of chapter 1738, and the terminal real-name seal of chapter 38. The theorem-level comparison sandwich of chapter 2163 consumes this regular Cauchy squeeze packet before the displayed limit route of chapter 1413 reaches the terminal Real seal. The packet supplies a non-quotient L10 route for squeeze arguments: lower, middle, and upper names are compared through displayed windows, dyadic tolerances, and a tail-enclosure ledger, not through host completeness, selected limits, trichotomy, or quotient equality.

Definition 1772.1 (Regular Cauchy squeeze carrier)**.** *A* $\mathsf{RegularCauchySqueeze}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q_{\mathrm{sq}} = (L, M, U, W, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. L, M, U *are the lower, middle, and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose regular rational observations form the squeeze boundary.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row exposing aligned finite observations of* L, M, U *for a requested precision.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii, slack budget, and endpoint comparison bounds used by the squeeze read.*
4. T *is the tail-enclosure ledger, certifying that the displayed middle observations remain between the displayed lower and upper observations on the shared tail window at the dyadic budget in* D*.*
5. E *is the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff row, used only after* L, M, U, W, D, T *have exposed the finite enclosure route.*
6. H *records componentwise* hsame *transport for the three source rows, shared windows, dyadic tolerance row, tail-enclosure ledger, tail-equivalence handoff, replay, provenance, local naming, and terminal seal rows.*

7. *C records displayed* Cont *replay from each Real-facing squeeze request through $L, M, U, W, D, T, E, H, P, N$ before the seal row is read.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySqueeze}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySqueeze}^{\uparrow}}$ *row carrying the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary named by the displayed route.*

The classifier compares accepted packets only through $L, M, U, W, D, T, E, H, C, P, N$ and the terminal seal boundary carried by N. It has no coordinate for quotient stream equality, host real trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchySqueezeUp.RegularCauchySqueezeTasteGate single carrier alignment`

Theorem 1772.2 (Regular Cauchy squeeze NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySqueeze}^{\uparrow}$ *carrier*

$$Q_{\mathrm{sq}} = (L, M, U, W, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySqueeze}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower, middle, and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the tail-enclosure ledger, the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff, transport, replay, provenance, local naming, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary carried by N;*

2. *source alignment, requiring W to expose observations from precisely the three source rows L, M, U named by the carrier;*

3. *tolerance exactness, requiring D to be the displayed dyadic budget consumed by the window row W and the tail-enclosure row T;*

4. *squeeze enclosure exactness, requiring T to store only the lower-to-middle and middle-to-upper tail comparisons read through W at the budget in D;*

5. *tail-equivalence handoff, requiring E to consume the same displayed L, M, U, W, D, T route before any Real-facing squeeze conclusion is exposed;*

6. *componentwise transport, displayed replay, provenance, local naming, and terminal seal preservation through H, C, P, N;*

7. *refusal of quotient stream equality, host real trichotomy, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No regular Cauchy squeeze obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1772.1. The packet displays exactly the three regular rational source rows, one shared finite window row, one dyadic tolerance row, one tail-enclosure ledger, one tail-equivalence handoff, and the structural rows.

Source alignment and tolerance exactness follow from the row order. The window row W has no source coordinate other than L, M, U, and the tolerance row D is the only dyadic budget available to the tail-enclosure row T.

The squeeze enclosure clause is therefore finite. The row T can compare the displayed lower-to-middle and middle-to-upper tail observations, but it cannot appeal to a completed real order, a trichotomy case split, or a selected limit.

The handoff row E is downstream of the same route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and the terminal seal preserve that route without adding analytic coordinates.

Inspecting the carrier inventory gives the refusal clause. Since quotient stream equality, host trichotomy, selected limits, countable choice, ambient completeness, Lean verification, and bridge checking are absent from Q_{sq}, none can appear in the local $\mathsf{NameCert}_{\mathsf{RegularCauchySqueeze}^{\uparrow}}$ surface. □

Theorem 1772.3 (Regular Cauchy squeeze tail enclosure route)**.** *Let*

$$Q_{\mathrm{sq}} = (L, M, U, W, D, T, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchySqueeze}^{\uparrow}$ *carrier. Every finite squeeze read for the middle row M factors through the displayed route*

$$L, M, U \longmapsto W \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently the read receives three regular Cauchy source rows, shared StreamName windows, one dyadic tolerance budget, one tail-enclosure ledger, one CauchyTailEquivalence handoff, componentwise transport, displayed replay, provenance, and local naming before it can be consumed as squeeze evidence.

Proof. Begin with an accepted squeeze read. Carrier admission forces the read to name the three source rows L, M, U before any window or tolerance data is available.

The read then passes through the shared window row W and the dyadic budget D. These two rows determine the only observations and tolerance bounds that the enclosure ledger T may inspect.

The row T supplies the lower-to-middle and middle-to-upper tail comparisons on that displayed data. Only after those comparisons are present can the handoff row E expose the tail-equivalence route to a Real-facing consumer.

The remaining rows are structural. They transport, replay, source, and name the same route, so the displayed factorization is exhaustive for the local classifier. □

Theorem 1772.4 (Regular Cauchy squeeze Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchySqueeze}^{\uparrow}$ *carrier reads the terminal seal only after the finite route*

$$L, M, U \longmapsto W \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N \longmapsto \mathsf{Real}^{\uparrow}$$

has been displayed. The exported seal is therefore a routed finite squeeze certificate for regular Cauchy real names. It is not quotient stream equality, a host real order comparison, trichotomy, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier by Definition 1772.1. The terminal $\mathsf{Real}^{\uparrow}$ seal boundary carried by N is not available before the lower, middle, upper, window, tolerance, enclosure, and handoff rows have been displayed.

The Real-facing read first receives the same squeeze route established in Definition 1772.3. Thus the seal is downstream of L, M, U, W, D, T, E and cannot bypass the tail-enclosure ledger.

The structural rows H, C, P, N preserve the displayed route. They add transport, replay, provenance, and local naming, but no quotient coordinate, host order predicate, trichotomy principle, selector, choice operator, or ambient completeness theorem.

Therefore every exported $\mathsf{Real}^{\uparrow}$ seal remains a finite squeeze certificate over regular Cauchy names, with exactly the boundary claimed. □

Theorem 1772.5 (Regular Cauchy squeeze RealSequenceLimit handoff)**.** *Any* RealSequenceLimit$^{\uparrow}$ *consumer of a* RegularCauchySqueeze$^{\uparrow}$ *packet must read the lower, middle, and upper regular names, the shared* StreamName$^{\uparrow}$ *windows, the* DyadicRatCore$^{\uparrow}$ *tolerance row, the* RegSeqRat$^{\uparrow}$ *readback route, and the terminal* Real$^{\uparrow}$ *seal in the same finite route. The handoff may then be consumed by the* SqueezeTheorem$^{\uparrow}$ *comparison sandwich, but it does not supply host sequence limits, quotient stream equality, trichotomy, selected limits, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $Q_{\mathrm{sq}} = (L, M, U, W, D, T, E, H, C, P, N)$. The rows L, M, U are the only lower, middle, and upper regular names, and W is the only shared window route through which their observations can be compared.

The dyadic and rational stages are forced by the carrier order. The tolerance row D supplies the budget for the tail-enclosure ledger T, and the same displayed route reaches the RegSeqRat$^{\uparrow}$ readback through the handoff row E before the terminal seal boundary carried by N can be read.

The theorem-level consumer in chapter 2163 therefore receives this packet as a finite lower-middle-upper route, and the displayed limit route of chapter 1413 can consume it only after those rows have been opened. Transport, replay, provenance, and local naming preserve the same route, so no excluded host principle can enter the handoff. □

Theorem 1772.6 (Regular Cauchy squeeze even-odd boundary)**.** *Suppose the lower and upper squeeze witnesses of an accepted* RegularCauchySqueeze$^{\uparrow}$ *packet are supplied by the even and odd parity rows of an accepted* EvenOddCauchyCriterion$^{\uparrow}$ *packet. Then the middle* RegularCauchySqueeze$^{\uparrow}$ *Real-facing read must pass through the parity selector, the shared* CauchyModulus$^{\uparrow}$ *ledger, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, and the* RealCauchyCriterion$^{\uparrow}$ *handoff before it reaches the squeeze seal.*

Proof. Start with the squeeze route of Definition 1772.3. It places the middle read between the lower and upper regular rows through the shared window row, dyadic tolerance row, tail-enclosure ledger, and tail-equivalence handoff.

Now apply Definition 1647.3. The even and odd rows are fused only through the parity selector, shared CauchyModulus ledger, DyadicRatCore tolerance ledger, and RealCauchyCriterion handoff carried by the accepted EvenOddCauchyCriterion$^{\uparrow}$ packet.

Composing the two routes gives the boundary. The lower and upper witnesses may enter the squeeze packet from parity rows, but the middle Real-facing read cannot reach the squeeze seal until the parity selector and shared budget have already been displayed. □

Falsifiable prediction: Every RegularCauchySqueeze$^{\uparrow}$ Real-facing read factors through three RegSeqRat source rows, one shared StreamName window route, one DyadicRatCore tolerance row, one tail-enclosure ledger, one CauchyTailEquivalence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and the terminal RealUp seal boundary carried by N.

Independence witness: regseqrat, streamname, cauchy-tail-equivalence, real: RegularCauchySqueeze$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lower, middle, and upper regular Cauchy source rows, a shared finite window route, dyadic squeeze tolerance data, a tail-enclosure ledger, and a Real-facing seal boundary.

Closure status for NameCert$_{\text{RegularCauchySqueeze}^{\uparrow}}$**.**

Constructive story: A RegularCauchySqueeze$^{\uparrow}$ packet is generated from lower, middle, and upper RegSeqRat rows, shared StreamName windows, one DyadicRatCore tolerance row, one tail-enclosure ledger, one CauchyTailEquivalence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and the terminal RealUp seal boundary carried by the NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchySqueeze}\uparrow}$, seed)

Scope closed: Definition 1772.1, Definition 1772.2, Definition 1772.3, Definition 1772.4, and Definition 1772.6 seed the finite squeeze route for regular Cauchy real names through displayed windows, dyadic tolerances, tail enclosure, tail equivalence, parity-tail fusion, and a terminal RealUp seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchySqueeze}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real order, trichotomy, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source alignment, tolerance exactness, squeeze enclosure exactness, tail-equivalence handoff, componentwise transport, displayed replay, Real seal boundary, and nonescape for BEDC.Derived.RegularCauchySqueezeUp.

Chapter 1773

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ packet records the finite route by which a regular Cauchy family of regular rational names is read along a displayed diagonal selector before any $\mathsf{Real}^{\uparrow}$ consumer treats the result as a completed real name. It sits over the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the parity-aware schedule handoff of chapter 414. The packet supplies a Real and Completion boundary for diagonal extraction; it does not assert quotient stream equality, choose a host limit, invoke countable choice, use trichotomy, claim ambient $\mathsf{Real}^{\uparrow}$ completeness, provide Lean verification, or record a checked bridge.

Definition 1773.1 (Regular Cauchy diagonal extraction carrier)**.** *A* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G_{\mathrm{diag}} = (F, \delta, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source-family row, naming a finite inspection boundary for a family of* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose members are regular Cauchy rational names.*
2. *δ is the unary diagonal selector row, recording the displayed rule that sends a requested diagonal precision to the source index and source-window coordinate read at that precision.*
3. *W is the aligned* $\mathsf{StreamName}^{\uparrow}$ *window family, exposing only the finite observations of F selected by δ and aligned with the requested diagonal tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic radius, slack, and comparison rows that justify the selected diagonal read.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row, built from the selected windows W and the tolerance ledger D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the family, selector, windows, tolerance ledger, and diagonal readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the source family, unary selector, aligned windows, tolerance ledger, diagonal readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from each Real-facing diagonal request through* $F, \delta, W, D, Q, E, H, P, N$.
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, \delta, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient streams, a selected host limit, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalExtractionUp.RegularCauchyDiagonalExtractionTasteGate`
`single carrier alignment`

Theorem 1773.2 (Regular Cauchy diagonal extraction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *carrier*

$$G_{\mathrm{diag}} = (F, \delta, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source family, unary diagonal selector, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *selector exactness, requiring δ to be the only row that chooses which source-family coordinate and which finite window coordinate are read for a requested diagonal precision;*
3. *window alignment, requiring W to expose precisely the selected source-family observations and no independent schedule;*
4. *dyadic tolerance exactness, requiring D to store the displayed radius, slack, and comparison rows consumed by the selected windows and by the diagonal readback;*
5. *regular readback exactness, requiring Q to be assembled from F, δ, W, D as the diagonal regular rational name;*
6. *Real seal routing, requiring E to be downstream of the finite source-selector-window-ledger-readback route;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *refusal of quotient stream equality, selected host limits, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No diagonal extraction obligation is stored outside these rows.

Proof. Project the carrier of Definition 1773.1. Its only source coordinate is the family row F, and its only selector coordinate is the unary diagonal row δ.

The finite observation route is therefore forced. A Real-facing precision request can reach an observed source-family value only through δ and then through the aligned window family W.

The tolerance and readback rows are downstream of that route. The dyadic ledger D accounts for the requested radius and slack before the regular readback row Q can be formed.

Finally the seal row E and the structural rows H, C, P, N preserve the same route. Since the excluded quotient, selector, choice, trichotomy, completeness, verification, and bridge objects do not occur as coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 1773.3 (Regular Cauchy diagonal extraction Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing diagonal extraction read from an accepted* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *carrier*

$$G_{\mathrm{diag}} = (F, \delta, W, D, Q, E, H, C, P, N)$$

factors through the displayed finite route

$$F \longmapsto \delta \longmapsto W \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a source family, one unary diagonal selector, aligned StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat diagonal readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. The route exports no quotient stream, selected host limit, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Proof. Begin with the accepted carrier and read the source-family row F. A diagonal request has no direct access to a member of the family; it must first pass through the unary selector δ.

The selector determines the finite observations exposed by W. The dyadic ledger D is the only tolerance row attached to those observations, and the diagonal readback row Q is formed only after W and D are visible.

The terminal Real seal E is downstream of F, δ, W, D, Q. The transport, replay, provenance, and naming rows H, C, P, N record the same finite route and do not add a second Real-facing path.

Because the carrier has no quotient-stream coordinate, selected host limit, countable-choice schedule, trichotomy principle, ambient completeness theorem, Lean evidence, or bridge data, every Real-facing read factors through exactly the route displayed above. □

Falsifiable prediction: Every $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ Real-facing read factors through a source family, one unary diagonal selector, aligned StreamName windows, one DyadicRatCore tolerance ledger, one RegSeqRat diagonal readback, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-interleaving: $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source family, a unary diagonal selector, aligned finite windows, a dyadic tolerance ledger, a regular rational diagonal readback, and a terminal RealUp seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ packet is generated from a source family, one unary diagonal selector, aligned StreamName windows, one DyadicRatCore tolerance ledger, one RegSeqRat diagonal readback, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1773.1, Definition 1773.2, and Definition 1773.3 seed the finite diagonal extraction route over regular Cauchy real names through displayed source-family, selector, window, tolerance, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector exactness, window alignment, dyadic tolerance exactness, regular readback exactness, Real seal routing, componentwise transport, displayed replay, and Real-facing nonescape for BEDC.Derived.RegularCauchyDiagonalExtractionUp.

Chapter 1774

A Concrete Naming Certificate for $\mathsf{CauchyMajorantSeries}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyMajorantSeries}^{\uparrow}$ packet records the finite majorant-series ledger used to turn tail estimates into regular rational and real-name control without selecting a completed sum. It sits over the dyadic tolerance scale of chapter 1768, the finite StreamName observation surface of chapter 126, the RegSeqRat readback route of chapter 301, the Bishop regular Cauchy completion boundary of chapter 1639, and the terminal Real seal of chapter 38. The packet gives later Real and Completion tail-control arguments one visible majorant schedule rather than asking them to recover a bound from quotient streams, chosen limits, or ambient completeness.

Definition 1774.1 (Cauchy majorant series carrier)**.** *A* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, D, S, R, B, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the majorant schedule row. It records the finite list of nonnegative rational or dyadic majorant terms, their displayed partial sums, and the tail index attached to each requested tolerance.*
2. *D is the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *tolerance row consumed by A, including the dyadic precision scale and comparison budget for the displayed tail request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the tail index chosen inside A and budgeted by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite window after the majorant schedule and tolerance scale have been displayed.*
5. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, recording that the regular readback has reached the completion-facing Cauchy boundary by the displayed tail route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after A, D, S, R, B have been read.*
7. *H records componentwise* hsame *transport for the majorant schedule, dyadic tolerance scale, StreamName window, RegSeqRat readback, Bishop regular Cauchy completion boundary, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tail-control request through $A, D, S, R, B, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMajorantSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, D, S, R, B, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyMajorantSeriesUp.CauchyMajorantSeriesTasteGate single carrier alignment`

Theorem 1774.2 (Cauchy majorant series NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *carrier*

$$M = (A, D, S, R, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMajorantSeries}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the majorant schedule, dyadic tolerance scale, StreamName finite window, RegSeqRat readback, Bishop regular Cauchy completion boundary, Real seal, transport, replay, provenance, and local naming rows;*
2. *schedule exactness, requiring A to store the displayed partial-sum ledger and the tail index attached to each dyadic tolerance request;*
3. *tolerance compatibility, requiring the row D to be the same dyadic scale consumed by A and later by the finite window S;*
4. *readback handoff, requiring S and R to expose only the finite StreamName window and RegSeqRat data opened by the scheduled tail request;*
5. *completion-boundary handoff, requiring B to consume A, D, S, R before any* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
6. *Real-seal non-escape, requiring E to be terminal with respect to A, D, S, R, B and to export no quotient equality, selected limit, countable-choice schedule, host equality, trichotomy, ambient completeness, Lean verification, or bridge data;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No Cauchy majorant-series obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1774.1. The visible packet consists exactly of the majorant schedule A, dyadic tolerance scale D, finite window S, regular readback R, completion boundary B, Real seal E, and structural rows H, C, P, N.

Schedule exactness is the local content of A. A tail-control request must name its finite partial-sum ledger and tail index before it may open a tolerance scale or a stream window.

Tolerance compatibility then follows from the placement of D. The same dyadic scale row budgets the scheduled tail request and the finite observations in S, so the route cannot split into an unstated precision ledger.

The readback and completion handoffs are downstream. The row R reads only the displayed StreamName window opened by S, and B reads only the majorant, tolerance, window, and readback rows before exposing the completion-facing Cauchy boundary.

Finally, E, H, C, P, N seal, transport, replay, and name the same route. Since the excluded objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1774.3 (Cauchy majorant series tail control)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *carrier must factor its tail-control request through the finite route*

$$A \longmapsto D \longmapsto S \longmapsto R \longmapsto B \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed majorant schedule, dyadic tolerance scale, finite StreamName window, RegSeqRat readback, Bishop regular Cauchy completion boundary, terminal Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives no quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy principle, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Project the accepted carrier $M = (A, D, S, R, B, E, H, C, P, N)$. The only row carrying tail-control data is the majorant schedule A, and the only row carrying the precision budget for that schedule is D.

The finite observation route is forced by the tuple order. The StreamName row S opens the scheduled window, the RegSeqRat row R reads back that window, and the Bishop regular Cauchy completion row B records the completion-facing boundary after both rows are visible.

The Real or Completion consumer reaches the terminal seal only through E and then through the structural rows H, C, P, N. These rows preserve and replay the displayed route; they do not add quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Falsifiable prediction: Every $\mathsf{CauchyMajorantSeries}^{\uparrow}$ tail-control read factors through one majorant schedule row, one DyadicToleranceScale row, one StreamName finite window, one RegSeqRat readback row, one BishopRegularCauchyCompletion boundary row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadic-tolerance-scale, streamname, regseqrat, bishop-regular-cauchy-completion, real: $\mathsf{CauchyMajorantSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a majorant partial-sum schedule, a dyadic tolerance scale, the finite observation window, the regular rational readback, and the completion-facing tail boundary read by Real and Completion consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMajorantSeries}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyMajorantSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1774.1, Definition 1774.2, and Definition 1774.3 seed the finite majorant-series route from a displayed majorant schedule through dyadic tolerance scale, StreamName finite window, RegSeqRat readback, Bishop regular Cauchy completion boundary, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyMajorantSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exactness, tolerance compatibility, readback handoff, completion-boundary handoff, Real-seal non-escape, transport, replay, provenance, and tail-control factorization for BEDC.Derived.CauchyMajorantSeriesUp.

Constructive story: A $\mathsf{CauchyMajorantSeries}^{\uparrow}$ packet is generated from one majorant schedule row, one DyadicToleranceScale row, one StreamName finite window, one RegSeqRat readback row, one BishopRegularCauchyCompletion boundary row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1775

A Concrete Naming Certificate for $\mathsf{CauchyContinuousImage}^{\uparrow}$

Bishop–Bridges style constructive analysis treats continuity on Cauchy names through displayed moduli and finite tail data rather than through an ambient host function. The $\mathsf{CauchyContinuousImage}^{\uparrow}$ packet records the finite route by which a regular Cauchy source name is read through a continuous-map modulus and then sealed as a Real-facing image. It sits over the StreamName finite-window interface of chapter 126, the RegSeqRat readback route of chapter 301, the DyadicRatCore tolerance arithmetic of chapter 291, the ContinuousMap modulus surface of chapter 130, and the terminal Real seal of chapter 38.

Definition 1775.1 (CauchyContinuousImage carrier)**.** *A* $\mathsf{CauchyContinuousImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, R, D, M, J, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source Cauchy name, including the displayed observation window used by the image computation.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the source windows and their regularity budget.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for source and image estimates, including dyadic radii, endpoint comparisons, and rounding rows.*
4. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row. It records the displayed input tolerance required for each output tolerance request and names the finite continuity route used by the packet.*
5. *J is the image-window row. It records the finite image observations computed only after S, R, D, M have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *image seal reached only after the source readback, dyadic ledger, continuity modulus, and image window are visible.*
7. *H records componentwise* hsame *transport for the source window, RegSeqRat readback, dyadic ledger, continuous-map modulus, image window, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each image precision request through $M, D, S, R, J, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyContinuousImage}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuousImage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, M, J, E, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousImageUp.TasteGate.CauchyContinuousImageTasteGate single carrier alignment`

Theorem 1775.2 (CauchyContinuousImage NameCert obligations)**.** *For every accepted* $\mathsf{CauchyContinuousImage}^{\uparrow}$ *carrier*

$$I = (S, R, D, M, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyContinuousImage}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName source window, RegSeqRat readback, DyadicRatCore tolerance ledger, ContinuousMap modulus row, image window, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *source-readback exactness, requiring S and R to expose only the displayed regular Cauchy source data before any image row is available;*
3. *tolerance compatibility, requiring D to be the shared dyadic ledger consumed by the source readback, the continuous-map modulus, and the image-window computation;*
4. *modulus exactness, requiring M to answer each requested image tolerance by a displayed source tolerance before J or E may be read;*
5. *image-seal nonescape, requiring J and E to remain downstream of S, R, D, M and to export no selected limit, quotient stream equality, host function extensionality, ambient Real completeness, or countable-choice selector;*
6. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No CauchyContinuousImage obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1775.1. The accepted packet displays exactly the source window S, regular readback R, dyadic ledger D, continuity modulus M, image window J, Real seal E, and structural rows H, C, P, N.

Source-readback exactness follows from the order of the displayed rows. A consumer first opens the finite StreamName window and then reads the RegSeqRat row attached to that window; the image side has no coordinate before this source route is fixed.

Tolerance compatibility and modulus exactness are the middle of the route. The DyadicRatCore ledger D supplies the common precision arithmetic, while M converts each requested output tolerance into a displayed source tolerance consumed by S and R before J is available.

The image-seal clause is terminal. The row J records only the finite image observations admitted by S, R, D, M, and E seals the resulting Real-facing datum only after those rows have been displayed.

Finally, H, C, P, N transport, replay, package, and name the same finite route. Since selected limits, quotient stream equality, host function extensionality, ambient Real completeness, and countable choice are absent from the carrier, no local obligation can export them. □

Theorem 1775.3 (CauchyContinuousImage tail stability)**.** *Let $I = (S, R, D, M, J, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyContinuousImage}^{\uparrow}$ *carrier. Every Real-facing consumer of the image seal factors through the finite tail route*

$$S \longmapsto R \longmapsto D \longmapsto M \longmapsto J \longmapsto E \longmapsto H, C, P, N.$$

Consequently replacing a source observation by a later observation inside the same displayed RegSeqRat tail changes no exported Real-facing image datum unless the replacement changes one of the displayed rows $S, R, D, M, J, E, H, C, P, N$. The consumer receives no selected limit, quotient stream equality, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, countable-choice selector, Lean verification, or bridge checking.*

Proof. Project the accepted carrier. The only Real-facing row is E, and Definition 1775.1 places it downstream of the source window, regular readback, dyadic ledger, continuity modulus, and image window.

A same-tail replacement inside the displayed RegSeqRat route preserves the rows S and R by hypothesis. The shared dyadic ledger D and the continuity modulus M therefore read the same source tolerance budget for every requested image tolerance.

The image window J is computed only from those displayed rows. If S, R, D, M are unchanged, then the finite image observations named by J and the terminal Real seal E are unchanged as exported packet coordinates.

The structural rows H, C, P, N preserve the same factorization under componentwise transport, displayed replay, package provenance, and local naming. No unlisted principle can distinguish the two tails, because selected limits, quotient stream equality, host function extensionality, ambient completeness, and countable choice are not coordinates of the carrier. □

Falsifiable prediction: Every $\mathsf{CauchyContinuousImage}^{\uparrow}$ image read factors through one StreamName source window, one RegSeqRat readback row, one DyadicRatCore tolerance ledger, one ContinuousMap modulus row, one finite image-window row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, continuousmap, real: $\mathsf{CauchyContinuousImage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source finite-window route, regular Cauchy readback, dyadic tolerance ledger, continuous-map modulus, finite image window, and Real-facing image seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuousImage}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyContinuousImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1775.1, Definition 1775.2, and Definition 1775.3 seed the finite Cauchy-image route from a displayed source window through RegSeqRat readback, DyadicRatCore tolerance arithmetic, ContinuousMap modulus data, image-window computation, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyContinuousImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-readback exactness, tolerance compatibility, modulus exactness, image-seal nonescape, transport, replay, provenance, and tail-stability factorization for BEDC.Derived.CauchyContinuousImageUp.

Constructive story: A $\mathsf{CauchyContinuousImage}^{\uparrow}$ packet is generated from a StreamName source window, RegSeqRat readback, DyadicRatCore tolerance ledger, ContinuousMap modulus row, finite image-window row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1776

A Concrete Naming Certificate for $\mathsf{BishopCompletionInduction}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{BishopCompletionInduction}^{\uparrow}$ packet records the finite induction principle by which a proof or construction defined on a dense source is extended across the completion-facing Real route without invoking ambient completeness. It sits over the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the extension-and-uniqueness surface of chapter 397, the regular Cauchy universal route of chapter 1425, and the located completion boundary of chapter 1455. The packet gives Real and Completion consumers a visible dense-source extension route rather than a quotient stream, a selected host limit, countable choice, host function equality, or a hidden completeness theorem.

Definition 1776.1 (Bishop completion induction carrier)**.** *A* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (Q, F, D, R, E, U, K, H, C, P, N)$$

with the following displayed rows:

1. *Q is the dense-source row, naming the source data on which the induction step is first displayed.*
2. *F is the finite-window row, recording the* $\mathsf{StreamName}^{\uparrow}$ *observations inspected from the dense source and from the completion-facing name.*
3. *D is the dyadic tolerance ledger used to compare dense approximants, finite windows, and the terminal Real seal.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after Q, F, D, R have been displayed.*
6. *U is the extension face, storing the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *extension-and-uniqueness data read from the same source route.*
7. *K is the uniqueness ledger, requiring two extension reads to agree once they coincide on the displayed dense-source row and preserve the same finite-window and tolerance route.*
8. *H records componentwise* hsame *transport for dense source, finite windows, dyadic tolerance ledger, readback, Real seal, extension face, uniqueness ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each dense-source proof step through $Q, F, D, R, E, U, K, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, F, D, R, E, U, K, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopCompletionInductionUp.BishopCompletionInductionTasteGate single carrier alignment`

Theorem 1776.2 (Bishop completion induction NameCert obligations)**.** *For every accepted* BishopCompletionInduc *carrier*

$$I = (Q, F, D, R, E, U, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dense source, finite windows, dyadic tolerance ledger, RegSeqRat readback, Real seal, extension face, uniqueness ledger, transport, replay, provenance, and local naming rows;*

2. *dense-source visibility, requiring every induction premise to be displayed first on the source row Q;*

3. *finite-window discipline, requiring every completion-facing read to pass through the same* $\mathsf{StreamName}^{\uparrow}$ *windows F and dyadic tolerance ledger D;*

4. *readback and seal routing, requiring R to consume only F, D and requiring E to be terminal with respect to Q, F, D, R;*

5. *extension-face exactness, requiring U to read the sibling universal-property and regular Cauchy completion rows from the same route;*

6. *uniqueness-ledger exactness, requiring K to compare two extension reads only by their dense-source agreement and their shared finite-window, tolerance, readback, and seal rows;*

7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No Bishop completion-induction obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1776.1. The accepted packet exposes exactly the dense source Q, finite windows F, dyadic tolerance ledger D, regular readback R, Real seal E, extension face U, uniqueness ledger K, and structural rows H, C, P, N.

The dense-source and finite-window clauses are forced by the displayed order. A proof step has no source coordinate except Q, and any completion-facing observation must pass through the same finite windows F and tolerance ledger D before the readback row can be inspected.

The readback and seal clauses are downstream. The row R consumes only the finite-window and dyadic-tolerance route, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is visible only after Q, F, D, R have been displayed.

The extension and uniqueness rows are then local. The extension face U reads the sibling universal-property data from the same route, while K compares two reads only through dense-source agreement and the shared finite route already present in the carrier.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the excluded objects are absent from the carrier, the displayed rows exhaust the local NameCert surface. □

Theorem 1776.3 (Bishop completion induction dense-source route)**.** *Every accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier routes a completion-facing proof step through the finite dense-source chain*

$$Q \longmapsto F \longmapsto D \longmapsto R \longmapsto E \longmapsto U \longmapsto K \longmapsto H, C, P, N.$$

Consequently the proof step receives a dense-source row, finite $\mathsf{StreamName}^{\uparrow}$ *windows, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, an extension face, a uniqueness ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. It receives no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, selected host limit, countable-choice selector, host function equality, Lean verification, or bridge checking.*

Proof. Project the accepted carrier $I = (Q, F, D, R, E, U, K, H, C, P, N)$. The dense-source row Q is the only coordinate on which the induction premise can be opened.

The finite observation route is then fixed. The window row F stores the inspected StreamName observations, the dyadic ledger D budgets those observations, and the RegSeqRat row R is the only readback coordinate available before the terminal Real seal E.

After the seal is visible, the extension and uniqueness rows preserve the same route. The row U exposes the completion universal-property face, while K records agreement of extension reads only through the dense-source row and the displayed finite route.

The structural rows add no analytic coordinate. Thus every completion-facing proof step factors through the stated dense-source chain and cannot obtain any excluded completeness, quotient, choice, host-equality, Lean, or bridge datum. □

Lean4 ✓ `BEDC.Derived.BishopCompletionInductionUp.BishopCompletionInductionCarrier dense source route`

Theorem 1776.4 (Bishop completion induction extension principle)**.** *Let* $I = (Q, F, D, R, E, U, K, H, C, P, N)$ *be an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier. Any consumer that extends a construction or proof from the dense source to the completion-facing Real route must read* U *only after the dense-source route*

$$Q \longmapsto F \longmapsto D \longmapsto R \longmapsto E$$

has been displayed, and must read uniqueness through K *before exporting the result as a local* $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *claim. The exported result is therefore an extension along finite dense-source evidence, not an appeal to ambient completeness, quotient stream identity, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.*

Proof. Begin with an extension consumer of I. By Definition 1776.2, the consumer can open the extension face only inside the carrier inventory.

The source route comes first. The dense-source row Q displays the premise, the finite windows F and dyadic ledger D give the inspected completion-facing observations, and R records the regular rational readback before the Real seal E is available.

Only then can the extension face be read. The row U is downstream of the displayed dense-source route, so the consumer obtains extension data as a finite handoff from the same Q, F, D, R, E rows.

The uniqueness export is the final step. The row K compares extension reads only by dense-source agreement and their shared finite route, while H, C, P, N transport, replay, source, and name the same evidence. Since no excluded object is present in the carrier, the exported local NameCert claim has exactly the stated constructive extension form. □

Theorem 1776.5 (Bishop completion induction extension uniqueness)**.** *Let $I = (Q, F, D, R, E, U, K, H, C, P, N)$ be an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier. Suppose two extension faces are read through U and agree on the dense-source row Q, and suppose both preserve the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows F,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal E. Then the two faces induce the same Real seal route under the* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *packet, and any consumer export through H, C, P, N names a single local* $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *extension route.*

Proof. The dense-source agreement is visible inside the packet by Definition 1776.3. Both faces start from the same row Q, so their proof reads enter the completion-facing route through the same displayed source.

Apply the extension principle of Definition 1776.4. It permits an extension face to be read only after the common route Q, F, D, R, E has been displayed and requires the uniqueness ledger K before a local NameCert export is made.

The shared finite readback data identify the route consumed by the two faces. The window row F, tolerance ledger D, regular readback R, and Real seal E are the same for both reads, so transport exactness in Definition 1776.8 preserves the same componentwise hsame data.

Finally, consumer nonescape in Definition 1776.9 prevents either face from exporting an ambient completeness, quotient, choice, host-equality, Lean, or bridge datum that could distinguish the two routes outside the displayed packet. The local export through H, C, P, N therefore names one Real seal route under the $\mathsf{BishopCompletionInduction}^{\uparrow}$ carrier. □

Theorem 1776.6 (Bishop completion induction obligation closure)**.** *For every accepted* BishopCompletionInduction *carrier $I = (Q, F, D, R, E, U, K, H, C, P, N)$, the carrier definition, NameCert obligation theorem, dense-source route theorem, and extension principle together close the paper-side obligation package for carrier admission, dense-source visibility, finite-window discipline, readback and seal routing, extension-face exactness, uniqueness-ledger exactness, componentwise transport, displayed replay, provenance, and local naming. No obligation row for ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected host limits, countable choice, host function equality, Lean verification, or bridge checking is exported by this package.*

Proof. The carrier admission and row inventory are exactly Definition 1776.1. It displays $Q, F, D, R, E, U, K, H, C,$ and no additional analytic or verification coordinate.

The local obligation surface is supplied by Definition 1776.2. That theorem assigns dense-source visibility, finite-window discipline, readback and seal routing, extension-face exactness, uniqueness-ledger exactness, transport, replay, provenance, and local naming to the same rows.

The routing and export conditions are supplied by Definition 1776.3 and Definition 1776.4. Together they force every completion-facing proof step to pass through the displayed dense-source chain before the extension and uniqueness rows can be read.

Since each cited result uses only the displayed carrier rows and each excluded object is absent from those rows, the four cited sites form the claimed paper-side obligation package. □

Theorem 1776.7 (Bishop completion induction scoped kernel route)**.** *Every accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier read, extension read, uniqueness comparison, classifier transport, and consumer handoff is*

scoped to the displayed kernel surface

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniver}$

No route in the packet factors through an unlisted completion principle or a host-level equality service.

Proof. Project the carrier of Definition 1776.1. The finite-window row F, dyadic tolerance row D, RegSeqRat readback row R, Real seal E, extension face U, uniqueness ledger K, and structural rows H, C, P, N name exactly the displayed kernel objects.

Definition 1776.2 keeps each NameCert obligation on those same rows. In particular, dense-source visibility begins at Q, finite-window discipline uses F, D, readback and seal routing uses R, E, and extension-face exactness uses U, K.

Definition 1776.3 and Definition 1776.4 then fix the consumer path. A proof step reaches extension and uniqueness only after the finite dense-source chain has been displayed.

Thus the packet has no route through an unlisted completion theorem, quotient stream service, host equality service, or choice principle. The scoped kernel surface is exactly the one stated. □

Theorem 1776.8 (Bishop completion induction transport exactness)**.** *For an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier* $I = (Q, F, D, R, E, U, K, H, C, P, N)$*, classifier transport is exactly componentwise* hsame *on the displayed carrier rows together with displayed* Cont *replay of the same dense-source route. Transport may preserve dense-source rows, finite windows, dyadic tolerances, readback, Real seal, extension face, uniqueness ledger, provenance, and local naming; it may not replace them by ambient Real completeness, quotient stream equality, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.*

Proof. The transport coordinates are named in Definition 1776.1: row H records componentwise hsame for the carrier rows, and row C records displayed Cont replay from each dense-source proof step through the same packet.

Definition 1776.2 makes those transport and replay rows part of the local NameCert surface. It does not provide a second classifier coordinate or an external equality principle.

The dense-source route theorem fixes what H and C may preserve. They transport and replay $Q, F, D, R, E, U, K, P, N$ along the displayed route, not along an ambient completion or quotient-stream interface.

Therefore classifier transport is exactly componentwise hsame plus displayed Cont replay for the accepted packet, with all excluded replacement routes outside the carrier. □

Theorem 1776.9 (Bishop completion induction consumer nonescape)**.** *No consumer of an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier may export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, countable choice, host function equality, Lean verification, or bridge checking. The consumer may export only the finite dense-source extension route named by* $Q, F, D, R, E, U, K, H, C,$ *and the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *evidence attached to those rows.*

Proof. Start with the carrier inventory of Definition 1776.1. The tuple contains rows for dense source, finite windows, dyadic tolerance, RegSeqRat readback, Real seal, extension face, uniqueness ledger, transport, replay, provenance, and local naming only.

The NameCert obligations of Definition 1776.2 exhaust the accepted packet. Each allowed export is tied to one of the displayed rows, and no excluded row is introduced by the obligation theorem.

The extension principle Definition 1776.4 forces every consumer to read U after Q, F, D, R, E and to read uniqueness through K before a local NameCert claim is exported.

Thus any exported consumer result remains inside the finite dense-source route. The listed ambient completeness, quotient, choice, host-equality, Lean, and bridge objects are absent from the carrier and cannot escape through the local packet. □

Theorem 1776.10 (Bishop completion induction regular-Cauchy route)**.** *Any extension consumer of an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier* $I = (Q, F, D, R, E, U, K, H, C, P, N)$ *must read* Q, F, D, R, E *in order before* U *and* K *may export the completion-facing extension and uniqueness rows. Here* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to the displayed finite windows and dyadic tolerance ledger, and* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route refuses ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, countable choice, host function equality, Lean verification, and bridge checking.*

Proof. Project the accepted carrier of Definition 1776.1. The dense source Q, finite windows F, dyadic tolerance ledger D, regular-rational readback R, and terminal real seal E are the only rows available before the extension face and uniqueness ledger.

Apply the NameCert obligations of Definition 1776.2. They require dense-source visibility, finite-window discipline, and readback and seal routing before any extension-face exactness or uniqueness-ledger exactness can be consumed.

The dense-source route of Definition 1776.3 fixes the displayed order from Q through E and then to U, K, H, C, P, N. The extension principle of Definition 1776.4 then allows U and K to export the completion-facing extension only after the same route has been displayed.

Since the carrier and the cited route theorems contain no ambient completeness, quotient-stream, selected-limit, countable-choice, host-function-equality, Lean-verification, or bridge-checking coordinate, the regular-Cauchy handoff is exactly the finite route stated. □

Theorem 1776.11 (Bishop completion induction limit-seal factorization)**.** *Let* $I = (Q, F, D, R, E, U, K, H, C, P, N$ *be an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier. Every completion-facing* $\mathsf{Real}^{\uparrow}$ *seal read factors through*

$$Q \longmapsto F \longmapsto D \longmapsto R \longmapsto E$$

before either U *or* K *may be consumed. Thus the terminal seal route is a finite dense-source, StreamName-window, DyadicRatCore-budget, RegSeqRat-readback, Real-seal factorization. It imports no quotient stream, selected host limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier of Definition 1776.1. The rows before the extension face are exactly the dense-source row Q, finite-window row F, dyadic tolerance ledger D, regular-rational readback R, and terminal Real seal E.

Use the dense-source route of Definition 1776.3. It fixes the consumer path through Q, F, D, R, E before any extension, uniqueness, transport, replay, provenance, or local naming row is exported.

Apply the extension principle of Definition 1776.4 and the regular-Cauchy route of Definition 1776.10. These results permit U and K only after the same displayed route has exposed the RegSeqRat readback and terminal Real seal.

Finally invoke consumer nonescape from Definition 1776.9. Since quotient streams, selected host limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, no hidden coordinate can bypass the factorization. □

Theorem 1776.12 (Bishop completion induction finite-window recursion)**.** *Let $I = (Q, F, D, R, E, U, K, H, C, P, N$ be an accepted* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *carrier. Every dense-source recursive step exported from I must first expose the* $\mathsf{StreamName}^{\uparrow}$ *window F, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *handoff inside U, the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *route inside U, the* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *boundary row named by P, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. Only after these rows are displayed may the step be exported through K, H, C, P, N as a local* $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$ *induction claim.*

Consequently Bishop completion induction transports dense-source proof data through finite StreamName windows, regular rational readback, dyadic tolerance control, completion-universal handoff, regular-Cauchy routing, located-boundary provenance, and Real sealing. It does not export a quotient stream, a selected host limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host function equality, Lean verification, or bridge checking.*

Proof. Inspect the accepted carrier rows in Definition 1776.1. The dense-source row Q is the only row on which the recursive premise is initially visible, while F, D, R, E are the displayed finite-window, tolerance, readback, and terminal seal rows available before any extension export.

The dense-source and finite-window route is fixed by Definition 1776.3. A recursive step cannot jump directly from Q to a completion-facing result; it must pass through the StreamName window F, the DyadicRatCore ledger D, the RegSeqRat readback R, and the Real seal E.

The extension handoff is then governed by Definition 1776.4, Definition 1776.10, and Definition 1776.11. These results place the $\mathsf{CompletionUniversalProperty}^{\uparrow}$ and $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ data in U downstream of Q, F, D, R, E, with the located-boundary provenance named in the package row P rather than supplied by an external completion principle.

Finally apply uniqueness and nonescape. The uniqueness ledger K compares exports only along the shared dense-source and finite-window route, while H, C, P, N transport, replay, source, and name the same rows. By Definition 1776.5 and Definition 1776.9, no quotient stream, selected host limit, countable-choice selector, ambient completeness theorem, host function equality, Lean verification, or bridge datum can replace the displayed recursion route. □

Falsifiable prediction: Every $\mathsf{BishopCompletionInduction}^{\uparrow}$ completion-facing proof read factors through one dense-source row, one finite-window row, one DyadicRatCore tolerance ledger, one RegSeqRat readback row, one terminal RealUp seal, one extension face, one uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, completionuniversalproperty, regular-cauchy-completion-universal, bishoplocatedcompletionboundary: $\mathsf{BishopCompletionInduction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a dense-source induction row, finite windows, dyadic tolerances, readback, terminal seal, extension face, and uniqueness ledger for proof transport across completion-facing Real data.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1776.1, Definition 1776.2, Definition 1776.3, Definition 1776.4, Definition 1776.6, Definition 1776.7, Definition 1776.8, and Definition 1776.9 seed the finite dense-source induction route through StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, extension face, uniqueness ledger, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding the displayed carrier admission, dense-source visibility, finite-window discipline, readback and seal routing, extension-face exactness, uniqueness-ledger exactness, transport, replay, provenance, consumer nonescape, and extension-principle factorization to the listed L10 kernel scope for BEDC.Derived.BishopCompletionInductionUp.

Constructive story: A BishopCompletionInduction$^{\uparrow}$ packet is generated from a dense-source row, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, a CompletionUniversalProperty and RegularCauchyCompletionUniversal extension face, a uniqueness ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1777

A Concrete Naming Certificate for $\mathsf{ContinuedFractionConvergents}^{\uparrow}$

Following Perron, Khinchin, and the Hardy–Wright treatment of continued fractions, the ContinuedFractionConverge packet names finite convergent data before any completion-facing consumer reads it as a regular rational sequence or as a real-name seal. It refines the partial-quotient surface of chapter 342 by separating the convergent numerator and denominator rows, the rational normalization rows of chapter 37, the finite-window route of chapter 126, the regular-rational handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet is a finite approximation certificate between continued fractions and Real or Completion routes; it is not a completeness theorem and not a quotient equality principle.

Definition 1777.1 (ContinuedFractionConvergents carrier)**.** *A* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, N, D, Q, W, E, R, S, H, C, P, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *partial-quotient source row, including the finite prefix of partial quotients and the local recurrence ledger that names which prefix is being read.*
2. *N and D are the* $\mathsf{Rat}^{\uparrow}$ *numerator and denominator convergent rows. They display the finite recurrence steps and the denominator-nonzero side condition needed to read each convergent as a rational endpoint.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *normalized rational-convergent row obtained from N and D by the displayed rational arithmetic route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing only the convergent indices requested by the downstream consumer.*
5. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error-ledger row. It records the dyadic radius, endpoint enclosure, and precision budget attached to each displayed finite window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row built from Q, W, E and the recurrence ledger of A, N, D.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational row R has been displayed.*
8. *H records componentwise* hsame *transport for partial quotients, numerator rows, denominator rows, normalized rationals, stream windows, dyadic ledgers, regular handoff, the Real seal, provenance, and local naming.*

9. *C records displayed* Cont *replay from each finite window request through* $A, N, D, Q, W, E, R, S, H, P, L$.
10. *P is the* Pkg *provenance row over* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{ContinuedFractionConvergents}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite continued-fraction tail, host rational equality, quotient real equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ContinuedFractionConvergentsUp.ContinuedFractionConvergentsTasteGate`
`single carrier alignment`

Theorem 1777.2 (ContinuedFractionConvergents NameCert obligations)**.** *For every accepted* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *carrier* $K = (A, N, D, Q, W, E, R, S, H, C, P, L)$, *the local* $\mathsf{NameCert}_{\mathsf{ContinuedFractionCo}}$ *surface consists exactly of the following six obligation rows:*

1. *carrier admission for the displayed partial-quotient source, rational numerator and denominator rows, normalized rational convergent row, finite stream windows, dyadic error ledger, regular handoff, Real seal, and structural rows* H, C, P, L;
2. *recurrence exactness, requiring each displayed numerator and denominator row to read the finite recurrence ledger of* A *before the rational row* Q *is available;*
3. *rational-window compatibility, requiring* Q *and* W *to expose the same finite convergent indices and no unrequested tail data;*
4. *dyadic error compatibility, requiring* E *to be attached to the same finite windows as* W *and to supply the precision budget consumed by* R;
5. *Real-route nonescape, requiring* S *to remain terminal with respect to* A, N, D, Q, W, E, R *and to expose no detached real object;*
6. *componentwise transport, replay, provenance, and naming, requiring* H, C, P, L *to preserve only the displayed route under* hsame *transport and* Cont *replay.*

No local obligation is stored outside these six rows.

Lean4 ✓ `BEDC.Derived.ContinuedFractionConvergentsUp.ContinuedFractionConvergentsNameCertObligations`

Proof. Carrier admission is projection from Definition 1777.1. The visible packet contains the partial-quotient source, the rational numerator and denominator rows, the normalized rational convergent row, finite windows, dyadic error data, regular handoff, Real seal, and the structural rows H, C, P, L.

Recurrence exactness reads the source row A before N and D are accepted. The rational row Q is therefore downstream of the finite recurrence ledger, not a detached rational sequence.

Window and dyadic compatibility read W and E over the same finite index set. The stream row exposes only requested convergent windows, and the dyadic row supplies the precision budget that the regular handoff row R consumes.

The Real-route clause follows from the placement of S after R. Since the carrier has no separate coordinate for completed tails, quotient equality, or selected limits, H, C, P, L can transport and name only the displayed finite route. □

Theorem 1777.3 (ContinuedFractionConvergents RegSeqRat handoff)**.** *Let $K = (A, N, D, Q, W, E, R, S, H, C, P,$ be an accepted* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer reads the packet through the displayed route*

$$A, N, D \longmapsto Q \longmapsto W, E \longmapsto R \longmapsto H, C, P, L.$$

Consequently the consumer receives finite continued-fraction prefixes, rational numerator and denominator rows, normalized rational convergents, finite stream windows, dyadic error ledgers, componentwise hsame *transport,* Cont *replay, package provenance, and the local NameCert row before any regular-rational data is available. The route cannot use quotient real equality, a choice-selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a $\mathsf{RegSeqRat}^{\uparrow}$ read of K. By Definition 1777.1, the only regular rational coordinate is R, and it is downstream of Q, W, E together with the recurrence ledger carried by A, N, D.

The rational part of the route is fixed by N, D, Q. The numerator and denominator rows expose the finite recurrence data, while Q records the normalized rational convergent surface read through chapter 37.

The window and precision part of the route is fixed by W and E. The finite stream surface of chapter 126 chooses the displayed windows, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger supplies the error budget consumed by the regular-rational row of chapter 301.

Finally, H, C, P, L transport, replay, package, and name the same route. Since the excluded objects have no coordinate in the carrier, every handoff to $\mathsf{RegSeqRat}^{\uparrow}$ factors through the displayed finite convergent packet. □

Theorem 1777.4 (ContinuedFractionConvergents Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *carrier factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R before it reaches the Real seal row S. The boundary exposes the same finite partial-quotient source, rational convergent rows, finite windows, dyadic error ledger, transport, replay, provenance, and local naming; it does not assert full real completeness, quotient equality of real names, or a choice-selected limit of the convergent sequence.*

Proof. Read the Real-facing coordinate of Definition 1777.1. The seal row is S, and the definition places S after the regular handoff row R.

Apply Definition 1777.3. The handoff row already factors through the finite partial-quotient source, rational numerator and denominator rows, normalized rational convergents, stream windows, dyadic error ledgers, and structural rows.

Thus any Real-facing consumer receives the same finite route before the seal is visible. No coordinate can bypass R to provide quotient equality, choice-selected limits, or ambient completeness for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuedFractionConvergents}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ packet is generated from a ContinuedFraction partial-quotient source, Rat numerator and denominator convergent rows, StreamName finite windows, a DyadicRatCore error ledger, RegSeqRat handoff, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ContinuedFractionConvergents}^{\uparrow}}$, seed)

Scope closed: Definition 1777.1, Definition 1777.2, Definition 1777.3, and Definition 1777.4 seed the finite continued-fraction convergent route consumed by RegSeqRat and Real packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ContinuedFractionConvergents}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full real completeness, quotient equality of real names, choice-selected limits of convergent sequences, total continued-fraction expansion for every real, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recurrence exactness, rational-window compatibility, dyadic error compatibility, Real-route nonescape, componentwise transport, provenance, and local naming for the same displayed packet.

Chapter 1778

A Concrete Naming Certificate for $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ packet records the finite closed-interval route by which endpoint bounds, interval nets, stream windows, regular rational readbacks, dyadic tolerance ledgers, and the Bishop regular Cauchy completion boundary are assembled before a Real-facing seal is consumed. It sits over the closed bounded interval net of chapter 1250, the finite observation surface of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, the Bishop regular Cauchy completion packet of chapter 1639, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a finite closed-interval completion surface; it does not import Heine–Borel compactness, open-cover compactness, selected limits, quotient streams, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1778.1 (Closed interval Cauchy completion carrier)**.** *A* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, I, S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower closed endpoint row and B is the upper closed endpoint row, both read through the same finite endpoint discipline as the source closed interval.*
2. *I is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row, recording the finite interval net, mesh scale, endpoint containment route, and interval-local coverage data consumed by the completion request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the interval-net request before any regular rational readback is exposed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed StreamName windows and endpoint-bounded interval route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radius, endpoint comparison budget, common denominator budget, and tail allowance used by the interval Cauchy read.*
6. *Q is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *handoff row, consuming A, B, I, S, R, D before any Real-facing completion boundary is visible.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the endpoint rows, interval-net row, finite windows, regular readback, dyadic tolerance ledger, and Bishop completion handoff have been displayed.*

8. *H records componentwise* hsame *transport for endpoints, interval-net data, StreamName windows, RegSeqRat readbacks, dyadic tolerance ledgers, Bishop completion handoff, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a closed-interval completion request through $A, B, I, S, R, D, Q, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, I, S, R, D, Q, E, H, C, P, N$. The carrier has no coordinate for open-cover compactness, selected limits, quotient streams, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedIntervalCauchyCompletionUp.ClosedIntervalCauchyCompletionTasteGate`
`single carrier alignment`

Theorem 1778.2 (Closed interval Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *carrier*

$$K = (A, B, I, S, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower endpoint, upper endpoint, ClosedBoundedIntervalNet row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Bishop regular Cauchy completion handoff, Real seal, transport, replay, provenance, and local naming rows;*

2. *endpoint-bounded interval admission, requiring the interval-net row I to be read from the displayed endpoint rows A, B rather than from a host closed interval;*

3. *finite-window locality, requiring S to expose exactly the stream observations opened by the interval-net request and the dyadic tolerance ledger D;*

4. *regular readback locality, requiring R to be read only from the displayed StreamName windows and endpoint-bounded interval route;*

5. *completion handoff ordering, requiring Q to consume A, B, I, S, R, D before E exposes the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*

6. *componentwise classifier transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N;*

7. *ledger non-escape, requiring the packet to export no open-cover compactness, selected limit, quotient stream, countable-choice schedule, trichotomy branch, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No closed-interval Cauchy completion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1778.1. The visible packet consists exactly of the two endpoint rows A, B, the interval-net row I, finite windows S, regular readback R, dyadic tolerance ledger D, Bishop completion handoff Q, terminal seal E, and structural rows H, C, P, N.

Endpoint-bounded interval admission is upstream of every completion read. The row I is the only interval-net coordinate, and it is attached to the displayed endpoints A, B, so a consumer cannot replace it by a host closed interval or by an unrecorded compactness theorem.

Finite-window and regular readback locality are the middle route. The StreamName row S opens exactly the observations allowed by I and D, and the RegSeqRat row R reads only those displayed windows before any completion handoff is available.

The completion handoff then follows the displayed order. The row Q consumes A, B, I, S, R, D, and the terminal Real seal E is exposed only after that handoff has been displayed.

Finally, H, C, P, N transport, replay, package, and name the same finite route. Since none of the excluded objects occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1778.3 (Closed interval Cauchy completion route)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *carrier factors its request through the finite route*

$$A, B \longmapsto I \longmapsto S \longmapsto R \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives displayed closed endpoints, a ClosedBoundedIntervalNet row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Bishop regular Cauchy completion handoff, a terminal RealUp seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. The route supplies no open-cover compactness, selected limit, quotient stream, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $K = (A, B, I, S, R, D, Q, E, H, C, P, N)$. The endpoint rows A, B and the interval-net row I are the only closed-interval source coordinates available to a consumer.

The finite observation route is then forced by the packet. The StreamName row S opens the window selected by the interval-net request, and the RegSeqRat row R reads back that window inside the displayed endpoint bounds.

The tolerance and completion boundary are downstream. The DyadicRatCore row D records the dyadic radius and comparison budget, the Bishop regular Cauchy completion row Q consumes the endpoint, net, window, readback, and tolerance rows, and the Real seal E is reached only after that handoff.

The remaining rows preserve the same route under componentwise hsame transport and displayed Cont replay, with P and N recording provenance and local naming. Since no excluded compactness, selection, quotient, choice, trichotomy, host-equality, or ambient-completeness coordinate is present, every public read is exhausted by the displayed route. □

Theorem 1778.4 (Closed interval Cauchy completion finite-net Real seal)**.** *For every accepted* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *carrier*

$$K = (A, B, I, S, R, D, Q, E, H, C, P, N),$$

every Real-facing read reaches the terminal seal row E only after the lower endpoint row A, upper endpoint row B, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row I,* $\mathsf{StreamName}^{\uparrow}$ *finite windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *handoff Q have been displayed. No open-cover compactness, selected limit, quotient stream, countable-choice*

schedule, trichotomy branch, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate is available to the read.*

Proof. Start with the carrier definition. It lists the terminal Real seal as the single row E, and every row preceding it in the completion route is explicitly displayed as A, B, I, S, R, D, Q.

Apply the NameCert obligations. Endpoint-bounded interval admission fixes A, B, I, finite-window locality fixes S, regular readback locality fixes R, and completion handoff ordering fixes D, Q before E can be exposed.

Apply the route theorem. Every Real or Completion consumer factors through the ordered path from endpoints to interval net, windows, readback, tolerance ledger, Bishop handoff, and only then the Real seal.

The excluded objects have no carrier coordinate and no NameCert obligation row. Thus the finite-net-to-Real-seal boundary is exactly the displayed route and cannot leak open-cover compactness, selected limits, quotient streams, countable choice, trichotomy, host real equality, or ambient Real completeness. □

Theorem 1778.5 (Closed interval Cauchy completion finite-net induction)**.** *For every accepted* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *packet*

$$K = (A, B, I, S, R, D, Q, E, H, C, P, N),$$

each inspected finite interval-net stage is exposed through the same displayed route

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{BishopRegularCauchyCompl}$$

before the terminal seal row E is read. The induction over displayed net stages uses only the carrier rows $I, S, R, D, Q, E, H, C, P, N$, the route theorem, and the finite-net Real seal theorem; it exports no open-cover compactness, selected limit, quotient stream, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct over the finite list of net stages displayed in the row I of Definition 1778.1. The base stage is the first inspected closed bounded interval net cell. Its only available observations are the interval-net row I, the StreamName windows S, the regular readback R, and the dyadic tolerance ledger D.

For the induction step, assume the route has been exposed for all earlier displayed stages. The next stage is another row of the same finite interval-net ledger I, so the consumer again opens only the windows recorded by S, reads them back through R, and accounts for the tolerance through D.

Apply the route theorem to the stage just inspected. It places the Bishop regular Cauchy completion handoff Q after I, S, R, D and before the Real seal E.

Finally apply the finite-net Real seal theorem. It prevents the terminal seal from being read before the displayed interval-net, window, readback, tolerance, and completion rows have appeared, and the structural rows H, C, P, N transport, replay, source, and name the same finite induction route. □

Falsifiable prediction: Every $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ read factors through displayed closed endpoints, one ClosedBoundedIntervalNet row, finite StreamName windows, one RegSeqRat readback row, one DyadicRatCore tolerance ledger, one BishopRegularCauchyCompletion handoff, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closedboundedintervalnet, streamname, regseqrat, dyadicratcore, bishop-regular-cauchy-completion, real: $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint-bounded interval-net data, finite observation windows, regular rational readback, dyadic tolerance accounting, the Bishop completion handoff, and the terminal Real seal as one closed-interval completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1778.1, Definition 1778.2, and Definition 1778.3 seed the finite closed-interval Cauchy completion route from displayed endpoints and interval-net rows through StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, Bishop regular Cauchy completion handoff, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient streams, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-bounded interval admission, finite-window locality, regular readback locality, completion handoff ordering, classifier transport, replay, provenance, local naming, and route factorization for BEDC.Derived.ClosedIntervalCauchyCompletionUp.

Constructive story: A $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ packet is generated from displayed closed endpoint rows, one ClosedBoundedIntervalNet row, finite StreamName windows, one RegSeqRat readback row, one DyadicRatCore tolerance ledger, one BishopRegularCauchyCompletion handoff, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1779

A Concrete Naming Certificate for $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ packet names the finite closed-interval criterion by which a uniformly Cauchy family of interval-local real windows is admitted before any uniform-limit endpoint or completion-facing seal is read. It sits after the closed-interval completion route of chapter 1778, uses the shared threshold surface of chapter 435, hands off to the uniform-limit packet of chapter 463, and keeps its finite observations inside the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sibling surfaces of chapter 126, chapter 301, and chapter 38. The chapter records a criterion packet for closed-interval Cauchy data; it does not import open-cover compactness, selected limits, quotient function-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1779.1 (Closed interval Cauchy criterion carrier)**.** *A* $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, B, I, F, W, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower closed endpoint row and B is the upper closed endpoint row, both read through the same finite closed-interval discipline as the source interval.*
2. *I is the closed interval row that records endpoint containment, interval-local request scope, and the closed-interval completion handoff consumed from* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$*.*
3. *F is the function-window family, recording the finite interval-local real-valued windows visible to the criterion.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by F for the finite family of interval requests.*
5. *T is the uniform Cauchy threshold row, a single shared threshold surface from* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *for every displayed tolerance and every retained interval-local window.*
6. *S is the criterion ledger asserting that all displayed pairs of windows beyond T are compared through the same interval row I and the same function-window family F.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W, T, S before any limit or completion-facing consumer reads the terminal row.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, F, W, T, S, R have been displayed.*

9. *H records componentwise* hsame *transport for endpoints, the closed-interval row, function-window rows, StreamName windows, uniform Cauchy threshold, criterion ledger, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a closed-interval Cauchy criterion request through $A, B, I, F, W, T, S, R, E, H$*
11. *P is the* Pkg *provenance over* ClosedIntervalCauchyCriterion$^{\uparrow}$, ClosedIntervalCauchyCompletion$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, UniformLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{ClosedIntervalCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, I, F, W, T, S, R, E, H, C, P, N$. The carrier has no coordinate for open-cover compactness, selected limits, quotient function-space equality, countable choice, host function equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedIntervalCauchyCriterionUp.ClosedIntervalCauchyCriterionTasteGate`
`single carrier alignment`

Theorem 1779.2 (Closed interval Cauchy criterion NameCert obligations)**.** *For every accepted* ClosedIntervalCauchyCriterion$^{\uparrow}$ *carrier*

$$J = (A, B, I, F, W, T, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{ClosedIntervalCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint rows, closed-interval row, function-window family, StreamName windows, uniform Cauchy threshold, criterion ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *closed-interval anchoring, requiring every criterion read to use the displayed row I obtained from the* ClosedIntervalCauchyCompletion$^{\uparrow}$ *route rather than an ambient compact interval object;*
3. *function-window locality, requiring F and W to expose exactly the finite interval-local windows inspected by the criterion request;*
4. *uniform-threshold exactness, requiring the single threshold row T from* UniformCauchyCriterion$^{\uparrow}$ *to govern all retained displayed window pairs;*
5. *readback ordering, requiring R and the terminal* Real$^{\uparrow}$ *seal E to be exposed only after I, F, W, T, S have been displayed;*
6. *componentwise classifier transport, displayed replay, provenance, and local naming through H, C, P, N;*
7. *ledger non-escape, requiring the packet to export no open-cover compactness, selected limit, quotient function-space equality, countable-choice schedule, host function equality, or ambient* Real$^{\uparrow}$ *completeness theorem.*

No closed-interval Cauchy criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1779.1. The visible packet consists exactly of the endpoint rows A, B, closed-interval row I, function-window family F, StreamName windows W, threshold row T, criterion ledger S, readback row R, terminal seal E, and structural rows H, C, P, N.

Closed-interval anchoring is upstream of every criterion read. The row I is the only closed-interval coordinate, and it is supplied by the $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ sibling route, so no host compact interval object can replace it.

Function-window locality and uniform-threshold exactness are the middle route. The rows F and W expose the finite interval-local windows, while T is the single shared $\mathsf{UniformCauchyCriterion}^{\uparrow}$ threshold governing all displayed window pairs recorded by S.

The readback order is then forced. The $\mathsf{RegSeqRat}^{\uparrow}$ row R and the terminal $\mathsf{Real}^{\uparrow}$ seal E occur only after the closed-interval, window, threshold, and criterion-ledger rows have been displayed.

Finally, H, C, P, N transport, replay, package, and name the same finite route. Since none of the excluded objects occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1779.3 (Closed interval Cauchy criterion uniform-window handoff)**.** *Every* $\mathsf{UniformLimit}^{\uparrow}$ *or completion-facing consumer that reads an accepted* $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ *carrier factors its request through the finite route*

$$A, B \longmapsto I \longmapsto F, W \longmapsto T, S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives displayed closed endpoints, the closed-interval completion row, interval-local function windows, StreamName windows, one shared UniformCauchyCriterion threshold, one criterion ledger, one RegSeqRat readback row, one RealUp seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. The handoff supplies no open-cover compactness, selected limit, quotient function-space equality, countable choice, host function equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $J = (A, B, I, F, W, T, S, R, E, H, C, P, N)$. The endpoint rows A, B and the closed-interval row I are the only interval source coordinates available to the consumer.

The finite observation route then opens through F and W. These rows expose only interval-local function windows and their displayed $\mathsf{StreamName}^{\uparrow}$ readings.

Uniformity is supplied before any readback. The threshold row T is shared across all retained windows, and the criterion ledger S records the displayed pairwise comparisons under that same threshold.

The downstream handoff reaches R and then E. Thus a $\mathsf{UniformLimit}^{\uparrow}$ or completion-facing consumer reads the $\mathsf{RegSeqRat}^{\uparrow}$ route and the terminal $\mathsf{Real}^{\uparrow}$ seal only after the closed-interval, window, and uniform-threshold rows are in scope.

The structural rows H, C, P, N preserve and name the same route. Because the carrier has no coordinate for the excluded compactness, selection, quotient, choice, host-equality, or completeness objects, every public read is exhausted by the displayed handoff. □

Falsifiable prediction: Every $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ read factors through displayed closed endpoints, one closed-interval completion row, interval-local function windows, StreamName windows, one UniformCauchyCriterion threshold, one criterion ledger, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closed-interval-cauchy-completion, uniformcauchycriterion, uniformlimit, streamname, regseqrat, real: $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries closed-interval completion anchoring, interval-local function windows, a shared uniform Cauchy threshold, the criterion ledger, regular rational readback, and the terminal Real seal as one criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCriterion}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1779.1, Definition 1779.2, and Definition 1779.3 seed the finite closed-interval Cauchy criterion route from displayed endpoints and closed-interval completion rows through interval-local function windows, StreamName windows, a shared UniformCauchyCriterion threshold, criterion ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient function-space equality, countable choice, host function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-interval anchoring, function-window locality, uniform-threshold exactness, readback ordering, classifier transport, replay, provenance, local naming, and uniform-window handoff for BEDC.Derived.ClosedIntervalCauchyCriterionUp.

Constructive story: A $\mathsf{ClosedIntervalCauchyCriterion}^{\uparrow}$ packet is generated from displayed closed endpoint rows, one closed-interval completion row, interval-local function windows, finite StreamName windows, one UniformCauchyCriterion threshold row, one criterion ledger, one RegSeqRat readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1780

A Concrete Naming Certificate for $\mathsf{RationalCauchyGap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalCauchyGap}^{\uparrow}$ packet records a finite rational Cauchy-gap witness that must pass through the rational, dyadic, stream-window, regular-sequence, and real-name route before any Completion consumer treats it as a completed real. It sits over the rational source schedule of chapter 37, the late-pair dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The chapter supplies the current-state witness that rational Cauchy information is not already a completed real object: the completion route is visible as finite NameCert data rather than quotient equality, a selected limit, countable choice, or host completeness.

Definition 1780.1 (Rational Cauchy gap carrier)**.** *A* $\mathsf{RationalCauchyGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source schedule, recording the rational observations and precision requests that generate the candidate Cauchy gap.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *late-pair tolerance ledger, storing the dyadic bounds, slack rows, and comparison budgets used to test the source schedule at later stages.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by Q and budgeted by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, recording the regular rational readback obtained from the displayed windows and dyadic late-pair ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after Q, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the rational source schedule, dyadic tolerance ledger, finite windows, regular rational handoff, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the rational precision request through Q, D, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalCauchyGap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCauchyGap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, W, R, E, H, C, P, N$. It has no coordinate for quotient equality of rational streams, a selected real limit, countable choice, host real comparison, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RationalCauchyGapUp.RationalCauchyGapTasteGate single carrier alignment`

Theorem 1780.2 (Rational Cauchy gap NameCert obligations)**.** *For every accepted* $\mathsf{RationalCauchyGap}^{\uparrow}$ *carrier*

$$G = (Q, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCauchyGap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{Rat}^{\uparrow}$ *source schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *late-pair tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *rational-source exactness, requiring Q to display the rational observations and precision requests that the gap read is allowed to inspect;*
3. *late-pair tolerance exactness, requiring D to store the dyadic bounds and slack rows used when later elements of the rational schedule are compared;*
4. *finite-window compatibility, requiring W to expose only the StreamName observations opened by the source schedule and budgeted by the late-pair ledger;*
5. *regular handoff exactness, requiring R to consume Q, D, W before any Real seal is visible;*
6. *Real-seal nonescape, requiring E to be terminal with respect to the route Q, D, W, R and to export no quotient stream equality, selected limit, countable-choice schedule, host comparison, ambient completeness theorem, Lean verification, or bridge data;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No rational Cauchy-gap obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1780.1. The accepted packet displays exactly the rational source schedule, dyadic late-pair tolerance ledger, finite windows, regular rational handoff, terminal Real seal, transport, replay, provenance, and local naming rows.

The source and tolerance clauses are then forced by the route. The row Q is the only coordinate that carries rational observations and precision requests, while D is the only coordinate that carries the late-pair dyadic comparison budget.

The finite-window and regular handoff clauses are downstream. The row W reads only the observations opened by Q and budgeted by D, and R is the first row that repacks those finite observations as regular rational readback.

Finally, E, H, C, P, N seal, transport, replay, and name the same finite route. Since quotient stream equality, selected limits, countable choice, host comparison, ambient completeness, Lean verification, and bridge data are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1780.3 (Rational Cauchy gap Real handoff)**.** *Every accepted rational Cauchy gap read that reaches a* $\mathsf{Real}^{\uparrow}$ *consumer must factor through the finite route*

$$Q \longmapsto D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives the rational source schedule, dyadic late-pair tolerance ledger, finite StreamName windows, regular rational handoff, terminal Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives no quotient equality of rational streams, selected limit, countable-choice schedule, host real comparison, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Project the accepted carrier $G = (Q, D, W, R, E, H, C, P, N)$. The rational gap data starts in Q, and the only late-pair tolerance data available to the read is the dyadic ledger D.

The observation route is finite. The StreamName row W exposes the bounded windows licensed by Q and D, and the RegSeqRat row R is the first point where those windows are repacked as regular rational readback.

The Real consumer reaches the terminal seal only through E and then through the structural rows H, C, P, N. These rows preserve and replay the same route; they do not add quotient stream equality, a selected limit, countable choice, host real comparison, ambient completeness, Lean verification, or bridge checking. □

Falsifiable prediction: Every $\mathsf{RationalCauchyGap}^{\uparrow}$ read into Real or Completion factors through one RatUp source schedule, one DyadicRatCore late-pair tolerance ledger, one StreamName finite-window row, one RegSeqRat handoff row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalCauchyGap}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a rational source schedule, late-pair dyadic tolerance ledger, finite stream windows, regular rational readback, and the terminal RealUp seal that witnesses why completion is a genuine route rather than an already available rational object.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCauchyGap}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalCauchyGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1780.1, Definition 1780.2, and Definition 1780.3 seed the finite rational Cauchy-gap route through RatUp source schedule, DyadicRatCore late-pair tolerance ledger, StreamName finite windows, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalCauchyGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of rational streams, selected limits, countable choice, host real comparison, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-source exactness, late-pair tolerance exactness, finite-window compatibility, regular handoff exactness, Real-seal nonescape, transport, replay, provenance, and Real-consumer factorization for BEDC.Derived.RationalCauchyGapUp.

Constructive story: A $\mathsf{RationalCauchyGap}^{\uparrow}$ packet is generated from one RatUp source schedule, one DyadicRatCore late-pair tolerance ledger, one StreamName finite-window row, one RegSeqRat handoff row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1781

A Concrete Naming Certificate for $\mathsf{FastCauchyModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FastCauchyModulus}^{\uparrow}$ packet records the fast-threshold discipline that turns an ordinary Cauchy modulus into the doubled-window schedule expected by regular Cauchy and real-name consumers. It sits over the generic modulus schedule of chapter 292, the finite observation windows of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives downstream RealCauchyModulus and RegSeqRat consumers one visible fast-modulus carrier before any Real or Completion route reads a seal.

Definition 1781.1 (Fast Cauchy modulus carrier)**.** *A* $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{CauchyModulus}^{\uparrow}$ *row, read as a finite threshold schedule for Cauchy observations.*
2. *F is the fast or doubled threshold discipline. It records, for each displayed precision request, whether the carrier uses the direct fast threshold or the doubled-window threshold, and it stores the comparison row showing that the selected threshold is strong enough for the requested tail estimate.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the threshold selected by F from M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger consumed by the selected window and by the regularity check.*
5. *Q is the precision-query row whose dyadic request is read jointly by M, F, S, D.*
6. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row exposed only after M, F, S, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the source modulus, fast discipline, stream window, dyadic ledger, precision query, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through $M, F, S, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FastCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, countable choice, trichotomy, selected limits, unbounded stream reads, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FastCauchyModulusUp.FastCauchyModulusUpTasteGate single carrier alignment`

Theorem 1781.2 (Fast Cauchy modulus doubling window)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. Every regular-Cauchy or Real-facing consumer that requests a precision row Q must read the finite route*

$$Q \longmapsto M, F \longmapsto S, D \longmapsto E \longmapsto H, C, P, N.$$

If F selects the direct fast threshold, the opened window S is already the thresholded finite window supplied by M. If F selects the doubled threshold, S is the displayed enlarged window and D records the dyadic slack showing that the doubled read implies the requested tail estimate. In both cases the consumer receives no unbounded stream read, quotient stream equality, host real equality, countable-choice schedule, trichotomy principle, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge data.*

Proof. Project the accepted carrier. The precision query Q can reach a stream window only through the displayed source modulus row M and the fast discipline row F, so the carrier exposes no separate threshold selector.

For the direct fast case, F records that the threshold read from M already satisfies the requested tail estimate. The window row S is therefore the finite StreamName window opened at that threshold, and the dyadic ledger D only records the requested tolerance account.

For the doubled case, F records the doubled threshold before any window is opened. The row S contains that enlarged finite window, and D stores the dyadic slack proving that the doubled read is strong enough for the original precision request.

Finally E, H, C, P, N hand the same displayed route to regular-Cauchy and Real-facing consumers. Since the excluded objects are absent from the carrier, no consumer can bypass the finite threshold-window-ledger path. □

Theorem 1781.3 (Fast Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FastCauchyModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source* $\mathsf{CauchyModulus}^{\uparrow}$ *row, fast threshold discipline,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, precision query,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, transport, replay, provenance, and local naming rows;*

2. *threshold exactness, requiring F to select either the direct fast threshold or the doubled-window threshold from the displayed source modulus row M for the same precision query Q;*

3. *finite-window exactness, requiring S to be precisely the finite StreamName window opened by the threshold selected in F;*

4. *dyadic slack exactness, requiring D to store the tolerance and slack row that makes the selected threshold sufficient for the requested tail estimate;*

5. *regular and Real handoff, requiring E to consume M, F, S, D, Q before exposing any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal;*
6. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N;*
7. *refusal of quotient stream equality, host real equality, countable choice, trichotomy, selected limits, unbounded stream reads, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No Fast Cauchy modulus obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FastCauchyModulusUp.FastCauchyModulusTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1781.1. The visible packet consists exactly of the source modulus, fast threshold discipline, finite window, dyadic ledger, precision query, handoff, and structural rows.

Threshold exactness is finite precision induction on the displayed query row. At the base precision, F records the selected threshold directly from M; at the next displayed precision, the same row either preserves the fast threshold discipline or opens the doubled threshold together with its comparison row.

Finite-window exactness follows by reading S only after F has selected the threshold. The induction step transports the selected threshold into the StreamName window, and the dyadic ledger D records the slack needed to interpret that finite window at the requested precision.

The handoff row E is downstream of M, F, S, D, Q, so regular-rational and Real consumers see only the displayed finite route. Componentwise hsame transport and displayed Cont replay preserve each coordinate through H and C, and P, N record the same carrier as package provenance and local name.

The excluded objects have no carrier coordinate. Therefore the listed rows exhaust the local NameCert obligation surface. □

Theorem 1781.4 (Fast Cauchy modulus threshold dichotomy)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. For the displayed precision query Q, the threshold discipline row F exposes exactly one of the following rows read from the same source modulus row M: the direct fast threshold row, or the doubled-window threshold row. The choice is part of F itself and is not supplied by a hidden selector, quotient stream equality, selected limit, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge datum.*

Proof. Project the accepted carrier using Definition 1781.1. The only coordinates that mention thresholds are the source modulus row M, the fast discipline row F, and the precision query row Q.

Apply Definition 1781.2. A consumer can open a StreamName window only after Q has passed through M and F, and F records whether the direct fast threshold or the doubled threshold is used.

Apply Definition 1781.3. Its threshold exactness row requires the selected threshold to be either the direct fast threshold or the doubled-window threshold from M for the same Q. Since no other selector is present in the carrier, the two alternatives are exclusive and exhaustive on accepted packets. □

Theorem 1781.5 (Fast Cauchy modulus window exactness)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. The* $\mathsf{StreamName}^{\uparrow}$ *finite window row* S *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row* D *are determined by the threshold selected in* F *for the precision query* Q*. If* F *selects the direct fast threshold, then* S *is the finite window opened at that threshold and* D *records the requested tolerance account. If* F *selects the doubled-window threshold, then* S *is the enlarged finite window and* D *records the dyadic slack proving that the doubled read preserves the requested tail estimate.*

Proof. Project the carrier and read the route displayed in Definition 1781.2. The row S appears only after the source modulus and threshold discipline rows have been read, so it is opened at the threshold selected in F.

In the direct case, the threshold stored by F already supplies the requested tail estimate. Thus the StreamName row is the finite window at that threshold, and the DyadicRatCore row stores the tolerance ledger consumed by that read.

In the doubled case, F stores the enlarged threshold before S is opened. The same theorem identifies S as the enlarged finite window and identifies D as the dyadic slack ledger that transports the doubled read back to the original precision request.

The NameCert obligations of Definition 1781.3 state that finite-window exactness and dyadic slack exactness are stored in those same displayed rows. No further window or tolerance coordinate is available. □

Theorem 1781.6 (Fast Cauchy modulus threshold minimality)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. The selected threshold row in* F *is exhausted by the direct fast threshold or the doubled-window threshold for the same precision query* Q*, and every downstream* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *read must use that selected row before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff is consumed.*

Proof. Project the accepted carrier from Definition 1781.1. The only threshold-bearing rows are the source modulus row M, the fast discipline row F, and the precision query row Q.

Apply Definition 1781.4. For the displayed query, F exposes either the direct fast threshold or the doubled-window threshold from the same source modulus row.

Apply Definition 1781.5. The finite window S and dyadic ledger D are determined by that selected threshold, and no additional window or tolerance coordinate is present.

Thus every downstream StreamName or DyadicRatCore read uses the selected row in F before the regular rational or Real handoff row E is consumed. The carrier has no third selector from which a competing threshold could be read. □

Theorem 1781.7 (Fast Cauchy modulus handoff nonescape)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff row* E *must consume the displayed rows* M, F, S, D, Q *before exposing a regular-rational readback or Real seal. The handoff exports no quotient stream equality, selected limit, countable-choice schedule, trichotomy principle, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, host real equality, Lean verification row, or bridge datum.*

Proof. Project the carrier from Definition 1781.1. The handoff coordinate E is listed downstream of the source modulus, threshold discipline, finite window, dyadic ledger, and precision query rows.

Apply Definition 1781.2. Every regular-Cauchy or Real-facing consumer follows the finite route through Q, then M, F, then S, D, and only then reaches E.

Apply Definition 1781.3. Its regular and Real handoff row requires E to consume M, F, S, D, Q before any readback or seal is exposed, while its refusal row excludes quotient stream equality, selected limits, choice, trichotomy, ambient completeness, Lean verification, and bridge data from the local certificate surface.

Therefore the handoff cannot escape the displayed fast-modulus route. It exposes only the readback or seal certified by the finite carrier rows. □

Theorem 1781.8 (Fast Cauchy modulus consumer factorization)**.** *Let*

$$M_{\text{fast}} = (M, F, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{FastCauchyModulus}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of this carrier factors through the displayed route*

$$\mathsf{CauchyModulus}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{N}$$

In particular, the consumer reads the precision query, threshold discipline, finite window, dyadic ledger, and handoff rows before any Real-facing seal. No hidden selector, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness row, Lean verification row, or bridge datum remains available outside the displayed carrier.*

Proof. Project the accepted carrier from Definition 1781.1. The visible rows are exactly the source modulus M, fast discipline F, finite window S, dyadic ledger D, precision query Q, handoff E, transport H, replay C, provenance P, and local name N.

Apply Definition 1781.4. The precision query can select only the direct fast threshold or the doubled-window threshold displayed by F from the same source modulus row M.

Apply Definition 1781.5. The StreamName window S and DyadicRatCore ledger D are determined by the selected threshold and the same query row Q.

Finally use Definition 1781.7. The handoff row E is downstream of M, F, S, D, Q, while H, C, P, N preserve the same route as transport, replay, provenance, and local naming. Since the refused objects have no carrier coordinate, every RegSeqRat or RealUp consumer factors through the displayed threshold, window, ledger, and handoff rows. □

Falsifiable prediction: Every $\mathsf{FastCauchyModulus}^{\uparrow}$ precision read factors through one CauchyModulus row, one fast or doubled threshold discipline row, one StreamName finite window, one DyadicRatCore tolerance ledger, one precision query, one RegSeqRat and RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchymodulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{FastCauchyModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source modulus row, the fast or doubled threshold choice, the opened finite window, the dyadic slack ledger, and the regular-rational or Real-facing handoff as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1781.1, Definition 1781.2, and Definition 1781.3 seed the finite fast-modulus route from a displayed CauchyModulus row through fast or doubled threshold discipline, StreamName finite window, DyadicRatCore tolerance ledger, precision query, RegSeqRat and Real handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{FastCauchyModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, unbounded stream reads, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exactness, finite-window exactness, dyadic slack exactness, regular and Real handoff, componentwise transport, displayed replay, provenance, and finite consumer factorization for BEDC.Derived.FastCauchyModulusUp.

Constructive story: A FastCauchyModulus$^{\uparrow}$ packet is generated from one CauchyModulus row, one fast or doubled threshold discipline row, one StreamName finite window, one DyadicRatCore tolerance ledger, one precision query, one RegSeqRat and RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1782

A Concrete Naming Certificate for RegularCauchyCompletionUniqueness$^{\uparrow}$

Following Bishop and Bridges' constructive regular Cauchy completion, the RegularCauchyCompletionUniqueness$^{\uparrow}$ packet isolates the finite uniqueness boundary for comparing two completion handoff routes before any quotient or ambient completeness principle is available. It sits on the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Bishop completion handoff of chapter 1639, and the frontier route of chapter 1180. The packet records only the displayed common-tail comparison by which two accepted regular-Cauchy completion routes expose the same terminal seal boundary.

Definition 1782.1 (Regular Cauchy completion uniqueness carrier)**.** *A* RegularCauchyCompletionUniqueness$^{\uparrow}$ *carrier is a paired finite* BHist *packet*

$$U = (L, R, D, S, Q, E, T, H, C, P, N)$$

with the following displayed rows:

1. *L is the left completion handoff route, read through the* BishopRegularCauchyCompletion$^{\uparrow}$ *boundary before any terminal seal is compared.*
2. *R is the right completion handoff route, read through the* RegularCauchyCompletionFrontier$^{\uparrow}$ *boundary with the same consumer-facing precision request.*
3. *D is the shared* DyadicRatCore$^{\uparrow}$ *tolerance row used by both routes.*
4. *S is the shared* StreamName$^{\uparrow}$ *finite-window row opened by the tolerance row D.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *regular rational readback row exposed inside the same finite window.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by both displayed handoffs after D, S, Q have been fixed.*
7. *T is the shared-tail comparison row, recording that the two routes are compared only after the common dyadic tolerance, stream window, and regular rational readback have been displayed.*
8. *H records componentwise* hsame *transport for the paired handoff rows, shared tolerance, window, readback, seal, tail comparison, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion-facing precision request through D, S, Q, T into the paired handoff rows L, R and the terminal seal row E.*

10. *P is the* Pkg *provenance over* RegularCauchyCompletionUniqueness$^{\uparrow}$, BishopRegularCauchyCompletion$^{\uparrow}$, RegularCauchyCompletionFrontier$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RegularCauchyCompletionUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, R, D, S, Q, E, T, H, C, P, N$. The carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient Real completeness.

Theorem 1782.2 (Regular Cauchy completion uniqueness NameCert obligation surface)**.** *For every accepted* RegularCauchyCompletionUniqueness$^{\uparrow}$ *carrier*

$$U = (L, R, D, S, Q, E, T, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyCompletionUniqueness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the paired completion handoff routes, shared dyadic tolerance row, stream-window row, regular rational readback row, terminal Real seal row, shared-tail comparison row, transport, replay, provenance, and local naming row;*
2. *paired-route exposure, requiring both L and R to be displayed before the local classifier compares their completion-facing terminal seal routes;*
3. *shared-tail comparison, requiring the comparison to pass through the same D, S, Q rows before either handoff route reaches E;*
4. *terminal-seal coincidence, requiring the consumer-visible seal row E to be read only as the common endpoint of the two displayed routes after T has fixed the shared tail surface;*
5. *classifier transport, requiring componentwise* hsame *in H and displayed* Cont *replay in C to preserve the ordered route D, S, Q, T, L, R, E;*
6. *ledger non-escape, requiring P and N to export no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient Real completeness theorem.*

No uniqueness obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUniquenessUp.RegularCauchyCompletionUniquenessUpTasteGate`
`single carrier alignment`

Proof. Carrier admission is projection from Definition 1782.1. The displayed tuple supplies exactly the two handoff rows, the shared tolerance-window-readback rows, the terminal seal, the comparison row, and the structural transport, replay, provenance, and naming rows.

Paired-route exposure is forced by the placement of L and R. A consumer cannot compare completion handoffs until both routes have been opened as finite BHist data, one through the Bishop completion boundary and the other through the frontier boundary.

The shared-tail comparison is the row T governed by D, S, Q. It fixes the common dyadic tolerance, the same finite StreamName window, and the same regular rational readback before either route is allowed to claim the terminal seal row.

Terminal-seal coincidence is therefore a displayed endpoint fact about E, not an equality of quotient streams or host real values. The seal is reached only after the common tail surface has already been read.

Finally, componentwise hsame in H and displayed Cont replay in C preserve the ordered route D, S, Q, T, L, R, E. Since the carrier contains no quotient, selected-limit, choice, host-equality, or Real-completeness coordinate, the provenance and local NameCert rows cannot export any such object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1782.1 and Definition 1782.2 seed the finite uniqueness boundary for paired regular-Cauchy completion handoffs through shared dyadic tolerance, stream-window, regular rational readback, terminal Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionUniquenessUp.RegularCauchyCompletionUniquenessUpTasteGate\_singl`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, paired-route exposure, shared-tail comparison, terminal-seal coincidence, classifier transport, and ledger non-escape for BEDC.Derived.RegularCauchyCompletionUniquenessUp.

Constructive story: A $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$ packet is generated from two completion handoff rows, one shared dyadic tolerance, one finite StreamName window, one RegSeqRat readback, one terminal Real seal, one shared-tail comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1783

A Concrete Naming Certificate for $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of real numbers by regular Cauchy data, the $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ packet records the finite comparison-principle surface used before a completed real seal is consumed. It sits over the regular rational source rows of chapter 301, the shared finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the equality-facing comparison row of chapter 411, the domination-test row of chapter 1459, and the terminal seal surface of chapter 38. The packet is a human-origin L10 comparison-principle boundary for composing equality and domination comparison rows before $\mathsf{Real}^{\uparrow}$ seal handoff; it is not quotient stream equality, host real comparison, trichotomy, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1783.1 (Regular Cauchy comparison principle carrier)**.** *A* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, Y, W, D, E, T, Q, R, H, C, K, N)$$

with the following displayed rows:

1. *X is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source row.*
2. *Y is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source row inspected at the same tolerance requests as X.*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window family on which X, Y, the dyadic ledger, and both comparison rows are read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the displayed dyadic scales, endpoint observations, and rational tolerance rows attached to the finite windows in W.*
5. *E is the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *equality row, recording that equality-facing inspection of X and Y is mediated by the same W, D surface.*
6. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *domination row, recording the finite majorant or target-test comparison on the same windows and tolerances.*
7. *Q is the comparison verdict row obtained only after E and T have both been displayed.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row consumed after the verdict row Q is fixed.*

9. *H records componentwise* hsame *transport for the two regular Cauchy sources, shared windows, dyadic ledger, equality row, domination row, verdict row, seal row, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a comparison request through W, D, E, T, Q, R and then through the structural rows.*

11. *K is the* Pkg *provenance over* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through these twelve displayed rows. There is no coordinate for quotient stream equality, host real comparison, trichotomy, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonPrincipleUp.TasteGate.RegularCauchyComparisonPrincipleTaste`
`single carrier alignment`

Theorem 1783.2 (Regular Cauchy comparison principle NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier*

$$P = (X, Y, W, D, E, T, Q, R, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the equality comparison row, the domination-test row, the comparison verdict, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, transport, replay, provenance, and local naming row;*

2. *shared-window exposure, requiring X and Y to be inspected only on the windows displayed by W;*

3. *tolerance-ledger exactness, requiring every comparison tolerance to be read from D before either comparison row is consumed;*

4. *equality-row routing, requiring the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row E to use the same X, Y, W, D surface;*

5. *domination-row routing, requiring the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *row T to use the same window and tolerance rows before contributing to the verdict Q;*

6. *seal handoff, requiring R to be reached only after E, T, Q have been displayed;*

7. *structural stability, requiring H, C, K, N to transport, replay, source, and name exactly the displayed route.*

No comparison-principle obligation is stored outside these rows.

Proof. Project the carrier of Definition 1783.1. The projection exposes exactly two regular Cauchy source rows, one shared window family, one dyadic tolerance ledger, one equality comparison row, one domination-test row, one verdict row, one seal handoff, and the structural transport, replay, provenance, and naming rows.

Shared-window exposure and tolerance-ledger exactness are forced by W and D. A comparison request first opens a finite StreamName window and then reads the dyadic tolerance ledger attached to that window, so neither E nor T can inspect a source outside the displayed finite surface.

The equality and domination rows are then read on the same surface. The row E contributes the equality-facing comparison route of Definition 411.3, while T contributes the domination-test route of Definition 1459.2. Since both rows are attached to X, Y, W, D, the verdict row Q is a finite comparison-principle read rather than a host real comparison.

Finally R, H, C, K, N close the route. The Real seal row is reachable only after E, T, Q have been displayed, and the structural rows only transport, replay, source, and name that route. Thus the local NameCert surface contains no hidden quotient, trichotomy, selected-limit, choice, completeness, Lean, or bridge coordinate. □

Theorem 1783.3 (Regular Cauchy comparison principle carrier admission)**.** *An accepted* RegularCauchyComparison *packet is admitted only as the twelve-row carrier*

$$P = (X, Y, W, D, E, T, Q, R, H, C, K, N)$$

of Definition 1783.1. Thus carrier admission displays the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, shared* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *equality row,* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *domination row, verdict,* $\mathsf{Real}^{\uparrow}$ *seal handoff,* BHist *transport through* hsame, Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Project the carrier definition. The displayed tuple supplies exactly $X, Y, W, D, E, T, Q, R, H, C, K, N$ and no additional comparison coordinate.

The source, window, and tolerance rows are read first, so admission is already finite before either comparison row is consumed. The equality and domination rows then attach to the same displayed data, and the verdict row has no independent source.

Finally R, H, C, K, N only seal, transport, replay, source, and name the admitted route. This proves that carrier admission is precisely the displayed NameCert surface and not a host comparison, quotient equality, trichotomy, selected-limit, choice, completeness, Lean, or bridge datum. □

Theorem 1783.4 (Regular Cauchy comparison principle shared-window exposure)**.** *For every accepted* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier* $P = (X, Y, W, D, E, T, Q, R, H, C, K, N)$*, the equality row* E*, domination row* T*, and verdict row* Q *inspect* X *and* Y *only through the shared* $\mathsf{StreamName}^{\uparrow}$ *window row* W *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*. In particular, no comparison-principle consumer can read a tail-order verdict before* W *and* D *have been exposed.*

Proof. Apply Definition 1783.2. Its shared-window and tolerance-ledger rows require a comparison request to open W and then read D before either comparison row is consumed.

Use Definition 1783.6. The displayed route places E, T, Q downstream of W, D, so equality and domination comparisons share the same finite inspection surface.

The Real seal handoff of Definition 1783.7 is later than Q. Hence a consumer that reaches a verdict or seal has already exposed the common windows and dyadic tolerances, and no hidden tail, host comparison, or ambient completeness row is available. □

Theorem 1783.5 (Regular Cauchy comparison principle equality-domination verdict)**.** *Every verdict exported by an accepted* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier is routed through both the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *equality row* E *and the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *domination row* T *on the same* X, Y, W, D *surface before the* $\mathsf{Real}^{\uparrow}$ *seal row* R *is read. The verdict row* Q *therefore records a finite equality-domination comparison and not a host real comparison, trichotomy, selected limit, countable choice, quotient equality, ambient completeness, Lean verification, or bridge check.*

Proof. Start from the carrier projection and read X, Y, W, D. These rows expose the two regular Cauchy sources, the shared finite windows, and the dyadic tolerance ledger.

Now read the equality and domination rows. The row E is attached to the $\mathsf{RegularCauchyComparison}^{\uparrow}$ equality-facing route, while T is attached to the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ domination route. Since both rows use the same X, Y, W, D data, the verdict Q is a comparison-principle row over a single finite surface.

Finally apply Definition 1783.7. The Real seal row R consumes the verdict only after E, T, Q have been displayed, so the exported verdict cannot be an unrecorded host comparison or any of the excluded escape data. □

Theorem 1783.6 (Regular Cauchy comparison principle tail-order route)**.** *Let*

$$P = (X, Y, W, D, E, T, Q, R, H, C, K, N)$$

be an accepted $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier. Every tail-order comparison exported by P factors through the finite route*

$$X, Y \longmapsto W, D \longmapsto E, T \longmapsto Q \longmapsto R, H, C, K, N.$$

The route first binds the two regular Cauchy sources to the shared StreamName windows and DyadicRatCore tolerance ledger, then composes the $\mathsf{RegularCauchyComparison}^{\uparrow}$ *equality row with the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *domination row before any Real-facing seal consumer can read a verdict.*

Proof. Begin with a tail-order comparison request. The carrier projection gives the source rows X, Y but admits no direct comparison between them; the request must first pass through the shared finite window family W.

The dyadic ledger D fixes the displayed tolerance rows on those windows. This pins the numerical inspection used by both comparison siblings to the same finite data.

Now read the two comparison rows. The equality-facing row E is the $\mathsf{RegularCauchyComparison}^{\uparrow}$ route over X, Y, W, D, and the domination row T is the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ route over the same windows and tolerances. Their combination supplies the verdict row Q.

The remaining rows only export the verdict. The seal handoff R consumes Q, and H, C, K, N preserve, replay, source, and name the displayed route. A tail-order consumer therefore sees the ordered finite route above and no quotient stream, host real comparison, trichotomy, selected limit, choice, completeness, Lean, or bridge datum. □

Theorem 1783.7 (Regular Cauchy comparison principle Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *carrier is downstream of the equality and domination comparison rows:*

$$W, D, E, T, Q \longmapsto R.$$

Consequently the seal handoff consumes a finite comparison-principle verdict before it reaches $\mathsf{Real}^{\uparrow}$*, and it does not assert quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Use Definition 1783.2 to place every accepted packet on the displayed NameCert route. The only seal row in the carrier is R, and the obligations require it to be read after the comparison rows E, T and verdict row Q.

Apply Definition 1783.6. Its factorization shows that E and T are already downstream of the common window and dyadic tolerance ledger, so the Real-facing consumer cannot bypass W, D or inspect an unrecorded tail.

Finally read R as the terminal handoff row. Since R is reached only through the finite route W, D, E, T, Q, the exported seal is a BEDC comparison-principle handoff and not a host equality, trichotomy, selected-limit, choice, completeness, Lean, or bridge assertion. □

Falsifiable prediction: A $\mathsf{Real}^{\uparrow}$ consumer that reaches a comparison verdict from accepted $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ data without first reading the shared $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegularCauchyComparison}^{\uparrow}$ equality row, and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ domination row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, regular-cauchy-comparison, regular-cauchy-comparison-test, real: no listed sibling supplies the whole twelve-row packet $P = (X, Y, W, D, E, T, Q, R, H,$ because each sibling contributes only source, window, tolerance, equality-comparison, domination-test, or seal data while this chapter binds all six faces with a verdict row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ packet is generated from two RegSeqRat source rows, shared StreamName windows, a DyadicRatCore tolerance ledger, a RegularCauchyComparison equality row, a RegularCauchyComparisonTest domination row, a comparison verdict, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1783.1, Definition 1783.2, Definition 1783.6, and Definition 1783.7 seed the finite comparison-principle surface over two regular Cauchy source rows, shared windows, dyadic tolerances, equality and domination comparison rows, verdict, seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host real comparison, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exposure, tolerance-ledger exactness, equality-row routing, domination-row routing, Real seal handoff, and structural stability for BEDC.Derived.RegularCauchyComparisonPrin

Chapter 1784

A Concrete Naming Certificate for $\mathsf{RealIntegerPart}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealIntegerPart}^{\uparrow}$ packet records the finite boundary at which a displayed real name may expose an integer-part read to decimal, approximation, and completion-facing consumers. It sits after the real-name seal of chapter 38, the Archimedean bound surface of chapter 430, the integer-bracketing certificate of chapter 1479, the residual interface of chapter 1648, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, and the regular-rational readback route of chapter 301. The packet names the public RealUp integer-part boundary; it is not a host floor operation, a trichotomy oracle, quotient real equality, a selected representative, countable choice, or ambient Real completeness.

Definition 1784.1 (RealIntegerPart carrier)**.** *A* $\mathsf{RealIntegerPart}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, B, Z, F, D, S, G, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row whose integer part is being read.*
2. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row attached to the same source real.*
3. *B is the* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row, displaying the finite lower integer candidate and successor comparison for R.*
4. *Z is the* $\mathsf{Int}^{\uparrow}$ *integer candidate exposed by the bracket row.*
5. *F is the* $\mathsf{FractionalPart}^{\uparrow}$ *residual row tied to the same source real and integer candidate.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording the tolerances and dyadic refinements used to observe the source, bracket, and residual rows.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for decimal, approximation, and completion-facing reads.*
8. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets the windows in S as regular rational data before any consumer receives the integer-part value.*
9. *H records componentwise* hsame *transport for the source real, Archimedean bound, integer bracket, integer candidate, residual, dyadic scale, stream window, readback, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from every precision, decimal-prefix, or approximation request through R, A, B, Z, F, D, S, G without inserting another integer search.*

11. *P is the* Pkg *provenance over* $\mathsf{RealIntegerPart}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{FractionalPart}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host floor, trichotomy over arbitrary real names, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1784.2 (RealIntegerPart NameCert obligations)**.** *For every accepted* $\mathsf{RealIntegerPart}^{\uparrow}$ *carrier*

$$K = (R, A, B, Z, F, D, S, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the source* $\mathsf{Real}^{\uparrow}$ *row,* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row,* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row,* $\mathsf{Int}^{\uparrow}$ *candidate row,* $\mathsf{FractionalPart}^{\uparrow}$ *residual row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and structural rows H, C, P, N;*

2. *bracket-route exactness, requiring the integer candidate Z to be read only through the displayed source row R, Archimedean bound row A, and ArchimedeanIntegerPart bracket row B;*

3. *residual handoff, requiring F to consume the same R, B, Z route before any fractional residual is exposed;*

4. *classifier transport, requiring the accepted status of R, A, B, Z, F, D, S, G to remain stable under the componentwise* hsame *transports in H and the displayed* Cont *replay in C;*

5. *ledger non-escape, excluding host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, ambient Real completeness, Lean verification, and bridge checking from the local certificate surface.*

No RealIntegerPart obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealIntegerPartUp.RealIntegerPartTasteGate single carrier alignment`

Proof. Project the accepted packet $K = (R, A, B, Z, F, D, S, G, H, C, P, N)$. The projection exposes exactly the real source, Archimedean bound, integer bracket, integer candidate, residual, dyadic scale, stream window, regular readback, transport, replay, provenance, and naming rows.

Bracket-route exactness follows from the sibling surface of chapter 1479. The row B is downstream of the source real and Archimedean bound rows, and the integer candidate Z is exposed only as the integer endpoint carried by that bracket.

Residual handoff follows from chapter 1648. The residual row F records the same source real and integer candidate before it opens any fractional read, so the residual cannot introduce a second integer-part route.

The transport and replay clauses are stored in H and C. They carry the visible rows componentwise and send each downstream request back through R, A, B, Z, F, D, S, G.

The excluded objects have no carrier coordinate and no classifier clause. Therefore the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}$ obligation surface. □

Theorem 1784.3 (RealIntegerPart bracket route)**.** *Every Real, decimal, or approximation consumer that reads an integer part from an accepted* $\mathsf{RealIntegerPart}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{ArchimedeanReal}^{\uparrow} \longmapsto \mathsf{ArchimedeanIntegerPart}^{\uparrow} \longmapsto \mathsf{Int}^{\uparrow} \longmapsto \mathsf{FractionalPart}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Str}$$

Concretely, the consumer first receives the source real row R, then the Archimedean bound row A, the ArchimedeanIntegerPart bracket row B, the integer candidate row Z, the fractional residual row F, the dyadic scale row D, the finite window row S, the regular readback row G, and finally the structural rows H, C, P, N.

Lean4 ✓ `BEDC.Derived.RealIntegerPartUp.RealIntegerPartCarrier bracket route`

Proof. Begin with a precision, decimal-prefix, or approximation request. The replay row C sends the request to the displayed $\mathsf{Real}^{\uparrow}$ source row R, so the route starts from a named real carrier rather than a host real value.

The Archimedean data then enter through A and B. The row A provides the finite bound surface, and the row B supplies the bracket route named by chapter 1479.

The integer candidate Z is the endpoint exported by that bracket. The residual row F is then read through chapter 1648, tying the integer endpoint and source real to the same fractional handoff.

The consumer can inspect the route only through the dyadic, window, and readback rows D, S, G. These rows expose finite tolerances, finite StreamName windows, and RegSeqRat readback before the integer-part value is usable by a Real or decimal consumer.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since no other coordinate is present, every integer-part read factors through the stated boundary. □

Falsifiable prediction: Every $\mathsf{RealIntegerPart}^{\uparrow}$ integer-part read factors through one $\mathsf{Real}^{\uparrow}$ source row, one $\mathsf{ArchimedeanReal}^{\uparrow}$ bound row, one $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, one $\mathsf{Int}^{\uparrow}$ candidate row, one $\mathsf{FractionalPart}^{\uparrow}$ residual row, one $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, one $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, archimedeanreal, archimedean-integer-part, int, fractional-part, dyadicratcore, streamname, regseqrat: no listed sibling is bijective to $\mathsf{RealIntegerPart}^{\uparrow}$ because this packet jointly binds the source real, Archimedean bound, integer bracket, integer candidate, fractional residual, finite tolerance scale, window read, readback route, transport, replay, provenance, and local naming for the Real-facing integer-part boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1784.1, Definition 1784.2, and Definition 1784.3 seed the finite Real-facing integer-part boundary from a displayed Real source through Archimedean bound, ArchimedeanIntegerPart bracket, Int candidate, FractionalPart residual, DyadicRatCore scale, StreamName window, RegSeqRat readback, and structural rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntegerPart}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, bracket-route exactness, residual handoff, classifier transport, and ledger non-escape for BEDC.Derived.RealIntegerPartUp.

Constructive story: A $\mathsf{RealIntegerPart}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ source row, an $\mathsf{ArchimedeanReal}^{\uparrow}$ bound row, an $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, an $\mathsf{Int}^{\uparrow}$ candidate row, a $\mathsf{FractionalPart}^{\uparrow}$ residual row, a $\mathsf{DyadicRatCore}^{\uparrow}$

scale row, a StreamName$^{\uparrow}$ window row, a RegSeqRat$^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1785

A Concrete Naming Certificate for $\mathsf{NewtonKantorovich}^{\uparrow}$

Following Kantorovich and Bishop–Bridges constructive analysis, the $\mathsf{NewtonKantorovich}^{\uparrow}$ packet records the finite Newton data that turns a displayed derivative source, inverse witness, and contraction neighbourhood into a seal-facing real root row without asserting host root existence. It consumes the finite step discipline of chapter 223, the contraction handoff of chapter 396, the derivative source of chapter 122, the regular rational readback route of chapter 301, and the terminal Real seal of chapter 38. The chapter is a Real-and-Completion frontier consumer: it exposes the finite certificate route from Newton ledgers to a $\mathsf{Real}^{\uparrow}$ root boundary while leaving convergence, completeness, and equality claims inside the named BEDC rows that provide them.

Definition 1785.1 (Newton-Kantorovich carrier)**.** *A* $\mathsf{NewtonKantorovich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, I, U, L, Q, B, N, R, E, H, C, P, Z)$$

with the following displayed coordinates:

1. *D is the* $\mathsf{Derivative}^{\uparrow}$ *source row, including the point context, function-value history, derivative-answer history, and local derivative classifier consumed by the Newton data.*
2. *I is the inverse witness row, recording the displayed inverse or one-sided inverse budget for the derivative row named by D.*
3. *U is the contraction neighbourhood row, storing the radius, local Lipschitz or majorant budget, and the nonescape side condition for all displayed Newton steps inside the named neighbourhood.*
4. *L is the finite* $\mathsf{NewtonIteration}^{\uparrow}$ *ledger, recording source points, function-value rows, derivative-answer rows, inverse-witness reads, next-step rows, and splice-compatible step transports.*
5. *Q is the Newton residual and contraction-ratio ledger obtained from D, I, U, L by finite rational comparisons.*
6. *B is the* $\mathsf{BanachFixedPoint}^{\uparrow}$ *handoff row attached to the Newton map determined by D, I, U, Q, exposing the contraction packet used downstream.*
7. *N is the finite Newton-to-Banach replay row, stating that the displayed Newton step ledger L is read as the Picard ledger consumed by B after the inverse and contraction rows have been opened.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the Banach handoff and the finite Newton residual ledger.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing root row exposed only after D, I, U, L, Q, B, N, R have been displayed.*
10. *H records componentwise* hsame *transport for the derivative source, inverse witness, contraction neighbourhood, Newton ledger, residual ledger, Banach handoff, replay, RegSeqRat readback, Real seal, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from the derivative source through the inverse witness, contraction neighbourhood, finite Newton ledger, Banach handoff, RegSeqRat readback, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{NewtonKantorovich}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *Z is the local* $\mathsf{NameCert}_{\mathsf{NewtonKantorovich}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, U, L, Q, B, N, R, E, H, C, P, Z$. It has no coordinate for host root existence, quotient-real equality, global invertibility, ambient completeness, selected limits, or bridge checking.

Lean4 ✓ `BEDC.Derived.NewtonKantorovichUp.NewtonKantorovichTasteGate single carrier alignment`

Theorem 1785.2 (Newton-Kantorovich NameCert obligations)**.** *For every accepted* $\mathsf{NewtonKantorovich}^{\uparrow}$ *carrier*

$$K = (D, I, U, L, Q, B, N, R, E, H, C, P, Z),$$

the local $\mathsf{NameCert}_{\mathsf{NewtonKantorovich}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, derivative-source stability for D, inverse-witness stability for I, contraction-neighbourhood nonescape for U, finite Newton-ledger stability for L, residual-ledger exactness for Q, Banach handoff compatibility for B, Newton-to-Banach replay for N, RegSeqRat readback for R, Real-seal non-escape for E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through Z.*

Proof. Carrier admission is projection from Definition 1785.1. Each listed row is a visible coordinate of the finite packet, so the local naming surface starts with those coordinates and cannot read a hidden root object.

The derivative, inverse, and neighbourhood obligations are the source-side checks. The row D supplies the derivative histories, I supplies the inverse witness attached to those histories, and U supplies the displayed radius and nonescape side condition used by the Newton rows.

The Newton ledger and residual rows are finite. The row L carries only displayed $\mathsf{NewtonIteration}^{\uparrow}$ steps, and Q records the rational comparisons that make those steps compatible with the contraction neighbourhood.

The downstream obligations are then forced in order. The Banach handoff B consumes the Newton map data; the replay row N identifies the Newton ledger as the Picard ledger accepted by B; the readback row R exposes the regular rational name; and the seal row E gives the terminal $\mathsf{Real}^{\uparrow}$ boundary. The transport, replay, provenance, and local naming rows H, C, P, Z repack the same route. □

Theorem 1785.3 (Newton-Kantorovich Banach handoff)**.** *Every accepted* $\mathsf{NewtonKantorovich}^{\uparrow}$ *carrier factors its root-read route through the finite handoff*

$$D, I, U, L, Q \longmapsto B \longmapsto N \longmapsto R \longmapsto E.$$

The row B is the only contraction-completion handoff available to the packet; the row N is the only bridge from the displayed $\mathsf{NewtonIteration}^{\uparrow}$ *ledger to the Picard ledger consumed by B; and the rows R, E are reached only after this handoff has been displayed.*

Proof. Read the coordinates of K. The derivative row D, inverse witness I, neighbourhood row U, Newton ledger L, and residual ledger Q are the only rows that describe the Newton map before a contraction packet is opened.

The Banach handoff row B is therefore the first row that may invoke the fixed-point surface of chapter 396. The replay row N records the finite identification between the Newton ledger and the Picard ledger that B consumes, so there is no second completion route outside the displayed handoff.

After B and N are present, the packet may read R and then E. This yields a regular rational readback and a terminal $\mathsf{Real}^{\uparrow}$ seal, but it does not add a host root, a quotient-real equality, a chosen limit, or an ambient completeness theorem. □

Theorem 1785.4 (Newton-Kantorovich nonescape boundary)**.** *Let $K = (D, I, U, L, Q, B, N, R, E, H, C, P, Z)$ be an accepted* $\mathsf{NewtonKantorovich}^{\uparrow}$ *carrier. Every public read of the seal row E must pass through the neighbourhood row U and the finite Newton ledger L before it reaches the Banach handoff B. Consequently the root boundary exposed by E is confined to the displayed contraction neighbourhood and cannot export a global root-existence theorem, global inverse theorem, host equality of roots, quotient-real equality, or ambient completeness beyond the carried rows.*

Proof. The only row carrying a neighbourhood boundary is U. Since E is downstream of the handoff route in Definition 1785.3, any read of E must first pass through the data that certify the Newton steps remain inside that neighbourhood.

The finite ledger L supplies those displayed Newton steps. The residual ledger Q and Banach handoff B may use them to produce the contraction route, but neither row introduces an additional domain or a global inverse principle.

Thus the exposed root boundary is local to U and to the rows transported by H and replayed by C. Because the carrier lacks coordinates for global root existence, quotient-real equality, host equality, selected limits, and ambient completeness, no public consumer can read those objects from E. □

Falsifiable prediction: Every $\mathsf{NewtonKantorovich}^{\uparrow}$ root-boundary read factors through one Derivative row, one inverse witness row, one contraction neighbourhood row, one finite NewtonIteration ledger, one residual ledger, one BanachFixedPoint handoff row, one Newton-to-Banach replay row, one RegSeqRat readback row, one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: derivative, newtoniteration, banachfixedpoint, regseqrat, real: $\mathsf{NewtonKantorovich}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the derivative source, inverse witness, contraction neighbourhood, finite Newton ledger, Banach handoff, regular readback, and seal-facing root boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonKantorovich}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NewtonKantorovich}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1785.1, Definition 1785.2, Definition 1785.3, and Definition 1785.4 seed the finite route from derivative data and inverse witness through a contraction neighbourhood, Newton finite ledger, Banach handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NewtonKantorovich}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host root existence, quotient-real equality, global invertibility, host equality of roots, selected limits, ambient completeness beyond the carried rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-source stability, inverse-witness stability, contraction-neighbourhood nonescape, Newton-ledger stability, residual-ledger exactness, Banach handoff compatibility, Newton-to-Banach replay, RegSeqRat readback, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.NewtonKantorovichUp.

Constructive story: A NewtonKantorovich$^{\uparrow}$ packet is generated from one Derivative row, one inverse witness row, one contraction neighbourhood row, one finite NewtonIteration ledger, one residual ledger, one BanachFixedPoint handoff row, one Newton-to-Banach replay row, one RegSeqRat readback row, one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1786

A Concrete Naming Certificate for $\mathsf{RealRootBracket}^{\uparrow}$

Following Bishop and Bridges constructive analysis, a root bracket is read as a finite sign-change interval together with the displayed continuity and bisection evidence that keeps the interval meaningful at a requested tolerance. The $\mathsf{RealRootBracket}^{\uparrow}$ packet packages that route as BEDC data: endpoint interval and sign rows are inspected through the intermediate-value surfaces of chapter 1402 and chapter 1422, retained windows are supplied by chapter 1407, image transport is routed through chapter 1775, and the terminal readback uses chapter 126, chapter 301, chapter 291, chapter 130, and chapter 38. The certificate names a bracket surface, not a selected root.

Definition 1786.1 (RealRootBracket carrier)**.** *A* $\mathsf{RealRootBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, S, M, V, K, W, A, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the endpoint interval row. It records the lower and upper endpoint windows, rational or dyadic cells, endpoint order evidence, and the interval identity consumed by the bracket.*
2. *S is the endpoint sign row. It stores the displayed lower and upper sign data and the sign-change orientation used by the bracket packet.*
3. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row for the inspected function, including the input tolerance demanded by each bracket tolerance request.*
4. *V is the* $\mathsf{IntermediateValue}^{\uparrow}$ *ledger row. It records the finite intermediate-value obligation surface attached to the interval, signs, and displayed continuity data.*
5. *K is the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *ledger row. It records the finite branch prefix, midpoint sign rows, and regular-window handoff used to refine the initial sign-change interval.*
6. *W is the* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *retained-window row. It stores the lower and upper retained endpoint windows after the requested branch prefix.*
7. *A is the* $\mathsf{CauchyContinuousImage}^{\uparrow}$ *image route row. It records how endpoint and midpoint function reads are replayed through the displayed continuity modulus and image-window route.*
8. *R is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the retained lower and upper endpoint names.*

9. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback ledger, containing the regular rational endpoint readbacks, dyadic tolerances, endpoint comparisons, branch radii, and rounding rows used by the bracket.*

10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the retained bracket endpoints and for any Real-facing bracket consumer.*

11. *H records componentwise* hsame *transport for the endpoint interval, endpoint signs, modulus row, intermediate-value ledgers, retained windows, image route, stream windows, regular and dyadic readback, Real seal, replay, provenance, and local naming rows.*

12. *C records displayed* Cont *replay from a bracket request through endpoint inspection, sign inspection, modulus use, intermediate-value admission, bisection refinement, retained-window exposure, image routing, regular readback, and Real-seal consumption.*

13. *P is the* Pkg *provenance over* $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{BisectionRootIsolation}^{\uparrow}$, $\mathsf{CauchyContinuousImage}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{RealRootBracket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, M, V, K, W, A, R, D, E, H, C, P, N$. It has no coordinate for a selected root, quotient real equality, real trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host root equality.*

Lean4 ✓ `BEDC.Derived.RealRootBracketUp.RealRootBracketTasteGate single carrier alignment`

Theorem 1786.2 (RealRootBracket NameCert obligations)**.** *For every accepted* $\mathsf{RealRootBracket}^{\uparrow}$ *carrier*

$$B = (I, S, M, V, K, W, A, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealRootBracket}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint interval, endpoint signs, continuous-map modulus, intermediate-value ledger, intermediate-value bisection ledger, retained isolating windows, continuous-image route, stream windows, regular and dyadic readback, Real seal, transports, replay, provenance, and local naming;*

2. *endpoint discipline, requiring I and S to expose the bracket interval and opposite displayed sign rows before any bisection or Real-facing row is available;*

3. *modulus discipline, requiring M to answer each requested bracket tolerance by a displayed source tolerance consumed by the endpoint and image rows;*

4. *intermediate-value discipline, requiring V and K to attach every sign-change branch and midpoint sign row to the already displayed endpoint and modulus data;*

5. *retained-window discipline, requiring W to store only windows retained by the finite bisection ledger and to expose them through R and D before the Real seal is read;*

6. *image-route discipline, requiring A to replay function-value reads through the* $\mathsf{CauchyContinuousImage}^{\uparrow}$ *surface rather than through host function extensionality;*

7. *seal nonescape, requiring E, H, C, P, N to export only the displayed bracket rows and no selected root, quotient real equality, real trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host root equality.*

No RealRootBracket obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1786.1. The accepted packet displays exactly the endpoint interval, sign rows, modulus, intermediate-value ledgers, retained windows, image route, regular readback, Real seal, and structural rows.

Endpoint discipline is the first stage of the route. The interval row I and sign row S must be opened before the intermediate-value or bisection rows can be inspected, so the packet cannot replace the bracket by a host interval or by a completed root.

The modulus and intermediate-value disciplines are the middle stage. The continuous-map row M supplies the tolerance conversion, the row V records the finite intermediate-value surface, and the row K records the branch prefix and midpoint signs that retain a sign-change window.

Retained-window discipline and image-route discipline are downstream of that branch prefix. The row W exposes only the retained windows; R and D read them as StreamName, RegSeqRat, and DyadicRatCore data; A replays function-value reads through the CauchyContinuousImage route.

Finally, E, H, C, P, N seal, transport, replay, package, and name the same finite route. Since selected roots, quotient real equality, real trichotomy, open-cover compactness, ambient Real completeness, and host root equality are absent from the carrier, no local obligation can export them. □

Theorem 1786.3 (RealRootBracket bisection handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealRootBracket}^{\uparrow}$ *carrier factors through the displayed route*

$$I, S, M, V \longmapsto K \longmapsto W \longmapsto R, D \longmapsto E, H, C, P, N.$$

The consumer first reads the endpoint interval, sign rows, modulus data, and intermediate-value ledger; then the finite IntermediateValueBisection branch prefix; then the retained BisectionRootIsolation windows; then the regular rational and dyadic readback; and only then the Real-facing bracket seal. The handoff exports a finite bracket window, not a selected root or host equality theorem.

Proof. Start with an accepted packet $B = (I, S, M, V, K, W, A, R, D, E, H, C, P, N)$. The only endpoint and sign coordinates are I and S, and the only continuity coordinate is M, so every bracket read begins with those rows.

The intermediate-value stage is recorded by V and K. The row V admits the sign-change obligation attached to the displayed endpoint and modulus data, while K records the finite branch prefix and midpoint sign rows used by the bisection route.

The retained-window stage is W. It is downstream of K and supplies the visible lower and upper windows that are then exposed through R and D as StreamName, RegSeqRat, and DyadicRatCore data at the requested tolerance.

The Real-facing stage is terminal. The seal E is read only after the retained windows and readback ledger are fixed, while H, C, P, N transport, replay, package, and name the same route. The image row A is also bound to this route, because its function-value reads consume the displayed modulus and retained endpoint windows.

Thus every listed consumer factors through the finite handoff route. No step introduces a selected root, quotient real equality, real trichotomy, open-cover compactness, ambient Real completeness, or host root equality. □

Falsifiable prediction: Every $\mathsf{RealRootBracket}^{\uparrow}$ read factors through endpoint interval and sign rows, one $\mathsf{ContinuousMap}^{\uparrow}$ modulus row, $\mathsf{IntermediateValue}^{\uparrow}$ and $\mathsf{IntermediateValueBisection}^{\uparrow}$ ledgers,

one BisectionRootIsolation$^{\uparrow}$ retained-window row, one CauchyContinuousImage$^{\uparrow}$ image route row, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ and DyadicRatCore$^{\uparrow}$ readback, one Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, dyadicratcore, continuousmap, intermediatevalue, intermediate-value-bisection, bisectionrootisolation, cauchy-continuous-image: RealRootBracket$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint sign data, a continuity modulus, intermediate-value admission, bisection branch data, retained isolating windows, continuous-image replay, regular and dyadic readback, and a Real-facing bracket seal.
