Scope closed: Definition 1786.1, Definition 1786.2, and Definition 1786.3 seed the finite constructive root-bracketing route from endpoint signs and continuity data through intermediate-value bisection, retained isolating windows, continuous-image replay, regular and dyadic readback, and Real-facing seal rows.

Formal verification: FormalStatus(NameCert$_{\text{RealRootBracket}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected roots, quotient reals, real trichotomy, open-cover compactness, ambient Real$^{\uparrow}$ completeness, host root equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint discipline, modulus discipline, intermediate-value ledger discipline, retained-window handoff, image-route replay, seal nonescape, and bisection-handoff factorization for BEDC.Derived.RealRootBracketUp.

Constructive story: A RealRootBracket$^{\uparrow}$ packet is generated from endpoint interval and sign rows, a ContinuousMap$^{\uparrow}$ modulus row, IntermediateValue$^{\uparrow}$ and IntermediateValueBisection$^{\uparrow}$ ledgers, BisectionRootIsolation$^{\uparrow}$ retained windows, a CauchyContinuousImage$^{\uparrow}$ image route, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ and DyadicRatCore$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1787

A Concrete Naming Certificate for $\mathsf{ApartnessCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ApartnessCompletion}^{\uparrow}$ packet records the generic separated completion boundary for sources whose equality information is exposed through apartness evidence. It sits between the real-specific boundary of chapter 1567, the Hausdorff separation surface of chapter 402, the constructive metric completion route of chapter 1556, the finite windows of chapter 126, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet is a finite boundary object for Real and Completion consumers; it is not a quotient completion, a host equality principle, a selected limit, countable choice, trichotomy, or ambient completeness.

Definition 1787.1 (Apartness completion carrier)**.** *An* $\mathsf{ApartnessCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Q, M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the apartness source row, carrying the positive separation evidence used by the completion boundary.*
2. *Q is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion route attached to the same source row.*
3. *M is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *completion route through which the separated source is replayed.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposed to consumers of the completion read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback extracted from those stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested positive gaps, radii, and comparison cells.*
7. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal handoff, present only when the generic completion route is consumed by a Real-facing boundary.*
8. *H records componentwise* hsame *transport for the apartness source, separated route, completion route, window schedule, readback row, tolerance ledger, optional seal, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from apartness inspection through separated completion, constructive metric completion, stream windows, regular readback, dyadic tolerance, and the optional Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{ApartnessCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion classes, host equality of completed points, selected limits, countable-choice schedules, trichotomy rows, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ApartnessCompletionUp.ApartnessCompletionTasteGate single carrier alignment`

Theorem 1787.2 (Apartness completion NameCert obligations)**.** *For every accepted* $\mathsf{ApartnessCompletion}^{\uparrow}$ *carrier $A = (X, Q, M, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ApartnessCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed apartness source row, separated completion route, constructive metric completion route, stream windows, regular readback, dyadic tolerance ledger, optional Real seal, transport, replay, provenance, and local naming rows;*

2. *apartness-source exactness, requiring the positive separation row X to be displayed before any separated completion route Q or completion route M is consumed;*

3. *finite readback discipline, requiring each consumer observation to pass through S, R, and D before the optional seal E is available;*

4. *componentwise stability, requiring H and C to transport and replay only the displayed rows $X, Q, M, S, R, D, E, P, N$;*

5. *provenance exhaustion, requiring P and N to export no quotient completion class, host equality, selected limit, countable-choice schedule, trichotomy row, or ambient-completeness principle.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1787.1. The tuple displays the apartness source, separated completion route, constructive metric completion route, finite windows, regular readback, dyadic tolerance ledger, optional Real seal, transport, replay, provenance, and local name.

Apartness-source exactness follows from the order of the displayed route. A consumer can inspect Q or M only after the positive separation row X has been named, so separated completion cannot hide its apartness source.

The readback discipline is carried by S, R, D, E. Each completion observation first opens a finite stream window, then reads the regular rational row, then consults the dyadic tolerance ledger; the optional Real seal is downstream of that finite route.

Componentwise stability and provenance exhaustion are the roles of H, C, P, N. These rows transport, replay, package, and name only the displayed packet, and therefore cannot add quotient completion classes, host equality, selected limits, countable choice, trichotomy, or ambient completeness. □

Theorem 1787.3 (Apartness completion Real seal boundary)**.** *Let $A = (X, Q, M, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{ApartnessCompletion}^{\uparrow}$ *packet. Every Real-facing completion read of A, when the optional seal row E is present, factors through the finite route*

$$X, Q, M, S, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus the Real seal receives only the displayed apartness source, Hausdorff separated route, constructive metric completion route, stream windows, regular readback, dyadic tolerance ledger, transport rows, continuation replay, provenance, and local NameCert row. It receives no quotient completion, host equality of completed points, selected limit, countable-choice schedule, trichotomy row, or ambient-completeness coordinate.

Proof. Start with a Real-facing completion read. Projection of the carrier gives a single ordered route from the apartness source row X through the separated route Q and constructive metric completion route M.

The finite observation rows then exhaust the readback path. The window schedule S, regular readback R, and dyadic tolerance ledger D must be displayed before the Real seal row E can be inspected.

Finally, the transport, replay, provenance, and local name rows H, C, P, N carry the same route without adding coordinates. Row exhaustion therefore blocks quotient completions, host equality, selected limits, countable choice, trichotomy, and ambient completeness from entering the Real seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1787.1, Definition 1787.2, and Definition 1787.3 seed the generic separated apartness-completion boundary over HausdorffCompletion, ConstructiveMetricCompletion, StreamName, RegSeqRat, DyadicRatCore, optional Real, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, host equality of completed points, selected limits, countable choice, trichotomy, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, apartness-source exactness, finite readback discipline, componentwise stability, provenance exhaustion, and Real seal boundary proofs for BEDC.Derived.ApartnessCompletionUp.

Constructive story: An $\mathsf{ApartnessCompletion}^{\uparrow}$ packet is generated from an apartness source row, a HausdorffCompletion separated route, a ConstructiveMetricCompletion route, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, an optional RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1788

A Concrete Naming Certificate for ApartnessCotransitivity$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the ApartnessCotransitivity$^{\uparrow}$ packet records the finite cotransitive apartness read by which an apart pair of real names separates through a third displayed name on either the left branch or the right branch. It sits over the Bishop-style apartness surface of chapter 304, the located apartness classifier of chapter 1380, the regular Cauchy order/apartness route of chapter 1710, the regular rational handoff of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the terminal real-name seal of chapter 38. Its role is to expose cotransitivity as finite NameCert data without importing trichotomy, ambient real equality, quotient streams, selected representatives, countable choice, or Real$^{\uparrow}$ completeness.

Definition 1788.1 (Apartness cotransitivity carrier)**.** *An* ApartnessCotransitivity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, L, R, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the left* Real$^{\uparrow}$ *name whose apartness from Y is being tested by a displayed regular Cauchy route.*
2. *Y is the right* Real$^{\uparrow}$ *name in the source apart pair.*
3. *Z is the third* Real$^{\uparrow}$ *name through which cotransitivity is read.*
4. *L is the left-branch row. When active, it records the witnessed apartness route from X to Z through the located apartness classifier and the regular Cauchy apartness-order surface.*
5. *R is the right-branch row. When active, it records the witnessed apartness route from Z to Y through the same classifier and regular Cauchy apartness-order surface.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row. It records the positive dyadic separation budget, slack, and finite precision data consumed by whichever branch is displayed.*
7. *H records componentwise* hsame *transport for the three real-name rows, the two branch rows, the dyadic tolerance row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an apartness-cotransitivity request through $X, Y, Z, L, R, D, H, P, N$.*
9. *P is the* Pkg *provenance over* ApartnessCotransitivity$^{\uparrow}$*,* ApartnessReal$^{\uparrow}$*,* LocatedApartness$^{\uparrow}$*,* RegularCauchyApartne RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessCotransitivity}^{\uparrow}}$ *row.*

The classifier admits exactly the finite packet in which the source apartness of X and Y is witnessed by one displayed branch, either L or R, together with the tolerance and structural rows needed to replay that branch. It has no coordinate for trichotomy, host real equality, quotient streams, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1788.2 (Apartness cotransitivity NameCert obligations)**.** *For every accepted* $\mathsf{ApartnessCotransitivity}^{\uparrow}$ *carrier*

$$K = (X, Y, Z, L, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ApartnessCotransitivity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two source real names, the third real name, the left and right branch rows, the dyadic tolerance row, transport, replay, provenance, and local naming rows;*
2. *branch stability under classifier transport, requiring H and C to preserve the displayed left-or-right branch tag and to transport the active branch through the same located-apartness and regular Cauchy apartness-order route;*
3. *dyadic tolerance preservation, requiring D to carry the positive separation budget, slack, and finite precision data consumed by the active branch before any* $\mathsf{Real}^{\uparrow}$ *seal is read;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring each active branch to pass through a displayed regular rational readback before it is treated as a real-name apartness read;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring the terminal real-name rows X, Y, Z to remain endpoints and branch parameters rather than sources of host equality, quotient equality, selected representatives, trichotomy, countable choice, or completeness;*
6. *ledger exclusion, requiring P and N to name exactly the displayed cotransitivity packet and to export no trichotomy, no host real equality, no quotient streams, no countable choice, no selected representatives, and no* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No apartness-cotransitivity obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.ApartnessCotransitivityUp.ApartnessCotransitivityTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1788.1. The accepted packet displays the source names X, Y, the third name Z, the two branch rows L, R, the dyadic tolerance row D, and the structural rows H, C, P, N.

Branch stability is componentwise. Transport may move the displayed names and structural rows, but it must preserve the branch tag and replay the same left-or-right route through the located apartness classifier and the regular Cauchy apartness-order surface.

The dyadic and regular handoff clauses are the finite middle of the route. The active branch consumes D before it reaches a regular rational readback, and the $\mathsf{RegSeqRat}^{\uparrow}$ row is the point at which finite Cauchy data is handed to the real-name seal.

The Real-seal and ledger clauses follow from the inventory. Since the only available rows are $X, Y, Z, L, R, D, H, C, P, N$, the packet cannot export trichotomy, host equality, quotient streams, choice, selected representatives, or completeness. □

Theorem 1788.3 (Apartness cotransitivity Real boundary)**.** *Every accepted* $\mathsf{ApartnessCotransitivity}^{\uparrow}$ *read with source apartness between* X *and* Y *and third real name* Z *reaches a Real-facing consumer only through the finite route*

$$\mathsf{ApartnessReal}^{\uparrow} \longmapsto \mathsf{LocatedApartness}^{\uparrow} \longmapsto \mathsf{RegularCauchyApartnessOrder}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto$$

The consumer receives exactly one displayed cotransitive branch: either the left branch witnessing X *apart from* Z*, or the right branch witnessing* Z *apart from* Y*. The consumer receives no trichotomy of* X, Z, Y*, no host real equality, no quotient stream equality, no countable-choice selection of branches, no selected representatives, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier $K = (X, Y, Z, L, R, D, H, C, P, N)$. The source apartness and third real name are visible only as displayed real-name rows and branch parameters.

The active branch is finite. If the left row is active, the read follows L through the located apartness classifier, the regular Cauchy apartness-order route, the regular rational handoff, and the dyadic tolerance row. If the right row is active, the same route is followed through R.

In both cases the Real-facing consumer reaches the endpoint names only after the displayed branch, regular handoff, and dyadic tolerance data have been opened. The structural rows H, C, P, N transport, replay, package, and name that same branch.

No unlisted principle can be read from the packet. Trichotomy, host equality, quotient streams, countable-choice branch selection, selected representatives, and ambient completeness are absent from the carrier and from the local NameCert obligations. □

Falsifiable prediction: Every $\mathsf{ApartnessCotransitivity}^{\uparrow}$ read factors through three RealUp name rows, one left-or-right branch row, one DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: apartnessreal, located-apartness, regular-cauchy-apartness-order, regseqrat, dyadicratcore, real: $\mathsf{ApartnessCotransitivity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source apart pair, a third RealUp name, an explicit left-or-right branch witness, dyadic tolerance data, regular rational handoff, and the ledger exclusions that keep cotransitivity separate from trichotomy and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessCotransitivity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessCotransitivity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1788.1, Definition 1788.2, and Definition 1788.3 seed the finite Bishop-style cotransitivity boundary for Real and RegSeqRat apartness through displayed branch, dyadic tolerance, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessCotransitivity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, host real equality, quotient stream equality, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch stability under classifier transport, dyadic tolerance preservation, RegSeqRat handoff, Real-seal non-escape, and ledger exclusion for BEDC.Derived.ApartnessCotransitivityUp.

Constructive story: An $\mathsf{ApartnessCotransitivity}^{\uparrow}$ packet is generated from two source RealUp names, one third RealUp name, a displayed left-or-right apartness branch, one DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1789

A Concrete Naming Certificate for $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$

Following Kelley and Bourbaki on Moore–Smith nets, filters, and uniform spaces, the CauchyNetFilterCorrespondence packet records the finite correspondence between Cauchy-net and Cauchy-filter completion routes as BEDC naming data. It sits over the directed-net surface of chapter 589, the filter-base surface of chapter 333, the uniform entourage surface of chapter 339, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the uniform-net route of chapter 1657. The chapter packages the correspondence as one finite NameCert object; it is not a quotient of nets, not a quotient of filters, not a selected limit, not countable choice, not host equality, and not ambient completeness.

Definition 1789.1 (Cauchy net-filter correspondence carrier)**.** *A* $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, F, U, W, R, E, J, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CauchyNet}^{\uparrow}$ *row, recording the directed index surface, displayed tail witnesses, and finite Cauchy-net requests available before any filter read is made.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, recording the filter-base trace generated from the displayed tails and the reverse filter request surface that can be read back as net data.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, storing the selected entourage requests, symmetric or composed tolerance cells, and finite comparison budget shared by the net and filter reads.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite windows inspected by the displayed K, F, U route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from those windows and tolerance cells.*
6. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary, reachable only after K, F, U, W, R have been consumed.*
7. *J is the common-refinement ledger, listing the finite tail/filter-base refinements through which the net-to-filter and filter-to-net reads are compared.*
8. *H records componentwise* hsame *transport for the Cauchy-net row, Cauchy-filter row, uniform entourage row, window row, readback row, seal boundary, common-refinement ledger, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite Cauchy request through K, F, U, W, R, J and then to the seal row E.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyUniformNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient net equality, quotient filter equality, selected limits, countable-choice refinements, host equality, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyNetFilterCorrespondenceUp.CauchyNetFilterCorrespondenceTasteGate`
`single carrier alignment`

Theorem 1789.2 (Cauchy net-filter correspondence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$ *carrier*

$$Q = (K, F, U, W, R, E, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier exposure: the accepted object exposes only the displayed packet Q with rows $K, F, U, W, R, E, J, H, C, P, N$*
2. *net-to-filter routing: every read from a displayed Cauchy-net tail to a filter-base trace passes through K, F, U before any finite window is inspected;*
3. *filter-to-net routing: every read from a displayed filter-base request back to a net tail passes through the same F, K, U rows before any finite window is inspected;*
4. *common-refinement comparison: both directions compare their visible outputs only through the ledger J, then through W, R, E when a real or completion-facing seal is requested;*
5. *provenance and name exhaustion: H, C, P, N transport, replay, name, and exhaust exactly this finite route and export no quotient nets, quotient filters, selected limits, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1789.1. The packet displays the Cauchy-net row, Cauchy-filter row, uniform entourage row, finite windows, regular rational readback, Real seal boundary, common-refinement ledger, and structural rows H, C, P, N.

The two routing clauses are read from the same finite packet. A net-to-filter read starts at the displayed tail witnesses in K, opens the filter-base trace F generated by those tails, and carries the selected entourage budget through U before any window in W is available. A filter-to-net read starts at the displayed request in F, returns to the net-tail row K, and uses the same U budget before it reaches W.

The comparison clause is forced by J. The ledger records the common refinements already displayed by both directions, so the two reads can be compared only at those visible refinements and then transported through the same W, R, E route when a seal-facing consumer asks for a real or completion boundary.

Finally, H and C transport and replay the listed route componentwise, while P and N name only those rows. Since the carrier has no excluded quotient, choice, host-equality, completeness, verification, or bridge coordinate, the five obligation rows exhaust the local certificate surface. □

Theorem 1789.3 (Cauchy net-filter common refinement)**.** *Let $Q = (K, F, U, W, R, E, J, H, C, P, N)$ be an accepted* $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$ *carrier. Every net-to-filter read and every filter-to-net read of Q compare their visible outputs only through displayed common refinements in J. In particular, a comparison has the finite route*

$$K, F, U \longmapsto J \longmapsto W, R, E, H, C, P, N,$$

and no comparison may use quotient net equality, quotient filter equality, a selected subnet, a selected ultrafilter, countable choice, host equality, or ambient completeness.

Proof. Project the accepted carrier. The rows K and F are both present before a comparison can be made, and the uniform budget row U is shared by the two directions.

Apply the routing obligations of Definition 1789.2. Each direction must reach the same finite comparison boundary before reading windows or rational readbacks. That boundary is exactly the ledger J.

Once J is fixed, the downstream route is unique in the carrier: windows are read through W, regular rational data through R, and the seal boundary through E, with H, C, P, N carrying transport, replay, provenance, and local naming. No row outside this displayed route can witness a comparison, so quotient, choice, host-equality, and completeness principles are unavailable. □

Theorem 1789.4 (Cauchy net-filter real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$ *carrier must factor through the same finite route*

$$K, F, U, J, W, R \longmapsto E$$

before it reads the seal boundary. Thus the consumer receives a Cauchy-net row, a Cauchy-filter row, a uniform entourage row, the displayed common-refinement ledger, finite StreamName windows, regular rational readback, and the Real seal, but receives no quotient net, quotient filter, selected limit, countable-choice selector, host equality, ambient completeness, Lean verification, or bridge checking.

Proof. The seal row E is a downstream coordinate of the carrier in Definition 1789.1. It is not available before the rows K, F, U, W, R, J have been displayed.

Use Definition 1789.3. Any route that compares the net and filter presentations must pass through J, and the only seal-facing route after that comparison is through the finite windows W and regular rational readback R.

Therefore a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reaches E only by the displayed route $K, F, U, J, W, R \longmapsto E$. The structural rows H, C, P, N preserve and name that route, and the absence of quotient, choice, host-equality, completeness, verification, and bridge rows prevents any alternate seal handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1789.1, Definition 1789.2, Definition 1789.3, and Definition 1789.4 seed the finite correspondence route tying Cauchy-net and Cauchy-filter completion reads through a shared uniform budget, common-refinement ledger, StreamName windows, RegSeqRat readback, and Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, quotient filters, selected limits, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, net-to-filter routing, filter-to-net routing, common-refinement comparison, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNetFilterCorr

Constructive story: A CauchyNetFilterCorrespondence$^{\uparrow}$ packet is generated from one CauchyNet row, one CauchyFilter row, one UniformSpace entourage row, finite StreamName windows, RegSeqRat readback, a Real seal boundary, a common-refinement ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1790

A Concrete Naming Certificate for $\mathsf{SeparatedMetricReflection}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Bourbaki universal-mapping language, the $\mathsf{SeparatedMetricReflection}^{\uparrow}$ packet records the separated-reflection route consumed by L10 completion uniqueness. It reads the separated classifier surface of chapter 1411, the completion adjunction route of chapter 1456, the extension boundary of chapter 397, the reflection consumer of chapter 403, and the terminal real-name seal of chapter 38. The packet records this route as finite NameCert data before any consumer treats zero-distance evidence as host equality or quotient-space structure.

Definition 1790.1 (SeparatedMetricReflection carrier)**.** *A* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, S, A, U, Z, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier and metric-distance witness surface available before separation is read.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier row, exposing only the finite route from a displayed zero-distance witness to point-classifier equivalence.*
3. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *completion route that carries dense-row admission, completion-seal access, extension, and uniqueness by dense agreement.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row read by completion-facing consumers after the separated classifier has been routed through A.*
5. *Z is the reflected classifier output, obtained by reading S through the completion route and then returning the classifier evidence at the separated-reflection surface.*
6. *H stores componentwise* hsame *transport for the metric source, separated classifier, completion adjunction, universal row, reflected classifier, continuation row, package row, and local naming row.*
7. *C stores the* Cont *replay from metric-distance witnesses to zero-distance readings, from those readings to the separated classifier, and from the separated classifier through the completion universal route to Z.*

8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, CompletionUniversalPropert $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedMetricReflection}^{\uparrow}}$ *row.*

The carrier exposes separated reflection only as a finite classifier route. It carries no quotient metric space, no host equality coordinate, no trichotomy row, no open-cover compactness principle, no countable-choice selector, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionTasteGate single carrier alignment`

Theorem 1790.2 (SeparatedMetricReflection NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{SeparatedMetricReflection}^{\uparrow}}$ *surface for Definition 1790.1 consists exactly of five finite obligation rows:*

1. *carrier exposure: an accepted object exposes only the packet $R = (X, S, A, U, Z, H, C, P, N)$;*
2. *zero-distance classifier exactness: every classifier read begins with the metric-distance witness in X, passes through the zero-distance classifier row S, and reaches the reflected classifier output Z;*
3. *adjunction compatibility: the completion-facing part of the route is read through the dense-row and extension coordinates carried by A;*
4. *universal-route preservation: the extension row U preserves the order* $\mathsf{Met}^{\uparrow} \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{CauchyCompletionAdjunction}^{\uparrow} \to \mathsf{CompletionUniversalProperty}^{\uparrow}$ *before a consumer reads Z;*
5. *ledger non-escape: the provenance row P exports no quotient metric space, host equality, trichotomy, open-cover compactness, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Thus the packet binds the separated-reflection boundary used by completion uniqueness without adding quotient, host-equality, choice, compactness, or ambient-completeness data.

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier namecert obligations`

↪ variant `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionNameCertObligations`

Proof. Carrier exposure is projection from the tuple in Definition 1790.1. The source row is X, the separated classifier is S, the completion adjunction is A, the universal row is U, the reflected classifier is Z, and the structural rows are H, C, P, N.

Zero-distance classifier exactness follows by reading the displayed route in order. A metric-distance witness starts in X, the zero-distance classifier row S converts that witness into point-classifier evidence, and the output coordinate Z records the reflected classifier read.

Adjunction compatibility and universal-route preservation are the completion-facing clauses. The row A is the only dense-row and extension route carried by the packet, while U keeps the order of the route fixed before any consumer reads the reflected classifier.

Ledger non-escape is an inventory check on P. Since quotient metric spaces, host equality, trichotomy, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking are not fields of R, no local NameCert obligation can use them. □

Theorem 1790.3 (SeparatedMetricReflection zero-distance exactness)**.** *For every accepted* SeparatedMetricReflecti *carrier $R = (X, S, A, U, Z, H, C, P, N)$, any reflected classifier read starts with metric-distance evidence in X, passes through the zero-distance classifier row S, then through the completion route*

rows A, U, and reaches the reflected classifier output Z. The read exports this finite classifier route only; it does not conclude quotient metric space structure or host equality.

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier zero distance exactness`

Proof. Project the carrier of Definition 1790.1. The row X is the only metric-distance source, S is the only zero-distance classifier row, and Z is the only reflected classifier output.

Apply the zero-distance classifier exactness clause of Definition 1790.2. It forces every classifier read to begin at X and pass through S before Z is available.

The universal route theorem then fixes the completion-facing segment. Rows A and U preserve the separated classifier through the completion adjunction and universal extension route, while the provenance row contains no quotient metric space or host-equality coordinate. □

Theorem 1790.4 (SeparatedMetricReflection universal route)**.** *Every completion-facing consumer of an accepted* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Met}^{\uparrow} \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{CauchyCompletionAdjunction}^{\uparrow} \to \mathsf{CompletionUniversalProperty}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{NameCert}$$

before reading the reflected classifier Z. The consumer may inspect the metric source row, the zero-distance classifier row, the completion adjunction route, the universal extension row, the real-name seal, the structural hsame *and* Cont *rows, the package provenance, and the local naming row. It may not bypass the route by reading quotient metric spaces, host equality, trichotomy, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier of Definition 1790.1. Its public consumer-facing rows occur in the order X, S, A, U, Z, with H, C, P, N supplying transport, replay, provenance, and local admission.

The metric source row X supplies distance witnesses, and S turns the relevant zero-distance readings into separated classifier evidence. The row A moves that evidence to the completion-facing boundary, while U records the universal extension surface a consumer is allowed to read.

The real-name seal and the local NameCert row are read only after this route has been preserved. Because P names no quotient, host-equality, trichotomy, open-cover compactness, choice, or ambient-completeness field, every accepted completion-facing read factors through the displayed chain before reaching Z. □

Theorem 1790.5 (SeparatedMetricReflection Cauchy uniqueness)**.** *Let*

$$R = (X, S, A, U, Z, H, C, P, N)$$

be an accepted $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *packet. Suppose two completion-facing reads of R agree on the separated zero-distance classifier row Z and on the completion adjunction and universal rows A, U. Then the two reads have the same reflected classifier output along the displayed route*

$$H, C, P, N.$$

Equivalently, the packet supplies Cauchy uniqueness only through its separated zero-distance classifier, adjunction route, universal route, componentwise transport, replay, provenance, and local naming rows; it supplies no quotient metric-space equality or host equality coordinate.

Proof. Project the carrier $R = (X, S, A, U, Z, H, C, P, N)$ from Definition 1790.1. The relevant completion-facing rows are the zero-distance classifier route through S, Z and the adjunction and universal rows A, U.

Apply Definition 1790.3. Agreement on the separated zero-distance classifier row forces both reads to pass through the same X, S, Z classifier route before any completion-facing output is available.

Next apply Definition 1790.4. Agreement on A, U keeps the completion adjunction and universal extension segment fixed, so the two reads reach the reflected classifier through the same displayed completion route.

Finally transport componentwise through H and replay the same displayed continuation through C, with provenance and local naming supplied by P, N. Since the packet contains no quotient metric-space row and no host equality coordinate, the common reflected classifier output is the only uniqueness conclusion available. □

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier cauchy uniqueness`
Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier universal route`

Theorem 1790.6 (SeparatedMetricReflection completion-uniqueness route)**.** *Every completion uniqueness consumer of an accepted* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *carrier*

$$R = (X, S, A, U, Z, H, C, P, N)$$

must expose the zero-distance classifier S, completion adjunction A, universal extension row U, reflected classifier Z, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before using uniqueness by separated reflection. The consumer receives the displayed separated-reflection route only; it receives no quotient metric space, host equality, trichotomy, choice principle, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with carrier projection. The completion uniqueness consumer can inspect only the rows $X, S, A, U, Z, H, C, P, N$ displayed in Definition 1790.1.

Use the NameCert obligations and zero-distance exactness. The obligations force the consumer to read the zero-distance classifier S as a finite row of the same packet, while Definition 1790.3 routes the classifier read from X through S and onward to Z.

Next apply Definition 1790.4. It places the completion-facing part of the read through A and U before the reflected classifier is consumed by a uniqueness argument.

Finally read the structural rows H, C, P, N. Transport and replay preserve the displayed route, provenance records the packet source, and local naming admits the route as $\mathsf{SeparatedMetricReflection}^{\uparrow}$ data. Since the carrier has no quotient, host-equality, trichotomy, choice, open-cover, or ambient-real-completeness coordinate, the uniqueness consumer cannot import any of those objects. □

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier completion uniqueness route`

Theorem 1790.7 (SeparatedMetricReflection obligation-closure package)**.** *Let*

$$R = (X, S, A, U, Z, H, C, P, N)$$

be an accepted $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *packet. Then Definition 1790.1, Definition 1790.2, and Definition 1790.4 assemble the five finite obligation rows required for obligation closure: carrier exposure, zero-distance classifier exactness, adjunction compatibility, universal-route preservation, and ledger non-escape for the same packet R.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier obligation closure package`

Proof. Project $R = (X, S, A, U, Z, H, C, P, N)$ from Definition 1790.1. The carrier exposure row is the displayed tuple itself: metric source X, separated classifier S, completion adjunction A, universal route U, reflected classifier Z, transport H, replay C, provenance P, and local naming N.

Zero-distance classifier exactness is the first named obligation in Definition 1790.2. A distance witness is read from $\mathsf{Met}^{\uparrow}$ through X, routed to the zero-distance classifier in $\mathsf{SeparatedMetric}^{\uparrow}$ through S, and returned as the reflected classifier output Z.

Adjunction compatibility and universal-route preservation are supplied by the completion-facing rows. The route passes through $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ in A and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ in U, so completion consumers read dense-row, extension, and uniqueness data only after the separated classifier route has been displayed.

Finally apply the universal-route theorem. It keeps every completion-facing read on the chain through $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while the provenance row P excludes quotient metric spaces, host equality, trichotomy, open-cover compactness, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1790.8 (SeparatedMetricReflection scoped dependency route)**.** *Every accepted* SeparatedMetricReflectio*packet whose obligation rows are read for completion uniqueness factors through the displayed route*

$$\mathsf{Met}^{\uparrow} \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{CauchyCompletionAdjunction}^{\uparrow} \to \mathsf{CompletionUniversalProperty}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{BHist} \to \mathsf{hs}$$

The route may read the metric source, separated classifier, completion adjunction, universal extension, real-name seal, history packet, transport, continuation, package provenance, and local naming rows of the same carrier. It has no quotient metric space, host equality, trichotomy, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row available.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier scope`

Proof. Project the carrier $R = (X, S, A, U, Z, H, C, P, N)$ from Definition 1790.1. The rows X, S, A, U, Z provide the metric, separated classifier, completion adjunction, universal extension, and reflected output coordinates, while H, C, P, N provide transport, replay, provenance, and local naming.

Use the NameCert obligations of Definition 1790.2. They force carrier exposure, zero-distance classifier exactness, adjunction compatibility, universal-route preservation, and ledger non-escape for the same packet.

Now apply the universal route theorem Definition 1790.4. It places every completion-facing consumer on the chain through $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the reflected classifier is read.

It remains only to read the structural rows. The history, hsame, Cont, Pkg, and NameCert coordinates are exactly R's finite support rows, and ledger non-escape from P excludes quotient metric spaces, host equality, trichotomy, choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.SeparatedMetricReflectionUp.SeparatedMetricReflectionCarrier scoped dependency route`

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedMetricReflection}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{SeparatedMetricReflection}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ source row, a $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance classifier row, a $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ completion route, a $\mathsf{CompletionUniversalProperty}^{\uparrow}$ extension

row, a reflected classifier output, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SeparatedMetricReflection}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1790.1, Definition 1790.2, Definition 1790.4, Definition 1790.5, and Definition 1790.6 bind the completion-uniqueness and universal-route coverage for separated reflection over the displayed metric, separated classifier, completion-adjunction, universal-property, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SeparatedMetricReflection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient metric spaces, host equality, trichotomy, open-cover compactness, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Bridged closure requires an explicit standard bridge for the separated-reflection schema, preserving the displayed route through Met$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, CauchyCompletionAdjunction$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert without adding quotient or host-equality data.

Chapter 1791

A Concrete Naming Certificate for $\mathsf{CauchyEntourageFilter}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures and filter bases, and Bishop–Bridges on constructive Cauchy completion, the $\mathsf{CauchyEntourageFilter}^{\uparrow}$ packet names the finite boundary between displayed entourage data and Cauchy-filter completion consumers. It sits over the uniform entourage surface of chapter 339, the basis-generator surface of chapter 1501, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the completion consumer boundary of chapter 1588. The packet is a finite induction surface for Cauchy-entourage requests; it is not a quotient filter, not a selected limit, not countable choice, not host equality, and not an ambient completeness principle.

Definition 1791.1 (Cauchy entourage-filter carrier)**.** *A* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, B, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row. It records the finite entourage filterbase, diagonal, refinement, symmetry, and composition data from which every Cauchy-entourage request starts.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator row. It turns displayed entourage requests into finite Cauchy-filter basis elements before any completion-facing consumer can read them.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by those generated basis elements.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite windows in S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare entourage radii with the regular rational readbacks.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after U, B, S, R, D have been replayed.*
7. *H records componentwise* hsame *transport for the entourage row, basis generator, finite windows, regular readback, dyadic ledger, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an entourage request through U, then through B, S, R, D, and finally to the seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyEntourageFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyEntourageFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed route $U, B, S, R, D, E, H, C, P, N$. The carrier has no coordinate for quotient filters, selected limits, countable-choice selectors, host equality, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyEntourageFilterUp.CauchyEntourageFilterTasteGate single carrier alignment`

Theorem 1791.2 (Cauchy entourage-filter NameCert obligations)**.** *For every accepted* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *carrier*

$$Q = (U, B, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyEntourageFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the displayed uniform entourage row, CauchyFilterBasis generator, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming row;*
2. *entourage-to-basis routing, requiring every Cauchy request read from U to pass through the finite generator row B before any window or rational readback is available;*
3. *dyadic readback comparison, requiring every generated basis element to inspect S and R before the tolerance ledger D compares the requested entourage scale;*
4. *completion handoff, requiring every* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer named by P to read the seal boundary E only after the route U, B, S, R, D has been replayed;*
5. *transport, replay, and provenance exhaustion, requiring H, C, P, N to preserve and name exactly this finite route and to export no quotient filter, selected limit, countable-choice selector, host equality, ambient completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1791.1. The projection exposes exactly the uniform entourage row, the basis generator, the finite windows, the regular readback, the dyadic tolerance ledger, the Real seal, and the structural rows H, C, P, N.

The entourage-to-basis route is fixed by the displayed row order. A Cauchy request begins at the finite entourage filterbase in U and is admitted to completion-facing use only after the generator row B has produced a displayed basis element.

The dyadic comparison is downstream of that generator. The basis element can inspect windows only through S, can read regular rational data only through R, and can compare the requested scale only through the ledger D.

The completion handoff is terminal for this packet. The provenance row P may mention $\mathsf{CompleteUniformSpace}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only as consumers of the already replayed route $U, B, S, R, D \longmapsto E$.

Finally, H transports each listed coordinate componentwise and C replays the same dependency order. Since the carrier has no quotient, choice, selected-limit, host-equality, completeness, verification, or bridge coordinate, P and N exhaust the local certificate surface. □

Theorem 1791.3 (Cauchy entourage-filter dyadic basis handoff)**.** *Let $Q = (U, B, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *carrier. Every generated Cauchy-filter basis read factors through the finite route*

$$U \longmapsto B \longmapsto S \longmapsto R \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

Thus an entourage request reaches the Cauchy-filter basis surface only with its StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance ledger displayed. It cannot bypass D by selecting a real representative, quotienting a filter, choosing a limit, or invoking ambient completeness.

Proof. Start with a generated basis read of the packet. The row U supplies only finite uniform-space entourage data, so the request first names a displayed entourage demand and its refinement ledger.

The row B consumes that demand as a finite Cauchy-filter basis generator. It does not create a completed filter object and does not expose a limit by itself.

The regular readback route is then forced. The generated basis element inspects finite windows through S, reads regular rational observations through R, and checks the dyadic scale and inclusion data through D.

Only after this route has been replayed can the seal row E and the structural rows H, C, P, N be read. Hence no selected representative, quotient filter, selected limit, choice schedule, host equality, or ambient completeness witness is available as a bypass. □

Theorem 1791.4 (Cauchy entourage-filter Real seal non-escape)**.** *For every accepted* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *carrier* $Q = (U, B, S, R, D, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{CompleteUniformSpace}^{\uparrow}$*-facing consumer exposed by* P *factors through the displayed route*

$$U, B, S, R, D \longmapsto E.$$

Consequently the packet cannot export a Real seal, completion boundary, quotient filter, selected limit, countable-choice selector, host equality, or ambient completeness principle from any earlier row.

Proof. Project the provenance row P. Its $\mathsf{Real}^{\uparrow}$ and $\mathsf{CompleteUniformSpace}^{\uparrow}$ occurrences are recorded as downstream consumers of the displayed entourage-filter route, not as separate coordinates.

The row E is available only after the route through U, B, S, R, D has been replayed. The rows S and R expose finite observations, and D supplies the dyadic tolerance comparison that ties those observations back to the original entourage request.

Transport and replay preserve this order. Componentwise hsame in H cannot introduce a new seal coordinate, and Cont replay in C repeats the same route for every accepted request.

Thus the local naming row N names a finite boundary between entourage data and completion consumers. It has no earlier point from which a Real seal, completion boundary, quotient filter, selected limit, choice schedule, host equality, or ambient completeness principle can escape. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyEntourageFilter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyEntourageFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1791.1, Definition 1791.2, Definition 1791.3, and Definition 1791.4 seed the finite boundary through which UniformSpace entourage data reaches CauchyFilterBasis, StreamName, RegSeqRat, DyadicRatCore, Real, and CompleteUniformSpace consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyEntourageFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, entourage-to-basis routing, dyadic readback comparison, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyEntourageFilterUp.

Constructive story: A $\mathsf{CauchyEntourageFilter}^{\uparrow}$ packet is generated from one UniformSpace entourage row, one CauchyFilterBasis generator row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1792

A Concrete Naming Certificate for $\mathsf{FiniteIntersectionProperty}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley-style compactness practice, the $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ packet records only the finite closed-family certificate used by the L10 Real-and-Completion route. It reads the closed-interval completion surface of chapter 1778, the nested-window compactness handoff of chapter 1584, the Cantor nested-intersection consumer of chapter 1421, the finite epsilon-net witness of chapter 1767, and the terminal real-name seal of chapter 38. The packet names finite closed-family intersection data; it does not import open-cover compactness, arbitrary closed-family compactness, countable choice, selected endpoints, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1792.1 (Finite intersection property carrier)**.** *A* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (J, F, A, Q, N, C, E, R, H, T, P, M)$$

with the following displayed rows:

1. *J is the finite family index row, recording the inspected closed-family cells and the finite subfamily request consumed by the packet.*
2. *F is the closed-family row, giving each displayed member as a closed interval or closed interval subpacket over the same Real-and-Completion route.*
3. *A is the finite-acceptance ledger, requiring every index in J to have a displayed closed-family member in F and requiring the finite subfamily request to be read only through those cells.*
4. *Q is the* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *row, supplying the endpoint-bounded Cauchy completion handoff for the displayed closed interval cells.*
5. *N is the* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *row, used when the finite family is routed through a nested-window refinement rather than through a general cover argument.*
6. *C is the* $\mathsf{CantorIntersection}^{\uparrow}$ *row, recording the finite Cantor-style nested-intersection handoff downstream of the displayed nested-window data.*
7. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row or interval-net witness row, recording the finite net, mesh, or interval-window data used to keep the finite family request inside visible compactness-shaped data.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after J, F, A, Q, N, C, E have been displayed.*

9. *H records componentwise* hsame *transport for the finite index, closed-family, completion, nested-window, Cantor handoff, finite-net, Real seal, replay, provenance, and local naming rows.*
10. *T records displayed* Cont *replay from a finite closed-family request through $J, F, A, Q, N, C, E, R, H, P, M$.*
11. *P is the* Pkg *provenance over* FiniteIntersectionProperty$^{\uparrow}$, ClosedIntervalCauchyCompletion$^{\uparrow}$, NestedIntervalCompa CantorIntersection$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *M is the local* NameCert$_{\text{FiniteIntersectionProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J, F, A, Q, N, C, E, R, H, T, P, M$. The carrier has no coordinate for open-cover compactness, arbitrary closed-family compactness, countable choice, selected endpoints, quotient real equality, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.FiniteIntersectionPropertyUp.FiniteIntersectionPropertyUp`

Theorem 1792.2 (Finite intersection property NameCert obligations)**.** *For every accepted* FiniteIntersectionProper *carrier*

$$K = (J, F, A, Q, N, C, E, R, H, T, P, M),$$

the local NameCert$_{\text{FiniteIntersectionProperty}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite family index, closed-family cells, finite-acceptance ledger, closed-interval Cauchy completion row, nested-window compactness row, Cantor handoff row, finite epsilon-net or interval-net witness, Real seal, transport, replay, provenance, and local naming rows;*
2. *finite-family exactness, requiring every accepted intersection request to name a finite subfamily through J and to read each member through the displayed closed-family row F;*
3. *closed-interval completion handoff, requiring Q to be consumed before any nested-window, Cantor, finite-net, or Real-facing conclusion is exported;*
4. *compactness-shape locality, requiring N, C, E to be read as displayed finite nested-window, Cantor handoff, and finite-net or interval-net rows rather than as an open-cover compactness theorem;*
5. *Real seal routing, requiring R to remain downstream of J, F, A, Q, N, C, E and upstream only of H, T, P, M;*
6. *componentwise classifier transport, displayed replay, provenance, and local naming for the same rows through H, T, P, M;*
7. *ledger non-escape, requiring the packet to export no open-cover compactness, arbitrary closed-family compactness, countable-choice schedule, selected endpoint, quotient real equality, trichotomy branch, or ambient* Real$^{\uparrow}$ *completeness theorem.*

No finite intersection property obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FiniteIntersectionPropertyUp.FiniteIntersectionPropertyNameCertObligations`

Proof. Carrier admission is projection from Definition 1792.1. The visible packet consists exactly of the finite family index J, the closed-family row F, the finite-acceptance ledger A, the completion row Q, the nested-window row N, the Cantor handoff row C, the finite-net or interval-net witness E, the Real seal R, and the structural rows H, T, P, M.

Finite-family exactness is rowwise. Every accepted request first names its finite subfamily through J, and every named member is read through F before any downstream intersection certificate is visible.

The completion and compactness-shaped handoffs are then ordered. The row Q supplies the closed-interval Cauchy completion boundary; the rows N, C, E consume that displayed route as nested-window, Cantor-style, and finite-net data rather than as a general open-cover theorem.

Finally, R, H, T, P, M seal, transport, replay, source, and name the same finite route. Since none of the excluded compactness, choice, endpoint-selection, quotient-equality, trichotomy, or ambient-completeness objects occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1792.3 (Closed interval completion finite intersection handoff)**.** *Every Real-and-Completion consumer that reads an accepted* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *carrier factors its closed-family intersection request through the finite route*

$$J, F, A \longmapsto Q \longmapsto N, C, E \longmapsto R \longmapsto H, T, P, M.$$

Consequently the consumer receives a displayed finite family index, displayed closed-family rows, finite-acceptance data, a closed-interval Cauchy completion handoff, nested-window and Cantor intersection handoffs, a finite epsilon-net or interval-net witness, a terminal $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* $\mathsf{NameCert}$ *row. The route supplies no open-cover compactness, arbitrary closed-family compactness, countable choice, selected endpoint, quotient real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $K = (J, F, A, Q, N, C, E, R, H, T, P, M)$. The finite family index J, closed-family row F, and acceptance ledger A are the only source coordinates available to a finite intersection request.

The completion boundary is downstream of those rows. By the closed-interval completion handoff obligation of Definition 1792.2, the row Q must be consumed before the packet exposes nested-window, Cantor, finite-net, or Real-facing data.

The compactness-shaped data remain finite. The rows N, C, E route the request through displayed nested-window, Cantor-style, and finite-net or interval-net witnesses, and none of these rows contains an open-cover compactness theorem or an arbitrary closed-family principle.

The Real-facing seal and structural rows preserve that order. The row R is reachable only after J, F, A, Q, N, C, E, while H, T, P, M transport, replay, source, and name the same displayed route. Thus every consumer factors through the stated finite handoff. □

Theorem 1792.4 (Finite intersection property Real seal nesting)**.** *For any accepted* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *carrier*

$$K = (J, F, A, Q, N, C, E, R, H, T, P, M),$$

the terminal $\mathsf{Real}^{\uparrow}$ *seal row R is accessible only after the finite family rows J, F, A, the* $\mathsf{ClosedIntervalCauchyCompletio}$ *row Q, and the compactness-shaped rows N, C, E. Therefore the packet cannot export open-cover compactness, arbitrary closed-family compactness, selected endpoints, quotient real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1792.1. The finite family index J, closed-family row F, finite-acceptance ledger A, closed-interval completion row Q, compactness-shaped rows N, C, E, and terminal seal R are the only analytic rows available before transport and replay.

Use the Real seal routing clause in Definition 1792.2. It requires R to remain downstream of J, F, A, Q, N, C, E and upstream only of H, T, P, M.

Finally apply Definition 1792.3. The handoff route places the finite family rows before Q, then the nested-window, Cantor, and finite-net rows before R. Since the excluded compactness, endpoint-selection, quotient, trichotomy, and ambient-completeness objects are absent from the carrier, the Real seal read cannot export them. □

Theorem 1792.5 (Finite intersection property compact-filter route)**.** *Whenever a* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer reads an accepted* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *carrier*

$$K = (J, F, A, Q, N, C, E, R, H, T, P, M),$$

any compact-filter conclusion must factor through the displayed finite-family route

$$J, F, A \longmapsto Q \longmapsto N, C, E \longmapsto R \longmapsto H, T, P, M.$$

The consumer must therefore expose the finite subfamily index, closed-family rows, closed-interval completion handoff, finite-net or interval-net witness, and terminal $\mathsf{Real}^{\uparrow}$ *seal before any compact-filter use is public. The packet exports no open-cover compactness theorem, arbitrary closed-family compactness principle, countable-choice schedule, selected endpoint, quotient real equality, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 1792.1. The only source rows for a compact-filter read are the finite family index J, the closed-family row F, and the finite-acceptance ledger A.

Apply Definition 1792.2. The NameCert surface forces closed-interval completion through Q before any nested-window, Cantor, finite-net, or Real-facing conclusion is exported.

Use Definition 1792.3 and Definition 1792.4. These route the compactness-shaped rows through N, C, E and place the terminal seal R downstream of the finite-family and completion data.

The structural rows H, T, P, M transport, replay, source, and name only that finite route. Since no excluded compactness, choice, endpoint-selection, quotient-equality, trichotomy, or ambient-completeness coordinate occurs in the carrier, a $\mathsf{Compact}^{\uparrow}$ or $\mathsf{CompactMetric}^{\uparrow}$ consumer receives only the displayed compact-filter boundary. □

Theorem 1792.6 (Finite intersection property compact subcover extraction)**.** *For an accepted* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *carrier*

$$K = (J, F, A, Q, N, C, E, R, H, T, P, M),$$

any compact finite-window consumer requesting a subcover or intersection witness must first expose the finite family index J, the closed-family row F, and the finite-acceptance ledger A; then the $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *row Q; then the compactness-shaped rows N, C, E; and only then the* $\mathsf{Real}^{\uparrow}$ *seal R and the structural rows H, T, P, M. The extracted witness is a finite row inside E, N, C, not an open-cover compactness theorem, arbitrary closed-family principle, or countable-choice schedule.*

Proof. Project the carrier of Definition 1792.1. The finite source data are J, F, A, so a consumer cannot ask for a subcover or intersection witness before the finite index, closed-family rows, and acceptance ledger are displayed.

Apply the NameCert obligations of Definition 1792.2. They force the closed-interval completion handoff through Q before any compactness-shaped row can be exported.

Use the compact-filter route of Definition 1792.5. It places N, C, E after Q and before the terminal $\mathsf{Real}^{\uparrow}$ seal R, so the witness available to a compact finite-window consumer is a finite nested-window, Cantor-handoff, or finite-net row.

Finally apply the closed interval completion handoff of Definition 1792.3. The structural rows H, T, P, M only transport, replay, source, and name the same finite route. Since open-cover compactness, arbitrary closed-family compactness, and countable choice have no carrier coordinate, the extracted witness remains inside E, N, C. □

Falsifiable prediction: Every $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ read factors through one displayed finite family index, one closed-family row, one finite-acceptance ledger, one ClosedIntervalCauchyCompletion row, NestedIntervalCompactness and CantorIntersection handoff rows, one FiniteEpsilonNet or interval-net witness, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closed-interval-cauchy-completion, nestedintervalcompactness, cantor-intersection, finite-epsilon-net, real: $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite closed-family indexing, closed-interval completion, compactness-shaped nested and Cantor handoffs, finite-net or interval-net witnesses, and the terminal Real seal as one finite intersection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntersectionProperty}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntersectionProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1792.1, Definition 1792.2, and Definition 1792.3 seed the finite closed-family intersection certificate from displayed finite family indices and closed interval rows through closed-interval Cauchy completion, nested-window and Cantor handoffs, finite-net or interval-net witnesses, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntersectionProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, arbitrary closed-family compactness, countable choice, selected endpoints, quotient real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-family exactness, closed-interval completion handoff, compactness-shape locality, Real seal routing, classifier transport, replay, provenance, local naming, and finite route factorization for BEDC.Derived.FiniteIntersectionPropertyUp.

Constructive story: A $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ packet is generated from a finite family index, displayed closed-family rows, a finite-acceptance ledger, a ClosedIntervalCauchyCompletion row, NestedIntervalCompactness and CantorIntersection handoff rows, a FiniteEpsilonNet or interval-net witness, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1793

A Concrete Naming Certificate for CauchyCompletionReflectiveSubcategory$^{\uparrow}$

Following Mac Lane's reflective-subcategory formulation and Bishop–Bridges constructive completion, the CauchyCompletionReflectiveSubcategory$^{\uparrow}$ packet records completion as a finite BEDC reflective-subcategory surface. It reads the reflector packet of chapter 1585, the functorial packet of chapter 423, the universal-property packet of chapter 397, the separated-reflection boundary of chapter 1790, the stream-name windows of chapter 126, the regular rational rows of chapter 301, and the terminal real-name surface of chapter 38. The chapter names the public boundary where completion is consumed as a reflective inclusion and reflector route without importing host completed spaces.

Definition 1793.1 (CauchyCompletionReflectiveSubcategory carrier)**.** *A* CauchyCompletionReflectiveSubcategory$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, M, J, U, Q, E, Z, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and name-data row, including the displayed source classifier, finite Cauchy observations,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *reads, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger available before completion is read.*
2. *M is the completed-object surface, exposed through the* CauchyCompletionReflector$^{\uparrow}$ *and* CauchyCompletionFuncto *packets and not through a quotient carrier or selected host limit.*
3. *J is the reflective inclusion row naming the completed objects as the full completion-facing subcategory surface visible to downstream consumers.*
4. *U is the reflector unit row admitting source data from S into M.*
5. *Q is the counit and idempotence row, recording return along already completed reads and reuse of the same completed-object surface after a second completion pass.*
6. *E is the universal-property factorization row for finite-window continuous consumers, read through* CompletionUniversalProperty$^{\uparrow}$ *after U, J, Q have been displayed.*
7. *Z is the separated-reflection boundary row, read through* SeparatedMetricReflection$^{\uparrow}$ *before any zero-distance or completion-facing classifier is exposed.*

8. *T is the local transport row through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *carrying source windows, regular rational readback, dyadic tolerances, and the real-name seal used by S, M, U, Q, E, Z.*

9. *H records componentwise* hsame *transport for the source metric/name data, completed-object surface, reflective inclusion, unit, counit/idempotence, universal-property factorization, separated-reflection boundary, local transport, continuation, provenance, and naming rows.*

10. *C records displayed* Cont *replay from source observations through unit admission, completed-object access, reflective inclusion, counit return, idempotent replay, universal-property factorization, separated reflection, and the local StreamName–RegSeqRat–DyadicRatCore–Real route.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}}$ *row.*

The carrier exposes only the finite reflective-subcategory boundary. It contains no quotient completion, no selected limit, no host equality for completed objects, no countable-choice selector, no ambient completeness theorem, and no full completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectiveSubcategoryUp.TasteGate.CauchyCompletionReflectiveSubcat`
`single carrier alignment`

Theorem 1793.2 (CauchyCompletionReflectiveSubcategory NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$ *carrier $B = (S, M, J, U, Q, E, Z, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric/name data, completed-object surface, reflective inclusion, unit, counit/idempotence, universal-property factorization, separated-reflection boundary, local transport, continuation, provenance, and local naming rows;*

2. *reflective inclusion exactness, requiring every completed-object read to pass through J after the completed-object surface M has been displayed;*

3. *unit and counit compatibility, requiring source admission to use U and already-completed return or repeated completion to use Q over the same M, J, T route;*

4. *universal-property factorization, requiring each finite-window consumer to reach its completion-facing read through E after the unit and inclusion rows have been projected;*

5. *separated-reflection boundary preservation, requiring every zero-distance or completion-facing classifier read to pass through Z before the local real-name route is consumed;*

6. *local transport discipline, requiring* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *reads to occur only through the row T;*

7. *ledger non-escape, requiring P and N to export no quotient completion, selected limit, host equality, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1793.1. The packet displays the source row, completed-object surface, reflective inclusion, unit, counit/idempotence, universal-property

factorization, separated-reflection boundary, local transport, continuation, provenance, and local name.

Reflective inclusion exactness reads the completed-object surface in order. A consumer may inspect M only as a completion-facing object admitted into the inclusion row J, so the public subcategory boundary is the displayed finite row rather than a host collection of completed spaces.

The unit, counit, and idempotence obligations are the two reflector directions. Source data enter through U, already-completed reads return through Q, and repeated completion reuses the same M, J, T route.

Universal-property factorization and separated-reflection preservation are downstream of that route. The row E is the only extension surface for finite-window consumers, and the row Z is the only boundary from which zero-distance or completion-facing classifier evidence can be read.

Finally, H, C, P, N transport, replay, package, and name exactly the displayed rows. Since quotient completions, selected limits, host equality, countable choice, ambient completeness, and full $\mathsf{Real}^{\uparrow}$ completeness are absent from those rows, no local NameCert obligation can export them. □

Theorem 1793.3 (CauchyCompletionReflectiveSubcategory reflection law)**.** *Let $B = (S, M, J, U, Q, E, Z, T, H, C,$ be an accepted* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$ *carrier. Every public completion consumer factors through the finite reflective route*

$$S \longmapsto U \longmapsto M \longmapsto J \longmapsto Q \longmapsto E, Z \longmapsto T \longmapsto H, C, P, N.$$

Thus the unit, counit, idempotence, universal-property factorization, separated-reflection boundary, and local StreamName–RegSeqRat–DyadicRatCore–Real transport are read as one BEDC reflective-subcategory surface. The route exposes no quotient completion, selected limit, host equality, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a public completion consumer and project the carrier rows of Definition 1793.1. The source row S is visible only through unit admission U, and unit admission leads to the completed-object surface M.

The reflective inclusion row J is then the public subcategory boundary. The counit and idempotence row Q compares already-completed reads and repeated completion requests only over the same M, J, T coordinates.

The universal-property row E and separated-reflection row Z are consumed after the reflector route is fixed. They supply extension factorization and classifier boundary data without adding a second completed-object carrier.

The local transport row T and structural rows H, C, P, N close the route. Because these rows exhaust the packet, the listed non-escape claims follow directly from the absence of quotient, selected-limit, host-equality, choice, ambient-completeness, and full real-completeness coordinates. □

Theorem 1793.4 (CauchyCompletionReflectiveSubcategory L10 handoff)**.** *Every L10 completion read exported by an accepted* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$ *packet is obtained by combining the sibling reflector, functor, universal-property, separated-reflection, stream-name, regular-rational, dyadic-tolerance, and real-name rows named in P. The handoff is exhausted by the carrier of Definition 1793.1, the obligations of Definition 1793.2, and the reflection law of Definition 1793.3.*

Proof. The provenance row P names exactly the sibling packets available to the handoff: CauchyCompletionReflector CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, SeparatedMetricReflection$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$.

Apply Definition 1793.2 to read those packets through the carrier rows $S, M, J, U, Q, E, Z, T, H, C, P, N$. Each read is assigned to the source, reflector, inclusion, extension, separated boundary, local transport, or naming part of the same finite packet.

Apply Definition 1793.3 to place the consumer on the displayed reflective route. The route is finite and public, so the L10 handoff has no remaining coordinate from which a quotient completion, selected limit, host equality, countable choice, ambient completeness, or full Real$^{\uparrow}$ completeness theorem could be obtained. □

Closure status for NameCert$_{\text{CauchyCompletionReflectiveSubcategory}^{\uparrow}}$.

Constructive story: A CauchyCompletionReflectiveSubcategory$^{\uparrow}$ packet is generated from source metric/name data, a completed-object surface, reflective inclusion, reflector unit, counit and idempotence rows, universal-property factorization, separated-reflection boundary, local StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionReflectiveSubcategory}^{\uparrow}}$, seed)

Scope closed: Definition 1793.1, Definition 1793.2, Definition 1793.3, and Definition 1793.4 seed the finite reflective-subcategory boundary for the L10 completion route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionReflectiveSubcategory}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality, countable choice, ambient completeness, full Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflective inclusion exactness, unit-counit-idempotence compatibility, universal-property factorization, separated-reflection preservation, local transport discipline, and ledger non-escape for BEDC.Derived.CauchyCompletionReflectiveSubcategoryUp.

Chapter 1794

A Concrete Naming Certificate for $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive regular-Cauchy completion, the $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ packet names the finite sequential-completeness surface that sits between regular rational names and the downstream real-facing limit consumer. It reads the dyadic endpoint ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence row of chapter 301, and the terminal real-name seal of chapter 38. It also records the completion-side compatibility supplied by chapter 1639, the real-facing consumer boundary of chapter 1544, and the extension-and-uniqueness surface of chapter 397. The packet is a finite NameCert bridge from regular Cauchy sequence data to a displayed limit seal; it is not a quotient stream construction, a selected host limit, countable choice, open-cover compactness, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 1794.1 (RegularCauchySequentialCompleteness carrier)**.** *A* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, M, L, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic endpoints and comparison budgets used to inspect the regular Cauchy sequence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the inspected stream windows needed by the sequential-completeness request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row read from the windows in S and the tolerance ledger in D.*
4. *M is the regular Cauchy modulus row, assigning each displayed dyadic tolerance a finite tail threshold for the sequence row R.*
5. *L is the displayed* $\mathsf{Real}^{\uparrow}$ *limit seal reached from R through the same D, S, M route.*
6. *U is the completion-universal compatibility row, read through* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *after the Bishop regular-Cauchy completion surface has supplied the source and limit routes.*
7. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular sequence row, modulus row, limit seal, universal-property row, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from a sequential-completeness request through M, D, S, R, L, U.*
9. *P is the* Pkg *provenance over* RegularCauchySequentialCompleteness$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BishopRegularCauchyCompletion$^{\uparrow}$, RealSequentialCompleteness$^{\uparrow}$, CompletionUniversalProperty BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchySequentialCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, M, L, U, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected host limits, countable choice, open-cover compactness, host real equality, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ BEDC.Derived.RegularCauchySequentialCompletenessUp.RegularCauchySequentialCompletenessUpTasteGa
single carrier alignment

Theorem 1794.2 (RegularCauchySequentialCompleteness NameCert obligations)**.** *For every accepted* RegularCauchySequentialCompleteness$^{\uparrow}$ *carrier $Q = (D, S, R, M, L, U, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchySequentialCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance ledger, stream-window row, regular rational sequence row, regular Cauchy modulus, limit seal, completion-universal compatibility row, transport, replay, provenance, and local naming row;*
2. *classifier stability, requiring componentwise* hsame *transport in H to preserve the rows D, S, R, M, L, U before the local classifier identifies two accepted packets;*
3. *regular-sequence tail control, requiring each tolerance request to read its finite threshold from M and then inspect the corresponding S, R, D rows;*
4. *limit-seal handoff, requiring the displayed* Real$^{\uparrow}$ *row L to be reached only after the regular Cauchy route M, D, S, R has been replayed;*
5. *completion compatibility, requiring the* CompletionUniversalProperty$^{\uparrow}$ *row U to be read only after the Bishop regular-Cauchy completion source route and the displayed limit seal have both been exposed;*
6. *ledger non-escape, requiring P and N to export no quotient streams, selected host limits, countable choice, open-cover compactness, host real equality, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1794.1. The visible packet consists of the dyadic ledger D, finite windows S, regular sequence row R, modulus row M, limit seal L, universal-property row U, and the structural rows H, C, P, N.

Classifier stability is componentwise. The transport row H preserves the displayed analytic rows and the structural rows, so a classified replacement cannot change the tolerance ledger, stream windows, regular readback, threshold schedule, limit seal, or universal-property compatibility route.

Regular-sequence tail control is forced by the order of the replay row C. A tolerance request first reads its threshold from M, then inspects the finite windows S, the regular rational readback R, and the dyadic ledger D attached to that threshold.

The limit-seal handoff and completion compatibility are downstream of the same route. The Real$^{\uparrow}$ seal L is reached only after M, D, S, R have been displayed, and the row U is then read as the completion-universal compatibility surface attached to that visible source-and-limit pair.

Finally, P and N record only provenance and local naming for the listed rows. Since no excluded coordinate occurs in the carrier, the local NameCert surface is exhausted by the six obligations displayed above. □

Theorem 1794.3 (RegularCauchy sequential tail seal)**.** *Let $Q = (D, S, R, M, L, U, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier. Any consumer reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal L must first expose a dyadic tolerance in D, the finite* $\mathsf{StreamName}^{\uparrow}$ *window in S, the regular rational readback in R, and the threshold/modulus row M. Componentwise* hsame *transport and displayed* Cont *replay preserve that route before L is consumed, so the carrier exports no quotient stream equality, selected host limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. The rows available before the terminal seal are the dyadic ledger D, stream-window row S, regular rational readback R, modulus row M, and the structural rows that transport and replay them.

Use the replay order in Definition 1794.2. A tolerance request reads its dyadic budget in D, exposes the inspected finite window in S, obtains the regular rational readback in R, and then reads the threshold/modulus row M before the terminal row L is available.

The transport and replay rows do not add a second route. Componentwise hsame in H preserves the displayed rows, while Cont replay in C repeats the same tolerance-window-readback-threshold path.

Finally apply the ledger non-escape rows P, N. Since the excluded quotient, host-limit, choice, host-equality, and ambient-completeness objects are not coordinates of the carrier, no consumer of L can export them. □

Theorem 1794.4 (RegularCauchySequentialCompleteness limit seal)**.** *Let $Q = (D, S, R, M, L, U, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier. Every real-facing sequential-completeness consumer of Q reaches the displayed limit only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BishopRegularCauchyCompletion}^{\uparrow},\ \mathsf{CompletionUniversalProperty}$$

The limit seal is the row L read after M, D, S, R and before U is consumed; it is not a selected host limit, quotient representative, countable-choice output, open-cover compactness consequence, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier Q. The only rows available to a real-facing consumer before the limit read are M, D, S, R together with the transport and replay rows that preserve their displayed order.

The consumer first reads the regular Cauchy request through M. The threshold supplied by M selects the finite stream windows in S, the regular rational readback in R, and the dyadic tolerance comparisons in D.

Only after that route is displayed can the consumer read L as the $\mathsf{Real}^{\uparrow}$ limit seal. The completion-universal row U is then available as compatibility data for the same visible route, not as a second source of limits.

The excluded objects are absent from the tuple. Hence the limit seal cannot be obtained by quotient streams, host representatives, choice, open covers, or an ambient completeness principle. □

Theorem 1794.5 (RegularCauchySequentialCompleteness modulus-limit determinacy)**.** *Let $Q = (D, S, R, M, L, U, H, C, P, N)$ and $Q' = (D', S', R', M', L', U', H', C', P', N')$ be accepted* RegularCauchySequentialCo

carriers. Suppose the transport rows display componentwise hsame *comparison between D and D', between S and S', between R and R', and between M and M'. Suppose also that C and C' give compatible displayed* Cont *replay for the same dyadic tolerance request through those transported rows. Then the two real-facing sequential-completeness reads reach the same displayed limit-seal route before either U or U' is consumed.*

Equivalently, the displayed seal comparison is determined by the transported modulus-source route M, D, S, R. No quotient stream, selected host limit, countable-choice row, host representative, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate can separate the seal route of Q from the seal route of Q'.*

Proof. Project both accepted carriers. By Definition 1794.2, classifier stability sees the dyadic ledger, stream-window row, regular rational readback, and modulus row only through componentwise hsame transport. Thus the displayed source route for the fixed tolerance request is the transported route M, D, S, R on the first carrier and the matching route M', D', S', R' on the second carrier.

The compatible Cont replay rows preserve the order of that route. The request first reads the modulus threshold, then the finite stream windows, then the regular rational sequence row and the dyadic comparison ledger. The two replays therefore expose the same finite source information before any completion-universal compatibility row is available.

Apply Definition 1794.4 to each carrier. In both reads, the $\mathsf{Real}^{\uparrow}$ seal is reached exactly after the displayed M, D, S, R route and strictly before the corresponding U row is consumed. Since the source route has already been identified by transport and compatible replay, the two reads display the same limit-seal route.

The remaining excluded data are not coordinates of either carrier before the seal. Quotient streams, selected host limits, countable choice, host representatives, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness therefore have no local row by which they could distinguish the two displayed seal routes. □

Theorem 1794.6 (RegularCauchySequentialCompleteness nonescape)**.** *Every completion-facing or real-facing read of an accepted* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier $Q = (D, S, R, M, L, U, H, C, P, N)$ is exhausted by the rows $D, S, R, M, L, U, H, C, P, N$. Thus the local packet exports only dyadic tolerances, finite stream windows, regular rational sequence data, regular Cauchy modulus thresholds, a displayed* $\mathsf{Real}^{\uparrow}$ *limit seal, completion-universal compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming data.*

It exports no quotient streams, selected host limits, countable choice, open-cover compactness, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. The carrier tuple lists every row admitted by the local certificate. A completion-facing or real-facing consumer can therefore obtain only $D, S, R, M, L, U, H, C, P, N$ by projection.

The structural rows do not enlarge the analytic surface. The hsame row transports already displayed coordinates, the Cont row replays the same ordered route, and the provenance and naming rows record the finite source of the packet.

Since the excluded objects are not coordinates of the carrier and are not produced by the replay route, no accepted read can escape the displayed regular-Cauchy sequential-completeness boundary. □

Theorem 1794.7 (RegularCauchySequentialCompleteness scoped kernel route)**.** *Every accepted* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier factors through the displayed L10 finite rows*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{BishopRegularCauchyCompletion}^{\uparrow} \longrightarrow \mathsf{RealSequer}$$

The factorization reads the dyadic tolerance rows, finite stream windows, regular rational readback, terminal limit seal, Bishop regular-Cauchy completion route, real-sequential-completeness consumer boundary, and completion-universal handoff in that order. It exports no quotient stream, selected limit, countable-choice witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier definition. The available analytic rows are the dyadic ledger D, finite windows S, regular rational sequence row R, modulus row M, displayed limit seal L, and completion-universal row U.

Use the limit-seal theorem to locate the $\mathsf{Real}^{\uparrow}$ read. It places L after the displayed M, D, S, R route and before the completion-universal row is consumed.

Use modulus-limit determinacy and nonescape. These results keep every real-facing read inside the transported finite rows and prevent quotient streams, selected limits, countable choice, and ambient completeness from entering as hidden coordinates.

Finally read the sibling dependencies in the order named in the chapter introduction: DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, RealUp seal, Bishop regular-Cauchy completion, RealSequentialCompleteness boundary, and CompletionUniversalProperty handoff. □

Theorem 1794.8 (RegularCauchySequentialCompleteness obligation surface)**.** *For every accepted* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *carrier*

$$Q = (D, S, R, M, L, U, H, C, P, N),$$

the rows $D, S, R, M, L, U, H, C, P, N$ *jointly supply the obligation surface for carrier admission, classifier stability, regular tail control, limit-seal handoff, completion compatibility, and ledger non-escape. This surface is exactly the displayed regular-Cauchy sequential-completeness route: it reads dyadic tolerances, finite windows, regular rational sequence data, modulus thresholds, a displayed* $\mathsf{Real}^{\uparrow}$ *limit seal, completion-universal compatibility, transport, replay, provenance, and local naming, and no quotient stream, selected host limit, countable-choice witness, open-cover compactness row, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Carrier admission and classifier stability are the first two obligations of Definition 1794.2. They identify $D, S, R, M, L, U, H, C, P, N$ as the whole accepted packet and make classifier transport componentwise through those rows.

Regular tail control and the limit-seal handoff are supplied by the same obligation theorem together with Definition 1794.4. These results place each tolerance request through M, D, S, R before L is exposed.

Completion compatibility is the downstream part of Definition 1794.7. It routes the displayed limit through the Bishop regular-Cauchy completion, real-sequential-completeness, and completion-universal surfaces without adding another analytic row.

Ledger non-escape is given by Definition 1794.5 and Definition 1794.6. They keep all transported reads inside the finite tuple and exclude quotient streams, selected host limits, choice, open covers, host equality, and ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, a RegSeqRat regular rational sequence row, a regular Cauchy modulus row, a displayed RealUp limit seal, a CompletionUniversalProperty compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1794.1, Definition 1794.2, Definition 1794.4, Definition 1794.5, and Definition 1794.6 seed the finite regular-Cauchy sequential-completeness surface between $\mathsf{RegSeqRat}^{\uparrow}$ data and the displayed $\mathsf{Real}^{\uparrow}$ limit seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySequentialCompleteness}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchySequentialCompletenessUp.RegularCauchySequentialCompletenessUpTasteGate\_s`

Bridge status: none

Not claimed: This chapter excludes quotient streams, selected host limits, countable choice, open-cover compactness, Real completeness as an ambient principle, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, regular-sequence tail control, limit-seal handoff, completion compatibility, and ledger non-escape for BEDC.Derived.RegularCauchySequentialCompletenessUp.

Chapter 1795

A Concrete Naming Certificate for $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$

Following Bishop and Bridges constructive completion and the Bourbaki-Kelley universal-mapping language, the packet records the two triangle composites for the Cauchy-completion adjunction as finite BEDC routes. It reads the monad packet of chapter 378, the unit packet of chapter 1527, the counit packet of chapter 1539, the adjunction packet of chapter 1456, the idempotence packet of **??**, the stream-name surface of chapter 126, the regular rational route of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter gives later completion associativity, functoriality, and Real-facing handoff packets a finite triangle-identity surface rather than a host categorical equality.

Definition 1795.1 (CauchyCompletionTriangleIdentity carrier)**.** *A* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, U, V, A, I, L, R, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row, including the finite unit-and-bind ledger used by completion consumers before any triangle composite is inspected.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row, admitting source* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data into the completion route.*
3. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *row, returning already-completed reads without selecting representatives or host limits.*
4. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *row, naming the unit-counit correspondence and its finite universal-mapping ledger.*
5. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *row, recording that a second completion pass reuses the same completion surface rather than adding a new quotient carrier.*
6. *L is the left triangle route ledger, from source admission through completion, counit return, adjunction comparison, and idempotent reuse.*
7. *R is the right triangle route ledger, from completed input through unit replay, monad bind, counit return, adjunction comparison, and idempotent reuse.*
8. *S is the* $\mathsf{StreamName}^{\uparrow}$ *handoff row, exposing only finite stream windows used by M, U, V, A, I, L, R.*

9. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *handoff row, recording tolerance budgets and dyadic comparison steps available to the two route ledgers.*
10. *E is the joint* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, sealing regular rational reads into the real-name boundary after the two triangle ledgers have been displayed.*
11. *H records componentwise* hsame *transport for the monad, unit, counit, adjunction, idempotence, left route, right route, stream, dyadic, real-regular handoff, continuation, provenance, and naming rows.*
12. *C records displayed* Cont *replay from source windows and regular rational reads through the unit, counit, adjunction, idempotence, both triangle ledgers, dyadic tolerance, real-name seal, and local naming rows.*
13. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}}$ *row.*

The carrier exposes only the finite triangle-coherence boundary. It contains no quotient completion, no selected representative, no host function equality, no countable-choice selector, no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, and no bridge-checked route.*

Lean4 (definition) `BEDC.Derived.CauchyCompletionTriangleIdentityUp.CauchyCompletionTriangleIdentityUp`

Theorem 1795.2 (CauchyCompletionTriangleIdentity NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *carrier* $T = (M, U, V, A, I, L, R, S, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed monad, unit, counit, adjunction, idempotence, left route, right route, stream, dyadic, real-regular, transport, continuation, provenance, and naming rows;*
2. *left triangle exactness, requiring every source-side triangle read to pass through U, M, V, A, I, L before it can be exported;*
3. *right triangle exactness, requiring every completed-side triangle read to pass through M, U, V, A, I, R before it can be exported;*
4. *handoff discipline, requiring all finite observations to use S, all dyadic budgets to use D, and all real or regular rational reads to use E;*
5. *route exhaustion, requiring H, C, P, N to replay and name no row except the displayed carrier rows;*
6. *non-escape, requiring the packet to export no quotient completion, selected representative, host function equality, countable choice, ambient real completeness, or bridge-checked coherence theorem.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1795.1. The packet displays the monad, unit, counit, adjunction, idempotence, two route ledgers, three handoff rows, transport, continuation, provenance, and local name.

The left and right triangle obligations are read separately. The left route ledger L starts from source admission through U, then reads the completion surface through M, returns through V, compares through A, and reuses completion through I.

The right route ledger R starts from completed input, replays unit and bind through M and U, returns through V, compares through A, and records repeated completion through I. Thus each triangle composite has a named finite route before any consumer inspects it.

The handoff rows are then forced by projection. Finite stream observations are in S, dyadic tolerances are in D, and real or regular rational reads are in E.

Finally, H, C, P, N transport, replay, package, and name only the displayed rows. Since quotient completions, selected representatives, host function equality, countable choice, ambient real completeness, and bridge checking are absent from those rows, the non-escape obligation follows by route exhaustion. □

Theorem 1795.3 (CauchyCompletionTriangleIdentity left route)**.** *Let* $T = (M, U, V, A, I, L, R, S, D, E, H, C, P, N$ *be an accepted* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *carrier. Every source-side completion read exported by the packet factors through the finite left triangle route*

$$S, E \longmapsto U \longmapsto M \longmapsto V \longmapsto A \longmapsto I \longmapsto L \longmapsto H, C, P, N.$$

The route identifies the source admission followed by completed return with the original finite completion-facing read only through the displayed rows.

Proof. Begin with a source-side read. The only source windows available to the packet are the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ coordinates displayed in S and E.

Project the unit row U to admit those windows into the completion route. The monad row M supplies the completion surface, while the counit row V supplies the return from the completed side.

The adjunction row A is the comparison ledger for this composite, and the idempotence row I records that no second completion carrier is created. The left route row L stores exactly this source-side order.

The structural rows H, C, P, N then transport, replay, package, and name the same route. Because no other row is displayed, the source-side triangle read cannot appeal to representative selection, host equality, choice, ambient completeness, or bridge checking. □

Theorem 1795.4 (CauchyCompletionTriangleIdentity right route)**.** *Let* $T = (M, U, V, A, I, L, R, S, D, E, H, C, P,$ *be an accepted* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *carrier. Every completed-side read exported by the packet factors through the finite right triangle route*

$$E, D \longmapsto M \longmapsto U \longmapsto V \longmapsto A \longmapsto I \longmapsto R \longmapsto H, C, P, N.$$

The route identifies completed input followed by unit replay and counit return with the original completed read only through the displayed rows.

Proof. Begin with a completed-side read. The available completed observation is the real and regular-rational handoff row E, together with the dyadic tolerance row D needed by the completion ledger.

Project M to expose the completion surface, then replay unit information through U and return through V. These projections are interpreted through the adjunction row A.

The idempotence row I records that the repeated completion request reuses the same surface. The right route row R stores exactly this completed-side order.

The rows H, C, P, N close the route by transport, continuation, provenance, and local naming. Since the route is exhausted by displayed rows, the packet exports no quotient completion, selected representative, host function equality, countable choice, ambient real completeness, or bridge-checked theorem. □

Theorem 1795.5 (CauchyCompletionTriangleIdentity Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *packet is obtained after the left or right triangle route has passed through the shared* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *handoff rows. The handoff is exhausted by the carrier of Definition 1795.1, the obligations of Definition 1795.2, the left route of Definition 1795.3, and the right route of Definition 1795.4.*

Proof. The provenance row P names the available sibling packets: $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 1795.3 for source-side consumers and Definition 1795.4 for completed-side consumers. In both cases the route reaches the handoff rows before the local name is consumed.

Now project S, D, E. The finite stream window is read from S, the dyadic budget is read from D, and the regular rational plus real-name seal is read from E.

By Definition 1795.2, no additional handoff row exists. Hence every Real-facing read is routed through the displayed finite triangle-coherence packet and cannot obtain quotient completion data, selected representatives, host function equality, countable choice, ambient real completeness, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ packet is generated from Cauchy-completion monad, unit, counit, adjunction, idempotence, left-route, right-route, StreamName, DyadicRatCore, Real-RegSeqRat handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1795.1, Definition 1795.2, Definition 1795.3, Definition 1795.4, and Definition 1795.5 seed the finite triangle-identity coherence boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier and route proofs for BEDC.Derived.CauchyCompletionTriangleIdentityUp, including both triangle ledgers and the StreamName-RegSeqRat-DyadicRatCore-Real handoff.

Chapter 1796

A Concrete Naming Certificate for $\mathsf{MetricCompletionUniqueness}^{\uparrow}$

Following Bishop–Bridges separated completion uniqueness and the Bourbaki presentation of completions by universal dense maps, the $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ packet records the finite BEDC boundary at which two completion presentations over the same metric source may be compared. It consumes the dense embedding route of chapter 1512, the finite-window completion handoff of chapter 1559, the separated classifier route of chapter 1790, and the general separated-completion boundary of chapter 1612. The packet names uniqueness only as a routed comparison between presentations; it does not introduce quotient completion objects, selected representatives, or host equality of completed points.

Definition 1796.1 (MetricCompletionUniqueness carrier)**.** *A* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, E_0, F_0, R_0, S_0, E_1, F_1, R_1, S_1, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the common* $\mathsf{Met}^{\uparrow}$ *source row whose point classifier and distance witnesses are shared by both completion-facing presentations.*
2. *E_i is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *dense row for presentation $i \in \{0, 1\}$, recording how source observations enter that presentation.*
3. *F_i is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *handoff row for presentation i, exposing only finite-window completion reads downstream of M and E_i.*
4. *R_i is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier route for presentation i, comparing completion-facing reads by separated zero-distance evidence.*
5. *S_i is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *uniqueness boundary for presentation i, read over the same M, E_i, F_i, R_i route.*
6. *Q is the local comparison ledger. It records that both presentations read the same source row M, that dense rows are consumed before finite handoff rows, that classifier routes are consumed before uniqueness rows, and that the comparison never leaves the displayed separated routes.*
7. *H stores componentwise* hsame *transport for M, the two dense rows, the two finite handoff rows, the two separated-reflection rows, the two separated-completion rows, the comparison ledger, and the structural rows.*

8. *C stores displayed* Cont *replay from source metric observations through each dense row, finite handoff, separated classifier, separated-completion boundary, and then through Q.*

9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{MetricCompletionFinite}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$ $\mathsf{SeparatedCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionUniqueness}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected representatives, host equality of completed points, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUniquenessUp.MetricCompletionUniquenessTasteGate single carrier alignment`

Theorem 1796.2 (MetricCompletionUniqueness NameCert obligations)**.** *For every accepted* MetricCompletionUnic *carrier*

$$U = (M, E_0, F_0, R_0, S_0, E_1, F_1, R_1, S_1, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionUniqueness}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the common source metric row, the two dense embedding rows, the two finite completion handoff rows, the two separated-reflection classifier routes, the two separated-completion uniqueness boundaries, the comparison ledger, transport, replay, provenance, and local naming rows;*

2. *common-source agreement, requiring both presentations to read the same M before any completion-facing comparison is admitted;*

3. *dense-to-finite order, requiring each E_i to precede the corresponding finite handoff F_i;*

4. *classifier-before-uniqueness order, requiring each separated-reflection route R_i to precede the corresponding separated-completion boundary S_i;*

5. *comparison exactness, requiring Q to compare only the two displayed routes M, E_i, F_i, R_i, S_i and their structural rows;*

6. *ledger non-escape, excluding quotient completion, selected representatives, host equality of completed points, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Lean4 ✓ `BEDC.Derived.MetricCompletionUniquenessUp.TasteGate.MetricCompletionUniquenessTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1796.1. The tuple lists the common source, the two completion-facing routes, the comparison ledger, and the structural rows.

Common-source agreement is the first dependency. Both presentations expose the same M, so a comparison cannot be formed from unrelated metric sources or from an external completed host space.

Dense-to-finite order is read separately on the two sides. For each i, the dense row E_i is displayed before the finite handoff F_i, so no selected representative or quotient point can replace the source-to-completion route.

Classifier-before-uniqueness order is also sidewise. The separated-reflection route R_i supplies the zero-distance classifier boundary before the separated-completion row S_i is read as a uniqueness boundary.

Finally Q, H, C, P, N compare, transport, replay, source, and name only those displayed rows. Since the carrier has no quotient, representative, host-equality, choice, compactness, ambient-completeness, Lean, or bridge coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1796.3 (MetricCompletionUniqueness separated route)**.** *Every comparison exported by an accepted* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *carrier factors through the finite separated route*

$$M \longmapsto (E_0, F_0, R_0, S_0) \quad \textit{and} \quad M \longmapsto (E_1, F_1, R_1, S_1) \longmapsto Q, H, C, P, N.$$

Thus separated uniqueness is read only after both completion presentations have consumed the same source metric row, dense embedding route, finite completion handoff, separated classifier route, and separated-completion boundary.

Proof. Begin with a consumer comparison admitted by the packet. Carrier admission exposes the two routes and the common source row M.

On each side, the dense row precedes the finite handoff. The consumer therefore reaches F_i only through E_i and never through a selected representative, quotient class, or host completion point.

The separated-reflection row R_i then supplies the classifier route used by the corresponding separated-completion row S_i. This places zero-distance classifier evidence before any uniqueness read.

The comparison ledger Q is downstream of both sidewise routes. The transport and continuation rows H, C preserve the same route, while P, N record provenance and local naming. Hence the exported comparison factors through the displayed separated route and nothing else. □

Theorem 1796.4 (MetricCompletionUniqueness separated classifier exactness)**.** *Let*

$$U = (M, E_0, F_0, R_0, S_0, E_1, F_1, R_1, S_1, Q, H, C, P, N)$$

be an accepted $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *packet. Every uniqueness-facing comparison is classifier-exact only when both presentations read, in order, the common source row M, their dense embedding rows E_0, E_1, their finite handoff rows F_0, F_1, their separated-reflection classifier routes R_0, R_1, their separated-completion boundaries S_0, S_1, and the comparison ledger Q, H, C, P, N. Thus the two completion presentations are compared through the same separated zero-distance classifier route, not through quotient completion equality or host equality of completed points.*

Proof. Apply the NameCert obligations of Definition 1796.2. They require common-source agreement at M, dense-to-finite order along each E_i, F_i side, classifier-before-uniqueness order along each R_i, S_i side, and comparison exactness through Q, H, C, P, N.

Use the separated route theorem, Definition 1796.3. It orders every exported comparison through the two displayed sidewise routes over the same source before the comparison ledger and structural rows can be consumed.

Finally invoke the non-escape theorem, Definition 1796.5. Since quotient completion, selected representatives, host equality of completed points, choice, compactness, ambient completeness, Lean evidence, and bridge evidence are not carrier coordinates, classifier exactness is exhausted by the shared separated zero-distance routes R_0, R_1 and the displayed comparison ledger. □

Theorem 1796.5 (MetricCompletionUniqueness non-escape)**.** *An accepted* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *packet exports no quotient completion, no selected representative, no host equality of completed*

points, no countable-choice schedule, no open-cover compactness row, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, no Lean verification, and no bridge checking. Every uniqueness-facing read is confined to the displayed rows*

$$M, E_0, F_0, R_0, S_0, E_1, F_1, R_1, S_1, Q, H, C, P, N.$$

Proof. Use the NameCert obligations of Definition 1796.2. They enumerate the common source row, the two dense-to-finite completion routes, the two separated classifier and uniqueness routes, the comparison ledger, transport, replay, provenance, and local naming as the whole public surface.

Use the separated route theorem, Definition 1796.3, for any uniqueness-facing comparison. It forces the comparison through M, E_i, F_i, R_i, S_i on both sides before Q, H, C, P, N can be consumed.

No remaining coordinate can supply quotient completion data, representatives, host equality, choice, compactness, ambient completeness, Lean evidence, or bridge evidence. Therefore those excluded objects cannot be projected from an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionUniqueness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1796.1, Definition 1796.2, Definition 1796.3, and Definition 1796.5 seed the separated uniqueness boundary for two metric-completion presentations over the same source metric row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, host equality of completed points, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-source agreement, dense-to-finite order, classifier-before-uniqueness order, comparison exactness, and ledger non-escape for BEDC.Derived.MetricCompletionUniquenessUp.

Constructive story: A $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ packet is generated from a common Metric source row, two CompletionEmbedding dense rows, two MetricCompletionFinite handoff rows, two SeparatedMetricReflection classifier routes, two SeparatedCompletion uniqueness boundaries, a local comparison ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1797

A Concrete Naming Certificate for $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$ packet records the uniqueness of the displayed dyadic embedding route from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ into the $\mathsf{Real}^{\uparrow}$ seal. It sits between the finite dyadic observation ledger of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is a finite route certificate for dyadic constants entering Real-facing completion consumers; it is not a quotient stream, host real equality, a selected limit, trichotomy, ambient Real completeness, or Lean verification.

Definition 1797.1 (Dyadic embedding uniqueness carrier)**.** *A* $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row naming the dyadic constant, its denominator scale, its tolerance cells, and the finite comparison data used by the route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row obtained from D, recording the inspected prefixes through which the dyadic constant is presented as a constant stream.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S, recording the regular rational sequence data read from the same dyadic observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from Q by the displayed finite embedding route.*
5. *E is the uniqueness ledger stating that any second accepted route with the same D, S, Q, R rows is componentwise the same BEDC route after* hsame *transport and* Cont *replay.*
6. *H records componentwise* hsame *transport for D, S, Q, R, E and for the structural rows of the packet.*
7. *C records displayed* Cont *replay from a dyadic observation request through stream windows and regular readback into the terminal Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite route certificate for the dyadic embedding into the Real seal. It contains no coordinate for quotient stream equality, host real equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or Lean verification.*

Lean4 ✓ `BEDC.Derived.DyadicEmbeddingUniquenessUp.DyadicEmbeddingUniquenessTasteGate single carrier alignment`

Theorem 1797.2 (Dyadic embedding uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$ *carrier* $U = (D, S, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic observation row, stream-window row, regular rational readback row, Real seal row, uniqueness ledger, transport row, replay row, provenance row, and local naming row;*
2. *dyadic source exactness, requiring every window in* S *to be read from the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
3. *constant-stream readback, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *to be obtained through* S *without changing the dyadic source or inserting a quotient stream representative;*
4. *Real seal route admission, requiring the* $\mathsf{Real}^{\uparrow}$ *row* R *to be exposed only after* D, S, Q *have been displayed in that order;*
5. *uniqueness stability, requiring* E, H, C *to identify any second accepted route by componentwise* hsame *transport and displayed* Cont *replay over the same rows;*
6. *ledger nonescape, requiring* P *and* N *to export no quotient stream equality, host real equality, selected limit, trichotomy, ambient Real completeness, or Lean verification witness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1797.1. The tuple displays exactly the dyadic observation row, stream windows, regular rational readback, Real seal, uniqueness ledger, componentwise transport, continuation replay, provenance, and local name.

Dyadic source exactness is the ordering of D before S. A consumer can inspect a constant-stream window only after the finite dyadic observation row has named the denominator scale, tolerance cells, and comparison data used by that window.

Constant-stream readback is the row Q read through S. Since Q is attached to the same displayed windows and the carrier has no quotient-stream coordinate, the readback cannot replace the dyadic source by an unshown representative.

The Real seal route admission is the displayed path D, S, Q, R. The Cont row C replays requests through that order, and the hsame row H transports only the same listed coordinates.

Uniqueness stability is the role of E. If another accepted packet presents the same dyadic observation, stream-window, readback, and Real-seal rows, E permits only componentwise hsame transport and the replay already stored in C, so no second route can add a distinct witness.

Finally, P and N package only the named finite dependencies. Because the carrier has no coordinate for quotient streams, host real equality, selected limits, trichotomy, ambient completeness, or Lean verification, the listed rows exhaust the local NameCert surface. □

Theorem 1797.3 (Dyadic embedding uniqueness Real seal route)**.** *Every accepted* $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$ *carrier* $U = (D, S, Q, R, E, H, C, P, N)$ *exposes a unique finite BEDC route*

$$D \longmapsto S \longmapsto Q \longmapsto R \longmapsto E, H, C, P, N$$

from the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *observations into the* $\mathsf{Real}^{\uparrow}$ *seal. Any Real-facing consumer receives the dyadic constant only through this route and receives no quotient stream equality, host real equality, selected limit, trichotomy, ambient Real completeness, or Lean verification witness.*

Proof. Start with an accepted packet $U = (D, S, Q, R, E, H, C, P, N)$. Projection gives the finite dyadic observation row D as the only source coordinate for the dyadic constant.

The stream-window row S is downstream of D, and the regular rational readback Q is downstream of those windows. Thus every Real-facing read first passes through the displayed dyadic observations and their finite constant-stream presentation.

The Real seal row R is exposed only after Q has been read. The continuation row C records this replay order, while the transport row H preserves the same coordinates componentwise.

The uniqueness ledger E then blocks competing finite routes over the same displayed rows. A second accepted route with the same D, S, Q, R data is identified by the hsame and Cont rows already present in the packet, rather than by a host equality principle or an external selected limit.

The provenance and local naming rows P, N do not enlarge the surface. They name the finite route and exclude quotient streams, host real equality, selected limits, trichotomy, ambient completeness, and Lean verification as source witnesses. Hence the Real seal receives exactly the displayed unique finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}}$, seed)

Scope closed: Definition 1797.1, Definition 1797.2, and Definition 1797.3 seed the finite uniqueness route from DyadicRatCore observations through StreamName and RegSeqRat into the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, trichotomy, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dyadic source exactness, constant-stream readback, Real seal route admission, uniqueness stability, and ledger nonescape proofs for BEDC.Derived.DyadicEmbeddingUniquenessUp.

Constructive story: A $\mathsf{DyadicEmbeddingUniqueness}^{\uparrow}$ packet is generated from a DyadicRatCore observation row, StreamName windows, RegSeqRat readback, a RealUp seal, a uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1798

A Concrete Naming Certificate for $\mathsf{BisectionRootCauchySeal}^{\uparrow}$

Following Bishop–Bridges constructive bisection, the $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ packet records the finite route by which sign-change bisection data become a regular Cauchy read and then a Real-facing seal. It sits after the located-sign surface of chapter 1402 and the bracket surface of chapter 1786, and it hands its retained windows to the finite stream, regular rational, dyadic tolerance, and real-name interfaces of chapter 126, chapter 301, chapter 291, and chapter 38. The certificate names the bisection-to-Cauchy seal route; it does not select a root, quotient real names, or import ambient completeness.

Definition 1798.1 (BisectionRootCauchySeal carrier)**.** *A* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, S, M, V, B, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row. It records the initial lower and upper endpoint windows, their rational or dyadic cells, the endpoint order evidence, and the interval identity inherited by each retained branch.*
2. *S is the sign row. It stores the displayed opposite endpoint signs and the branch orientation used by the bisection route.*
3. *M is the modulus row. It records the requested regular Cauchy tolerance, the bisection depth sufficient for that tolerance, and the endpoint precision consumed by sign and midpoint reads.*
4. *V is the* $\mathsf{IntermediateValue}^{\uparrow}$ *ledger row. It records the finite located-sign obligation surface that admits the sign-change interval and its displayed continuity data.*
5. *B is the branch ledger. It stores the finite bisection choices, midpoint sign rows, retained subintervals, and regularity checks for the requested depth.*
6. *W is the retained-window row. It records the lower and upper windows retained after the branch prefix and the diameter comparison demanded by the regular Cauchy read.*
7. *R is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It exposes the retained bisection windows as finite stream observations, one request depth at a time.*

8. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row. It stores the regular rational readback, dyadic tolerance rows, midpoint-radius bounds, and rounding discipline used by completion-facing consumers.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is available only after the retained windows and regular readback rows have been read.*

10. *H records componentwise* hsame *transport for the interval, signs, modulus, intermediate-value ledger, branch ledger, retained windows, stream windows, regular and dyadic readback, Real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a root-location or completion request through endpoint inspection, sign inspection, modulus use, intermediate-value admission, finite bisection, retained-window exposure, regular readback, and Real-seal consumption.*

12. *P is the* Pkg *provenance over* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionRootCauchySeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, M, V, B, W, R, D, E, H, C, P, N$. It has no coordinate for selected roots, quotient reals, real trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host root equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BisectionRootCauchySealUp.TasteGate.BisectionRootCauchySealTasteGate`
`single carrier alignment`

Theorem 1798.2 (BisectionRootCauchySeal NameCert obligations)**.** *For every accepted* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *carrier*

$$X = (I, S, M, V, B, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BisectionRootCauchySeal}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the interval, signs, modulus, intermediate-value ledger, branch ledger, retained windows, stream windows, regular and dyadic readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *endpoint, sign, and modulus discipline, requiring I, S, M to display the initial sign-change interval, the precision budget, and the bisection depth before any retained window is exposed;*

3. *finite bisection branch regularity, requiring V and B to keep every midpoint sign row, branch choice, retained interval, and diameter comparison attached to the same displayed sign-change packet;*

4. *StreamName, RegSeqRat, and Dyadic handoff, requiring W, R, D to expose retained windows first as finite stream observations and then as regular rational readback with dyadic tolerance rows;*

5. *Real-seal nonescape, requiring E, H, C, P, N to export only the displayed bisection-to-Cauchy route and no selected root, quotient real equality, real trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host root equality, Lean verification, or bridge checking.*

No BisectionRootCauchySeal obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1798.1. The accepted packet displays exactly the interval, signs, modulus, intermediate-value ledger, branch ledger, retained windows, regular readback, Real seal, and structural rows.

The endpoint, sign, and modulus discipline is the entry stage. The rows I, S, and M must be read before a branch prefix can be inspected, so the packet cannot replace the finite sign-change data by a host interval or selected root.

Finite bisection branch regularity is the middle stage. The row V admits the located-sign surface, while B records only midpoint signs and retained intervals produced from that surface at the depth requested by M.

The StreamName, RegSeqRat, and Dyadic handoff is the readback stage. The retained windows W are exposed through R as finite stream observations and through D as regular rational and dyadic tolerance rows before the Real seal is available.

Finally, E, H, C, P, N seal, transport, replay, package, and name the same route. Since the omitted principles have no coordinates in the carrier, none of the five obligation rows can export them. □

Theorem 1798.3 (BisectionRootCauchySeal regular handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing root-location read of an accepted* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *carrier factors through the displayed finite bisection route*

$$I, S, M, V \longmapsto B \longmapsto W \longmapsto R, D \longmapsto E, H, C, P, N$$

before consuming the $\mathsf{Real}^{\uparrow}$ *seal. The read first opens the sign-change interval and modulus rows, then the finite branch ledger, then the retained windows, then the StreamName, RegSeqRat, and Dyadic readback rows, and only then the Real-facing seal. The handoff exports a regular Cauchy seal surface rather than a selected root or host equality theorem.*

Proof. Start with an accepted packet $X = (I, S, M, V, B, W, R, D, E, H, C, P, N)$. The only entry coordinates for a root-location read are the interval, sign, and modulus rows I, S, M, together with the intermediate-value ledger V.

The bisection stage is then forced through B. This row stores the finite branch prefix, midpoint signs, retained intervals, and diameter comparisons, so no downstream consumer can read a regular Cauchy window before the branch data have been fixed.

The regular readback stage is W, R, D. The retained windows in W become finite stream observations through R, and the regular rational and dyadic tolerance rows in D supply the completion-facing read.

The Real-facing stage is terminal. The seal E is consumed only after the regular readback route is fixed, while H, C, P, N transport, replay, package, and name the same finite route. Thus every listed read factors through the displayed bisection route before it reaches the $\mathsf{Real}^{\uparrow}$ seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionRootCauchySeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ packet is generated from an interval row, endpoint sign rows, a modulus row, an $\mathsf{IntermediateValue}^{\uparrow}$ ledger, a finite bisection branch ledger, retained windows, $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionRootCauchySeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1798.1, Definition 1798.2, and Definition 1798.3 seed the finite route from constructive bisection data through regular Cauchy readback and Real-facing seal rows.

Lean target: `BEDC.Derived.BisectionRootCauchySealUp.TasteGate.BisectionRootCauchySealTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close selected roots, quotient reals, real trichotomy, open-cover compactness, ambient $\mathrm{Real}^{\uparrow}$ completeness, host root equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint/sign/modulus discipline, finite bisection branch regularity, StreamName/RegSeqRat/Dyadic handoff, Real-seal nonescape, and regular-handoff factorization for BEDC.Derived.BisectionRootCauchySealUp.

Chapter 1799

A Concrete Naming Certificate for $\mathsf{SummableTailModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SummableTailModulus}^{\uparrow}$ packet records the finite tail-summability modulus by which a summable error schedule is turned into dyadic tolerance control before any completion-facing or Real-facing consumer reads a boundary. It sits over the majorant-series route of chapter 1774, the squeeze route of chapter 1772, the dyadic tolerance scale of chapter 1768, the finite StreamName interface of chapter 126, the RegSeqRat readback route of chapter 301, the Bishop regular Cauchy completion boundary of chapter 1639, and the terminal Real seal of chapter 38. The packet gives Real and Completion tail-control arguments one BEDC-finite modulus surface rather than letting them infer a hidden summability witness from quotient streams, selected limits, or ambient completeness.

Definition 1799.1 (Summable tail modulus carrier)**.** *A* $\mathsf{SummableTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, D, S, R, B, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the summable tail modulus row. It records the displayed summability schedule, the finite partial-tail ledger, and the tail index assigned to each requested tolerance.*
2. *D is the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *tolerance row consumed by M, including the dyadic precision budget and comparison slack for the displayed tail request.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened at the tail index named by M and budgeted by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite window after the summability schedule and tolerance scale have been displayed.*
5. *B is the Bishop regular Cauchy completion boundary row, recording that the regular readback reaches a completion-facing boundary only by the displayed M, D, S, R route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after M, D, S, R, B have been read.*
7. *H records componentwise* hsame *transport for the summable tail modulus, dyadic tolerance, StreamName window, RegSeqRat readback, completion boundary, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tail-control request through $M, D, S, R, B, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{RegularCauchySqueeze}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SummableTailModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, S, R, B, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SummableTailModulusUp.SummableTailModulusTasteGate single carrier alignment`

Theorem 1799.2 (Summable tail modulus NameCert obligations)**.** *For every accepted* $\mathsf{SummableTailModulus}^{\uparrow}$ *carrier*

$$T = (M, D, S, R, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummableTailModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the summable tail modulus row, dyadic tolerance row, StreamName finite window, RegSeqRat readback, Bishop regular Cauchy completion boundary, Real seal, transport, replay, provenance, and local naming rows;*
2. *summability schedule exactness, requiring M to store the displayed summability ledger and the tail index attached to each dyadic tolerance request;*
3. *monotone tail-index stability, requiring later displayed tolerances to reuse or enlarge the tail index recorded by M without replacing it by a hidden selector;*
4. *tolerance compatibility, requiring D to be the same dyadic scale consumed by M and later by the finite window S;*
5. *readback handoff, requiring S and R to expose only the finite StreamName window and RegSeqRat data opened by the scheduled tail request;*
6. *completion-boundary handoff, requiring B to consume M, D, S, R before any completion-facing boundary is visible;*
7. *Real-seal non-escape, requiring E to be terminal with respect to M, D, S, R, B and to export no quotient equality, selected limit, countable-choice schedule, trichotomy, host equality, ambient completeness, Lean verification, or bridge data;*
8. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No summable tail modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1799.1. The visible packet consists exactly of the summable tail modulus row M, dyadic tolerance row D, finite StreamName window S, RegSeqRat readback R, completion boundary B, Real seal E, and structural rows H, C, P, N.

Summability schedule exactness is the local content of M. The row stores the finite partial-tail ledger and the tail index for each displayed tolerance request, so the schedule is not recovered from an unrecorded convergence theorem or selected limit.

Monotone tail-index stability follows from the same row. Later displayed tolerances may reuse or enlarge the named tail index, but the carrier has no separate selector that could replace the finite schedule after the request has entered M.

Tolerance compatibility and readback handoff are downstream. The row D is the only dyadic budget consumed by the scheduled request and the window row S, while R reads back only the observations opened by that window.

Finally, B, E, H, C, P, N expose the completion boundary, terminal seal, transport, replay, provenance, and local name along the same displayed route. Since the excluded objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1799.3 (Summable tail modulus regular Cauchy criterion)**.** *Let*

$$T = (M, D, S, R, B, E, H, C, P, N)$$

be an accepted $\mathsf{SummableTailModulus}^{\uparrow}$ *carrier. Every accepted summable tail request routes through the finite chain*

$$M \longmapsto D \longmapsto S \longmapsto R$$

before any completion boundary is exposed. Consequently the request reaches B only after it has displayed the summability schedule, dyadic tolerance budget, finite StreamName window, and RegSeqRat readback.

Proof. Project the accepted carrier. The only coordinate that stores summability data is M, and the only coordinate that stores the tolerance budget for that data is D.

The finite observation route is then forced by the tuple order. The StreamName row S opens the window named by the modulus row and budgeted by the tolerance row, and the RegSeqRat row R reads back that finite window.

The completion boundary B is downstream of M, D, S, R. Therefore a completion-facing consumer cannot expose B before the summable tail request has passed through the displayed modulus, tolerance, window, and readback rows. □

Theorem 1799.4 (Summable tail modulus Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{SummableTailModulus}^{\uparrow}$ *carrier reads the terminal seal E only after the finite route*

$$M \longmapsto D \longmapsto S \longmapsto R \longmapsto B \longmapsto E$$

has been displayed. The consumer receives the routed summable tail modulus, dyadic tolerance, finite StreamName window, RegSeqRat readback, completion boundary, and terminal Real seal, but receives no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Read the Real-facing request through Definition 1799.3. Before the request reaches any completion boundary, it has already displayed the modulus, tolerance, window, and readback rows.

The seal row E is listed after the completion boundary B in Definition 1799.1. Thus every Real-facing consumer reaches E only after the displayed M, D, S, R, B route.

The structural rows H, C, P, N transport, replay, source, and name that route. They add no quotient coordinate, selected limit, choice operator, trichotomy principle, host equality predicate, ambient completeness theorem, Lean verification row, or bridge datum. □

Falsifiable prediction: Every $\mathsf{SummableTailModulus}^{\uparrow}$ Real-facing tail-control read factors through one summable tail modulus row, one DyadicToleranceScale row, one StreamName finite window, one RegSeqRat readback row, one Bishop regular Cauchy completion boundary row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-majorant-series, regular-cauchy-squeeze, dyadic-tolerance-scale, streamname, regseqrat, real: $\mathsf{SummableTailModulus}^{\uparrow}$ is not bijective to any listed sibling because

it jointly carries a summable tail schedule, monotone tail-index stability, dyadic tolerance control, finite observation window, regular rational readback, and a completion-to-Real seal handoff as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SummableTailModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SummableTailModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1799.1, Definition 1799.2, Definition 1799.3, and Definition 1799.4 seed the finite summable tail modulus route through dyadic tolerance, StreamName finite window, RegSeqRat readback, completion boundary, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SummableTailModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, summability schedule exactness, monotone tail-index stability, tolerance compatibility, readback handoff, completion-boundary handoff, Real-seal non-escape, transport, replay, provenance, and finite route factorization for BEDC.Derived.SummableTailModulusUp.

Constructive story: A $\mathsf{SummableTailModulus}^{\uparrow}$ packet is generated from one summable tail modulus row, one DyadicToleranceScale row, one StreamName finite window, one RegSeqRat readback row, one Bishop regular Cauchy completion boundary row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1800

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ packet records the finite diagonal-limit seal that joins the budget surface of chapter 853, the diagonal-limit surface of chapter 374, the representative surface of chapter 1205, the regular Cauchy extraction route of chapter 1773, and the terminal real-name boundary of chapter 38. It is the public L10 packet by which separate diagonal budget, limit, representative, extraction, and Real seal rows are consumed as one finite NameCert route without importing host completion.

Definition 1800.1 (Cauchy diagonal limit carrier)**.** *A* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_{\mathrm{diag}} = (R, B, D, V, E, S, Q, Y, T, H, C, P, N)$$

with the following displayed rows:

1. *R is the precision-request row, naming the Real-facing tolerance request and the finite diagonal window it is permitted to inspect.*
2. *B is the* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *row, recording the budget, slack, and comparison ledger attached to the request R.*
3. *D is the* $\mathsf{DiagonalLimit}^{\uparrow}$ *row, storing the displayed diagonal-limit coordinate reached after the budget row has been read.*
4. *V is the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *row, fixing the representative readback used by the diagonal-limit coordinate.*
5. *E is the* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *row, routing the representative through the source family, selector, aligned windows, dyadic ledger, and regular rational diagonal readback.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for the finite windows selected by the diagonal route.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the selected windows and the displayed tolerance data.*
8. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row containing the dyadic radius, slack, and comparison entries consumed by B, E, S, Q.*
9. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after R, B, D, V, E, S, Q, Y have been displayed.*

10. *H records componentwise* hsame *transport for the precision request, budget, diagonal-limit row, representative row, extraction row, StreamName readback, RegSeqRat readback, DyadicRatCore ledger, Real seal, continuation, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from each Real-facing precision request through $R, B, D, V, E, S, Q, Y, T, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$, $\mathsf{CauchyDiagonalBudget}^{\uparrow}$, $\mathsf{DiagonalLimit}^{\uparrow}$, $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, B, D, V, E, S, Q, Y, T, H, C, P, N$. It has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalLimitUp.TasteGate.CauchyDiagonalLimitTasteGate single carrier alignment`

Theorem 1800.2 (Cauchy diagonal limit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ *carrier*

$$L_{\mathrm{diag}} = (R, B, D, V, E, S, Q, Y, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyDiagonalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the precision request,* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *budget row,* $\mathsf{DiagonalLimit}^{\uparrow}$ *diagonal-limit row,* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *representative row,* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *extraction row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *budget exactness, requiring B to be the only row that assigns radius, slack, and comparison data to the precision request R;*
3. *diagonal-limit routing, requiring D to be read only after B and before any representative, extraction, or Real-seal coordinate is consumed;*
4. *representative exactness, requiring V to be the only representative row attached to the diagonal-limit coordinate D;*
5. *extraction exactness, requiring E to route the representative through the displayed regular Cauchy diagonal extraction surface;*
6. *readback alignment, requiring S, Q, Y to expose only the StreamName windows, RegSeqRat diagonal readback, and DyadicRatCore ledger selected by R, B, D, V, E;*
7. *Real seal non-escape, requiring T to be downstream of the finite budget-limit-representative-extraction-readback route;*
8. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
9. *refusal of quotient streams, selected host limits, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No Cauchy diagonal limit obligation is stored outside these rows.

Proof. Project the carrier of Definition 1800.1. The precision request R is the only public entry point, and the budget row B is the only row that assigns the dyadic radius, slack, and comparison data for that request.

The diagonal-limit route is then forced. The row D reads the limit coordinate only after B, while V fixes the representative attached to that coordinate before any extraction or seal can be inspected.

The extraction and readback rows are downstream of the representative. The row E supplies the regular Cauchy diagonal extraction route, and S, Q, Y expose exactly the selected finite windows, regular rational readback, and dyadic ledger.

Finally, the Real seal T and structural rows H, C, P, N preserve the same finite route. Since quotient streams, selected host limits, countable choice, trichotomy, ambient completeness, Lean evidence, and bridge data do not occur as coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 1800.3 (Cauchy diagonal limit Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing diagonal limit read from an accepted* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ *carrier*

$$L_{\mathrm{diag}} = (R, B, D, V, E, S, Q, Y, T, H, C, P, N)$$

factors through the displayed finite route

$$R \longmapsto B \longmapsto D \longmapsto V \longmapsto E \longmapsto S, Q, Y \longmapsto T \longmapsto H, C, P, N.$$

Consequently the consumer receives one precision request, one CauchyDiagonalBudget row, one DiagonalLimit row, one DiagonalLimitRepresentative row, one RegularCauchyDiagonalExtraction row, aligned StreamName windows, one RegSeqRat readback, one DyadicRatCore ledger, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. The route exports no quotient stream, selected host limit, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Proof. Begin with the accepted carrier and read the precision request row R. A Real-facing consumer has no direct access to a diagonal limit or a representative; it must first pass through the budget row B.

After the budget is fixed, the diagonal-limit coordinate D and representative row V determine the only extraction route available to the consumer. The extraction row E then supplies the regular Cauchy diagonal route.

The readback rows S, Q, Y are aligned with that route. They expose the finite StreamName windows, the RegSeqRat readback, and the DyadicRatCore ledger selected by the budget, limit, representative, and extraction rows.

The terminal Real seal T is therefore downstream of the entire route, and H, C, P, N merely transport, replay, record provenance, and name the same packet. Because the carrier has no quotient-stream coordinate, selected host limit, countable-choice schedule, trichotomy principle, ambient completeness theorem, Lean evidence, or bridge data, every Real-facing read factors through exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ packet is generated from a precision request, a CauchyDiagonalBudget row, a DiagonalLimit row, a DiagonalLimitRepresentative row, a RegularCauchyDiagonalExtraction row, StreamName windows, a RegSeqRat readback, a DyadicRatCore ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyDiagonalLimit}^{\uparrow}}$, seed)

Scope closed: Definition 1800.1, Definition 1800.2, and Definition 1800.3 seed the finite diagonal-limit route joining budget, limit, representative, extraction, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyDiagonalLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget exactness, diagonal-limit routing, representative exactness, extraction exactness, readback alignment, Real seal non-escape, componentwise transport, displayed replay, and local naming for BEDC.Derived.CauchyDiagonalLimitUp.

Chapter 1801

A Concrete Naming Certificate for $\mathsf{LocatedSequenceModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedSequenceModulus}^{\uparrow}$ packet records the finite data by which a located rational sequence exposes a reusable modulus surface before it is consumed as a regular Cauchy or real-name object. It reads the located bounds of **??**, the stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the modulus surface of chapter 292, and the real-name seal of chapter 38. The chapter isolates the constructive sequence-modulus packet used by the current real and completion route without assuming quotient streams, selected limits, trichotomy, countable choice, or ambient real completeness.

Definition 1801.1 (Located sequence modulus carrier)**.** *A* $\mathsf{LocatedSequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located sequence-window row. It records the finite rational interval or ball witnesses available at each inspected sequence index, together with the BEDC marks that say which windows are presently exposed.*
2. *M is the modulus schedule row. It assigns each displayed tolerance request to a finite index bound and records monotone reuse when a tighter or later request is inspected.*
3. *D is the dyadic tolerance-scale row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and carrying the rational error budgets against which the sequence windows are compared.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It names exactly the finite stream coordinates that may be queried before the regular rational or real-facing read is formed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular Cauchy-facing rational sequence obtained from the located windows, the schedule, the dyadic tolerance scale, and the stream-name window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It packages the real-facing consumer boundary after the regular rational readback has been displayed, without adding a selected limit or quotient-stream coordinate.*
7. *H records componentwise* hsame *transport for the located windows, modulus schedule, dyadic tolerance scale, stream-name window, regular rational readback, real seal, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from located finite windows through the modulus schedule, dyadic tolerances, stream-name windows, regular rational readback, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedSequenceModulus}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceModulus}^{\uparrow}}$ *row.*

The carrier exposes only the finite located-window, modulus, tolerance, stream, readback, and seal boundary. It contains no quotient stream, selected limit, trichotomy principle, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification certificate, or checked bridge.*

Lean4 ✓ `BEDC.Derived.LocatedSequenceModulusUp.LocatedSequenceModulusTasteGate single carrier alignment`

Theorem 1801.2 (Located sequence modulus NameCert obligations)**.** *For every accepted* LocatedSequenceModulus *carrier $B = (L, M, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located sequence windows, modulus schedule, dyadic tolerance scale, stream-name window, regular rational readback, real seal, transport, continuation, provenance, and local naming rows;*
2. *located-window coverage, requiring every sequence coordinate used by a consumer to be witnessed in L before it can be compared against the tolerance scale;*
3. *monotone modulus stability, requiring a bound stored in M to remain valid under later index requests and tighter finite tolerance requests displayed by the packet;*
4. *dyadic tolerance compatibility, requiring each comparison between sequence windows and scheduled bounds to use the row D rather than an ambient rational approximation convention;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the readback row R to be formed only after the located-window, modulus, tolerance, and stream-name rows have been projected;*
6. *real-seal non-escape, requiring E, P, N to export no quotient stream, selected limit, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification certificate, or checked bridge.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1801.1. The packet displays the located-window row L, modulus schedule M, dyadic tolerance row D, stream-name row S, regular rational readback R, real seal E, and the structural rows H, C, P, N.

Located-window coverage is forced before any readback can occur. A consumer that inspects a sequence coordinate must obtain the corresponding finite witness from L, and the witness is compared only after the tolerance request has been routed through D.

Monotone modulus stability is stored in the schedule row. The same scheduled bound may be reused for later index windows or tighter displayed tolerances only through M, so no external choice of a bound is available to the consumer.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is then determined by the visible route L, M, D, S, R. The readback row R cannot be projected until the located windows, schedule, dyadic tolerance scale, and stream-name window have already been displayed.

Finally, the real seal E is downstream of that readback. Since the remaining rows only transport, replay, package, and name the displayed finite data, the local NameCert has no coordinate

from which a quotient stream, selected limit, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification certificate, or checked bridge could be obtained. □

Theorem 1801.3 (Located sequence modulus regular Cauchy handoff)**.** *Let $B = (L, M, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSequenceModulus}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer of B factors through the finite route*

$$L \longmapsto M \longmapsto D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer reads located sequence windows, a monotone modulus schedule, dyadic tolerances, a $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal as one BEDC packet. The route exposes no quotient stream, selected limit, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification certificate, or checked bridge.*

Proof. Project the accepted carrier rows. A regular Cauchy-facing consumer first reads the located sequence data through L and obtains its finite bound discipline through M.

The tolerance and stream coordinates are then fixed by D and S. These rows determine which dyadic error budgets and stream-name windows can participate in the readback, so the consumer has no second route to an unrecorded approximation convention.

The row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback surface, and the row E is the only $\mathsf{Real}^{\uparrow}$ seal surface. Any real-facing consumer must therefore pass through R before reading E.

The structural rows H, C, P, N close the displayed route by transporting, replaying, packaging, and naming exactly those finite coordinates. Because the packet contains no additional completion or choice coordinate, the non-escape claims follow from exhaustion of the carrier rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSequenceModulus}^{\uparrow}$ packet is generated from located sequence windows, a monotone modulus schedule, dyadic tolerance data, a StreamName window, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1801.1, Definition 1801.2, and Definition 1801.3 seed the finite located sequence modulus boundary for the current real and completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window coverage, monotone modulus stability, dyadic tolerance compatibility, RegSeqRat handoff, real-seal non-escape, and the regular Cauchy handoff for BEDC.Derived.LocatedSequenceModulusUp.

Chapter 1802

Rational Interval Enclosure NameCert Construction

Following Bishop–Bridges constructive analysis, the $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ packet records the finite rational bracket by which a regular Cauchy real name becomes observable before any quotient-real or completeness principle is invoked. It sits over the rational carrier of chapter 37, the dyadic tolerance and rounding discipline of chapter 291, the regular rational stream boundary of chapter 301, the terminal real-name seal of chapter 38, and the located interval surface of chapter 1709. The packet names finite endpoint rows, not a completed equality class of real numbers.

Definition 1802.1 (RationalIntervalEnclosure carrier)**.** *A* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, U, Q, D, S, R, I, T, H, C, P, N)$$

with the following displayed rows:

1. *L is the rational lower-endpoint row, read through* $\mathsf{Rat}^{\uparrow}$ *and carrying the displayed lower bracket value.*
2. *U is the rational upper-endpoint row, read through* $\mathsf{Rat}^{\uparrow}$ *and carrying the displayed upper bracket value.*
3. *Q is the rational order ledger, recording $L \leq U$ and the rational comparisons requested by the enclosure consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic radius, rounding rows, and rational-to-dyadic comparison data used to justify the displayed bracket width.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, naming the regular Cauchy rational stream inspected by the bracket.*
6. *R is the regular readback row, recording the finite index and tolerance request at which the source stream is read into the bracket.*
7. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *interval row, exposing the bracket as located interval data without adding a host interval object.*
8. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, Q, D, S, R, I have been displayed.*
9. *H records componentwise* hsame *transport for rational endpoints, rational order, dyadic tolerance, regular source, regular readback, located interval, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an enclosure request through $L, U, Q, D, S, R, I, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalEnclosure}^{\uparrow}}$ *row.*

The classifier compares accepted enclosures only through $L, U, Q, D, S, R, I, T, H, C, P, N$. It has no coordinate for Dedekind-cut equivalence, host real equality, trichotomy, quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RationalIntervalEnclosureUp.RationalIntervalEnclosureUp`

Theorem 1802.2 (RationalIntervalEnclosure NameCert obligations)**.** *For every accepted* RationalIntervalEnclosure *carrier*

$$E = (L, U, Q, D, S, R, I, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalIntervalEnclosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational endpoint rows, rational order ledger, dyadic tolerance ledger, regular Cauchy source, regular readback, located interval row, Real seal, transports, replay, provenance, and local naming;*
2. *rational endpoint exactness, requiring every enclosure read to expose L, U, Q before any dyadic tolerance or real-facing row is available;*
3. *dyadic tolerance compatibility, requiring D to justify the displayed bracket radius and endpoint comparisons through* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows rather than through host real arithmetic;*
4. *regular-source readback, requiring S and R to identify the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *name, index, and tolerance request from which the bracket is read;*
5. *located-interval routing, requiring I to expose the same rational endpoints and tolerance ledger as located interval data;*
6. *Real-seal ordering, requiring T to be read only after L, U, Q, D, S, R, I have been displayed;*
7. *ledger non-escape, requiring H, C, P, N to export no Dedekind-cut equivalence, host real equality, trichotomy, quotient stream, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No RationalIntervalEnclosure obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1802.1. The accepted packet displays exactly the lower and upper rational endpoint rows, rational order ledger, dyadic tolerance ledger, regular Cauchy source, regular readback, located interval row, terminal Real seal, and structural rows.

Rational endpoint exactness is the first stage. The rows L, U, Q are the only endpoint and order coordinates available to the classifier, so a consumer cannot replace the bracket by a host real interval or a completed equality class.

Dyadic tolerance compatibility and regular-source readback form the middle stage. The row D records the finite dyadic radius and rounding comparisons, while S and R identify the regular Cauchy rational name, index, and tolerance request that produced the displayed endpoint bracket.

The located-interval and Real-seal rows are downstream. The row I exposes the same endpoint and tolerance data as located interval evidence, and T is terminal because it appears only after the endpoint, dyadic, source, and interval rows.

Finally, H, C, P, N transport, replay, package, and name the same finite route. Since the excluded cut, equality, trichotomy, quotient, selection, choice, and completeness objects are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1802.3 (RationalIntervalEnclosure RegSeqRat readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read of an accepted* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ *carrier factors through the displayed route*

$$S \longmapsto R \longmapsto D \longmapsto L, U, Q \longmapsto I \longmapsto T, H, C, P, N.$$

Consequently the consumer receives one regular Cauchy rational source, one finite readback row, one dyadic tolerance ledger, rational lower and upper endpoint rows with their order ledger, one located interval row, one terminal $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. The readback supplies a finite bracket around the name and does not identify quotient streams or host real equality.*

Proof. Project the accepted carrier $E = (L, U, Q, D, S, R, I, T, H, C, P, N)$. The only regular Cauchy source coordinate is S, and the only finite readback coordinate attached to it is R.

The tolerance stage then passes through D. This row records the dyadic radius and rounding comparisons that make the rational endpoints readable at the requested precision.

The endpoint stage is L, U, Q. These rows expose the lower endpoint, upper endpoint, and rational order ledger after the source and tolerance request have been fixed.

The downstream stage is I, T, H, C, P, N. The located interval row and terminal Real seal consume the displayed bracket, while the structural rows preserve and name the same route. No quotient-stream or host-real-equality coordinate is present, so every $\mathsf{RegSeqRat}^{\uparrow}$ readback factors through the displayed finite bracket. □

Theorem 1802.4 (RationalIntervalEnclosure Real-seal nonescape)**.** *Let* $E = (L, U, Q, D, S, R, I, T, H, C, P, N)$ *be an accepted* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedRealInterval}^{\uparrow}$ *consumer read of* E *must pass through the rational endpoint rows, dyadic tolerance ledger, regular-source readback, and located interval row before the terminal seal* T *is available. Therefore the seal exports only the displayed finite rational bracket and its structural replay; it exports no Dedekind-cut equivalence, host real equality, trichotomy, quotient streams, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The terminal Real-facing coordinate of the carrier is T. By the displayed packet order in Definition 1802.1, T is downstream of L, U, Q, D, S, R, I.

A $\mathsf{LocatedRealInterval}^{\uparrow}$ consumer must therefore read I through the same endpoint and tolerance rows that produced the bracket. There is no second interval coordinate and no host interval object.

A $\mathsf{Real}^{\uparrow}$ consumer must also read through the same route before reaching T. The structural rows H, C, P, N then transport, replay, package, and name only that route.

Since the carrier inventory omits Dedekind-cut equivalence, host real equality, trichotomy, quotient streams, selected limits, countable choice, and ambient Real completeness, none of those objects can escape through the terminal seal. □

Falsifiable prediction: Every $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ read factors through rational lower and upper endpoint rows, one rational order ledger, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ source row, one finite regular readback row, one $\mathsf{LocatedRealInterval}^{\uparrow}$ interval row, one $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: rat, dyadicratcore, regseqrat, located-real-interval, real: $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rational endpoints, rational order,

dyadic tolerance, regular Cauchy readback, located interval exposure, and a terminal Real-facing seal as one finite bracket packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalEnclosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalEnclosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1802.1, Definition 1802.2, Definition 1802.3, and Definition 1802.4 seed the finite rational interval enclosure route from regular Cauchy rational names through rational endpoint rows, dyadic tolerance, located interval exposure, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalEnclosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut equivalence, host real equality, trichotomy, quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational endpoint exactness, dyadic tolerance compatibility, regular-source readback, located-interval routing, Real-seal ordering, ledger non-escape, and consumer factorization for BEDC.Derived.RationalIntervalEnclosureUp.

Constructive story: A $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ packet is generated from rational lower and upper endpoint rows, a rational order ledger, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ source row, one finite readback row, a $\mathsf{LocatedRealInterval}^{\uparrow}$ interval row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1803

A Concrete Naming Certificate for $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley on filters and Moore–Smith nets, the $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ packet records the finite handoff between Cauchy-filter evidence and Cauchy-net evidence before either route is consumed by completion. It sits over the Cauchy-filter surface of chapter 333, the Cauchy-net directed-window surface of chapter 589, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the metric completion consumer of chapter 1506, the uniform completion consumer of chapter 1473, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite L10 bridge: it records displayed evidence routes, not quotient filters, selected host nets, countable choice, selected limits, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1803.1 (Cauchy filter-net correspondence carrier)**.** *A* $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, D, W, R, T, M, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, recording the filter-base requests, late-set witnesses, and finite Cauchy evidence available before a directed net is read.*
2. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row, recording the directed index surface and finite upper-window witnesses generated from the displayed filter requests.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by both the filter read and the directed-window read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from those windows.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row shared by the filter and net evidence routes.*
6. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row, visible only after F, D, W, R, T have been displayed.*
7. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer row, visible only after the same filter-net handoff route has been displayed.*
8. *H records componentwise* hsame *transport for $F, D, W, R, T, M, U, C, P, N$.*
9. *C records displayed* Cont *replay from a finite Cauchy-filter request through the directed-window handoff and then to the completion consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected host nets, countable-choice schedules, selected limits, ambient completion, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyFilterNetCorrespondenceUp.CauchyFilterNetCorrespondenceTasteGate`
`single carrier alignment`

Theorem 1803.2 (Cauchy filter-net NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ *carrier*

$$Q = (F, D, W, R, T, M, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}}$ *surface consists exactly of four finite obligation rows:*

1. *carrier exposure: the accepted object exposes only the displayed packet Q with rows $F, D, W, R, T, M, U, H, C, P, N$*
2. *filter-to-net routing: every filter-base Cauchy request reaches the directed-window row D only through the displayed filter row F and the shared tolerance row T;*
3. *net-to-filter routing: every directed-window read back to filter evidence returns through the same D, F, T boundary before any completion consumer sees the route;*
4. *consumer non-escape: the* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *rows read only the displayed F, D, W, R, T route, with H, C, P, N supplying transport, replay, provenance, and local naming.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1803.1. The accepted packet contains the filter row, directed-window row, window row, readback row, tolerance row, the two completion consumer rows, and the structural rows H, C, P, N.

For the filter-to-net obligation, start with a finite Cauchy request in F. The only directed output coordinate in the carrier is D, and the route to it is mediated by the shared dyadic tolerance row T before any window in W or readback in R can be inspected.

For the net-to-filter obligation, reverse the displayed route at the level of evidence rows. A directed-window read in D returns to the same filter boundary F and uses the same tolerance row T, so the reverse handoff cannot introduce a second base, a host subnet, or a choice-selected branch.

Finally, M and U are downstream consumer rows. Since they occur after F, D, W, R, T in the carrier and have only H, C, P, N as structural support, they receive exactly the displayed handoff route and no quotient, choice, selected-limit, ambient-completion, Real-completeness, verification, or bridge coordinate. □

Theorem 1803.3 (Cauchy filter-to-net finite handoff)**.** *Let $Q = (F, D, W, R, T, M, U, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ *carrier. Every displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *request in F that is admitted to a completion-facing route factors through a finite directed-window handoff*

$$F, T \longmapsto D \longmapsto W, R.$$

Thus the filter branch supplies Cauchy evidence to $\mathsf{CauchyNet}^{\uparrow}$ *as displayed directed-window data, not as a quotient filter, selected host net, countable-choice selector, selected limit, or ambient completion object.*

Proof. Project the accepted carrier and read the filter row F. A completion-facing filter request has no direct edge to M or U inside the packet; the displayed bridge route first records its tolerance demand in T.

The directed-window row D is then the only net-facing coordinate. The replay row C sends the finite request from F, T to D, and H keeps the row identities stable under componentwise transport.

After D is displayed, the route may inspect finite windows W and regular rational readback R. The carrier contains no excluded quotient, host-net, choice, selected-limit, or ambient-completion coordinate, so the handoff remains the finite route shown above. □

Theorem 1803.4 (Cauchy net-to-filter finite handoff)**.** *Let $Q = (F, D, W, R, T, M, U, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ *carrier. Every displayed* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window read in D that is compared with filter Cauchy evidence factors through*

$$D, T \longmapsto F \longmapsto W, R.$$

The reverse read returns to the displayed $\mathsf{CauchyFilter}^{\uparrow}$ *row and does not export quotient-filter equality, selected host nets, countable choice, selected limits, ambient completion, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the directed-window row D. The carrier makes no autonomous completion claim from D alone; any comparison with filter evidence must use the same dyadic tolerance row T that the forward handoff used.

The filter row F is the unique filter-facing coordinate. Replaying the route through C therefore returns the directed-window read to F before windows or regular rational readback are exposed.

The downstream rows W and R are shared by both directions. Since P and N name only this packet and H transports only its displayed rows, the reverse handoff cannot create quotient-filter equality, host-net selection, countable choice, selected limits, ambient completion, or Real completeness. □

Theorem 1803.5 (Cauchy filter-net consumer non-escape)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ *carrier factors through the displayed route*

$$F, D, T, W, R \longmapsto M, U.$$

Consequently the completion consumers may read finite Cauchy-filter evidence, finite directed-window Cauchy-net evidence, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance data, but they receive no quotient filters, selected host nets, countable choice, selected limits, ambient completion, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The consumer rows M and U are coordinates of the carrier in Definition 1803.1. They are not source rows; each is reached only after the filter row F, directed-window row D, tolerance row T, window row W, and readback row R have been displayed.

Apply Definition 1803.3 for reads that start from filter evidence, and apply Definition 1803.4 for reads that start from directed-window evidence. Both routes meet the same finite F, D, T, W, R boundary before any completion consumer is visible.

The $\mathsf{Real}^{\uparrow}$-facing part of the route is therefore mediated by the same readback and completion rows. Because the carrier has no excluded quotient, selected-host, choice, selected-limit, ambient-completion, or Real-completeness coordinate, every consumer read remains inside the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1803.1, Definition 1803.2, Definition 1803.3, Definition 1803.4, and Definition 1803.5 seed the finite L10 correspondence surface between filter and net Cauchy evidence for completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected host nets, countable choice, selected limits, ambient completion, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, filter-to-net routing, net-to-filter routing, consumer non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterNetCorrespondenceUp.

Constructive story: A $\mathsf{CauchyFilterNetCorrespondence}^{\uparrow}$ packet is generated from one CauchyFilter row, one CauchyNet directed-window row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance row, MetricCompletion and UniformCompletion consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1804

A Concrete Naming Certificate for $\mathsf{BisectionConvergence}^{\uparrow}$

Bishop–Bridges constructive bisection/interval-halving analysis treats convergence as finite retained-window data at each requested precision, not as a hidden completed choice of a limit point. The $\mathsf{BisectionConvergence}^{\uparrow}$ packet names that finite route over the dyadic branch surface of chapter 361, the located interval bisection surface of chapter 1711, the retained nested-window discipline of chapter 320, the finite StreamName interface of chapter 126, the RegSeqRat readback route of chapter 301, and the terminal Real seal of chapter 38. It supplies a named convergence surface for intermediate-value and root-bracketing consumers without exporting selected limits, quotient stream equality, real trichotomy, countable choice, or compactness principles.

Definition 1804.1 (Bisection convergence carrier)**.** *A* $\mathsf{BisectionConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, D, W, T, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row. It records the initial lower and upper endpoint windows, locatedness reads, endpoint order data, and the interval identity consumed by the finite bisection request.*
2. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger. It stores the finite left-or-right branch prefix, midpoint cells, child-window records, and branch depth used by the requested tolerance.*
3. *W is the retained* $\mathsf{NestedInterval}^{\uparrow}$ *window row. It records the lower and upper retained windows after each branch listed in D.*
4. *T is the tail-diameter schedule. It assigns to each requested tolerance a displayed branch depth and the retained-window diameter bound available at that depth.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened from W at the depth named by T.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite StreamName windows and the displayed diameter budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the retained windows, tail-diameter schedule, StreamName windows, and RegSeqRat readback have been displayed.*

8. *H records componentwise* hsame *transport for the located interval source, branch ledger, retained windows, tail schedule, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a convergence request through interval inspection, finite branch retention, tail-diameter scheduling, finite window opening, regular readback, and Real-seal consumption.*

10. *P is the* Pkg *provenance over* $\mathsf{BisectionConvergence}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, W, T, S, Q, E, H, C, P, N$. It has no coordinate for selected limits, quotient stream equality, real trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host interval equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BisectionConvergenceUp.BisectionConvergenceTasteGate single carrier alignment`

Theorem 1804.2 (Bisection convergence NameCert obligations)**.** *For every accepted* $\mathsf{BisectionConvergence}^{\uparrow}$ *carrier*

$$B = (I, D, W, T, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BisectionConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval source, dyadic branch ledger, retained nested windows, tail-diameter schedule, StreamName windows, RegSeqRat readback, Real seal, transports, replay, provenance, and local naming;*

2. *source discipline, requiring every endpoint, locatedness, and order read to factor through I before any branch or tail row is inspected;*

3. *branch-retention discipline, requiring D to display the finite branch prefix and requiring W to store only the retained windows produced by that prefix;*

4. *tail-diameter exactness, requiring T to attach each requested tolerance to a displayed branch depth and a displayed retained-window diameter bound;*

5. *finite readback discipline, requiring S and Q to consume the retained window and tail schedule before any regular rational observation is visible;*

6. *Real-seal non-escape, requiring E, H, C, P, N to export only the displayed finite route and no selected limit, quotient stream equality, real trichotomy, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host interval equality, Lean verification, or bridge data.*

No bisection convergence obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1804.1. The visible packet consists exactly of the source interval row I, branch ledger D, retained-window row W, tail-diameter schedule T, StreamName row S, RegSeqRat readback Q, Real seal E, and structural rows H, C, P, N.

Source discipline is the first stage of the route. The endpoint windows, locatedness reads, and order data are supplied by I, so a convergence request cannot replace the source by a host interval equality theorem or by a completed limit object.

Branch-retention discipline is the middle stage. The ledger D displays the finite branch prefix and midpoint cells, while W records only the retained windows produced by that ledger.

Tail-diameter exactness is local to T. For each requested tolerance, the schedule stores the branch depth and the corresponding retained-window diameter bound; no unrecorded convergence principle or countable choice operator chooses the depth.

Finally, S, Q, E, H, C, P, N expose finite windows, regular readback, terminal seal, transport, replay, provenance, and naming along the same displayed route. Since the excluded objects have no carrier coordinate, no local NameCert obligation can export them. □

Theorem 1804.3 (Bisection convergence tail-diameter route)**.** *Let*

$$B = (I, D, W, T, S, Q, E, H, C, P, N)$$

be an accepted $\mathsf{BisectionConvergence}^{\uparrow}$ *carrier. Every accepted convergence request factors through the finite route*

$$I \longmapsto D \longmapsto W \longmapsto T$$

before any $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is exposed. Consequently each requested tolerance is answered by a displayed branch depth and retained-window diameter bound rather than by a selected limit or ambient completeness principle.*

Proof. Project the accepted carrier. The only source interval coordinate is I, and the only branch coordinate is D, so the request first reads the located interval data and then the finite branch prefix.

The retained-window row W is downstream of that branch prefix. It stores the lower and upper windows that remain after the displayed bisection choices, and it provides the visible window data consumed by the tail schedule.

The tail-diameter row T then answers the tolerance request. It names the branch depth and diameter bound available for the retained window at that depth.

Since S and Q occur only after T in the carrier route, no StreamName or RegSeqRat readback is visible before the finite diameter schedule has been displayed. The route therefore supplies finite convergence data without selected limits or ambient completeness. □

Theorem 1804.4 (Bisection convergence Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BisectionConvergence}^{\uparrow}$ *carrier reads the terminal seal* E *only after the finite route*

$$I \longmapsto D \longmapsto W \longmapsto T \longmapsto S \longmapsto Q \longmapsto E$$

has been displayed. The consumer receives the located interval source, dyadic branch ledger, retained nested windows, tail-diameter schedule, StreamName windows, RegSeqRat readback, and terminal Real seal, but receives no selected limit, quotient stream equality, real trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host interval equality.*

Proof. Read the Real-facing request through Definition 1804.3. Before any readback is exposed, the request has already displayed the located interval source, finite branch ledger, retained windows, and tail-diameter schedule.

The finite observation stage is S followed by Q. The StreamName row opens the retained windows at the scheduled depth, and the RegSeqRat row reads back only those displayed finite observations under the recorded diameter budget.

The Real seal E is terminal with respect to that route. Transport, replay, provenance, and local naming through H, C, P, N preserve the same displayed data and introduce no analytic coordinate beyond it.

Thus every Real-facing consumer receives the named finite bisection convergence handoff. The excluded limit-selection, quotient-equality, trichotomy, countable-choice, compactness, completeness, and host-equality principles have no row from which they could be projected. □

Falsifiable prediction: Every $\mathsf{BisectionConvergence}^{\uparrow}$ Real-facing convergence read factors through one located interval source row, one DyadicBisection branch ledger, one retained NestedInterval window row, one tail-diameter schedule, one StreamName finite-window row, one RegSeqRat readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicbisection, located-interval-bisection, nestedinterval, streamname, regseqrat, real, real-root-bracket: $\mathsf{BisectionConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite branch ledger, retained nested windows, a tolerance-indexed tail-diameter schedule, finite StreamName windows, RegSeqRat readback, and a Real-seal handoff as one convergence certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1804.1, Definition 1804.2, Definition 1804.3, and Definition 1804.4 seed the finite bisection convergence route through located interval source data, dyadic branch ledger, retained nested windows, tail-diameter schedule, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BisectionConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, real trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, host interval equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source discipline, branch-retention discipline, tail-diameter exactness, finite readback discipline, Real-seal non-escape, and route factorization for BEDC.Derived.BisectionConvergenceUp.

Constructive story: A $\mathsf{BisectionConvergence}^{\uparrow}$ packet is generated from one located interval source row, one DyadicBisection branch ledger, one retained NestedInterval window row, one tail-diameter schedule, one StreamName finite-window row, one RegSeqRat readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1805

A Concrete Naming Certificate for $\mathsf{LocatedCompletionSeal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCompletionSeal}^{\uparrow}$ packet names the finite seal by which located Cauchy source data reaches the terminal Real route without turning that route into an ambient completeness theorem. It sits over the regular Cauchy completion boundary of chapter 1639, the located regular source of chapter 1454, the tail envelope of chapter 1769, the regular rational route of chapter 301, the finite stream interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite located-completion boundary for $\mathsf{Real}^{\uparrow}$ consumers; it is not Real completeness, quotient stream equality, a selected limit, countable choice, trichotomy, or host real equality.

The same seal is consumed by chapter 3703, where the dense unit and completion seal become the extension-and-uniqueness source row.

Definition 1805.1 (Located completion seal carrier)**.** *A* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, Q, E, A, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance row, containing the dyadic radii, comparisons, and interval endpoints read by the located completion route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened before any regular rational or located-tail read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, recording the regular rational observations available on the windows named by S and measured by D.*
4. *Q is the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *source row, binding the regular rational source to the displayed locatedness and modulus data.*
5. *E is the* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ *row, recording the finite tail window through which the located source is exposed to completion consumers.*
6. *A is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *completion-facing boundary row, consuming the same dyadic, stream, and regular rational data as D, S, R.*
7. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after D, S, R, Q, E, A have been displayed.*
8. *H records componentwise* hsame *transport for dyadic, stream, regular rational, located-source, tail-envelope, completion-boundary, Real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each located-completion precision request through $D, S, R, Q, E, A, T, H, P, N$*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletionSeal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, Q, E, A, T, H, C, P, N$. The carrier has no coordinate for Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.LocatedCompletionSealUp.LocatedCompletionSealTasteGate single carrier alignment`

Theorem 1805.2 (Located completion seal NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *carrier*

$$L = (D, S, R, Q, E, A, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompletionSeal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the dyadic ledger, finite stream windows, regular rational source, regular located Cauchy source, located tail envelope, Bishop regular completion boundary, terminal Real seal, transport, replay, provenance, and local naming row;*
2. *located-source routing, requiring every completion-facing request to read D, S, R before it may read the regular located source row Q;*
3. *tail-envelope compatibility, requiring E to consume the same dyadic, stream, regular rational, and located-source rows as the request that enters the packet;*
4. *completion-boundary compatibility, requiring A to expose only the displayed regular Cauchy completion boundary over D, S, R and not a selected point of a completed space;*
5. *Real handoff, requiring T to be downstream of D, S, R, Q, E, A for every* $\mathsf{Real}^{\uparrow}$ *consumer named by P;*
6. *ledger non-escape, requiring H, C, P, N to preserve and name exactly this finite route and to export no Real completeness, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedCompletionSealUp.LocatedCompletionSealNameCert obligation rows exact`

Proof. Carrier exposure is projection from Definition 1805.1. The displayed packet contains the dyadic row D, stream windows S, regular rational row R, located source row Q, located tail envelope E, Bishop regular completion boundary A, terminal Real seal T, and the structural rows H, C, P, N.

The located-source route is fixed by the row order. A precision request first opens the dyadic tolerance ledger, then the finite stream windows, then the regular rational observations, and only then the regular located Cauchy source.

The tail envelope and completion boundary are compatible because they read the same preceding rows. The row E packages the finite located tail route over D, S, R, Q, while the row A packages the regular Cauchy completion-facing boundary over D, S, R.

The Real handoff is terminal. The row T is exposed only after the located source, tail envelope, and completion boundary have all been displayed.

Finally, the rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded objects appears as a coordinate of the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1805.3 (Located completion seal Real handoff)**.** *Let $L = (D, S, R, Q, E, A, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer read factors through the finite route*

$$D \longmapsto S \longmapsto R \longmapsto Q \longmapsto E \longmapsto A \longmapsto T \longmapsto H, C, P, N.$$

Consequently the consumer receives a dyadic tolerance ledger, finite stream windows, regular rational observations, regular located Cauchy source data, a located tail envelope, a Bishop regular Cauchy completion boundary, a terminal Real seal, transport, replay, provenance, and local naming. The handoff cannot use Real completeness, quotient stream equality, a selected limit, countable choice, trichotomy, or host real equality.

Proof. Project the accepted carrier by Definition 1805.1. The only Real-facing endpoint is T, and the carrier places T after the dyadic, stream, regular rational, located-source, tail-envelope, and completion-boundary rows.

The analytic route starts with D, S, R. These rows fix the tolerance ledger, finite observation windows, and regular rational readback before any located completion claim is visible.

The located completion seal is then read through Q, E, A. The row Q binds the source as a regular located Cauchy real, E exposes the finite located tail envelope, and A records the completion-facing boundary without selecting a completed point.

The structural rows preserve the same order. Componentwise hsame transport and displayed Cont replay cannot introduce a second route to T, and the provenance and local naming rows add no excluded coordinate. Hence every $\mathsf{Real}^{\uparrow}$ read factors through the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionSeal}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCompletionSeal}^{\uparrow}}$, seed)

Scope closed: Definition 1805.1, Definition 1805.2, and Definition 1805.3 seed the finite located-completion seal through which DyadicRatCore, StreamName, RegSeqRat, RegularLocatedCauchyReal, LocatedRealTailEnvelope, BishopRegularCauchyCompletion, and Real rows are read in one displayed route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCompletionSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, located-source routing, tail-envelope compatibility, completion-boundary compatibility, Real handoff, and ledger non-escape for BEDC.Derived.LocatedCompletionSealUp.

Constructive story: A $\mathsf{LocatedCompletionSeal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, a RegSeqRat source row, a RegularLocatedCauchyReal source row, a LocatedRealTailEnvelope row, a BishopRegularCauchyCompletion boundary row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1806

A Concrete Naming Certificate for BishopRealUniformCompletion$^{\uparrow}$

Following Bishop and Bridges and the Bourbaki–Kelley uniform-completion viewpoint, the BishopRealUniformComp packet records the finite route by which the Real uniformity is consumed by Cauchy completion without turning that consumption into a Real-completeness theorem. It reads the Real-induced entourage surface of chapter 1624, the reflective completion inclusion of chapter 1793, the triangle route of chapter 1795, and the terminal real-name seal of chapter 38. The chapter names the L10 bridge between uniform Real reads and completion-facing Cauchy routes while keeping quotient streams, selected limits, host real equality, countable choice, ambient completeness, and bridge credentials outside the packet.

Definition 1806.1 (BishopRealUniformCompletion carrier)**.** *A* BishopRealUniformCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, U, J, T, S, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* Real$^{\uparrow}$ *endpoint and seal row, exposing only named Real observations and the local seal consumed by the bridge.*
2. *U is the* RealUniformStructure$^{\uparrow}$ *entourage row, generated from Real metric-ball requests before any completion-facing read is available.*
3. *J is the reflective completion inclusion row, read through* CauchyCompletionReflectiveSubcategory$^{\uparrow}$ *as the public completion route for the Real-uniform data.*
4. *T is the* CauchyCompletionTriangleIdentity$^{\uparrow}$ *route row, recording that both completion composites reuse the same finite Real-uniform and reflective-inclusion surface.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window row inspected by Real and completion consumers.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used by the Real-uniform entourage request and by the completion-side route comparison.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the stream windows and dyadic tolerances.*
8. *H records componentwise* hsame *transport for the Real seal, Real-uniform entourage, reflective completion inclusion, triangle route, stream, dyadic, regular-rational, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Real endpoint request through the Real-uniform entourage row, reflective inclusion, triangle route, stream window, dyadic tolerance, regular rational readback, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealUniformCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, U, J, T, S, D, Q, H, C, P, N$. The carrier contains no quotient stream, selected limit, host real equality, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, metric-completeness datum, or bridge credential.*

Lean4 ✓ `BEDC.Derived.BishopRealUniformCompletionUp.BishopRealUniformCompletionTasteGate single carrier alignment`

Theorem 1806.2 (BishopRealUniformCompletion NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *carrier $B = (R, U, J, T, S, D, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealUniformComplet}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Real endpoint and seal row, Real-uniform entourage row, reflective completion inclusion row, triangle route row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, transport, replay, provenance, and local naming row;*

2. *uniform entourage handoff, requiring every completion-facing Real read to consume U after projecting R and before inspecting J or T;*

3. *reflective route exactness, requiring every completion inclusion read to pass through J over the same R, U, S, D, Q coordinates;*

4. *triangle route exactness, requiring both completion composites to use T after the reflective route has fixed the finite inclusion surface;*

5. *L10 handoff discipline, requiring StreamName, DyadicRatCore, and RegSeqRat observations to be read only through S, D, Q along the displayed Real-uniform and completion route;*

6. *non-escape, requiring H, C, P, N to replay and name no row from which quotient streams, selected limits, host real equality, countable choice, ambient Real completeness, metric-completeness data, or bridge credentials can be exported.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1806.1. The packet displays the Real seal, Real-uniform entourage, reflective inclusion, triangle route, finite-window, tolerance, readback, transport, replay, provenance, and local naming rows.

The uniform entourage handoff is ordered by the carrier. A Real-facing request first projects R, then reads the Real-induced entourage row U, and only then may continue toward completion through J or T.

Reflective exactness is the completion-side projection. The row J is the only displayed inclusion surface, so every completion inclusion read is forced to reuse the same R, U, S, D, Q coordinates rather than selecting a host completion object.

Triangle exactness is then downstream of J. The row T records both completion composites over the fixed inclusion route, and it has no separate quotient, representative, or host-equality coordinate.

Finally, the L10 handoff and non-escape clauses are exhausted by S, D, Q, H, C, P, N. These rows transport, replay, source, and name the displayed route, and none of them contains quotient streams, selected limits, host real equality, countable choice, ambient Real completeness, metric-completeness data, or bridge credentials. □

Theorem 1806.3 (BishopRealUniformCompletion L10 handoff)**.** *Every completion-facing* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *carrier factors through the finite rows*

$$R \longmapsto U \longmapsto J \longmapsto T \longmapsto S, D, Q \longmapsto H, C, P, N.$$

Consequently the packet exports no quotient stream, selected limit, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness datum, or bridge credential.*

Proof. Start with a completion-facing Real read and project the carrier rows. The Real endpoint and seal data are visible only through R, and the uniformity consumed by the read is visible only through U.

The reflective completion route then passes through J. This fixes the finite inclusion surface before the triangle route is inspected, so the read cannot branch into a host completion carrier or selected limit.

Project T to record the two completion composites over the same route. The finite observation rows S, D, Q supply StreamName windows, dyadic tolerances, and regular rational readback for that route and no other one.

The structural rows H, C, P, N close the handoff by transport, replay, provenance, and local naming. Since these rows exhaust the packet, there is no coordinate from which a quotient stream, selected limit, host real equality, countable choice, ambient Real completeness, metric-completeness datum, or bridge credential could be exported. □

Theorem 1806.4 (BishopRealUniformCompletion diagonal seal ledger)**.** *For every accepted* $\mathsf{BishopRealUniformCor}$ *carrier* $B = (R, U, J, T, S, D, Q, H, C, P, N)$*, any diagonal or completion-facing seal read factors through*

$$R \longmapsto U \longmapsto J \longmapsto T \longmapsto S, D, Q \longmapsto H, C, P, N.$$

Thus the diagonal route consumes the $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage, reflective completion inclusion, triangle route,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any* $\mathsf{Real}^{\uparrow}$ *seal is public.*

Proof. Project the accepted carrier and apply Definition 1806.2. The obligation surface orders the Real endpoint row R, the Real-uniform entourage row U, the reflective route J, the triangle route T, and the L10 handoff through S, D, Q.

Apply Definition 1806.3. It identifies the completion-facing read as the finite route

$$R \longmapsto U \longmapsto J \longmapsto T \longmapsto S, D, Q \longmapsto H, C, P, N.$$

The diagonal seal ledger is this same route read from the Real-uniform side toward the completion-facing seal boundary.

The carrier has no quotient stream, selected limit, host real equality, countable-choice selector, ambient completeness theorem, metric-completeness datum, or bridge credential coordinate. Therefore the diagonal or completion-facing seal cannot leave the displayed RealUniformStructure, reflective completion, triangle, StreamName, DyadicRatCore, and RegSeqRat rows before the local seal is consumed. □

Theorem 1806.5 (BishopRealUniformCompletion obligation rows)**.** *Let $B = (R, U, J, T, S, D, Q, H, C, P, N)$ be an accepted* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *carrier. The obligation surface exposed by B is exactly the six rows named in Definition 1806.2: carrier admission; uniform-entourage handoff; reflective-route exactness; triangle-route exactness; L10 handoff through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$*; and non-escape from quotient streams, selected limits, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, and bridge credentials.*

Proof. Project the accepted carrier. The rows $R, U, J, T, S, D, Q, H, C, P, N$ are the only displayed coordinates, so any local obligation must be read through the Real endpoint, Real-uniform entourage, reflective inclusion, triangle route, finite stream window, dyadic tolerance, regular rational readback, transport, replay, provenance, and local naming rows.

Apply Definition 1806.2. It lists exactly carrier admission, uniform-entourage handoff, reflective-route exactness, triangle-route exactness, L10 handoff discipline, and non-escape, and it states that no local obligation is stored outside those rows.

Finally apply Definition 1806.3. The handoff identifies the route order

$$R \longmapsto U \longmapsto J \longmapsto T \longmapsto S, D, Q \longmapsto H, C, P, N,$$

so the L10 row is precisely the StreamName, DyadicRatCore, and RegSeqRat readback surface downstream of the Real-uniform and completion rows. □

Theorem 1806.6 (BishopRealUniformCompletion density handoff)**.** *Every accepted* $\mathsf{BishopRealUniformCompletion}$ *packet whose* $\mathsf{Real}^{\uparrow}$ *endpoint row is read through a dyadic or regular-rational dense approximation route exposes that route through*

$$R, U, J, T, S, D, Q, H, C, P, N$$

before the completion seal is public. The packet therefore records the density handoff needed by completion consumers, but it does not claim ambient $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit, a quotient stream, host equality, countable choice, metric-completeness data, or a bridge credential.*

Proof. Start from the accepted carrier of Definition 1806.1. The endpoint row R is not read in isolation; the Real-uniform entourage row U, reflective completion route J, and triangle route T determine how a completion-facing consumer reaches it.

Apply Definition 1806.2. The obligation rows require L10 handoff through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$, so any dyadic or regular-rational dense approximation route must be displayed through S, D, Q before the endpoint row is public.

Apply Definition 1806.3 and Definition 1806.4. Together they identify the route

$$R \longmapsto U \longmapsto J \longmapsto T \longmapsto S, D, Q \longmapsto H, C, P, N.$$

The structural rows then transport, replay, source, and name the displayed density handoff, while the carrier still contains no coordinate for completeness, selected limits, quotient streams, host equality, countable choice, metric-completeness data, or bridge credentials. □

Theorem 1806.7 (BishopRealUniformCompletion uniform-filter roundtrip)**.** *Let $B = (R, U, J, T, S, D, Q, H, C, P,$ be an accepted* $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ *packet. Any completion-facing consumer of B whose read begins from a Cauchy-filter basis must factor first through the* $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage row U, then through the reflective completion inclusion J, the triangle route T, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and finally the structural rows H, C, P, N. The roundtrip records the same finite Real-uniform basis named by Definition 1624.6; it exports no quotient filters, selected limits, countable choice, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, or bridge credential.*

Proof. Project the carrier of Definition 1806.1. A Cauchy-filter read has no independent row in B; it must be read through the Real-uniform entourage coordinate U together with the Real endpoint row R.

Apply Definition 1624.6. The Cauchy-filter basis available to a Real-uniform consumer is downstream of the displayed RealUniformStructure entourage row, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, transport, replay, provenance, and local naming.

Apply Definition 1806.2 and Definition 1806.3. The completion-side route therefore proceeds from U to the reflective inclusion J, then to the triangle row T, and then through S, D, Q, H, C, P, N before the completion-facing seal is public.

Finally apply Definition 1806.6. The density handoff reuses the same finite route, so the consumer cannot bypass the RealUniformStructure row or obtain quotient filters, selected limits, countable choice, host equality, ambient Real completeness, metric-completeness data, or bridge credentials from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealUniformCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealUniformCompletion}^{\uparrow}$ packet is generated from a Real endpoint and seal row, a RealUniformStructure entourage row, a CauchyCompletionReflectiveSubcategory inclusion row, a CauchyCompletionTriangleIdentity route row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1806.1, Definition 1806.2, and Definition 1806.3 seed the finite Real-uniform completion bridge for L10 consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, metric-completeness data, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform entourage handoff, reflective route exactness, triangle route exactness, L10 handoff, and non-escape proofs for BEDC.Derived.BishopRealUniformCompletionUp.

Chapter 1807

A Concrete Naming Certificate for $\mathsf{FiniteBracketingInterval}^{\uparrow}$

Following Bishop and Bridges' constructive interval methods, the $\mathsf{FiniteBracketingInterval}^{\uparrow}$ packet records the finite BEDC surface at which a real approximation route is bracketed by dyadic endpoints before any $\mathsf{Real}^{\uparrow}$ read is exported. It sits on the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the finite density route of chapter 1809. The packet is a bracketing certificate for displayed endpoint windows; it is not a quotient real interval, selected host limit, trichotomy row, ambient completeness principle, or open-cover compactness argument.

Definition 1807.1 (Finite bracketing interval carrier)**.** *A* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, W, R, E, S, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint rows, both named inside the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
2. *D is the dyadic-radius containment row, recording the requested tolerance and the finite comparison budget for $L \leq U$.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation window inspected under the same tolerance request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window handoff row that reads W as regular rational data between the endpoint rows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after L, U, D, W, R have been displayed.*
6. *S is the* $\mathsf{RealSeparability}^{\uparrow}$ *density-support row, recording that a finite rational candidate can be inspected inside the same bracket when a density consumer requests one.*
7. *H stores componentwise* hsame *transport for endpoint, radius, window, readback, seal, density-support, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a bracketing request through L, U, D, W, R, E, S.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteBracketingInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteBracketingInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, quotient stream equality, selected limits, countable choice, ambient completeness, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.FiniteBracketingIntervalUp.FiniteBracketingIntervalTasteGate single carrier alignment`

Theorem 1807.2 (Finite bracketing endpoint order)**.** *For every accepted* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *carrier*

$$I = (L, U, D, W, R, E, S, H, C, P, N),$$

the endpoint order read is exhausted by the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *rows* L, U, D*. A consumer may read the bracket only after the same finite comparison budget has recorded* $L \leq U$*, and no host order on* $\mathsf{Real}^{\uparrow}$*, trichotomy row, quotient stream equality, selected midpoint, or ambient completeness datum can replace that dyadic endpoint ledger.*

Proof. Project the carrier of Definition 1807.1. The only endpoint rows are L and U, and the only comparison budget attached to them is D.

Read these rows through the dyadic tolerance surface of chapter 291. The comparison is therefore a finite ledger entry over named dyadic endpoints, not an external order assertion about host reals.

The remaining rows W, R, E, S, H, C, P, N preserve, replay, source, and name the same endpoint packet. Since none of them contains host real equality, quotient stream equality, selected midpoint data, trichotomy, or ambient completeness, the endpoint order is exhausted by L, U, D. □

Theorem 1807.3 (Finite bracketing dyadic-radius containment)**.** *Every accepted* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *containment read is witnessed by the same finite dyadic-radius row* D *together with the endpoint rows* L, U *and the opened* $\mathsf{StreamName}^{\uparrow}$ *window* W*. The read states that the inspected window is contained in the displayed bracket at the requested dyadic radius before the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff or* $\mathsf{Real}^{\uparrow}$ *seal is available.*

Proof. Begin with an accepted containment read. By Definition 1807.1, the tolerance request has only one dyadic-radius row D, and it is tied to the endpoint rows L, U.

The finite window stage is then W. The StreamName surface of chapter 126 supplies exactly the inspected observations at the requested radius, so containment is checked before regular rational readback.

Only after L, U, D, W are displayed may the route pass to R and then E. Thus the containment read cannot be supplied by a quotient stream, selected host limit, countable choice, ambient completeness, or a detached $\mathsf{Real}^{\uparrow}$ equality. □

Theorem 1807.4 (Finite bracketing RegSeqRat handoff)**.** *Every finite-window consumer of an accepted* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *packet factors through the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads L, U, D*, then the finite window* W*, then the regular rational handoff* R*, and only then the terminal seal* E*.*

Proof. Project the carrier. The dyadic endpoint and radius rows L, U, D precede the finite observation row W, and W precedes the readback row R.

Use the RegSeqRat chapter chapter 301. Its public handoff reads finite StreamName windows as regular rational data before any Real-facing seal can consume them.

The terminal row is E, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The route has no coordinate for quotient stream equality, selected limits, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, so the displayed handoff is the whole public consumer surface. □

Theorem 1807.5 (Finite bracketing RealUp seal non-escape)**.** *An accepted* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *packet exports a* $\mathsf{Real}^{\uparrow}$ *read only through the terminal seal row E after the endpoint order, dyadic-radius containment, finite-window read, RegSeqRat handoff, and RealSeparability density-support rows have already been displayed. No consumer can escape from the bracket into host real equality, selected limits, quotient streams, countable choice, ambient completeness, open-cover compactness, or a detached dense subset.*

Proof. Apply the preceding endpoint, containment, and handoff theorems. They force a Real-facing read to pass through L, U, D, W, R before E is available.

The density-support row S is read through chapter 1809. It supplies only the finite rational-window support for a density request inside the same bracket, not an externally chosen dense point.

Finally inspect the structural rows H, C, P, N. They transport, replay, source, and name the displayed packet, and the carrier contains no coordinate for host real equality, selected limits, quotient streams, countable choice, ambient completeness, open-cover compactness, or detached dense subsets. Therefore the terminal seal row is a non-escape boundary. □

Theorem 1807.6 (Finite bracketing interval sibling route)**.** *Every bracket accepted by the* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *carrier reads the located interval endpoint surface, dyadic endpoint ledger,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{RealSeparability}^{\uparrow}$ *density-support row in that order. The route consumes chapter 1709 for the endpoint surface and chapter 1809 for the finite density support before the local structural rows H, C, P, N package the bracket.*

Proof. Project the carrier. The endpoint rows L, U and dyadic-radius ledger D provide the finite endpoint surface, and the local introduction ties that surface to the located real interval route.

Use the finite-window RegSeqRat handoff theorem. It forces the consumer through the $\mathsf{StreamName}^{\uparrow}$ window W and $\mathsf{RegSeqRat}^{\uparrow}$ readback R before the terminal $\mathsf{Real}^{\uparrow}$ seal E can be read.

Use the RealUp seal non-escape theorem. It requires the density-support row S to remain the $\mathsf{RealSeparability}^{\uparrow}$ row cited from chapter 1809, not a detached dense subset or chosen point.

Therefore the sibling route is exactly the located endpoint surface, dyadic endpoint ledger, finite window, regular rational handoff, real seal, and separability support, followed only by transport, replay, provenance, and local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBracketingInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteBracketingInterval}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, a dyadic-radius containment ledger, a StreamName finite observation window, a RegSeqRat handoff row, a RealUp terminal seal, a RealSeparability density-support row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBracketingInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1807.1, Definition 1807.2, Definition 1807.3, Definition 1807.4, and Definition 1807.5 seed the finite bracketing route over dyadic endpoints, StreamName windows, RegSeqRat readback, RealUp seal, and RealSeparability density support.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBracketingInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient stream equality, selected limits, countable choice, ambient completeness, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint order, dyadic-radius containment, finite-window RegSeqRat handoff, and RealUp seal non-escape for BEDC.Derived.FiniteBracketingIntervalUp.

Chapter 1808

A Concrete Naming Certificate for $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$

Following Bishop and Bridges' constructive interval compactness and finite-net methods, the $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ packet names the finite BEDC surface at which a located closed interval admits a displayed mesh row before any completion-facing consumer reads a cover claim. It sits after the located endpoint surface of chapter 1709, the bracketing packet of chapter 1807, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet records a finite net for a displayed located interval; it is not a general Heine-Borel theorem, an open-cover compactness principle, a quotient interval, a selected host limit, or an ambient completeness coordinate.

Definition 1808.1 (Located closed interval finite-net carrier)**.** *A* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, M, N, D, W, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, displaying the lower and upper endpoint names together with the located interval boundary that consumers may inspect.*
2. *M is the mesh-scale row, a finite dyadic tolerance request read through the same endpoint boundary.*
3. *N is the finite net row, listing the displayed mesh points admitted between the located endpoints at scale M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *coverage ledger, recording endpoint comparisons, mesh-step arithmetic, and the finite containment checks for the net row.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row opened only for the endpoint and mesh requests already displayed by I, M, D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets the opened windows as regular rational data along the same finite mesh route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the located interval, mesh, net, dyadic ledger, windows, and readback rows have been displayed.*

8. *H records componentwise* hsame *transport for the interval source, mesh scale, net row, coverage ledger, window row, readback row, seal row, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from a finite-net request through I, M, N, D, W, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{FiniteBracketingInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, general Heine-Borel compactness, host interval equality, quotient representatives, selected real limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedClosedIntervalFiniteNetUp.LocatedClosedIntervalFiniteNetTasteGate`
`single carrier alignment`

Theorem 1808.2 (Located closed interval finite-net coverage)**.** *For every accepted* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *carrier*

$$F = (I, M, N, D, W, R, E, H, C, P, L),$$

each point read by the local finite-net consumer is covered only through the displayed route

$$\mathsf{LocatedRealInterval}^{\uparrow} \longrightarrow \mathsf{FiniteBracketingInterval}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}.$$

Concretely, the consumer first reads the located interval source I, then the mesh scale M, then the finite net row N, then the dyadic coverage ledger D, and only then opens the finite windows W and readback row R.

Proof. Project the accepted carrier. The source interval row is I, and the only mesh data are the scale M, the net row N, and the dyadic coverage ledger D.

Use chapter 1709 for the endpoint surface and chapter 1807 for the finite bracketing route. The bracket read is therefore a displayed interval-and-endpoint computation before any stream window is opened.

The remaining coverage work is finite. The dyadic ledger D records the mesh-step arithmetic and containment checks, while W and R expose only the StreamName windows and RegSeqRat readback attached to that displayed ledger.

The excluded compactness principles have no coordinate in F. Thus the coverage read is a finite-net route over the listed rows, not an open-cover or ambient-completeness argument. □

Theorem 1808.3 (Located closed interval finite-net Real seal non-escape)**.** *An accepted* LocatedClosedIntervalFinite *packet exports a* $\mathsf{Real}^{\uparrow}$ *read only through the terminal seal row E after I, M, N, D, W, R have already been displayed. No consumer can escape from the finite net into general Heine-Borel compactness, open-cover compactness, host interval equality, quotient representatives, selected real limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the finite-net coverage theorem above. It forces a consumer read through the located source, mesh scale, finite net row, dyadic coverage ledger, finite windows, and regular rational readback before the terminal seal is available.

The seal row E is downstream of that finite route. It records the $\mathsf{Real}^{\uparrow}$ boundary attached to the displayed interval-net computation and does not supply an independent completed-real object.

Finally inspect the structural rows H, C, P, L. They transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for the excluded principles or host objects, the terminal seal is a non-escape boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ packet is generated from a located closed interval source, a dyadic mesh scale, a finite net row, a DyadicRatCore coverage ledger, StreamName finite windows, RegSeqRat readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1808.1, Definition 1808.2, and Definition 1808.3 seed the finite L10 interval-net route over located endpoints, bracketing rows, dyadic coverage, finite windows, regular rational readback, and the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.LocatedClosedIntervalFiniteNetUp.LocatedClosedIntervalFiniteNetTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close general Heine-Borel compactness, open-cover compactness, host interval equality, quotient representatives, selected real limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedClosedIntervalFiniteNetUp.

The $\mathsf{RealSeparability}^{\uparrow}$ hub routes rational density through chapter 1820, chapter 291, chapter 126, chapter 301, and chapter 38. Completion-facing density exports pass through chapter 1453 before any metric-completion consumer reads a countable dense surface.

The $\mathsf{RealSeparability}^{\uparrow}$ hub consumes the Cauchy-equivalence setoid route of chapter 1820 before dense real-name reads are public.

The dense schedule is read through $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rather than through quotient stream equality. The setoid route compares regular names by displayed finite classifier rows, the regular-rational route supplies the readback window, and the Real seal is consumed only after those rows are visible to the separability carrier.

Chapter 1809

A Concrete Naming Certificate for $\mathsf{RealSeparability}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of the real line by rational approximants, and the Bourbaki description of separability by a countable dense subset, the $\mathsf{RealSeparability}^{\uparrow}$ packet records the finite BEDC surface at which rational density is available to $\mathsf{Real}^{\uparrow}$ consumers. It sits on the rational naming row of chapter 37, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the countable density boundary of chapter 1566. Thus $\mathsf{RealSeparability}^{\uparrow}$ consumes the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ source surfaces of chapter 126 and chapter 301 before the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names rational dense enumeration as finite Real data; it does not introduce host real equality, choice over balls, quotient streams, or ambient completeness.

Definition 1809.1 (Real separability carrier)**.** *A* $\mathsf{RealSeparability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *enumeration row. It exposes rational candidates by finite index windows and records the order in which a density request may inspect them.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same request window, supplying the dyadic precision against which the rational candidates are tested.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row opened by D, so the consumer reads only the finite name segment required by the requested tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, transporting the inspected rational candidate and window data into the regular rational route used by the real-name interface.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It records that the dense rational window is consumed as Real data only after Q, D, W, R have already been displayed.*
6. *T is the dense-window exactness ledger. It records that every density read first cites an index in Q, then a dyadic tolerance in D, then a finite window in W, then the regular readback in R, and only then the terminal seal E.*
7. *H stores componentwise* hsame *transport for the rational enumeration, tolerance, window, readback, seal, exactness ledger, replay, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from a Real-facing density request through Q, D, W, R, T and into the terminal seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, a choice-selected dense point, quotient stream equality, ambient completeness, trichotomy, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.RealUp.RealSeparabilityCarrier`

The sibling lattice route is explicit: $\mathsf{RealSeparability}^{\uparrow}$ consumes chapter 1484 for the dyadic tolerance witness and chapter 1409 for the rational interval witness before $\mathsf{CountableDenseSubset}^{\uparrow}$ names the dense source. This places the separability packet downstream of the dyadic and rational density witnesses rather than treating density as a detached Real-side fact.

The same dyadic tolerance witness and rational interval witness feed the finite precision requests of chapter 1423: a modulus consumer may read the dyadic tolerance row D as its requested precision and the rational interval witness carried by Q, T as the finite interval evidence before opening the StreamName and RegSeqRat rows.

Theorem 1809.2 (Real separability NameCert obligations)**.** *For every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational enumeration, dyadic tolerance, StreamName window, RegSeqRat readback, Real seal, dense-window exactness ledger, transport, replay, provenance, and local naming rows;*
2. *rational enumeration exposure, requiring every density read to cite the displayed* $\mathsf{Rat}^{\uparrow}$ *index row Q before any tolerance, window, readback, or Real seal is consumed;*
3. *dense-window exactness, requiring T to bind the same request through Q, D, W so that the inspected rational candidate is tested only inside the opened finite window;*
4. *RegSeqRat handoff, requiring the finite rational data exposed by Q, D, W to pass through R before it can be read by the Real-facing boundary;*
5. *RealUp seal non-escape, requiring E, P, N to export no host real equality, choice-selected dense point, quotient stream equality, ambient completeness, trichotomy, Lean verification, or bridge checking.*

No separability obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1809.1. The tuple lists exactly the rational enumeration, tolerance, finite observation window, regular rational readback, Real seal, exactness ledger, and structural rows.

Rational enumeration exposure is forced by the placement of Q. A density request cannot inspect a candidate until the displayed $\mathsf{Rat}^{\uparrow}$ index row has been read as finite packet data.

Dense-window exactness is the row T governed by Q, D, W. It fixes the same rational index, dyadic tolerance, and finite StreamName window before any Real-facing read is admitted.

The RegSeqRat handoff is then the row R. It transports the inspected rational candidate and window data into the regular rational route, so the Real boundary receives a regular readback rather than a host real point.

Finally E, H, C, P, N seal, transport, replay, source, and name only the displayed route. Since the carrier contains no coordinate for host equality, selected dense points, quotient streams, ambient completeness, trichotomy, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSeparabilityNameCertObligations`

Theorem 1809.3 (Real separability rational dense handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *density consumer admitted by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before any separability read is exported. In particular, the consumer reads the same displayed rational enumeration row Q, dyadic tolerance row D, finite window row W, regular rational readback row R, and terminal seal row E before it can consume the local $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *surface.*

Proof. Begin with a density consumer admitted by the carrier of Definition 1809.1. Projection exposes the finite rows $Q, D, W, R, E, T, H, C, P, N$.

The first analytic row is Q, the rational enumeration. The consumer therefore starts with a displayed $\mathsf{Rat}^{\uparrow}$ index window, not with a choice-selected dense point or an ambient real value.

The tolerance and observation rows follow. The dyadic row D supplies the requested precision, and the StreamName row W opens exactly the finite window read at that precision.

The handoff to R places the inspected rational candidate into the regular rational route. Only after that readback does the terminal seal E present the datum as $\mathsf{Real}^{\uparrow}$.

The exactness ledger T, componentwise transport H, replay C, provenance P, and local naming row N preserve this order. Hence every exported density read factors through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before separability is consumed. □

Theorem 1809.4 (Real separability Cauchy-equivalence forward consumption)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that compares two regular rational windows must consume the finite classifier route of chapter 1820 before the rational dense handoff is exported. Thus an accepted separability carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

receives a finite $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison surface rather than quotient stream equality, selected representatives, host real equality, countable-choice selectors, or ambient completeness.*

Proof. Project the carrier of Definition 1809.1. A density read has only the rational enumeration row Q, dyadic tolerance row D, finite window row W, regular readback row R, terminal seal row E, exactness ledger T, transport H, replay C, provenance P, and local name N.

Apply Definition 1809.3. The rational dense handoff is exported only after the read has passed through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

When two regular rational windows are compared, read the classifier route of chapter 1820 before that export. The classifier supplies the finite Cauchy and RegSeqRat comparison surface, so the separability packet cannot replace it with quotient stream equality, selected representatives, host real equality, countable-choice selectors, or ambient completeness. □

Theorem 1809.5 (Real separability L10 density certificate)**.** *Every dense dyadic schedule exported by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it can serve a countable-density consumer. The route uses the Cauchy-equivalence classifier of chapter 1820 to compare regular rational windows, and it exports no quotient stream equality, selected dense point, host real equality, countable-choice selector, or ambient completeness witness.*

Proof. Project the carrier of Definition 1809.1. A dense dyadic schedule can read only the displayed rational enumeration row Q, dyadic tolerance row D, finite window row W, regular readback row R, terminal seal row E, exactness ledger T, transport H, replay C, provenance P, and local name N.

Apply Definition 1809.3. The exported density read must pass through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any separability consumer can use it.

Next apply Definition 1809.4. When the schedule compares two regular rational windows, the comparison is routed through $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ and not through quotient stream equality or a selected representative.

Finally route the displayed schedule to the countable-density boundary by Definition 1809.12. The same rows $Q, D, W, R, E, T, H, C, P, N$ carry the dyadic schedule to the separability export, so no host equality, selected dense point, countable-choice selector, or ambient completeness witness is introduced. □

Theorem 1809.6 (Real separability dyadic-rational density handoff)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density consumer whose tolerance row is served by an accepted* $\mathsf{DyadicDensityReal}^{\uparrow}$ *witness and whose interval witness is served by* $\mathsf{RationalDensityReal}^{\uparrow}$ *factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{DyadicDensityReal}^{\uparrow} \longrightarrow \mathsf{RationalDensityReal}^{\uparrow} \longrightarrow \mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow$$

The route uses only the displayed carrier rows $Q, D, W, R, E, T, H, C, P, N$ together with the dyadic-density surface of chapter 1484 and the rational-density surface of chapter 1409. It exports no host real equality, choice-selected dense point, quotient stream, trichotomy, or ambient completeness witness.

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier as

$$S = (Q, D, W, R, E, T, H, C, P, N).$$

The row D is the only tolerance row exposed to the density consumer, while Q, W, R, E are the rational enumeration, finite window, regular readback, and terminal Real seal rows consumed by the existing rational dense handoff.

Read the tolerance request through chapter 1484. An accepted $\mathsf{DyadicDensityReal}^{\uparrow}$ witness names the dyadic source inside $\mathsf{DyadicRatCore}^{\uparrow}$ before the Real-facing window and readback rows are inspected, so the request supplies a displayed dyadic witness rather than a selected host real point.

Next read the interval witness through chapter 1409. The accepted $\mathsf{RationalDensityReal}^{\uparrow}$ packet turns the displayed interval and dyadic tolerance into a visible $\mathsf{Rat}^{\uparrow}$ witness row, with the rational witness routed through its own finite window and ledger rows before any Real seal is available.

Compose those two witness routes with Definition 1809.3. The consumer first sees the $\mathsf{DyadicRatCore}^{\uparrow}$ source, then the dyadic-density witness, then the rational-density witness, and only then the rational enumeration, StreamName window, RegSeqRat readback, and Real seal recorded by Q, W, R, E.

The remaining rows T, H, C, P, N preserve the same order as exactness ledger, componentwise transport, displayed replay, provenance, and local naming. Since none of the three packets contains a coordinate for host real equality, a choice-selected dense point, quotient stream equality, trichotomy, or ambient completeness, the composed handoff cannot export any such data. □

Theorem 1809.7 (Real separability dyadic witness family)**.** *An accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density read determines a finite family of rational witnesses indexed only by the displayed dyadic tolerance row* D *and finite* $\mathsf{StreamName}^{\uparrow}$ *window* W *of its carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N).$$

Every witness in that family is routed through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before separability is exported. The family contains no choice-selected dense point, host real equality, quotient stream, trichotomy row, or ambient completeness witness.*

Proof. Project the carrier of Definition 1809.1. The only rows that can index a finite density family are the dyadic tolerance row D and the finite StreamName window row W, with the rational enumeration row Q supplying the visible rational candidates.

Apply Definition 1809.3. Each candidate read starts in $\mathsf{Rat}^{\uparrow}$, passes through the dyadic tolerance and finite window rows, and reaches $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Next apply Definition 1809.6. The dyadic-density and rational-density witnesses attach the family to the same displayed route, so the candidate family is indexed by D, W rather than by a choice function over Real balls.

Finally apply Definition 1809.12. The $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary receives exactly the finite rational family already routed through $Q, D, W, R, E, T, H, C, P, N$. Since the carrier and handoff theorems expose no host equality, quotient stream, trichotomy, selected dense point, or ambient completeness coordinate, the witness family exports none of them. □

Theorem 1809.8 (Real separability dyadic countable-dense scope)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense read exporting a countable dense witness must display the dyadic tolerance request, rational interval locator,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before the countable-dense consumer reads the witness. For an accepted carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the countable-dense route is scoped by the same rational enumeration row Q*, dyadic tolerance row* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, regular rational readback* R*, terminal seal* E*, exactness ledger* T*, transport* H*, replay* C*, provenance* P*, and local naming row* N*. It exports no host real equality, quotient stream, countable-choice selector, selected dense point, or ambient completeness witness.*

Proof. Project the carrier rows from Definition 1809.1. A countable-dense export has no data beyond the rational enumeration Q, dyadic tolerance D, finite window W, readback R, Real seal E, exactness ledger T, transport H, replay C, provenance P, and local naming row N.

Use Definition 1809.7. The exported witness family is indexed by the displayed dyadic tolerance request D and finite StreamName window W, with the rational enumeration row Q supplying the visible rational candidates. The rational interval locator is therefore consumed as part of the finite rational-density handoff rather than as a choice over Real balls.

Next use Definition 1809.13. Every comparison of regular-rational names passes through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before the dense rational row is exported, so the readback R is classified by displayed Cauchy-setoid data and not by quotient stream equality.

Finally apply Definition 1809.12. The $\mathsf{CountableDenseSubset}^{\uparrow}$ consumer receives the witness only after the route through $Q, D, W, R, E, T, H, C, P, N$ has reached the terminal $\mathsf{Real}^{\uparrow}$ seal. Since the carrier and cited routes have no coordinate for host real equality, quotient streams, countable-choice selectors, selected dense points, or ambient completeness, the countable-dense export cannot expose any of them. □

Theorem 1809.9 (Real separability RegSeqRat dense-window induction)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window read for a carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

can be consumed by induction over the displayed finite $\mathsf{StreamName}^{\uparrow}$ *window* W *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *are opened. The induction exposes only the rational enumeration row* Q*, dyadic tolerance row* D*, finite window* W*, dense-window exactness ledger* T*, transport* H*, replay* C*, provenance* P*, and local naming row* N *until the readback and seal rows are explicitly displayed. It exports no selected dense point, quotient stream, trichotomy branch, ambient completeness witness, host real equality, or countable-choice selector.*

Proof. Project the carrier of Definition 1809.1. Before R and E are opened, the dense-window read has exactly the rational enumeration, dyadic tolerance, finite StreamName window, exactness ledger, transport, replay, provenance, and local naming rows available.

Apply the rational dense handoff Definition 1809.3. It orders every density consumer through Q, D, W before the RegSeqRat readback and Real seal can be used.

Use the Cauchy-equivalence forward consumption theorem Definition 1809.4. Any comparison of regular rational windows is deferred to the displayed classifier route, so the induction over W cannot become quotient stream equality or host real equality.

Finally apply the dyadic witness family theorem Definition 1809.7. The rational witnesses form a finite family indexed by D and W, hence the dense-window read is consumed by finite-window induction before R and E are opened. The refused principles are absent from the carrier inventory. □

Theorem 1809.10 (Real separability finite-density selector)**.** *Every finite density selector exported by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

factors through the displayed route

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The selector first reads the rational enumeration row Q*, then the dyadic tolerance row* D*, then the finite StreamName window* W*, then the RegSeqRat readback row* R*, and only then the terminal Real seal* E*. It cannot expose a chosen dense point, quotient stream, host real equality, ambient completeness witness, selected nearest point, or detached dense subset.*

Proof. Project the accepted carrier. The rows available to a finite density selector are exactly the rational enumeration Q, dyadic tolerance D, finite window W, readback R, Real seal E, exactness ledger T, transport H, replay C, provenance P, and local naming row N.

Apply Definition 1809.3. It forces the selector to begin at the $\mathsf{Rat}^{\uparrow}$ enumeration row and to pass through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any separability boundary is exported.

Next apply Definition 1809.6. The dyadic tolerance and rational-density witness surfaces attach the selector to the same finite request, so the selected datum is displayed as a routed rational witness rather than as a point chosen from an ambient Real ball.

Finally apply Definition 1809.7. The admissible witnesses form a finite family indexed by D and W, and each family member is consumed through Q, R, E, T, H, C, P, N. Since no listed row contains a quotient stream, host equality, ambient completeness witness, selected nearest point, or detached dense subset, the selector cannot export any such object. □

Theorem 1809.11 (Real separability stream-window stability)**.** *Let*

$$S = (Q, D, W, R, E, T, H, C, P, N)$$

and

$$S' = (Q', D', W', R', E', T', H', C', P', N')$$

be accepted $\mathsf{RealSeparability}^{\uparrow}$ *packets whose rational enumeration, dyadic tolerance, and finite stream-window rows are componentwise transported by displayed* hsame *data*

$$Q\mathsf{hsame}Q', \qquad D\mathsf{hsame}D', \qquad W\mathsf{hsame}W',$$

and whose replay rows display the same Cont *route from a Real-facing density request through those transported rows. Then the finite rational witness family determined by S and the family determined by S' are the same displayed density route. In particular, the RegSeqRat readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff agree as packet data, and no choice-selected dense point, host real equality, quotient stream equality, trichotomy row, or ambient completeness witness is introduced by replacing S with S'.*

Proof. Project the two carriers. The hypotheses identify the only rows that index the finite rational witness family: the rational enumeration rows Q, Q', the dyadic tolerance rows D, D', and the StreamName windows W, W'.

Apply Definition 1809.3 to both packets. Since the displayed Cont replay carries the same request through transported Q, D, W rows, the inspected rational candidates are read along the same finite route before any RegSeqRat or Real seal row is visible.

Apply Definition 1809.6. The dyadic-density and rational-density surfaces attach to the transported tolerance and window rows, so the two packets expose the same dyadic-rational density witness route.

Finally apply Definition 1809.7 and Definition 1809.12. The witness family is exhausted by the displayed route through $Q, D, W, R, E, T, H, C, P, N$ and the transported route through $Q', D', W', R', E', T', H', C', P', N'$, with no additional coordinate available for a selected dense point, host equality, quotient stream, trichotomy, or ambient completeness. □

Theorem 1809.12 (Real separability finite-density exhaustion)**.** *Every admitted* $\mathsf{RealSeparability}^{\uparrow}$ *density read is exhausted by the displayed finite route*

$$\mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{CountableDenseSubset}^{\uparrow}.$$

Equivalently, the consumer reads only the carrier rows $Q, D, W, R, E, T, H, C, P, N$ together with the finite rational-density and dyadic-density handoff surfaces before the local separability certificate is exported.

The route exports no choice-selected dense point, quotient stream, trichotomy row, ambient completeness witness, host real equality, selected nearest point, or detached dense subset.

Proof. Project the carrier of Definition 1809.1. The rows Q, D, W, R, E give the rational enumeration, dyadic tolerance, StreamName window, RegSeqRat readback, and terminal Real seal, while T, H, C, P, N provide exactness, transport, replay, provenance, and the local naming row.

Apply Definition 1809.3. It forces every density consumer through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any separability read is available.

Next apply Definition 1809.6. The dyadic and rational density witnesses are inserted into the same finite route, so the density source is displayed by the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary and not by an external dense point.

The structural rows T, H, C, P, N preserve that order and add no analytic coordinate. Since the carrier and the two handoff routes contain no choice-selected dense point, quotient stream, trichotomy, ambient completeness, host real equality, selected nearest point, or detached dense subset, the displayed finite route exhausts the admitted density read. □

Theorem 1809.13 (Real separability Cauchy-setoid density stability)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that compares two regular-rational names must pass through the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier of chapter 1820 before the dense rational row is exported. For an accepted separability carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the exported density route is therefore the composite of $Q, D, W, R, E, T, H, C, P, N$ *with the displayed Cauchy-equivalence classifier rows, and it exposes no quotient stream equality, selected representative, countable choice, host real equality, or ambient completeness.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier. The rows $Q, D, W, R, E, T, H, C, P, N$ list the rational enumeration, dyadic tolerance, finite window, regular rational readback, Real seal, dense-window exactness, transport, replay, provenance, and local naming available to the density consumer.

When the consumer compares two regular-rational names, the comparison is not a free equality on streams. It must open the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier of chapter 1820, where the two StreamName windows, RegSeqRat readbacks, dyadic tolerance ledger, setoid-test row, Real seal boundary, transport, replay, provenance, and local naming rows are displayed.

Compose that classifier route with Definition 1809.6. The dense rational row is exported only after the regular readback R, dyadic row D, window row W, and terminal seal E have been compared through the Cauchy-setoid surface.

The structural rows T, H, C, P, N preserve this composite route. Since neither the separability carrier nor the Cauchy-setoid classifier carries quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness, the density read cannot export any of those objects. □

Theorem 1809.14 (Real separability completion-facing density handoff)**.** *Every completion-facing* $\mathsf{RealSeparability}^{\uparrow}$ *density read factors through* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformSpaceCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, *or other completion consumer reads it. For an accepted carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the exported density data is exactly the displayed finite route through the rational enumeration row Q, dyadic tolerance row D, finite stream window W, regular rational readback R, Real seal E, dense-window ledger T, transport H, replay C, provenance P, and local naming row N. It exports no selected nearest point, quotient stream equality, countable-choice selector, host dense subset, or ambient Real completeness.

Proof. Project the carrier of Definition 1809.1. The rows $Q, D, W, R, E, T, H, C, P, N$ are the only data available to a density read before it reaches a completion-facing consumer.

Apply Definition 1809.12. The density read is already exhausted by the route through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CountableDenseSubset}^{\uparrow}$; no selected dense point or external dense subset is introduced.

Next apply Definition 1809.13. Any comparison of regular rational names required by the completion-facing read passes through the displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before the dense row is exported.

Finally hand the same finite route to the completion consumer. Since the carrier rows and cited sibling routes contain no selected nearest point, quotient stream equality, countable-choice selector, host dense subset, or ambient Real completeness coordinate, the completion-facing consumer receives only the displayed density handoff. □

Theorem 1809.15 (Real separability seed-density ledger)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density read exposes the finite L10 seed route*

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{CountableDenseSub}$$

in that order before the read is exported as $\mathsf{RealSeparability}^{\uparrow}$ *data. For an accepted carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the ledger rows $Q, D, W, R, E, T, H, C, P, N$ supply respectively the rational enumeration, dyadic tolerance, finite stream window, regular-rational readback, terminal real seal, dense-window exactness, componentwise transport, replay, provenance, and local naming. The route exports no host $\mathsf{Real}^{\uparrow}$ *equality, selected dense point, quotient stream, countable-choice selector, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier of Definition 1809.1. The rational enumeration row Q, dyadic tolerance row D, finite $\mathsf{StreamName}^{\uparrow}$ window W, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, terminal $\mathsf{Real}^{\uparrow}$ seal E, exactness ledger T, transport H, replay C, provenance P, and local name N are the only rows available to a density consumer.

Apply the rational dense handoff of Definition 1809.3. It places every accepted density read first on the displayed $\mathsf{Rat}^{\uparrow}$ enumeration and then through the dyadic tolerance, finite window, regular readback, and terminal seal rows.

Next apply the dyadic-rational density handoff of Definition 1809.6. The $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance source and rational-density witness are inserted before the separability export, so the route is a finite density route rather than a selected point from an ambient Real ball.

Use Definition 1809.12 to pass the same finite family to the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary. Then use Definition 1809.13 to force every comparison of regular-rational names through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before that boundary is read.

The structural rows T, H, C, P, N preserve the displayed order and add no analytic principle. Since the carrier and the cited routes contain no coordinate for host Real equality, selected dense points, quotient streams, countable choice, trichotomy, or ambient Real completeness, the exported $\mathsf{RealSeparability}^{\uparrow}$ data contains none of them. □

Theorem 1809.16 (Real separability obligation-closure route)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density export factors through the finite L10 seed chain*

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{CountableDenseSub}$$

before any public separability data is read. For an accepted carrier

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the obligation surface consists only of the rational dense handoff, dyadic-rational density handoff, finite-density exhaustion, Cauchy-setoid density stability, and seed-density ledger rows. It exports no selected dense point, quotient stream, countable-choice selector, trichotomy branch, host real equality, or ambient completeness witness.

Proof. Project the carrier of Definition 1809.1. The rows $Q, D, W, R, E, T, H, C, P, N$ are the only displayed data available to a density consumer.

Apply the rational dense handoff and the dyadic-rational density handoff. These two routes place every density export behind the $\mathsf{Rat}^{\uparrow}$ enumeration, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal before the separability row is visible.

Next apply finite-density exhaustion. It packages the same finite family as the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary rather than as a selected point from an ambient real ball.

Use Cauchy-setoid density stability for every comparison of regular-rational names. The comparison must pass through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before the dense row is exported, so the route never becomes quotient stream equality or host real equality.

Finally apply the seed-density ledger. The structural rows T, H, C, P, N preserve the displayed order and add no analytic coordinate, so the excluded selected dense point, quotient stream, countable-choice, trichotomy, host-equality, and ambient-completeness data cannot be exported by the accepted $\mathsf{RealSeparability}^{\uparrow}$ packet. □

The dense Real route also reads Cauchy-equivalent regular names through the classifier of chapter 1820 before export. Classifier stability keeps equivalent regular names on the same displayed density-consumer route, so the separability packet transports dense witnesses through finite RegSeqRat and Real rows rather than through quotient real equality or ambient completeness.

Chapter 1810

A Concrete Naming Certificate for $\mathsf{RealClamping}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealClamping}^{\uparrow}$ packet records the finite interval-clamp surface by which a displayed real name is forced through a located rational interval before any classical order principle is available. It sits over the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the equality boundary of chapter 1636, the located interval surface of chapter 1709, the finite min/max operation of chapter 1674, and the positive-radius discipline of chapter 1587. The packet gives interval-enclosure and bisection consumers one bounded Real-facing clamp route; it does not import host trichotomy, quotient equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1810.1 (RealClamping carrier)**.** *A* $\mathsf{RealClamping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (X, L, U, D, W, R, E, I, M, A, H, T, P, N)$$

with the following displayed rows:

1. *X is the displayed* $\mathsf{Real}^{\uparrow}$ *source seal whose interval clamp is being named.*
2. *L and U are the displayed lower and upper bound rows, read as* $\mathsf{Real}^{\uparrow}$ *data and constrained by the same located interval request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radius, endpoint slack, and rational comparison budget used by the clamp.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the precision named by D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from X, L, U, W, D before any clamp value is exposed.*
6. *E is the* $\mathsf{RealEquality}^{\uparrow}$ *boundary row used only when the source and an endpoint are indistinguishable at the displayed tolerance.*
7. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *interval row exposing the same lower endpoint, upper endpoint, positive radius, and containment request as finite interval data.*
8. *M is the* $\mathsf{RealMinMax}^{\uparrow}$ *operation row, displaying the constructive min/max route used to form the bounded clamp from X, L, U, R, E, I.*
9. *A is the* $\mathsf{PositiveReal}^{\uparrow}$ *radius row. It records that the interval has a positive displayed separation budget, not a trichotomy witness.*

10. *H records componentwise* hsame *transport for the source seal, endpoints, tolerance ledger, finite window, readback, equality boundary, interval row, min/max row, positive-radius row, replay, provenance, and local naming rows.*

11. *T records displayed* Cont *replay from an interval-clamp request through D, W, R, E, I, M, A and back to the public clamp boundary.*

12. *P is the* Pkg *provenance over* $\mathsf{RealClamping}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealMinMax}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive interval-clamp packet. It has no coordinate for host trichotomy, quotient equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1810.2 (RealClamping NameCert obligations)**.** *For every accepted* $\mathsf{RealClamping}^{\uparrow}$ *carrier*

$$C = (X, L, U, D, W, R, E, I, M, A, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Real seal, endpoint Real rows, dyadic tolerance ledger, finite window, regular rational readback, equality boundary, located interval row, min/max row, positive-radius row, transport, replay, provenance, and local naming;*

2. *interval-bound exposure, requiring L, U, I, A to be displayed before the clamp row can be consumed as bounded Real data;*

3. *finite readback exactness, requiring every clamp request to pass through D, W, R before either equality-boundary or min/max data are inspected;*

4. *equality-boundary confinement, requiring E to serve only as the displayed endpoint-overlap boundary and not as quotient equality of reals;*

5. *min/max routing, requiring M to form the clamp through the displayed* $\mathsf{RealMinMax}^{\uparrow}$ *row rather than through host trichotomy or host order;*

6. *non-escape, requiring H, T, P, N to export no host trichotomy, quotient equality, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

No RealClamping obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1810.1. The accepted packet displays exactly the source Real seal, two endpoint rows, the dyadic tolerance ledger, finite window, regular rational readback, equality boundary, located interval row, min/max row, positive-radius row, and structural rows.

Interval-bound exposure is forced by the rows L, U, I, A. A consumer cannot read a bounded clamp value before the endpoints, located interval row, and positive-radius budget have been displayed as finite packet data.

Finite readback exactness is the middle route D, W, R. The tolerance ledger fixes the requested precision, the StreamName row opens the finite observations, and the RegSeqRat row repacks those observations before equality or min/max data are available.

The equality-boundary and min/max obligations are separate. The row E records only the displayed overlap boundary at the requested tolerance, while M records the constructive min/max route that forms the bounded clamp.

Finally H, T, P, N transport, replay, source, and name the same finite route. Since the carrier inventory omits host trichotomy, quotient equality, selected limits, countable choice, ambient Real completeness, Lean verification, and bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 1810.3 (RealClamping interval seal)**.** *Let $C = (X, L, U, D, W, R, E, I, M, A, H, T, P, N)$ be an accepted* $\mathsf{RealClamping}^{\uparrow}$ *carrier. Every* $\mathsf{LocatedRealInterval}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read of the clamp factors through the displayed route*

$$X, L, U \longmapsto D, W, R \longmapsto E, I, A \longmapsto M \longmapsto H, T, P, N.$$

Consequently the exported clamp is sealed only as a bounded interval value over the displayed Real, RegSeqRat, StreamName, DyadicRatCore, RealEquality, LocatedRealInterval, RealMinMax, and PositiveReal rows. It is not a host-order projection, quotient representative, selected limit, or ambient completeness consequence.

Proof. Start with the accepted carrier and project the rows $X, L, U, D, W, R, E, I, M, A, H, T, P, N$. The only Real-facing inputs are the source seal and the two endpoint rows.

The readback route then passes through D, W, R. These rows determine the finite tolerance request, the observation window, and the regular rational readback before any interval or clamp output can be consumed.

The interval seal is E, I, A. The equality row handles endpoint overlap at the displayed tolerance, the located interval row exposes the bounded containment request, and the positive-radius row records the separation budget.

The min/max row M is downstream of those interval rows. It forms the clamp through the displayed constructive operation and then hands the result to H, T, P, N for transport, replay, provenance, and local naming.

No other coordinate is present. Hence every consumer receives only the displayed bounded interval seal and cannot extract host trichotomy, quotient equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1810.4 (RealClamping Cauchy stability)**.** *For every accepted* $\mathsf{RealClamping}^{\uparrow}$ *carrier $C = (X, L, U, D, W, R, E, I, M, A, H, T, P, N)$, replacing X, L, U, W, R by componentwise* hsame-*transported* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows preserves the same public clamp boundary whenever the transported packet keeps the displayed D, E, I, M, A, T, P, N rows. The stabilized boundary is again the finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealEquality}^{\uparrow}$*,* $\mathsf{LocatedRealInterval}^{\uparrow}$*,* $\mathsf{RealMinMax}^{\uparrow}$*,* $\mathsf{PositiveReal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*; it does not require a selected limit or ambient Real completeness theorem.*

Proof. Componentwise transport is supplied by the row H. It relates the source seal, endpoint rows, finite window, and regular readback without adding any coordinate outside the carrier.

The fixed rows D, E, I, M, A keep the analytic boundary unchanged. They preserve the same dyadic tolerance ledger, equality boundary, located interval request, min/max operation row, and positive-radius budget.

Displayed replay is supplied by T. The transported request therefore follows the same finite route from Real seals through StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, RealEquality boundary, LocatedRealInterval containment, RealMinMax operation, and PositiveReal radius.

The provenance and local naming rows P, N repack that route as the same public $\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}$ surface. Since no selected limit, quotient equality, host trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness field is present, Cauchy stability is exactly stability of the displayed finite packet. □

Falsifiable prediction: Every $\mathsf{RealClamping}^{\uparrow}$ read factors through one $\mathsf{Real}^{\uparrow}$ source seal, two $\mathsf{Real}^{\uparrow}$ endpoint rows, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{StreamName}^{\uparrow}$ finite window, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{RealEquality}^{\uparrow}$ boundary row, one $\mathsf{LocatedRealInterval}^{\uparrow}$ interval row, one $\mathsf{RealMinMax}^{\uparrow}$ operation row, one $\mathsf{PositiveReal}^{\uparrow}$ radius row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore, real-equality, located-real-interval, real-min-max, positivereal: $\mathsf{RealClamping}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source and endpoint Real rows, finite tolerance readback, equality-boundary handling, located interval exposure, min/max clamping, positive-radius data, and one public bounded clamp boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1810.1, Definition 1810.2, Definition 1810.3, and Definition 1810.4 seed the finite constructive interval-clamp route from displayed Real rows through dyadic tolerance, finite windows, regular rational readback, equality boundary, located interval data, min/max operation, positive-radius budget, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealClamping}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-bound exposure, finite readback exactness, equality-boundary confinement, min/max routing, interval sealing, and Cauchy stability for BEDC.Derived.RealClampingUp.

Constructive story: A $\mathsf{RealClamping}^{\uparrow}$ packet is generated from one RealUp source seal, two endpoint RealUp rows, a DyadicRatCore tolerance ledger, StreamName finite window, RegSeqRat readback, RealEquality boundary, LocatedRealInterval row, RealMinMax operation row, PositiveReal radius row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{RealSeparability}^{\uparrow}$ rational dense enumeration is read through the dyadic-density surface of chapter 1484, the rational-density surface of chapter 1409, and the countable dense subset boundary of chapter 1566 before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Theorem 1810.5 (RealSeparability finite-density lattice)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *density packet presents its sibling dependency lattice as the finite route through chapter 37, chapter 291, chapter 126, chapter 301, chapter 38, and chapter 1566. A density consumer reaches the local separability row only after these sibling certificates expose the rational source, dyadic tolerance, finite window, regular readback, terminal Real seal, and countable dense support.*

Proof. Project the carrier of Definition 1809.1. Its displayed rows are the rational enumeration, dyadic tolerance, StreamName window, RegSeqRat readback, Real seal, dense-window exactness ledger, transport, replay, provenance, and local naming row.

Read those rows through the sibling chapters named in the statement. The rational source is supplied by $\mathsf{Rat}^{\uparrow}$, tolerance by $\mathsf{DyadicRatCore}^{\uparrow}$, finite observation by $\mathsf{StreamName}^{\uparrow}$, regular readback by $\mathsf{RegSeqRat}^{\uparrow}$, the terminal public exit by $\mathsf{Real}^{\uparrow}$, and dense support by $\mathsf{CountableDenseSubset}^{\uparrow}$.

Since the carrier has no coordinate for host real equality, choice-selected dense points, quotient streams, trichotomy, or ambient completeness, this displayed sibling lattice is the whole finite-density dependency route. □

Theorem 1810.6 (Finite Cauchy density nets extract RealUp separability)**.** *Let* $N = (D_{\mathrm{net}}, W_{\mathrm{net}}, R_{\mathrm{net}}, E_{\mathrm{net}}, M_{\mathrm{net}},$ *be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet over dyadic and regular-Cauchy windows, and let*

$$S = (Q, D, W, R, E, T, H, C, P, N_S)$$

be the $\mathsf{RealSeparability}^{\uparrow}$ *density carrier whose finite observation request reads the same dyadic mesh, finite stream window, regular-Cauchy readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. Then the finite density-net certificate induces the finite observation row needed by* $\mathsf{RealSeparability}^{\uparrow}$*:* $D_{\mathrm{net}}, W_{\mathrm{net}}, R_{\mathrm{net}}, E_{\mathrm{net}}, M_{\mathrm{net}}$ *supply the dyadic witness family, finite window, regular readback, Real seal, and precision budget for* Q, D, W, R, E*, while* $T_{\mathrm{net}}, C_{\mathrm{net}}, P_{\mathrm{net}}, L_{\mathrm{net}}$ *transport, replay, source, and name the same separability route. Classifier stability is inherited from regular-Cauchy tail equivalence and dyadic mesh refinement, so the induced observation row exports no host countability assumption, selected dense point, quotient stream equality, trichotomy branch, or ambient completeness witness.*

Proof. First project the finite density-net packet. Its rows display the dyadic net ledger, finite StreamName window, RegSeqRat readback, Real seal, and precision budget before any density read is exported.

Next align those rows with the $\mathsf{RealSeparability}^{\uparrow}$ carrier. The rational enumeration and dyadic tolerance rows Q, D consume the net ledger and budget, the finite window W consumes W_{net}, and the regular readback and Real seal rows R, E consume $R_{\mathrm{net}}, E_{\mathrm{net}}$.

The classifier comparison is stable because regular-Cauchy tail equivalence preserves the readback row, while dyadic mesh refinement preserves the finite net ledger and its tolerance budget. The transport and replay rows of the density-net packet therefore induce the transport and replay required by the separability carrier.

Finally apply the finite-density exhaustion route for $\mathsf{RealSeparability}^{\uparrow}$. The separability read receives only the displayed finite observation rows and their provenance. Since neither packet contains host countability, a selected dense point, quotient stream equality, trichotomy, or ambient completeness, the induced observation row cannot export any of those surfaces. □

Every $\mathsf{RealSeparability}^{\uparrow}$ density read is consumed through the sibling lattice $\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$, with substantive producer and consumer rows supplied by $\mathsf{CountableDenseSubset}^{\uparrow}$ in chapter 1566, $\mathsf{DyadicDensityReal}^{\uparrow}$ in chapter 1484, and $\mathsf{RationalDensityReal}^{\uparrow}$ in chapter 1409. The $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is the only public exit, the finite windows are those of chapter 126, regular readback is the route of chapter 301, and the tolerance ledger is the dyadic surface of chapter 291; thus a separability consumer reads density data as finite rational-window evidence before it reaches the real seal, with no host equality, selected dense point, quotient stream, or ambient completeness row.

Theorem 1810.7 (RealSeparability dependency route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density consumer reaches the local* NameCert *row only after passing through the rational source of chapter 37, the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. Thus the separability packet exposes density as a finite rational-window route over displayed BEDC rows, not as a host dense subset, quotient real equality, selected nearest point, or ambient completeness principle.*

Proof. Project the $\mathsf{RealSeparability}^{\uparrow}$ carrier through its local construction file. The density consumer first reads the rational enumeration row, so the route begins with the $\mathsf{Rat}^{\uparrow}$ source surface rather than an external dense set.

The dyadic tolerance and finite-window stages are then forced by the displayed tolerance ledger. The $\mathsf{DyadicRatCore}^{\uparrow}$ row fixes the requested rational scale, and the $\mathsf{StreamName}^{\uparrow}$ row supplies exactly the inspected finite windows.

The readback and seal stages are $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Regular rational readback consumes the same finite windows, and the terminal real-name seal is reached only after that readback is displayed.

The local NameCert row packages this route with its hsame, Cont, and Pkg provenance. Since the route has no coordinate for a host dense subset, quotient real equality, selected nearest point, or completeness theorem, every density consumer factors through the listed sibling chapters before the local certificate row. □

Theorem 1810.8 (Real separability dyadic lattice link)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read consumes the dyadic density lattice through chapter 38, chapter 37, and chapter 291 before any separability observation is exported. The* $\mathsf{Real}^{\uparrow}$ *row supplies the terminal real-name seal, the* $\mathsf{Rat}^{\uparrow}$ *row supplies the rational dense source, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row supplies the finite tolerance lattice that controls each displayed approximation window.*

The same dependency route reads dense dyadic witnesses through chapter 291, regular-sequence readback through chapter 301, and the completed real seal through chapter 38 before the $\mathsf{RealSeparability}^{\uparrow}$ *carrier exports its finite density row.*

Proof. Project the accepted separability packet to its displayed density route. A consumer first reads the real-name seal so that the observation is a $\mathsf{Real}^{\uparrow}$-facing read rather than a host dense-subset claim.

The rational source is then supplied by the $\mathsf{Rat}^{\uparrow}$ row. Its enumeration is meaningful for separability only after the dyadic tolerance lattice has fixed the finite scale at which the approximation is inspected.

The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies that finite scale and feeds the same request into the existing density route. Hence the separability observation cannot float as a kernel-only island: it is exported only after the real, rational, and dyadic lattice rows have all been consumed. □

Theorem 1810.9 (Real separability Cauchy completion route)**.** *Every dense dyadic witness exported by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet feeds* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{BishopCompletionCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *only through finite windows and dyadic readback. The route first displays the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and only then the completion or Real-facing seal. It has no coordinate for quotient stream equality, ambient completeness, selected host limits, or an unbounded dense-set search.*

Proof. Use the density carrier and finite density lattice already present in the $\mathsf{RealSeparability}^{\uparrow}$ packet. They expose dense dyadic witnesses as finite certificate rows rather than as a global choice function.

The dyadic lattice link places each witness on a $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and tolerance ledger. The sibling route through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ then reads that ledger through a finite window before any completion-facing consumer can use it.

Finally the completion consumers receive the same finite readback. Since the packet has no row for quotient streams, ambient completeness, selected host limits, or unbounded dense search, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ and $\mathsf{BishopCompletionCriterion}^{\uparrow}$ can consume the witness only through the displayed finite-window and dyadic-readback route. □

Theorem 1810.10 (Real separability Cauchy-equivalence lattice route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *finite density read that is consumed by a Cauchy-equivalence or completion classifier must pass through the displayed* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$

sibling rows. The route exposes finite density windows and dyadic readback before the Cauchy-equivalence classifier is read, and it exports no quotient real equality, selected dense enumeration, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the density routes of Definition 1809.12 and Definition 1809.3, whose dyadic-rational handoff is recorded in Definition 1809.6. They read the rational dense enumeration through finite dyadic and rational-density surfaces before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Next use the completion-facing sibling route, Definition 1810.9. It forces the same density witness through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ finite windows before any completion-facing consumer receives the read.

Finally attach the Cauchy-equivalence classifier of chapter 1820. The classifier may consume only the displayed finite windows and sibling rows already supplied by the separability route. Since neither route includes quotient real equality, a selected dense enumeration, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, the reciprocal lattice edge cannot export any of those claims. □

The Cauchy-equivalence route for $\mathsf{RealSeparability}^{\uparrow}$ is the finite density-row consumer in which $\mathsf{RegSeqRat}^{\uparrow}$ windows and the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier are both visible before the $\mathsf{Real}^{\uparrow}$ density row is exported. A separability consumer reads chapter 301 for the regular rational windows, then chapter 1820 for the comparison surface that keeps equivalent regular names on the same finite density route, and only then chapter 38 for the terminal Real seal. Thus the dependency edge records finite readback and classifier data, not quotient real equality, a selected dense enumeration, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Lemma 1810.11 (Real separability Cauchy-equivalence dependency route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that is consumed through a Cauchy-equivalence classifier must display the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback windows and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier before the* $\mathsf{Real}^{\uparrow}$ *density row is exported. The route is a child dependency of chapter 1809, chapter 301, and chapter 1820; it exports no quotient stream equality, selected dense point, host real equality, or ambient completeness.*

Proof. Project the Real separability density read through the displayed finite route. The rational candidate and tolerance request are not yet Real data; they must first be read through the regular rational windows supplied by $\mathsf{RegSeqRat}^{\uparrow}$.

Next read the Cauchy-equivalence classifier. It compares the regular names only through the displayed finite classifier rows of $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, so equivalent names replay the same density route before the Real seal is available.

Finally export the terminal $\mathsf{Real}^{\uparrow}$ density row. Since the preceding rows contain no quotient stream equality, selected dense point, host real equality, or ambient completeness coordinate, the exported separability read contains none of them. □

Every $\mathsf{RealSeparability}^{\uparrow}$ finite-density read that compares two regular real names first consumes the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier surface of chapter 1820 before the density row is exported. The route displays the $\mathsf{RegSeqRat}^{\uparrow}$ readback windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before any separability consumer reads density; it exports no quotient real equality, selected dense enumeration, countable choice, host equality, or ambient completeness. The hub status route for $\mathsf{RealSeparability}^{\uparrow}$ is the child closurestatus block in Definition 1810.19, whose scoped surface is recorded inside the routed child file before the hub exposes the Real and completion dependency lattice. The $\mathsf{RealSeparability}^{\uparrow}$ hub is seeded by its displayed child routes: density, Cauchy-equivalence, dyadic-lattice, completion, RegSeqRat, MetricCompletion, and countable-dense siblings jointly expose the finite separability surface without adding theorem content to the

hub. Its seed route binds $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, density, completion, and countable-dense routes as the visible finite rows through which dense Real names are read, and the hub-level seed registration records exactly this child-route family. The adjacent obligation marker on the hub points to the same child-route family: the route becomes obligation-level only through the carrier, route exactness, density coverage, Cauchy compatibility, dyadic compatibility, completion handoff, transport, replay, provenance, and local naming rows named in this child status block.

Theorem 1810.12 (Real separability seed status)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *seed status binds the existing Cauchy-equivalence,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *density routes as the displayed child-route family through which dense Real names are read. It does not claim countable choice, quotient Real equality, full Real completeness, or any verified density theorem beyond the rows named in the seed ledger.*

Proof. The seed child lists the visible route family and fixes the route at seed with $\mathsf{unformalized}$ formal status. Thus the record is a ledger statement about displayed child routes, not a proof object for the formal axis.

The closure and verification axes remain separate: the former says which paper rows are named, while the latter is still bounded by the absence of a checked carrier admission, route exactness theorem, density coverage theorem, and completion handoff for $\mathsf{RealSeparability}^{\uparrow}$. □

Theorem 1810.13 (Real separability finite dense-window seed target)**.** *Finite dense-window packets over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *provide the paper-side seed target for* $\mathsf{RealSeparability}^{\uparrow}$*. The target reads dyadic tolerance rows, finite stream observations, regular-rational readback, and the terminal Real seal as displayed packet data before any dense-name consumer is exposed. It does not claim classical separability of* $\mathsf{Real}^{\uparrow}$*, a chosen countable dense subset, quotient Real equality, or countable choice.*

Proof. Read the finite-window rows already displayed by the seed status block. The dyadic row supplies the tolerance ledger, the StreamName row supplies bounded observations, the RegSeqRat row supplies regular rational readback, and the Real row supplies the terminal seal.

The conclusion is therefore a paper-side seed target over those finite packets. It remains on the theory axis: no `\leanchecked{}` marker is attached here, and the formal verification axis is still the one recorded in the surrounding closurestatus block.

The refused endpoints follow from the same row inspection. None of the displayed finite-window rows contains a classical separability theorem, a selected dense enumeration, quotient Real equality, or a countable-choice schedule. □

Theorem 1810.14 (Real separability scoped density route)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density read factors through the L10 source chain*

$$\mathsf{CauchyEquivalenceSetoid}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before exposing a countable-dense seal. The route reads the Cauchy-equivalence classifier, dyadic tolerance ledger, finite stream windows, regular-rational readback, and terminal Real seal as displayed rows, and it exports no quotient stream equality, selected dense enumeration, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the seed route named by Definition 1810.12. Its child-route family keeps density, Cauchy-equivalence, dyadic approximation, finite StreamName windows, RegSeqRat readback, and the Real seal visible as separate rows.

Use the Cauchy-equivalence routes, including Definition 1810.10 and Definition 1810.21. They place the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier on the density read without converting it into quotient stream equality.

Next compose with the dyadic-density and L10 source routes, including Definition 1809.6 and Definition 1809.5. These keep the dyadic tolerance, stream-window, RegSeqRat, and Real rows visible before a countable-dense consumer receives the seal.

The refused endpoints follow from the same route discipline. Because the seed packet exposes only the listed child rows, it supplies neither a selected dense enumeration nor countable choice nor ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1810.15 (RealSeparability seed closure route)**.** *The seed closure route for* $\mathsf{RealSeparability}^{\uparrow}$ *is the child-file route that binds dyadic and rational density,* $\mathsf{RegSeqRat}^{\uparrow}$ *windows,* $\mathsf{StreamName}^{\uparrow}$ *witnesses, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any dense-name consumer reads a separability row. It is the critical-path to-seed rotation witness over the displayed child ledger of Definition 1810.12 and Definition 1810.14; it exports no host dense enumeration, quotient Real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1810.12 to identify the seed ledger as the child-route family rather than as theorem content on the hub. The visible rows include density, Cauchy-equivalence, dyadic approximation, StreamName windows, RegSeqRat readback, completion-facing handoff, and the Real seal.

Then apply Definition 1810.14. It orders the Cauchy-equivalence, dyadic, StreamName, RegSeqRat, and Real rows before the countable-dense seal is exposed, so the seed route is exactly the displayed finite closure route stated above. □

Theorem 1810.16 (Real separability seed status route)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *seed-status route is the displayed L10 chain through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal, with* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming kept visible before any dense-name or countable-dense consumer reads the packet. It records the existing separability rows as a finite child-route family and exports no quotient Real equality, selected dense enumeration, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 1810.12. It identifies the seed surface as a child-route family rather than as data stored on the hub.

Apply the scoped density route and seed closure route, Definition 1810.14 and Definition 1810.15. They order the dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, and terminal Real seal before the countable-dense row is visible.

Finally read the structural rows componentwise. The hsame, Cont, Pkg, and NameCert entries preserve and name the same child ledger, so the seed-status route contains exactly the displayed separability rows and none of the refused endpoints. □

Theorem 1810.17 (Real separability Cauchy-setoid dyadic density obligation)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density request must expose the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any countable-dense row is consumed. The obligation is exactly the finite child-route coverage named by Definition 1810.12, Definition 1810.14, and Definition 1810.15; it exports no quotient Real equality, selected dense enumeration, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 1810.12. It identifies the $\mathsf{RealSeparability}^{\uparrow}$ seed surface as the displayed child-route family rather than as content stored on the hub.

Apply Definition 1810.14. The route orders the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier, dyadic approximation, finite StreamName windows, RegSeqRat readback, and terminal Real seal before the countable-dense seal is visible.

Finally use Definition 1810.15. It records the same child ledger as the seed closure route, so the density request is covered precisely by those finite rows. Since the route contains no quotient Real equality, selected enumeration, countable-choice schedule, or ambient completeness row, those endpoints are explicitly outside the obligation. □

Theorem 1810.18 (Real separability dyadic enumeration route)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *dense read that exports a countable-dense surface factors first through the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *density ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The exported surface is therefore a finite dyadic schedule read from the displayed child ledger, not a countable-choice selector, host enumeration, quotient Real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 1810.12. It fixes the dense read as a child-route family over Cauchy equivalence, dyadic approximation, StreamName windows, RegSeqRat readback, and the terminal Real seal.

Apply Definition 1810.14 to order those rows before the countable-dense seal is visible. Then use Definition 1810.17; it requires the Cauchy-equivalence classifier and dyadic tolerance row before any dense consumer can inspect the exported surface.

The remaining endpoints are absent from the packet. Since the route contains only the displayed finite rows, it cannot supply a countable-choice selector, a host enumeration, quotient Real equality, or an ambient completeness theorem. □

Theorem 1810.19 (Real separability seed closure status block)**.** *The scoped closurestatus for* $\mathsf{RealSeparability}^{\uparrow}$ *is read from the displayed child-route family of Definition 1810.12, Definition 1810.14, Definition 1810.15, Definition 1810.17, and Definition 1810.18. It records only the paper-side scope over dyadic density, StreamName windows, RegSeqRat readback, the Real seal, and regular-Cauchy dense embedding routes, and it does not upgrade the formal verification axis.*

Proof. Read the displayed child-route theorems in order. They identify the seed ledger, the scoped density route, the seed closure route, the Cauchy-setoid dyadic density obligation, and the dyadic enumeration route as paper rows under the $\mathsf{RealSeparability}^{\uparrow}$ hub.

The closurestatus block records that same child-route family at scopedClosed. Its unformalized formalstatus remains unchanged, so the displayed block is a scope ledger and not a Lean verification claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSeparability}^{\uparrow}$ packet is generated from the existing child routes for density, Cauchy-equivalence, dyadic approximation, StreamName windows, RegSeqRat readback, Real seal, MetricCompletion handoff, completion-facing handoff, and countable dense Real-facing schedules.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: The scoped surface binds dyadic density, StreamName finite windows, RegSeqRat readback, the Real seal, and the regular-Cauchy dense embedding route under chapter 1809, without claiming classical separability for arbitrary spaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This seed status does not claim classical separability of arbitrary spaces, $\mathsf{Real}^{\uparrow}$ completeness, a countable-choice dense enumeration, a checked Lean carrier, bridge checking, or a standalone separability theorem beyond the child-route packet surface.

Upgrade path: Public closure requires checked carrier admission, route exactness, density coverage, Cauchy and dyadic compatibility, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealSeparabilityUp.

Theorem 1810.20 (Real separability Cauchy-setoid dependency)**.** *The* RealSeparability$^{\uparrow}$ *finite dense-read surface consumes the* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier route of chapter 1820 and the regular rational readback route of chapter 301 before any countable dense* Real$^{\uparrow}$ *read is exported. Thus the separability packet may expose finite dense witnesses only after the setoid comparison, regular-rational readback, tolerance ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows are visible.*

Proof. Read the dependency route in order. The Cauchy-equivalence setoid fixes when two regular Cauchy names may be treated as the same dense-read source, and the RegSeqRat$^{\uparrow}$ row supplies the finite rational windows that the separability packet later counts.

Only after those two sibling routes are visible may the RealSeparability$^{\uparrow}$ packet expose its countable dense Real readback. The route therefore exports no quotient real equality, selected dense enumeration, countable choice, or ambient completeness theorem. □

The RealSeparability dense-read route exposes the Cauchy-equivalence classifier as a downstream consumer edge, not as a free equality principle. A dense-read consumer receives the classifier data of chapter 1820 only after the finite StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ tolerance rows, and Real$^{\uparrow}$ seal rows of the separability route have been displayed.

Theorem 1810.21 (Real separability Cauchy-equivalence dense-read route)**.** *Every* RealSeparability$^{\uparrow}$ *dense-read consumer that uses* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier data must first display the* StreamName$^{\uparrow}$ *windows, the* RegSeqRat$^{\uparrow}$ *readback row, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, and the terminal* Real$^{\uparrow}$ *seal carried by the RealSeparability route. Thus the classifier is consumed as finite Cauchy-equivalence data after the L10 source rows have been shown, not as quotient stream equality, selected dense enumeration, host real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the displayed RealSeparability route. The density read begins with finite source windows and rational readback; those rows are not yet a Cauchy-equivalence classifier.

Next expose the dyadic tolerance and Real-seal rows. They place the dense-read request on the same L10 route used by the existing RealSeparability children, so the classifier cannot be consumed before the source data are displayed.

Only then read the Cauchy-equivalence classifier of chapter 1820. Since the route has no coordinate for quotient stream equality, selected dense enumeration, host real equality, countable choice, or ambient completeness, the consumer receives only the finite classifier data. □

The RealSeparability$^{\uparrow}$ dense reads that compare equivalent regular Cauchy names pass through chapter 1820 after the RegSeqRat$^{\uparrow}$ window route has displayed regular rational readback and before the terminal Real$^{\uparrow}$ density export is consumed.

Theorem 1810.22 (RealSeparability forward Cauchy-equivalence route)**.** *Every* RealSeparability$^{\uparrow}$ *dense-read consumer that uses* CauchyEquivalenceSetoid$^{\uparrow}$ *data factors through the finite classifier boundary of chapter 1820. The route first displays the* RegSeqRat$^{\uparrow}$ *readback rows, the* DyadicRatCore$^{\uparrow}$ *tolerance rows, the finite* StreamName$^{\uparrow}$ *windows, and the terminal* Real$^{\uparrow}$ *seal before exporting a dense-read surface. Thus the Cauchy-equivalence classifier is consumed as finite BEDC data, not as quotient stream equality, selected dense enumeration, countable choice, host real equality, or ambient completeness.*

Proof. Read the RealSeparability hub through its existing dense-read children. Those files expose finite stream windows, regular rational readback, dyadic tolerance rows, and the terminal real seal before any dense surface is exported.

Only after those rows are displayed may a consumer call the Cauchy-equivalence classifier. The classifier boundary is therefore the chapter named by chapter 1820, with $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ providing the finite route into it.

Since the route has no coordinate for quotient stream equality, selected dense enumeration, countable choice, host real equality, or ambient completeness, it exports only the displayed dense-read classifier data. □

Theorem 1810.23 (RealSeparability completion-facing display route)**.** *Every completion-facing* $\mathsf{RealSeparability}^{\uparrow}$ *consumer reaches* $\mathsf{Real}^{\uparrow}$ *only after the rational enumeration of chapter 37, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route of chapter 301, the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *source of chapter 1566, and the terminal seal of chapter 38 have all been displayed. The completion-facing route exports finite density data only through that lattice, not through quotient real equality, selected nearest points, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the rational source row in the $\mathsf{RealSeparability}^{\uparrow}$ carrier. It provides the enumerated rational data through the $\mathsf{Rat}^{\uparrow}$ sibling surface rather than through an external dense-set selector.

The dyadic tolerance and finite-window stages then force the request through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$. The $\mathsf{RegSeqRat}^{\uparrow}$ row reads back the same displayed windows at the requested precision.

Finally the dense-source row is named by $\mathsf{CountableDenseSubset}^{\uparrow}$, and the terminal public boundary is $\mathsf{Real}^{\uparrow}$. Since no carrier row stores quotient real equality, a selected nearest point, countable choice, or ambient completeness, completion-facing Real routes can consume only the displayed lattice. □

The dense-embedding route is the completion-facing dependency between the density siblings and the public separability row. A $\mathsf{RealSeparability}^{\uparrow}$ density consumer first reads the dyadic and rational density routes of Definition 1809.6 and Definition 1809.12; when the same consumer asks for completion-facing reuse, the finite dense image-window and approximation ledger of chapter 3617 are read before the $\mathsf{CountableDenseSubset}^{\uparrow}$ row is exported.

Theorem 1810.24 (Real separability dense-embedding route)**.** *Every completion-facing* $\mathsf{RealSeparability}^{\uparrow}$ *density read that consumes canonical* $\mathsf{DenseEmbedding}^{\uparrow}$ *data factors through the displayed dense image-window and approximation ledger before it reaches the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *boundary. Thus the separability packet may reuse dense-embedding data only as finite source, window, tolerance, approximation, and handoff rows, not as host topological density, a selected dense point, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite density exhaustion of Definition 1809.12. The RealSeparability consumer already passes through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary.

Now insert the canonical dense-embedding packet of chapter 3617. Its completion handoff exposes only the dense image-window, approximation ledger, and local handoff rows before a completion-facing read is available.

Composing the two routes leaves the CountableDenseSubset row downstream of finite density data and finite dense-embedding data. Since neither route carries host topological density, selected

dense points, quotient real equality, countable choice, or ambient completeness, the composed separability read exports none of those objects. □

Theorem 1810.25 (Real separability RegSeqRat dependency)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read consumes the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *window route and the dyadic-density witness before it exports separability. The read first reaches the terminal real-name surface of chapter 38, then routes the requested rational approximation through chapter 301, and finally checks the tolerance witness through chapter 1484. The resulting separability observation is therefore a finite regular-sequence and dyadic-density handoff, not a host dense-subset assertion, selected nearest point, quotient stream, or ambient completeness claim.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier through the local density route. The Real-facing consumer can only read the terminal $\mathsf{Real}^{\uparrow}$ seal after the rational enumeration, dyadic tolerance, StreamName window, and regular rational readback rows have been displayed.

The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the finite-window readback. It carries the inspected rational candidate and the opened observation window as regular sequence data, so the separability consumer does not receive a detached host rational point.

The dyadic-density sibling then supplies the tolerance witness. It binds the displayed dyadic scale to the same Real-facing request before any separability row is exported.

At the horizontal dependency level, the finite density rows are read through the dyadic endpoints of chapter 291 and the regular-rational windows of chapter 301 before the $\mathsf{Real}^{\uparrow}$ seal can present them as separability evidence. This makes the route a concrete dyadic-window handoff rather than a detached dense-subset assertion.

The structural hsame, Cont, Pkg, and local NameCert rows replay only those displayed rows. Since none of the routes contains a coordinate for a host dense subset, selected nearest point, quotient stream, or ambient completeness, every $\mathsf{RealSeparability}^{\uparrow}$ density read depends on the RegSeqRat finite-window route and dyadic-density witness before export. □

Theorem 1810.26 (RealSeparability RegSeqRat density pullback)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *countable-density export factors first through the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window readback and the dyadic-density witness before it reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In particular, the dependency route of Definition 1810.25 and the countable dense route of Definition 1810.39 force each exported dense read to display its regular rational window, dyadic tolerance witness, and Real seal boundary; no host dense subset, countable-choice selector, or ambient completeness coordinate can supply the density export.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier. Its density row can expose only the displayed rational or dyadic schedules, finite readback rows, Real-facing seal, transport, replay, provenance, and local naming data.

Use the RegSeqRat dependency of Definition 1810.25. It places the finite-window readback before any Real-facing separability export, so the density read cannot start from an untracked host subset.

Next use the dyadic-density sibling route and Definition 1810.39. The dyadic witness supplies the tolerance row consumed by the countable dense schedule before the terminal $\mathsf{Real}^{\uparrow}$ seal is read.

Thus the Real seal receives only the displayed RegSeqRat windows, dyadic witness, and certificate rows. Since the carrier has no coordinate for a host dense subset, choice selector, or ambient completeness theorem, every countable-density export factors through the stated pullback route. □

Theorem 1810.27 (RealSeparability located RegSeqRat density readback)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density-window consumer must pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route of chapter 301, the* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *locatedness route of chapter 2376, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before exporting a dense-read handoff. The exported handoff is finite regular-sequence and locatedness data; it is not quotient real equality, a selected dense point, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the RealSeparability carrier. Its density-window route names finite observations and regular-rational reads before any real-facing handoff is available.

Apply the RegSeqRat schedule route. The schedule supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback and finite $\mathsf{StreamName}^{\uparrow}$ windows, while the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance cells record the displayed comparison budgets consumed by the density request.

The located regular-sequence route then supplies the $\mathsf{LocatedRegSeqRat}^{\uparrow}$ locatedness data. Only after these rows are displayed can the handoff reach the terminal $\mathsf{Real}^{\uparrow}$ seal.

Thus the dense-read handoff is a finite readback route through regular sequences, locatedness, stream windows, dyadic tolerances, and the Real seal. Since the carrier exports none of the excluded coordinates, no quotient real equality, selected dense point, countable choice, or ambient completeness coordinate is exported. □

Theorem 1810.28 (Real separability dyadic density dependency)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read factors through the regular rational windows of chapter 301, the dyadic tolerance surface of chapter 291, and the terminal seal of chapter 38 before it exports a separability witness. The dense dyadic candidate is visible only as a finite* $\mathsf{RegSeqRat}^{\uparrow}$ *window with a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and a downstream* $\mathsf{Real}^{\uparrow}$ *seal, not as a detached host dense subset or selected nearest point.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ packet to its density route. The requested approximation is first read through the finite $\mathsf{RegSeqRat}^{\uparrow}$ window, so the consumer receives a displayed regular rational observation rather than an unlogged rational point.

The $\mathsf{DyadicRatCore}^{\uparrow}$ row then supplies the density scale and the tolerance comparison used by that same window. This makes the dyadic witness part of the finite dependency lattice, not an external density theorem.

Finally the $\mathsf{Real}^{\uparrow}$ seal consumes the regular window and dyadic tolerance rows before the separability row is public. Hence separability reads dense dyadic witnesses only through RegSeqRat windows and RealUp sealing. □

Theorem 1810.29 (Real separability dyadic density induction)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *rational-density read used by a completion-facing consumer factors through a finite induction on dyadic windows before reaching* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. At each induction stage the consumer reads the displayed dyadic tolerance row, the finite stream window, the regular rational readback, and the terminal real-name seal already carried by the RealSeparability route; it receives no classical countable choice, no selected dense subsequence, no quotient equality of Real names, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with Definition 1810.28. It places every density request behind the dyadic tolerance surface and the finite regular-rational window before the terminal real-name seal can be read.

Use induction over the displayed dyadic window length. The base window is the empty or initial tolerance request already visible in the $\mathsf{DyadicRatCore}^{\uparrow}$ row, so no density witness can be consumed before the dyadic scale is named.

For the extension step, append one displayed dyadic refinement window and replay the existing RegSeqRat and StreamName dependencies. The dependency route keeps the new rational candidate inside the same finite window ledger rather than selecting a point from an ambient dense subset.

Finally compose with Definition 1810.25 and Definition 1810.76. These routes pass the finite dyadic-window induction through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal, while excluding countable choice, selected dense subsequences, quotient Real equality, and ambient completeness. □

Theorem 1810.30 (Real separability dyadic density scope)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that consumes a dyadic rational witness factors through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *numerator and exponent rows, the finite observation windows of* $\mathsf{StreamName}^{\uparrow}$*, the regular readback surface of* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports a scoped finite density witness only after these four surfaces have been read, and it exports no selected representative, quotient stream, host-countable enumeration, nearest-dyadic selector, or ambient completeness theorem.*

Proof. Start with the dyadic-density dependency and induction routes. Theorem 1810.28 places each density request behind the dyadic tolerance ledger, while Definition 1810.29 keeps each refinement step inside a finite dyadic window.

Next read the stream and regular-rational routes. The finite $\mathsf{StreamName}^{\uparrow}$ observation window records which prefixes are inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ dependency route supplies the regular rational readback before the separability ledger is exported.

Finally compose with the forward dyadic-density link and the terminal $\mathsf{Real}^{\uparrow}$ seal. The resulting route is the single finite chain

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

inside the $\mathsf{RealSeparability}^{\uparrow}$ packet, so no selected representative, quotient stream, host-countable enumeration, nearest-dyadic selector, or ambient completeness theorem can be recovered from the accepted density read. □

Theorem 1810.31 (Real separability regular Cauchy completion criterion route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that reaches the L10 completion tail consumes the* $\mathsf{RegularCauchyCompletionCriterion}^{\uparrow}$ *route of chapter 3452 through the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows. The dyadic-density dependency of Definition 1810.28 supplies the finite dyadic witness, while the RegSeqRat dependency of Definition 1810.25 keeps that witness on the displayed regular-rational readback route before the terminal Real seal exports separability.*

Proof. Read the accepted $\mathsf{RealSeparability}^{\uparrow}$ packet through its existing density dependencies. The dyadic-density row names the finite tolerance witness, and the RegSeqRat row keeps the witness inside a displayed regular rational window rather than a host dense subset.

Now pass to the completion tail. The regular Cauchy completion criterion consumes precisely those finite windows, dyadic tolerance rows, regular readback rows, and local $\mathsf{Real}^{\uparrow}$ seal rows. Therefore the separability consumer can cite the completion criterion only through the same finite dyadic witness and RegSeqRat route already named by the RealSeparability packet.

The route adds no selected nearest point, quotient real equality, ambient completeness, or detached dense subset. It records a sibling edge from RealSeparability to the regular Cauchy completion criterion along the finite dyadic and regular-rational surface. □

The $\mathsf{RealSeparability}^{\uparrow}$ dependency lattice consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301, the dyadic-density embedding route of chapter 1484, and the located $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 2376 before exposing its separability ledger. Thus the separability packet reads rational candidates through regular sequence windows, dyadic density through the real-density sibling, and located regular readback through the located route already carried by the hub before any $\mathsf{Real}^{\uparrow}$ density observation is named. Every $\mathsf{RealSeparability}^{\uparrow}$ density witness reads through finite $\mathsf{StreamName}^{\uparrow}$ windows before it reaches any Real-facing separability row. The route first opens the displayed window of chapter 126, then transports the inspected rational data through the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, checks the tolerance against the $\mathsf{DyadicRatCore}^{\uparrow}$ rows of chapter 291, and only then consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Thus the separability packet exports a finite density route, not a detached dense subset, selected nearest point, quotient real equality, countable choice, or ambient completeness.

Theorem 1810.32 (Real separability L10 Cauchy-net dependency)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *countable dense read that is presented to an L10 Cauchy-net consumer first opens the dyadic tolerance rows of chapter 291, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301. Only after those finite-window rows are visible does the read reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 and become available as countable dense data for Cauchy-net or completion-facing routes.*

Proof. Project the separability source route. A dense-read consumer sees rational or dyadic candidates only through displayed finite windows and regular rational readback, so the dyadic ledger, stream window, and RegSeqRat rows are upstream of the Real-facing density claim.

The Real seal is terminal. It receives the inspected dense candidate after the finite rows have been displayed; it does not create a host dense subset, selected nearest point, quotient equality, or ambient completion coordinate.

Thus an L10 Cauchy-net consumer reads $\mathsf{RealSeparability}^{\uparrow}$ through the same DyadicRatCore, StreamName, RegSeqRat, and Real rows before any countable dense handoff is public. □

The $\mathsf{RealSeparability}^{\uparrow}$ dense-read route is not a free-standing lattice float. Every countable-density packet reads $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names from chapter 301, $\mathsf{StreamName}^{\uparrow}$ pointwise observation windows from chapter 126, and $\mathsf{DyadicRatCore}^{\uparrow}$ dyadic approximation rows from chapter 291 before exporting its dense enumeration evidence.

Proposition-style dependency spine: if a $\mathsf{RealSeparability}^{\uparrow}$ consumer claims countable-density evidence while omitting the regular-rational source, the stream-window observation row, or the dyadic approximation ledger, then the read is outside the displayed finite BEDC route. The admissible route is regular Cauchy naming, finite stream observation, dyadic approximation, transport, replay, provenance, and only then the countable-density handoff.

Theorem 1810.33 (Real separability Cauchy locator forward link)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that feeds the locator surface of chapter 3410 passes through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyRealLocator}^{\uparrow}.$$

Concretely, the dyadic tolerance row is read before the finite StreamName window, the regular rational readback is read before the terminal Real seal, and the Cauchy locator receives only this finite-window density route. The link exports no quotient stream equality, selected nearest dense point, countable-choice search, trichotomy branch, or ambient Real completeness.

Proof. Start with the density carrier of Definition 1809.1. Its rows $Q, D, W, R, E, T, H, C, P, N$ place every density request behind the rational enumeration, dyadic tolerance, finite window, regular readback, and Real seal.

Use the existing separability routes. The rational dense handoff, dyadic-rational density handoff, and Cauchy completion route keep the density witness inside the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows already named by the packet.

Finally pass to chapter 3410. Its locator requests consume dyadic tolerances, finite windows, regular readbacks, and the terminal Real seal in that order. Therefore a RealSeparability density read can feed $\mathsf{CauchyRealLocator}^{\uparrow}$ only through the displayed finite route, with no hidden selector, quotient equality, choice schedule, trichotomy, or ambient completeness coordinate.

The same forward link is a consumer-side input for chapter 3895: its apartness request first reads the $\mathsf{CauchyRealLocator}^{\uparrow}$ row, so the density support supplied by $\mathsf{RealSeparability}^{\uparrow}$ remains attached to the finite locator route rather than becoming an independent search principle. □

The $\mathsf{RealSeparability}^{\uparrow}$ packet supplies the dense finite rational rows consumed by finite-cover and uniformly located finite-cover routes. The real carrier of chapter 38, the regular rational sequence route of chapter 301, and the stream-window naming surface of chapter 126 provide the finite rational windows that chapter 2377 reads before coverage and radius ledgers are exposed.

Proposition 1810.34 (Real separability finite-cover forward link)**.** *Every finite-cover consumer of* $\mathsf{RealSeparability}^{\uparrow}$ *receives dense rational data only as displayed finite windows over* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$*. The handoff may feed* $\mathsf{FiniteRealCover}^{\uparrow}$ *and later uniformly located finite-cover packets through those rows, together with* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *evidence; it does not provide a choice-selected dense subsequence, an arbitrary open-cover refinement, quotient real equality, trichotomy, or ambient completeness.*

The forward route from $\mathsf{RealSeparability}^{\uparrow}$ to completion-facing density data is finite: a separability consumer first reads the regular rational handoff of chapter 301, then the source-to-seal discipline of chapter 1453, and only then the dense-image packet of chapter 3617.

Theorem 1810.35 (Real separability RegSeqRat forward route)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet that reuses dense-embedding data factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the finite* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *source-to-seal route, and the* $\mathsf{DenseEmbedding}^{\uparrow}$ *image-window ledger before it exports a dense source to completion, finite-net, compact-metric, or* $\mathsf{CountableDenseSubset}^{\uparrow}$ *consumers. The route supplies no host dense subset, selected nearest point, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with the RegSeqRat dependency of Definition 1810.25. It places the rational candidate, opened StreamName window, dyadic tolerance row, and regular readback before any Real-facing separability export.

Next read the regular Cauchy dense-embedding boundary of chapter 1453. Its source-to-seal route keeps the same $\mathsf{RegSeqRat}^{\uparrow}$ row visible while the $\mathsf{Real}^{\uparrow}$ seal is reached.

Finally pass that visible source row through the dense-embedding packet of chapter 3617. The image-window and approximation ledger are then the only completion-facing dense data available to downstream finite-net, compact-metric, and countable-density consumers.

Because each stage exposes only displayed rows and none carries a host dense subset, selected nearest point, quotient real equality, countable-choice schedule, or ambient completeness witness, the composed forward route exports no such coordinate. □

Theorem 1810.36 (Real separability RegSeqRat forward dependency)**.** *Any* RealSeparability$^{\uparrow}$ *dense-completion export must first expose the* RegSeqRat$^{\uparrow}$ *rational candidate, the* StreamName$^{\uparrow}$ *finite window, the* DyadicRatCore$^{\uparrow}$ *tolerance row, and the regular readback before it uses* RegularCauchyDenseEmbeddin *and* DenseEmbedding$^{\uparrow}$*. Consequently completion, compact-metric, finite-net, and countable-density consumers receive only the displayed regular dense route; they receive no host dense subset, selected nearest point, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness coordinate.*

Proof. Apply Definition 1810.35. It already places every completion-facing dense export downstream of the RegSeqRat readback row, the regular Cauchy dense-embedding source-to-seal route, and the DenseEmbedding image-window ledger.

Unpack the first step of that route. The RegSeqRat dependency exposes a rational candidate, an opened StreamName window, a DyadicRatCore tolerance row, and a regular readback before any dense-completion consumer can reach the embedding rows.

The later RegularCauchyDenseEmbedding$^{\uparrow}$ and DenseEmbedding$^{\uparrow}$ rows therefore consume only displayed finite data. Since neither row introduces a host dense subset, nearest-point selector, quotient equality oracle, choice schedule, or ambient completeness witness, the export has exactly the stated dependency surface. □

Theorem 1810.37 (Real separability dyadic density forward link)**.** *Every* RealSeparability$^{\uparrow}$ *density route that consumes a dyadic-density witness must pass that witness through the finite* RegSeqRat$^{\uparrow}$ *readback surface and the regular Cauchy completion route before it exports a separability ledger. In particular, the dyadic witness of chapter 1484 and Definition 1810.28, the RegSeqRat dependency of Definition 1810.25, the regular Cauchy completion criterion route of Definition 1810.31, and the terminal* Real$^{\uparrow}$ *seal of chapter 38 form one displayed dependency chain rather than four detachable facts.*

The exported separability ledger therefore records a finite dyadic-density route through DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, regular Cauchy completion, and* Real$^{\uparrow}$*. It does not select nearest dyadics, identify quotient Real representatives, invoke ambient completeness, or detach the dense set from the displayed regular-rational readback route.*

Proof. Start with the dyadic-density dependency. Theorem 1810.28 exposes the dyadic witness only through a finite tolerance row and a regular rational observation window.

Next read the RegSeqRat route. Theorem 1810.25 keeps that witness on the displayed regular-rational surface before any RealSeparability$^{\uparrow}$ ledger is exported.

Now pass through regular Cauchy completion. Theorem 1810.31 consumes the same finite dyadic and regular-rational rows before the terminal Real$^{\uparrow}$ seal is read.

Thus the separability ledger receives one finite dependency chain through dyadic density, RegSeqRat readback, regular Cauchy completion, and Real sealing. Since none of those rows is a nearest-point selector, quotient-real equality, ambient completeness theorem, or detached dense subset, the forward link exports only the displayed separability route. □

The RealSeparability$^{\uparrow}$ packet supplies the dense dyadic window route consumed by MetricCompletion$^{\uparrow}$ in chapter 1506 and by the Cauchy comparison surface of chapter 1820. A completion-facing read first observes the existing Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ route, then uses those finite dyadic windows as the separability source for regular readbacks and Cauchy-equivalence comparisons.

The ledger edge is theorem-free: Real separability is used only as a displayed dense-window supplier for metric completion and Cauchy equivalence consumers, not as a host countable dense subset, selected enumeration, quotient real equality, or ambient completeness principle.

Theorem 1810.38 (RealSeparability forward metric-completion route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *consumer of a* $\mathsf{RealSeparability}^{\uparrow}$ *packet first reads the* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *dense-embedding, and* $\mathsf{CountableDenseSubset}^{\uparrow}$ *rows displayed by the separability carrier. The route exports finite density and readback data only through those rows; it exports no host dense subset, selected nearest point, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the Cauchy completion route of Definition 1810.9. It places every dense dyadic witness on finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback rows before a completion-facing consumer receives it.

Next use the completion-facing display route of Definition 1810.23. That route adds the dense source and $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary required by metric-completion consumers.

Finally apply the RegSeqRat dependency of Definition 1810.25. It keeps the witness on the displayed regular-rational surface, so a $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ consumer cannot obtain a host dense subset, selected nearest point, quotient real equality, countable choice, or ambient completeness principle from the separability packet. □

The forward density route from $\mathsf{RealSeparability}^{\uparrow}$ to substantive sibling consumers is the L10 corridor through chapter 1566, the dyadic-density surface of chapter 1484, the rational-density surface of chapter 1409, the finite window discipline of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. A density read therefore opens a countable dense-subset row, checks dyadic and rational density against displayed stream windows, routes the tolerance through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$, and reaches the Real seal only after the same finite rows have been exposed.

This route makes the hub dependency visible before any Real-facing consumer treats separability as an available dense surface. It exports no selected nearest point, host dense subset, quotient real equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Lemma 1810.39 (RealSeparability countable dense route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that is exported as a countable dense surface factors through the countable dense subset boundary of chapter 1566, the dyadic-density witness surface of chapter 1484, and the rational-density witness surface of chapter 1409 before reaching any terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

The route reads the displayed rational enumeration, dyadic tolerance, finite $\mathsf{StreamName}^{\uparrow}$ *window, regular rational readback, and local* $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *rows as one finite dependency chain. It exports no host dense subset, selected nearest point, quotient real equality, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier to its rational enumeration, dyadic tolerance, finite window, regular readback, Real seal, exactness ledger, transport, replay, provenance, and local naming rows. The countable dense subset boundary supplies only the displayed indexed dense-source row, so the separability read first cites chapter 1566.

The tolerance and witness rows then pass through the two density siblings. The dyadic-density surface of chapter 1484 supplies the dyadic tolerance witness, and the rational-density surface of chapter 1409 supplies the rational interval witness.

Finally the existing $\mathsf{RealSeparability}^{\uparrow}$ route consumes those witnesses through the finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the terminal $\mathsf{Real}^{\uparrow}$ seal. Since every row is displayed in that chain, no host dense subset, selected nearest point, quotient equality, choice selector, or ambient completeness object is available. □

Theorem 1810.40 (RealSeparability countable dense window budget)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window read that is consumed as countable dense data factors through the same finite L10 source route:*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Concretely, the read must display the $\mathsf{DyadicRatCore}^{\uparrow}$ *rational-density row, the* $\mathsf{StreamName}^{\uparrow}$ *finite request schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the* BHist *transport ledger, the displayed* Cont *replay route, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *row before any countable-dense consumer can use the window.*

The theorem does not assert full $\mathsf{Real}^{\uparrow}$ *completeness, a choice-selected enumeration of reals, a host dense subset, quotient real equality, or a selected nearest rational for each real name.*

Proof. Start with the countable dense route of Definition 1810.39. It already orders every exported dense surface through the countable dense subset boundary, dyadic-density witness surface, rational-density witness surface, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal.

Use the dyadic-density dependency and RegSeqRat schedule rows in this hub. They force each dense-window request to carry a displayed dyadic tolerance row and a finite stream request schedule before the regular rational readback is available.

Now route the read through the Real seal route. The $\mathsf{Real}^{\uparrow}$ seal is downstream of the same dyadic, stream, and regular-rational rows, and the structural BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows retain that dependency for the countable-dense consumer.

Thus the window budget is exactly the displayed L10 source route. Since none of those rows stores real completeness, a choice-selected enumeration, a host dense subset, quotient real equality, or nearest-rational selection, the exported countable dense read cannot claim any of those principles. □

Theorem 1810.41 (Real separability choice-free dense modulus)**.** *For every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet* $S = (Q, D, W, R, E, T, H, C, P, N)$ *and every finite precision request, the dyadic density row,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal produce a finite rational witness and modulus ledger without a selector over all reals. The witness is read from the displayed route*

$$Q, D, W, R, E, T, H, C, P, N$$

and not from a host dense subset, countable-choice schedule, quotient stream, selected nearest point, or ambient completeness principle.

Proof. Project the accepted carrier of Definition 1809.1. The precision request first reads the rational enumeration row Q and the dyadic tolerance row D.

Use the dyadic witness family of Definition 1809.7. It supplies the finite rational witnesses indexed by the displayed dyadic request and the finite StreamName window, not by a selector over all real points.

Push the witness through the StreamName and RegSeqRat boundary. Window stability keeps the read inside W, and the regular-rational readback R carries the same finite rational datum toward the Real-facing boundary.

Finally seal via E and record the modulus ledger through T, H, C, P, N. The rows only replay, transport, source, and name the finite density route, so no Classical.choice, quotient construction, host sequence selection, selected nearest point, or ambient completeness witness is introduced. □

The $\mathsf{RealSeparability}^{\uparrow}$ connected-local route supplies dense finite rational and dyadic reads to connected and locally connected consumers only after the source has passed through $\mathsf{Real}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$. A connected-space consumer may compare these reads with chapter 2353, while a local neighbourhood-component consumer may use the same finite density surface in chapter 5809. Thus the hub records a substantive horizontal dependency from real separability to connected-space and local-connectedness reads, without selecting a nearest rational, quotient real representative, host dense subset, path, arc, or ambient completeness principle. Every $\mathsf{RealSeparability}^{\uparrow}$ density consumer that reuses interval data first reads the rational interval carrier of chapter 354, then the dyadic-density comparison route of chapter 3513, and finally the regular rational readback surface of chapter 301. Density consumers needing explicit lower and upper rational brackets also pass through the locator route of chapter 4202 before the $\mathsf{Real}^{\uparrow}$-facing readback is exported. Thus the separability route exports a finite rational-interval, locator, and dyadic-density ledger rather than a detached dense subset, selected nearest point, quotient real equality, countable-choice schedule, or ambient completeness coordinate.

Theorem 1810.42 (Real separability closed bounded interval route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density route that feeds a closed bounded interval consumer factors through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the consumer named by chapter 1591 may inspect its interval certificate. The route exposes dyadic rational cells, regular rational readback, terminal Real seals, and the shared transport, replay, provenance, and local naming rows; it does not expose a selected dense point, quotient real equality, hidden endpoint chooser, open-cover compactness, or ambient completeness row.*

Proof. Start with the carrier of Definition 1809.1. Its density data is finite and is already attached to dyadic rational cells, regular rational readback, terminal Real seals, transport, replay, provenance, and local naming.

Route the density data to chapter 1591. A closed bounded interval consumer can use the separability packet only after the dyadic cell and the regular rational readback have been displayed.

The $\mathsf{Real}^{\uparrow}$ seal is then read as the terminal boundary of the same finite route. Since no coordinate of the separability packet contains a selected dense point, quotient equality, endpoint chooser, open-cover compactness, or ambient completeness row, the closed bounded interval handoff is exactly the displayed dependency route. □

Theorem 1810.43 (Real separability to closed bounded interval forward route)**.** *Every* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density packet reads the finite dense windows only through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route. In particular, the endpoint and containment consumers of chapter 1591 receive rational cells, dyadic tolerance rows, finite stream windows, regular rational readback, and terminal Real seals before any local interval row is inspected.*

The forward route exports no selected dense point, quotient real equality, ambient completeness row, hidden endpoint chooser, or open-cover compactness principle.

Proof. Start with the carrier of Definition 1809.1. Its finite density rows expose rational candidates together with the dyadic tolerance ledger, stream-window schedule, regular rational readback, terminal Real seal, componentwise transport, replay, provenance, and local naming.

Next read the interval-facing route through chapter 354. A closed bounded interval consumer can inspect endpoint and containment data only after the rational cell row has been displayed, and the dyadic refinement remains attached to that same finite rational ledger.

Now pass through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. They supply the finite endpoint windows, the regular rational readbacks, and the terminal Real seals that chapter 1591 may consume when forming its local interval certificate.

Since the separability packet contains no selected dense point, quotient real equality, ambient completeness row, hidden endpoint chooser, or open-cover compactness principle, the handoff is exactly the displayed finite route. □

Lemma 1810.44 (Real separability to uniform convergence forward link)**.** *Every* $\mathsf{UniformConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density packet first reads the* $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows displayed by the separability carrier. In particular, the consumer reaches the uniform-convergence boundary of chapter 3417 only after the finite dense source, dyadic tolerance ledger, stream-window schedule, regular rational readback, terminal Real seal, componentwise transport, replay, provenance, and local naming rows have all been exposed.*

The forward link exports no selected dense point, quotient real equality, host dense subset, countable-choice search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with the carrier of Definition 1809.1. Its rows $Q, D, W, R, E, T, H, C, P, N$ expose the rational source, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, dense-source row, transport, replay, provenance, and local naming.

Use the completion-facing and density routes already displayed by the separability chapter. They place the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary downstream of the dyadic and rational density rows, while the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows remain the only route by which Real-facing consumers inspect the dense packet.

Now pass to chapter 3417. A uniform-convergence consumer may reuse the density packet only through finite tolerance and window data, so it must read the same $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before reaching its own uniform boundary.

Since the separability carrier contains no host dense subset, selected dense point, quotient real equality, countable-choice search, or ambient completeness row, the forward link supplies only the displayed finite lattice edge. □

Every completion-facing read of a $\mathsf{RealSeparability}^{\uparrow}$ density packet that needs filter-completion data must pass through the finite rows already displayed by the separability hub before it reaches chapter 1569. The route first exposes the dyadic tolerance row, StreamName window, RegSeqRat readback, and terminal Real seal; only then may the downstream consumer inspect the Cauchy-filter completion packet.

Theorem 1810.45 (Real separability to CauchyFilterCompletion forward link)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet factors through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 1809.1 before the consumer may read the completion boundary named by chapter 1569. The handoff exports only finite density windows, dyadic tolerances, regular rational readback, terminal Real seals, transport, replay, provenance, and local naming; it exports no selected dense point, quotient filter, selected completion limit, host real equality, countable choice, or ambient completeness row.*

Proof. Project the carrier of Definition 1809.1. Its rows $Q, D, W, R, E, T, H, C, P, N$ expose the rational enumeration, dyadic tolerance, finite StreamName window, regular rational readback, terminal Real seal, dense-window exactness ledger, transport, replay, provenance, and local naming.

Use the existing dyadic, StreamName, RegSeqRat, and Real handoff route. A completion-facing consumer cannot reach completion data until the density request has passed through D, W, R, E and the exactness ledger T has tied those rows to the same finite rational read.

Now pass to chapter 1569. The completion packet reads Cauchy-filter source data, finite windows, dyadic tolerances, regular readback, and a terminal Real seal, so the separability packet can feed it only through the rows already displayed in the separability carrier.

Since neither carrier contains a coordinate for a selected dense point, quotient filter, selected limit, host equality, countable choice, or ambient completeness theorem, the forward link supplies exactly the finite horizontal route to the Cauchy-filter completion consumer. □

The formalization target is the finite handoff theorem for the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier rows $Q, D, W, R, E, T, H, C, P, N$. The statement should require the downstream $\mathsf{CauchyFilterCompletion}^{\uparrow}$ read to display, in order, the dyadic tolerance row D, the finite $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, the terminal $\mathsf{Real}^{\uparrow}$ seal E, and the exactness ledger T before any completion-facing row is consumed. Its conclusion is only that this displayed route feeds the completion packet through finite windows; it is not a selected dense point, quotient filter, selected completion limit, host equality, countable choice, or ambient completeness theorem. The $\mathsf{RealSeparability}^{\uparrow}$ source ledger consumes the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ route of chapter 1569 and the $\mathsf{ClosedBoundedInterval}^{\uparrow}$ interval route of chapter 1591 through the same finite dense rational and dyadic witness rows. Concretely, the density request reads the rational candidate row, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, the finite stream window, and the regular readback before the Cauchy-filter completion consumer sees a completion-facing dense witness, while the closed bounded interval consumer reads the same witness as an endpoint-contained interval-window row. Thus both source routes consume the displayed dense-window ledger, not a detached host dense subset, selected nearest point, quotient real equality, or ambient completeness principle.

Proposition 1810.46 (RealSeparability metric-completion reverse route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *consumer that uses* $\mathsf{RealSeparability}^{\uparrow}$ *dense data first reads the displayed* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. After those rows are exposed, the consumer may pass through chapter 1506 and chapter 1585 as a finite completion-facing route. The route exports no selected dense points, quotient* $\mathsf{Real}^{\uparrow}$ *equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the rational and dyadic rows from the separability dependency route before any completion-facing consumer receives dense data. The $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows identify the finite rational windows, while the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows keep the readback inside the displayed real-name corridor.

Then pass the displayed data through the metric-completion and reflector chapters named in the statement. Since the route has already exposed all dense rows and has no coordinate for selecting points, quotienting real names, invoking countable choice, or importing ambient completeness, every completion-facing use remains a finite BEDC route. □

The $\mathsf{RealSeparability}^{\uparrow}$ density packet exposes its regular-Cauchy-facing route only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301 and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291 have been displayed. Those rows feed the existing real-density and finite-window surfaces before any downstream regular Cauchy limit uniqueness consumer may inspect a terminal $\mathsf{Real}^{\uparrow}$ seal; the handoff exports no selected dense point, quotient real equality, countable-choice row, or ambient completeness coordinate.

Theorem 1810.47 (Real separability compact-continuous sup-norm forward link)**.** *Every compact-continuous sup-norm or uniform-modulus consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density packet first reads the displayed dyadic-density route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the compact-uniform surfaces of chapter 388 and chapter 369. In particular, the consumer may reach chapter 3807 only through those finite density, readback, window, Real-seal, compact-continuity, and modulus rows.*

The forward link exports no selected dense point, host dense subset, quotient Real equality, open-cover compactness, selected supremum, countable-choice search, or ambient completeness coordinate.

Proof. Project the carrier of Definition 1809.1. Its rows expose the rational source, dyadic tolerance ledger, StreamName windows, regular rational readback, terminal Real seal, density exactness, transport, replay, provenance, and local naming.

Use the existing dyadic-density and RegSeqRat routes. They keep every density request on the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surface before any compact-continuous consumer can inspect the data.

Now pass to the compact-uniform route. The compact-continuity and uniform-modulus packets consume only displayed finite windows, modulus ledgers, and Real-sealed comparison rows, and the $\mathsf{ContinuousSupNorm}^{\uparrow}$ packet reads those rows as its finite bound source.

Thus the separability packet supplies a dependency edge to compact-continuous norm and modulus consumers only through the named BEDC rows. The excluded host dense subset, selected point, quotient equality, open-cover, supremum, choice, and completeness objects are absent from the route. □

Theorem 1810.48 (Real separability Cauchy-dense forward link)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *packet routes finite dyadic density witnesses through the dense Cauchy route of chapter 1453 and the Cauchy completion reflector of chapter 1585 before a downstream metric-completion consumer reads a countable dense surface. The read exposes the rational enumeration, dyadic tolerance row, finite stream window, regular rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealSeparability}^{\uparrow}}$ *row; it exports no selected dense point, quotient completion class, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier to its rational enumeration, dyadic tolerance, finite window, regular readback, terminal Real seal, transport, replay, provenance, and local naming rows. The dyadic witness is therefore a finite row of the separability packet rather than a detached dense subset.

The dense-embedding consumer may read that witness only through chapter 1453. After this route has displayed the dense Cauchy source, the Cauchy completion reflector named by chapter 1585 supplies the completion-facing handoff.

Finally, componentwise hsame transport and Cont replay preserve the same displayed route into downstream metric-completion consumers. Since no row in the packet names quotient equality, a selected dense point, countable choice, or ambient completeness, none of those objects is exported by the forward link. □

Definition 1810.49 (Real separability RegSeqRat schedule)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *RegSeqRat schedule is the finite route row that presents a dense-read request through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal*

$\mathsf{Real}^{\uparrow}$ *seal in that order. A schedule instance is a* BHist *surface*

$$\Sigma = (S, R, D, E, H, C, P, N)$$

where S opens the finite stream window, R records the regular rational candidate read on that window, D fixes the dyadic tolerance used by the density request, E is the $\mathsf{Real}^{\uparrow}$ *seal reached only after those rows have been displayed, and H, C, P, N provide componentwise transport, replay, provenance, and local naming. The schedule has no coordinate for a host dense subset, selected nearest point, quotient real equality, countable choice, or ambient Real completeness.*

Theorem 1810.50 (Real separability RegSeqRat schedule handoff)**.** *Every dense-read consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet factors through the schedule of Definition 1810.49. In particular, the consumer first opens the finite* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, then reads the regular rational row of chapter 301, then fixes the dyadic tolerance row of chapter 291, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. No dense-read handoff exports a host dense subset, selected nearest point, quotient real equality, countable-choice schedule, or ambient Real completeness coordinate.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ density route. The local carrier already exposes density through finite observation rows, so the consumer cannot reach the Real-facing seal before the stream window, regular rational readback, and dyadic tolerance data are displayed.

The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite window S. The $\mathsf{RegSeqRat}^{\uparrow}$ row R then reads the rational candidate on that window, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D binds the tolerance used by the density request.

Only after those rows are fixed does the consumer reach the $\mathsf{Real}^{\uparrow}$ seal E. The structural rows H, C, P, N transport, replay, source, and name the same finite schedule.

Because the schedule contains no host dense subset, selected nearest point, quotient real equality, countable-choice schedule, or ambient completeness coordinate, every dense-read consumer factors through the displayed RegSeqRat schedule before separability is exported. □

Theorem 1810.51 (Real separability Cauchy realizer link)**.** *Every density read exported by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet to a* $\mathsf{CauchyRealizer}^{\uparrow}$ *consumer factors through the finite rational-window route of chapter 1771, chapter 301, chapter 126, and chapter 291. The read first displays a stream window, then a regular rational candidate, then the dyadic tolerance ledger used by the Cauchy realizer, and only then reaches the terminal Real-facing density seal. It exports no host dense subset, selected nearest point, quotient real equality, countable-choice schedule, or ambient Real completeness coordinate.*

Proof. Begin with the RegSeqRat schedule handoff of Definition 1810.50. It routes every density read through the finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal.

The $\mathsf{CauchyRealizer}^{\uparrow}$ consumer reads exactly that kind of finite request-to-window route by chapter 1771. Feeding the density read to the realizer therefore changes only the downstream consumer, not the rows inspected by the separability packet.

Since neither the schedule nor the Cauchy realizer chapter supplies host dense subsets, selected nearest points, quotient equality, countable choice, or ambient completeness as carrier coordinates, the linked route remains a finite rational-window handoff. □

The $\mathsf{RealSeparability}^{\uparrow}$ countable dense route is consumed through the $\mathsf{RegSeqRat}^{\uparrow}$ schedules of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291, and the Cauchy-modulus and

majorant schedule of chapter 292 and chapter 4087 before any $\mathsf{Real}^{\uparrow}$ separability read becomes public.

Theorem 1810.52 (Real separability RegSeqRat and dyadic-density schedule dependency)**.** *Every countable dense route exported by an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet consumes the regular-Cauchy schedule through chapter 301, the dyadic-density witness surface of chapter 1484, and the terminal seal of chapter 38. The route is therefore the existing finite schedule through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicDensityReal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert rows; it exports no selected nearest point, host dense subset, quotient real equality, countable-choice selector, or ambient completeness coordinate.*

Proof. Use Definition 1810.49 to expose the finite schedule rows S, R, D, E, H, C, P, N. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational readback consumed by the density request, while the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row fixes the scale at which that request is inspected.

Next read the dyadic-density surface through chapter 1484. Its witness is attached to the same finite window and tolerance rows before the route reaches the terminal $\mathsf{Real}^{\uparrow}$ seal.

The transport, replay, provenance, and local naming rows are the same rows already carried by the accepted $\mathsf{RealSeparability}^{\uparrow}$ packet. Since no carrier coordinate names a selected nearest point, host dense subset, quotient equality, countable-choice selector, or ambient completeness theorem, the schedule dependency is exactly the displayed RegSeqRat and dyadic-density route. □

Theorem 1810.53 (RealSeparability RegSeqRat density-window handoff)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read consumed by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing route factors through a finite* $\mathsf{StreamName}^{\uparrow}$ *window, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximant row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the regular-Cauchy dense embedding route before the consumer may read the separability surface. The handoff is the displayed finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the regular-Cauchy dense embedding certificate; it exports no quotient stream equality, selected host dense subset, countable-choice selector, or ambient completeness coordinate.

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ packet through the existing schedule dependency of Definition 1810.52. The density request first opens a finite $\mathsf{StreamName}^{\uparrow}$ window and reads a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row at that window.

The $\mathsf{RegSeqRat}^{\uparrow}$ row then supplies the regular rational readback attached to the same finite window. This is the only route by which a rational approximant reaches the terminal $\mathsf{Real}^{\uparrow}$ seal in the separability packet.

Finally use the dense embedding route of chapter 1453. A completion-facing consumer receives the already displayed regular-Cauchy dense embedding certificate after the window, dyadic, and readback rows have been fixed.

Since the carrier has no coordinate for quotient stream equality, selected host dense subsets, countable-choice selectors, or ambient completeness, every such density read remains inside the finite density-window handoff. □

Theorem 1810.54 (RealSeparability RegSeqRat forward anchor)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that is forwarded to a Real-facing consumer first consumes the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback of chapter 301 and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route of chapter 38. The read is therefore anchored in displayed regular-rational windows and Real seal data before the separability row is exported.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier to its density route. The consumer can inspect rational density only after the regular readback rows have exposed the finite $\mathsf{RegSeqRat}^{\uparrow}$ window data.

The same route then passes through the $\mathsf{Real}^{\uparrow}$ seal before any density observation is exported. Thus the forward read is a child route of the RegSeqRat and Real chapters, not a detached dense subset, quotient real equality, selected dense point, countable-choice schedule, or ambient completeness principle. □

The $\mathsf{RealSeparability}^{\uparrow}$ packet supplies countable dense readback to the $\mathsf{BishopCompleteMetric}^{\uparrow}$ completion surface of chapter 3424. A Bishop-complete-metric consumer first reads the separability carrier's dyadic density windows, $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal, then passes those finite rows to the complete-metric route already mediated by the existing Real separability completion links.

Theorem 1810.55 (Real separability to BishopCompleteMetric forward link)**.** *Every* $\mathsf{BishopCompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet factors through the displayed countable dense readback rows of Definition 1809.1 before it may read the complete-metric surface of chapter 3424. The handoff exports finite density windows, dyadic tolerances, regular rational readback, Real sealing, transport, replay, provenance, and local naming; it exports no selected dense point, quotient real equality, host completion object, countable-choice selector, or ambient completeness theorem.*

Proof. Project the Real separability carrier. Its dense-readback rows expose the rational enumeration, dyadic tolerance, StreamName window, regular rational readback, terminal Real seal, exactness ledger, transport, replay, provenance, and local naming.

Use the existing Real separability routes to metric completion and Cauchy-filter completion. Those child routes already force completion-facing reads through finite dyadic windows, regular readback, and the Real seal.

Now pass to chapter 3424. The Bishop-complete-metric packet consumes metric-completion, Cauchy-filter, regular readback, separated metric, complete-metric, and Real-seal rows, so Real separability can feed it only through the displayed countable dense readback surface.

Since neither packet contains selected dense points, quotient real equality, host completion objects, countable-choice selectors, or ambient-completeness coordinates, the link is exactly the finite forward handoff stated above. □

The $\mathsf{RealSeparability}^{\uparrow}$ dependency lattice also factors through the Bishop regular-real route of chapter 4058. A separability read that enumerates finite dyadic approximants must first expose the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the dyadic tolerance rows of chapter 291, and the regular-real handoff surface before treating the resulting $\mathsf{Real}^{\uparrow}$ seal as part of a countable dense family.

This keeps the separability route inside displayed L10 data: dyadic density supplies finite approximation addresses, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational names, and $\mathsf{BishopRegularReal}^{\uparrow}$ records the bounded regular real carrier that the separability certificate may consume. No host density theorem, quotient equality of real names, or ambient completion principle is introduced by this child route. The $\mathsf{RealSeparability}^{\uparrow}$ finite dyadic dense-family reads consume the Bishop regular-real handoff of chapter 4058, after the $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301, the dyadic tolerance rows of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Thus the separability packet reaches its dense-family read through displayed L10 regular-sequence and dyadic data before it treats a Bishop regular real as a source for finite real-density evidence. The $\mathsf{RealSeparability}^{\uparrow}$ metric-density route reads its countable dense surface through the finite regular-rational and metric witnesses already exposed by sibling chapters. A density consumer first reads the $\mathsf{RegSeqRat}^{\uparrow}$ schedule of chapter 301, the

$\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{StreamName}^{\uparrow}$ finite windows; only then may it inspect the $\mathsf{Met}^{\uparrow}$ distance witnesses of chapter 57. Thus the separability packet exports a finite density readback over regular rational windows and metric distance rows, not a selected dense point, quotient real equality, countable-choice selector, host dense subset, or ambient completeness principle.

Theorem 1810.56 (Real separability metric density route)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density read that is consumed by a metric route factors through* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{Met}^{\uparrow}$ *distance witnesses before the local separability row is exported.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier through its rational enumeration, dyadic tolerance, finite stream-window, regular readback, terminal real-seal, transport, replay, provenance, and local naming rows. The metric consumer can read no dense datum before those rows have been displayed.

The regular rational schedule supplies the dense candidate as a finite readback rather than as a host dense subset. The dyadic tolerance and stream-window rows record the precision and observed entries used by that candidate.

The metric row is then read only as a displayed distance witness. Transport and replay preserve the same route, so the exported density surface remains finite and carries no selected nearest point, quotient real equality, countable-choice selector, or ambient completeness theorem. □

Lemma 1810.57 (RealSeparability Polish-space forward link)**.** *Every* $\mathsf{PolishSpace}^{\uparrow}$ *complete-separable consumer that reads a* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window route consumes the RealSeparability packet of chapter 1809 only after the* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, and the* $\mathsf{Real}^{\uparrow}$ *seal route of chapter 38 have been displayed. The resulting read is a forward edge into chapter 1490, not a selected dense point, quotient completion equality, countable-choice schedule, or ambient completeness claim.*

Proof. Project the $\mathsf{RealSeparability}^{\uparrow}$ density route through its real-facing sibling rows. The forward read first exposes finite stream windows, regular rational observations, dyadic tolerance checks, and the terminal real seal before the dense-window data are exported.

The $\mathsf{PolishSpace}^{\uparrow}$ carrier then consumes that route through its own S, R, W observation ledger and complete-separable boundary. Since neither carrier has a coordinate for selected dense points, quotient completion equality, countable choice, or ambient completeness, the forward link preserves only the displayed finite rows. □

Theorem 1810.58 (RealSeparability Polish forward criterion)**.** *A* $\mathsf{PolishSpace}^{\uparrow}$ *consumer may read* $\mathsf{RealSeparability}^{\uparrow}$ *only when the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal route, and the dense-window route of* $\mathsf{RealSeparability}^{\uparrow}$ *are all displayed. The criterion exports no completeness theorem, no choice principle, no selected dense point, and no quotient-completion equality.*

Proof. Project the forward link of Definition 1810.57. It already orders the PolishSpace read through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, and the terminal Real seal before the dense-window route is consumed.

The local RealSeparability route files identify the same dense-window data as finite BEDC rows. Repacking those rows gives the stated criterion for PolishSpace consumers, while the excluded completeness, choice, selected-point, and quotient-completion coordinates remain absent from the displayed carrier surfaces. □

Theorem 1810.59 (RealSeparability dense Real forward link)**.** *Every accepted* RealSeparability$^{\uparrow}$ *dense finite schedule that exposes* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows feeds both the* PolishSpace$^{\uparrow}$ *countable dense surface of chapter 1490 and the* SeparatedCompletion$^{\uparrow}$ *zero-distance completion route of chapter 1612. The forward link carries only displayed finite schedules, stream windows, regular rational readbacks, dyadic tolerances, and Real seals; it does not select dense points, invoke countable choice, identify quotient completion classes, or use ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted RealSeparability$^{\uparrow}$ schedule. Its dense rows are finite: a consumer sees named windows, regular rational readbacks, dyadic tolerance comparisons, and terminal Real seals before any dense-surface claim is public.

For the PolishSpace branch, read the same finite schedule as a countable dense surface. The route supplies a displayed dense inventory to the PolishSpace$^{\uparrow}$ consumer, but no point is selected outside the schedule and no countable-choice operator is introduced.

For the SeparatedCompletion branch, pass the Real-seal comparisons through the zero-distance completion route. The SeparatedCompletion$^{\uparrow}$ consumer reads the same StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ evidence before the separated classifier is available.

The two branches therefore share one dense Real source. Since the carrier has no coordinate for chosen dense points, quotient completion equality, countable choice, or ambient completeness, the forward link is exhausted by the displayed finite RealSeparability route. □

Theorem 1810.60 (Real separability Cauchy approximation-tree forward link)**.** *Every* CauchyApproximationTree$^{\uparrow}$ *consumer that reads a countable dense* RealSeparability$^{\uparrow}$ *surface does so through the finite dense-readback route named by this chapter. The consumed branch window first reads the* DyadicRatCore$^{\uparrow}$ *tolerance row of chapter 291, then the finite* StreamName$^{\uparrow}$ *observation surface of chapter 126, then the* RegSeqRat$^{\uparrow}$ *readback row of chapter 301, and finally the* Real$^{\uparrow}$ *seal of chapter 38 before entering the finite tree packet of chapter 5716. Thus the dense route exports finite approximation-tree windows, not a detached dense subset, a selected real representative, quotient stream equality, countable choice, or ambient completeness.*

Proof. Use the dense readback rows already displayed by RealSeparability$^{\uparrow}$. They expose countable dense data only through dyadic tolerances, finite stream observations, regular rational readbacks, and Real seals.

Now read the CauchyApproximationTree$^{\uparrow}$ carrier. Its branch windows consume exactly those four rows before a Real-facing endpoint is sealed, so the dense surface is passed forward as finite tree-window data.

The carrier has no coordinate for detached dense subsets, selected representatives, quotient stream equality, countable choice, or ambient completeness. The forward link therefore preserves the concrete dense readback surface and adds no independent completion principle. □

The countable dense RealSeparability$^{\uparrow}$ rows are consumed by the PolishSpace$^{\uparrow}$ root surface of chapter 1490 only after the StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ readbacks are displayed. This route supplies a finite consumer edge from real separability to the Polish complete-separable package, but it does not provide selected dense points, quotient equality, or ambient completeness. The countable dense rows of RealSeparability$^{\uparrow}$ give sequential consumers a displayed source of rational and regular-Cauchy probes before any topology or limit read is accepted. A SequentialSpace$^{\uparrow}$ packet may consume those rows through chapter 4112 only after the finite density route has passed through the StreamName$^{\uparrow}$ and LimitSpace$^{\uparrow}$ surfaces of chapter 126 and chapter 3845. When the same read is completion-facing, the CauchySpace$^{\uparrow}$ comparison boundary of chapter 1847 remains

part of the route, so the dense source is not reread as a selected limit, quotient real equality, countable-choice selector, or ambient completeness principle. The $\mathsf{RealSeparability}^{\uparrow}$ Cauchy-setoid modulus route records the density-side dependency that keeps regular rational names comparable before a countable dense handoff is claimed. It reads chapter 301 for finite regular windows, chapter 1820 for the classifier that identifies equivalent regular Cauchy presentations, and the RealUp L10 input factorization before exporting a density route.

Theorem 1810.61 (Real separability Cauchy setoid route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that consumes* $\mathsf{RegSeqRat}^{\uparrow}$ *regular names factors through the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier before it claims a countable dense route. The consumer may then use the RealUp L10 route, but only after the regular readback, Cauchy-equivalence classifier, dyadic tolerance, terminal seal, transport, replay, provenance, and local naming rows are visible; it exports no quotient real equality, selected dense enumeration, host equality, countable choice, or ambient completeness.*

Proof. Start with the regular rational names. A density read that consumes $\mathsf{RegSeqRat}^{\uparrow}$ data first opens the finite windows and dyadic tolerances described by chapter 301; those rows are not yet a Real-facing countable dense route.

Next pass through the Cauchy-equivalence classifier of chapter 1820. Equivalent regular Cauchy presentations replay the same density read only through the displayed classifier row, so the consumer cannot replace the route by quotient real equality or a selected representative.

Finally use the RealUp L10 input factorization. The factorization keeps the terminal Real seal downstream from finite stream windows, regular readback, and dyadic tolerance data, so the countable dense route is claimed only after the setoid comparison has already fixed the regular-name boundary. □

The RealSeparability dense-modulus route records the classifier boundary that a regular Cauchy dense-read consumer must cross before a displayed dense modulus is exported. It reads the Cauchy-equivalence classifier of chapter 1820 together with the existing RealSeparability Cauchy-setoid and dense-read routes, including Definition 1810.61 and Definition 1810.21.

Theorem 1810.62 (RealSeparability Cauchy-setoid dense-modulus route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-read consumer that uses a regular Cauchy name must first consume the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{Real}^{\uparrow}$ *seal before exporting the dense modulus. The exported modulus is therefore a finite classifier-mediated RealSeparability route, not quotient real equality, host stream equality, selected dense enumeration, countable choice, or ambient completion.*

Proof. Start with the regular Cauchy name boundary. The classifier route of chapter 1820 compares regular presentations through finite displayed rows, so the dense-read consumer cannot begin from a quotient real object or a selected representative.

Next compose with the existing RealSeparability Cauchy-setoid route of Definition 1810.61. It places the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before any countable dense handoff and keeps the comparison inside the displayed regular-name boundary.

Finally use the dense-read route of Definition 1810.21. The consumer then reads $\mathsf{RegSeqRat}^{\uparrow}$ regular readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{StreamName}^{\uparrow}$ windows, and the terminal $\mathsf{Real}^{\uparrow}$ seal before the dense modulus is exported, leaving quotient equality, host equality, selected dense enumerations, countable choice, and ambient completion outside the packet. □

The $\mathsf{RealSeparability}^{\uparrow}$ countable-dense route depends on the classifier surface of chapter 1820 before dense readback can be consumed. This child route pins the separability lattice to the dis-

played Cauchy-equivalence setoid rows, so the dense enumeration reads a finite classifier boundary rather than quotient path equality or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 1810.63 (Real separability Cauchy-setoid forward route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-read consumer that identifies regular Cauchy names must expose the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row before the* $\mathsf{Real}^{\uparrow}$ *separability seal is exported. The route passes through the regular rational readback and dyadic tolerance rows already visible in Definition 1810.61 and the local Real-separability carrier, then reaches chapter 1820 as a classifier boundary rather than as quotient stream equality.*

Proof. Project the Real-separability dense-read rows from Definition 1809.1. The consumer first reads the displayed density schedule, StreamName windows, RegSeqRat readback, dyadic tolerance row, terminal Real seal, transport, replay, provenance, and local naming.

Apply the Cauchy-setoid route of Definition 1810.61. It places the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier between regular Cauchy readback and the public dense-route handoff, so the consumer cannot export the $\mathsf{Real}^{\uparrow}$ separability seal before the classifier row is visible.

Finally use the sibling chapter chapter 1820. Its carrier supplies finite StreamName, RegSeqRat, DyadicRatCore, setoid-test, and Real-seal rows, not a quotient stream equality, selected representative, countable-choice selector, host real equality, or ambient completeness witness. □

The $\mathsf{RealSeparability}^{\uparrow}$ density route reads finite regular windows through chapter 301 and identifies comparable presentations through chapter 1820 before exporting countable dense readback. $\mathsf{RealSeparability}^{\uparrow}$ consumes the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 through the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ routes of chapter 301 and chapter 126; its displayed dense source is the finite rational row family supplied by $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$, with chapter 291 fixing the dyadic tolerance ledger used by each L10 read. The same dense dyadic and rational source supplies downstream $\mathsf{Pseudometric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ distance-read routes through chapter 1614 and chapter 1506.

Theorem 1810.64 (RealSeparability L10 source route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer that reads finite dense-window data through the L10 source chain must display the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows cited by chapter 126, chapter 301, chapter 291, and chapter 38. The route exposes finite stream windows, regular rational sequence readback, dyadic tolerance control, and the terminal Real seal before any separability-density handoff is consumed.*

Proof. Project the RealSeparability packet through its displayed density route. The source side can read only finite window data, so the first visible dependency is the $\mathsf{StreamName}^{\uparrow}$ row named by the sibling source chapter.

The window data are then interpreted through $\mathsf{RegSeqRat}^{\uparrow}$ and bounded by the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger. These rows supply the finite regular-name and dyadic-readback surface used by separability consumers.

The terminal read is the $\mathsf{Real}^{\uparrow}$ seal. Since the route has no coordinate for quotient real equality, ambient completeness, or a choice-selected dense sequence, the L10 source chain is exhausted by the four displayed sibling chapters. □

Theorem 1810.65 (RealSeparability countable-dense Cauchy handshake)**.** *Every* $\mathsf{CountableDenseSubset}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSeparability}^{\uparrow}$ *packet must first display finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance control, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and only then read rational density. The handshake routes the dense subset surface of chapter 1566 through the L10 source chain of Definition 1810.64; it exports no selected dense sequence, quotient stream equality, ambient completeness, or host enumeration of completed reals.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier and apply Definition 1810.64. The source route already forces finite $\mathsf{StreamName}^{\uparrow}$ windows to be visible before any density read is consumed.

The windows are then read back by $\mathsf{RegSeqRat}^{\uparrow}$ and bounded by the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger. These rows supply the finite Cauchy-facing data needed by the countable dense subset consumer.

Only after the terminal $\mathsf{Real}^{\uparrow}$ seal is displayed may the consumer read rational density from chapter 1566. Since no selected dense sequence, quotient stream equality, ambient completeness, or host enumeration row appears in the displayed route, none can be exported by the handshake. □

Theorem 1810.66 (RealSeparability nested-set density handoff)**.** *Every nested located closed-set packet over* $\mathsf{Real}^{\uparrow}$ *that consumes rational density must expose the* $\mathsf{RealSeparability}^{\uparrow}$ *countable dense row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it passes diameter-modulus data to completion consumers. In particular, the handoff to chapter 7594 is routed through the L10 source chain of Definition 1810.64 and the countable-dense handshake of Definition 1810.65; it exports no sequential compactness, open-cover compactness, countable-choice selector, quotient stream equality, or ambient completeness row.*

Proof. First read the density source through Definition 1810.64. It forces a density consumer to expose finite $\mathsf{StreamName}^{\uparrow}$ windows before the rational density row is consumed.

Next use Definition 1810.65. The handshake routes the countable dense surface through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any downstream consumer treats density as Real-facing data.

For a nested located closed-set packet, the diameter-modulus row is downstream of the same finite density surface. Thus the completion-facing handoff can pass only the displayed countable dense row, dyadic approximation row, regular rational readback row, Real seal, transport, replay, provenance, and local naming rows.

Since none of these rows contains sequential compactness, open-cover compactness, countable choice, quotient stream equality, or ambient completeness, the nested-set consumer cannot export any of those claims. □

The dense dyadic schedule of $\mathsf{RealSeparability}^{\uparrow}$ also consumes the located-comparison readback of chapter 1730 and the rate-extraction route of chapter 2085. The schedule is therefore not a free host enumeration: it is a finite $\mathsf{NameCert}$ ledger whose comparison cells are inherited from $\mathsf{LocatedRealComparison}^{\uparrow}$ and whose precision rates are inherited from $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ before any dense real-name consumer can read them. Every $\mathsf{RealSeparability}^{\uparrow}$ dense-countable read that is consumed by a located real completion argument first passes through the finite $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ comparison surface of chapter 1820 and the $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ route of chapter 6045. The separability packet exports dense reads only after the displayed regular-name comparison, located Cauchy completeness handoff, hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows have been shown; it exports no quotient real equality, selected dense enumeration, countable choice, host completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completion. The child dependency route for $\mathsf{RealSeparability}^{\uparrow}$ is the finite L10 path through chapter 301 and chapter 38: a density request first reads the existing separability schedule rows of Definition 1810.25, then consumes the dense dyadic and rational rows of Definition 1809.6, and only after those rows reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. Thus the hub surface records a substantive horizontal dependency from separability to regular-rational readback and Real sealing, with no route through a host dense subset, selected nearest point, quotient stream, or ambient completeness claim.

Theorem 1810.67 (Real separability L10 certificate route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read that consumes the* $\mathsf{Real}^{\uparrow}$ *seal factors through the displayed L10 route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{CountableDenseSubset}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route is grounded in chapter 301, chapter 126, chapter 291, chapter 37, chapter 1566, and chapter 38. Thus a separability consumer receives regular-rational readback, finite stream windows, dyadic tolerance rows, rational endpoint rows, countable dense subset naming, and the terminal Real seal as displayed sibling data, with no host dense subset, selected nearest point, quotient real equality, countable-choice enumeration, or ambient completeness coordinate.

Proof. Read the $\mathsf{RealSeparability}^{\uparrow}$ consumer as a request for a displayed density route. The regular-rational row supplies the source readback, while the stream row supplies the finite windows on which the density request is inspected.

The dyadic and rational rows then expose the tolerance and endpoint data used by the dense subset certificate. The $\mathsf{CountableDenseSubset}^{\uparrow}$ row names the countable dense boundary as a sibling certificate rather than as an external host enumeration.

Only after those rows are displayed can the consumer reach the $\mathsf{Real}^{\uparrow}$ seal. Since the route has no coordinate for a host dense subset, selected nearest point, quotient equality, choice enumeration, or ambient completeness, none of those objects can be exported by the separability packet. □

The $\mathsf{RealSeparability}^{\uparrow}$ route reads dense rational windows through chapter 301 and dyadic tolerances through chapter 291 before the terminal $\mathsf{Real}^{\uparrow}$ seal. This places the L10 dependency on displayed regular-rational schedules and dyadic modulus rows, rather than on an external countable dense subset or a choice-selected enumeration. The $\mathsf{RealSeparability}^{\uparrow}$ source lattice is not a kernel-only island: its rational enumeration is read from chapter 37, its dyadic tolerance route is read from chapter 291, and its density handoff reaches $\mathsf{CountableDenseSubset}^{\uparrow}$ only after the StreamName, RegSeqRat, and Real route has displayed finite windows, regular rational readback, and the terminal real-name seal. Every $\mathsf{RealSeparability}^{\uparrow}$ density read that reaches the public countable-dense boundary factors through $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{DyadicDensityReal}^{\uparrow}$, and $\mathsf{RationalDensityReal}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is available. The route is grounded in chapter 1566, chapter 1484, chapter 1409, and chapter 38, while the L10 source lattice remains the finite chain through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$; no host dense subset, selected nearest point, quotient real equality, countable choice, or ambient completeness row is exported by this seal route.

Theorem 1810.68 (RealSeparability countable dense choice-free filter)**.** *An accepted* $\mathsf{RealSeparability}^{\uparrow}$ *dense read is exported as a countable dense filter only after the dyadic rational candidate row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal are all displayed. The route exports the countable dense filter ledger carried by those rows and exports no selected representative, quotient stream equality, trichotomy, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted separability carrier to its finite density rows. The dyadic-density dependency of Definition 1810.28 supplies the dyadic rational candidate and tolerance ledger through $\mathsf{DyadicRatCore}^{\uparrow}$, so the dense read begins from displayed rational data rather than from a selected host representative.

Next use the countable dense route of Definition 1810.39. Its schedule is finite-window data, and the $\mathsf{StreamName}^{\uparrow}$ row records exactly the windows inspected by the density ledger.

Finally apply the RegSeqRat pullback of Definition 1810.26 and the countable-dense seal route immediately above this theorem. These bind the regularity readback and the terminal $\mathsf{Real}^{\uparrow}$ seal before the filter is public. Since no row in the chain carries quotient stream equality, trichotomy, countable choice, or ambient completeness, the exported object is precisely the displayed countable dense filter ledger. □

Theorem 1810.69 (RealSeparability regular Cauchy dense countable route)**.** *Every accepted* $\mathsf{RealSeparability}^{\uparrow}$ *density request that reaches a countable dense row first factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The request reads dyadic tolerance rows, finite stream windows, regular rational readback, the Cauchy-equivalence classifier, and the terminal real-name seal before the countable dense row is consumed. The route exports no quotient $\mathsf{Real}^{\uparrow}$ *equality, selected dense enumeration, countable-choice branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with an accepted density request for $\mathsf{RealSeparability}^{\uparrow}$. The hub route already places such a request downstream of the dyadic rational core, stream-name window, regular-rational readback, Cauchy-equivalence classifier, and terminal real-name seal.

The dyadic and stream rows provide the finite observation data. The $\mathsf{RegSeqRat}^{\uparrow}$ readback attaches those observations to a regular Cauchy name, and the Cauchy-equivalence classifier is the only equality classifier inspected before the name reaches the $\mathsf{Real}^{\uparrow}$ seal.

Only after that seal is fixed may the countable dense row be read. Since none of the displayed rows contains quotient real equality, a selected dense enumeration, countable choice, or an ambient completeness coordinate, the countable-density export remains exactly the finite regular-Cauchy route stated above. □

Every $\mathsf{RealSeparability}^{\uparrow}$ density read that is forwarded to a public dense-source consumer first consumes $\mathsf{CountableDenseSubset}^{\uparrow}$ through chapter 1566, $\mathsf{DyadicDensityReal}^{\uparrow}$ through chapter 1484, and $\mathsf{RationalDensityReal}^{\uparrow}$ through chapter 1409. Only after those sibling rows have been displayed may the route pass through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal; it exports no host dense subset, selected nearest point, quotient real equality, countable choice, or ambient real completeness. The $\mathsf{RealSeparability}^{\uparrow}$ route supplies the countable dense schedule read by the complete-separable consumers of chapter 1490 and chapter 1458. A Polish-space or separable-metric consumer reaches that schedule only after the Real-facing density packet has exposed its $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, dyadic tolerance rows, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row. The dependency is therefore a finite L10 dense-schedule handoff, not a host dense subset, selected nearest point, quotient real equality, countable-choice selector, or ambient completeness claim.

Theorem 1810.70 (Real separability lawless-sequence forward link)**.** *Any* $\mathsf{RealSeparability}^{\uparrow}$ *density consumer that reuses lawless or Baire finite-prefix observations must pass through chapter 1495, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the dyadic tolerance row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it exports separability. For an accepted separability carrier*

$$S = (Q, D, W, R, E, T, H, C, P, N),$$

the lawless or Baire observation is admitted only as a finite prefix read routed through W*, tested against* D*, transported through* R*, and sealed by* E*.*

The route refuses host infinite sequences, countable choice, quotient streams, selected dense points, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted $\mathsf{RealSeparability}^{\uparrow}$ carrier. The density consumer has access only to the rational enumeration row Q, dyadic tolerance row D, finite StreamName window W, RegSeqRat readback R, terminal Real seal E, exactness ledger T, transport H, replay C, provenance P, and local naming N.

If the consumer cites a lawless or Baire finite-prefix observation, the citation first enters through chapter 1495. That chapter exposes only finite StreamName windows, Bool digit rows, Nat prefix indices, transport, replay, provenance, and local naming; it does not export an infinite sequence or a countable-choice source.

Compose that finite-window scope with the separability density route. The cited prefix window is read as the separability row W, the requested precision is read through the dyadic row D, the observed rational data are transported through the RegSeqRat row R, and the terminal Real boundary is reached only at E.

The rows T, H, C, P, N preserve the same route as exactness, componentwise transport, displayed replay, provenance, and local naming. Since neither packet contains host infinite sequences, countable choice, quotient streams, selected dense points, or ambient Real completeness, the composed density consumer cannot export any of them. □

The $\mathsf{RealSeparability}^{\uparrow}$ route consumes the Cauchy readback boundary of chapter 3413 and the completion universal-property boundary of chapter 2124 before exporting dense countable real reads. This pins the separability packet to its Cauchy-window source and completion-facing universal route, rather than letting the hub appear as a kernel-only index. The $\mathsf{RealSeparability}^{\uparrow}$ density windows used by compact interval or uniform-continuity consumers pass through chapter 5863 when the consumer asks for a finite prefix bar. The fan route supplies the finite window bound; ordinary dyadic density still comes from the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301 and the dyadic arithmetic route of chapter 291. Thus the separability lattice distinguishes density supply from window certification without introducing a selected dense subsequence, open-cover compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The dense-window reads exported by $\mathsf{RealSeparability}^{\uparrow}$ consume the finite cofinal tail-window service of chapter 4060 before presenting rational density windows to $\mathsf{Real}^{\uparrow}$ consumers. This route keeps the separability dossier tied to displayed regular-Cauchy windows, cofinal tail schedules, rational-density rows, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming rather than to an ambient countable dense subset or a selected completion limit.

Theorem 1810.71 (RealSeparability hub sibling route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density read exported by chapter 1809 factors first through the regular rational schedule of chapter 301, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, and the terminal real-name seal of chapter 38. Only after those sibling rows are displayed may the packet expose a countable dense surface to a downstream consumer.*

Proof. Read the existing RealSeparability carrier and sibling-lattice files through the hub. The regular rational schedule gives the rational approximants, the dyadic core gives the tolerance rows, and the stream-name route gives the finite observation windows that the density read may inspect.

The terminal $\mathsf{Real}^{\uparrow}$ seal is then read before the density surface is exported. Thus the hub route records a concrete L10 dependency through RegSeqRatUp, DyadicRatCoreUp, StreamNameUp, and RealUp rather than a detached dense subset, selected representative, quotient real equality, countable-choice selector, or ambient completeness row. □

Theorem 1810.72 (RealSeparability countable-dense forward read)**.** *Every* $\mathsf{CountableDenseSubset}^{\uparrow}$ *or* $\mathsf{RealCauchyModulus}^{\uparrow}$ *consumer reading* $\mathsf{RealSeparability}^{\uparrow}$ *must pass through the sibling route*

named in Definition 1810.71, then through the countable-dense source of chapter 1566 before exporting density. The route exports no selected dense point, quotient real equality, countable-choice selector, or ambient completeness row.

Proof. Start with Definition 1810.71. It places every density read behind the RegSeqRat, DyadicRatCore, StreamName, and RealUp sibling rows before the hub exports a countable dense surface.

Project the carrier rows of Definition 1809.1. The rational enumeration, dyadic tolerance, finite window, regular readback, terminal Real seal, exactness, transport, replay, provenance, and local naming rows are the only data available to the separability consumer.

The countable-dense source of chapter 1566 is therefore read after those sibling rows and before density is exported to either a $\mathsf{CountableDenseSubset}^{\uparrow}$ or $\mathsf{RealCauchyModulus}^{\uparrow}$ consumer. Since the carrier contains no selected dense point, quotient real equality, countable-choice selector, or ambient completeness row, the forward read cannot export any of them. □

Theorem 1810.73 (RealSeparability Cauchy setoid forward link)**.** *Every countable-dense* $\mathsf{RealSeparability}^{\uparrow}$ *route that exports rational names to a Real-facing consumer supplies a forward read of the Cauchy equivalence classifier in chapter 1820. Dense rational names remain compared through the displayed setoid ledger after the RegSeqRat, DyadicRatCore, StreamName, and RealUp sibling rows are exposed, rather than by a separate real-name equality predicate.*

Proof. Begin with Definition 1810.72. It forces each density export through the regular rational schedule, dyadic tolerance ledger, finite observation windows, terminal Real seal, and countable-dense source.

Now read the Cauchy equivalence setoid boundary. The same rational names that witness density are compared by the displayed classifier ledger of chapter 1820, so the separability route has no extra coordinate for host real equality or a separate real-name equality predicate. □

Theorem 1810.74 (Real separability public status route)**.** *Every public* $\mathsf{RealSeparability}^{\uparrow}$ *density read is exported only after the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal are displayed. The route presents a finite density surface for Real and Completion consumers; it exports no quotient real equality, selected dense enumeration, countable choice, hidden host dense subset, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the density rows already routed through chapter 1809. A public consumer may read a candidate only as a finite density witness, not as a selected host enumeration.

Next pass the witness through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows. These rows expose the finite observation windows and regular-rational readback before any Real-facing density claim is public.

The $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger and the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier then fix the comparison boundary for the read. Equivalent regular presentations replay the same displayed density route rather than becoming quotient real equality.

Only after those rows are visible does the consumer reach the terminal $\mathsf{Real}^{\uparrow}$ seal. Since no row contains a selected dense enumeration, countable-choice schedule, hidden host dense subset, quotient real equality, or ambient completeness principle, the public status route is exhausted by the displayed finite data. □

Theorem 1810.75 (RealSeparability rotation-selected public route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *public-route consumer selected by the rotation frontier must pass through* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *the countable-dense seal, transport, replay, provenance, and local naming before any separability read is exported. The route exposes the finite Cauchy classifier, dyadic tolerance, stream window, regular-rational readback, terminal Real seal, and countable dense support; it exports no quotient Real equality, selected dense point, countable-choice selector, or ambient completeness coordinate.*

Proof. Read the hub route through Definition 1810.74. Its public status row already orders the density request through the finite L10 source route before a public countable-dense read is available.

Next use the Cauchy-equivalence and countable-dense child routes. They force the consumer to display the CauchyEquivalenceSetoid$^{\uparrow}$ classifier, dyadic tolerance, finite StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, terminal Real$^{\uparrow}$ seal, transport, replay, provenance, and local naming before the separability read is exported.

Since the route names only those displayed rows, the refused quotient equality, selected dense point, countable-choice selector, and ambient completeness coordinates have no public export path. □

Every RealSeparability$^{\uparrow}$ countable-density read consumes the RationalDensityReal$^{\uparrow}$ route of chapter 1409 before a rational witness can be treated as dense in the displayed real carrier. The sibling route keeps rational interval witnesses, finite stream windows, RegSeqRat$^{\uparrow}$ readback, and the terminal Real$^{\uparrow}$ seal inside the L10 Real packet, with no host dense subset, selected nearest point, quotient real equality, countable choice, or ambient completeness row. The RealSeparability$^{\uparrow}$ packet supplies countable dense dyadic reads for the same finite Real-facing corridor used by effective finite-cover compactness and compact-uniform modulus routes. Its dense readback surface is grounded in the existing L10 siblings chapter 301 and chapter 38, and it is consumed by chapter 6035 as the dyadic observation side of a finite-cover handoff.

Theorem 1810.76 (Real separability dyadic lattice forward route)**.** *Every accepted* RealSeparability$^{\uparrow}$ *dense-read route that exports a countable dense ledger factors first through the dyadic rational density rows of chapter 291, then through the regular rational readback surface of chapter 301, and finally through the terminal real-name seal of chapter 38. The exported ledger is therefore a displayed dyadic, regular-sequence, and Real-sealed route, not a host countability claim, quotient real equality, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Read the existing RealSeparability child routes. The density route and dyadic lattice link expose rational candidates only after the dyadic tolerance rows have fixed the finite approximation scale.

The RegSeqRat forward route then supplies the regular rational readback. It keeps the StreamName window and dyadic tolerance visible before a dense-completion or countable-density consumer can inspect the exported row.

Finally the Real seal route closes the read at Real$^{\uparrow}$. Since the hub child routes carry no host countability oracle, quotient equality token, or ambient completeness coordinate, the countable dense ledger is exported only through the displayed dyadic, RegSeqRat, and Real-sealed dependency chain. □

RealSeparability$^{\uparrow}$ supplies the countable dense real-window rows consumed by the compact-uniform-continuity finite-net route. The downstream packet of chapter 388 may read those windows only after the Real$^{\uparrow}$ seal of chapter 38, the RegSeqRat$^{\uparrow}$ regularity schedule of chapter 301, and the DyadicRatCore$^{\uparrow}$ observation rows of chapter 291 remain visible through the RealSeparability$^{\uparrow}$ dense-window surface. The edge therefore contributes a finite source ledger for compact finite-net

consumers, not an ambient separability theorem or a choice of all real points. The $\mathsf{RealSeparability}^{\uparrow}$ separability packet consumes the equality-facing boundary of chapter 1820 before it reads the countable dense real route through the regular-rational readback of chapter 301 and the dyadic tolerance core of chapter 291. Thus a dense-read consumer first identifies regular-Cauchy presentations through $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, then reads the dyadic density windows exposed by $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$. The route exports no host countable choice principle and no selected enumeration outside the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. The $\mathsf{RealSeparability}^{\uparrow}$ hub reads the classifier boundary of chapter 1820 as the sibling surface that supplies separability readback for regular Cauchy presentations; this ledger line exposes the local dependency without adding a separate theorem claim. The $\mathsf{RealSeparability}^{\uparrow}$ route consumes the CauchyEquivalenceSetoid classifier of chapter 1820 together with the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301 when it turns countable dyadic density into a Real-facing separability packet. This link records that separability is read through the setoid classifier and regular-rational presentation before it is exposed to Real consumers.

Theorem 1810.77 (Real separability StreamName witness route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *countable dense witness consumed by an L10* $\mathsf{Real}^{\uparrow}$ *route must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before it is read as density data. The witness route is grounded in chapter 126, chapter 301, and chapter 38; when the dense witness is compared as a regular Cauchy presentation, it reads density only through the Cauchy-equivalence classifier route of chapter 1820 before the Real seal. It supplies no host dense subset, selected enumeration, quotient real equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with the L10 certificate route of Definition 1810.67. It places the density read on displayed sibling rows rather than on a host dense subset or selected enumeration.

The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite windows at which the candidate dense witness is inspected. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational readback attached to those windows, so the density datum is not available as a detached rational list.

When a consumer compares the resulting regular presentation, the comparison passes through the Cauchy-equivalence classifier of chapter 1820. This keeps density attached to displayed classifier rows before the Real seal is available.

Only after those two rows have been displayed can the route consume the terminal $\mathsf{Real}^{\uparrow}$ seal. Therefore every L10 separability witness read exposes StreamName windows, RegSeqRat readback, and the Real seal before it is read as density data, with all excluded choice and quotient coordinates remaining absent. □

Theorem 1810.78 (Real separability seed registration)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *seed route is registered by the displayed finite lattice*

$$\mathsf{CountableDenseSubset}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Every dense-read consumer of the seed must first expose countable-dense source rows, dyadic tolerance rows, finite stream windows, regular-rational readback, and the terminal Real seal before any separability datum is exported. The hub marker points to the seed-status theorem Definition 1810.12, while this child records the finite registration text that keeps the $\mathsf{RealSeparability}^{\uparrow}$ *route at the same scoped marker site. The registration claims only seed-level routing; it does not claim scoped closure, selected dense points, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the countable-dense route from the existing child lattice. The separability packet exposes density through countable source rows and dyadic tolerance rows before a Real-facing consumer can inspect a dense witness.

Next use the StreamName and RegSeqRat sibling routes. They place the finite observation window and regular-rational readback between the dyadic tolerance ledger and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The seed-status child records the resulting closure axis at seed level. Therefore this registration is a finite route marker for $\mathsf{RealSeparability}^{\uparrow}$ and not a stronger separability theorem or a completeness principle. □

Theorem 1810.79 (Real separability seed child route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *density request factors through the displayed child route consisting of a* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any countable-dense row is consumed. The route is the seed-level child of Definition 1810.12, Definition 1810.14, and Definition 1810.15; it exports no quotient Real equality, selected dense enumeration, countable choice, host dense subset, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the seed status Definition 1810.12. It identifies the separability seed as the displayed child-route family rather than theorem content stored on the hub.

Apply the scoped density route Definition 1810.14. The dyadic approximation row, finite StreamName windows, RegSeqRat readback, Cauchy-equivalence comparison, and Real seal are exposed before the countable-dense row can be read.

Finally use the seed closure route Definition 1810.15. It records the same child ledger as the seed closure surface, so the density request remains inside the finite route and cannot supply quotient Real equality, selected enumeration, countable choice, a host dense subset, or ambient completeness. □

Theorem 1810.80 (RealSeparability to-seed status route)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *to-seed status is recorded by the displayed child route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the existing Cauchy-equivalence, density, completion-facing, transport, replay, provenance, and local naming rows under chapter 1809. The route records only seed-level paper scope for dense-window reads: it does not upgrade the verification axis, does not assert mature $\mathsf{Real}^{\uparrow}$ *completeness, and does not introduce a chosen dense enumeration or countable-choice schedule.*

Proof. Read the hub registration Definition 1810.12. It identifies $\mathsf{RealSeparability}^{\uparrow}$ as a child-route family rather than as theorem body stored on the hub.

Next use Definition 1810.16 and Definition 1810.79. They keep the dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, and terminal Real seal visible before any density consumer receives the separability packet.

The status conclusion is therefore a theory-axis statement about the seed route. The formal verification row remains the one recorded by the surrounding closurestatus block, and the route contains no mature Real-completeness coordinate, selected dense enumeration, or countable-choice data. □

Theorem 1810.81 (Real separability additive seed-status route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *seed-status consumer reads the displayed child route*

$\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbed}$

before it treats the separability packet as a dense Real source. The Cauchy-equivalence classifier is read from chapter 1820; dyadic tolerance, stream-window, regular-rational, and terminal Real rows are read through chapter 291, chapter 126, chapter 301, and chapter 38; and completion-facing density is handed to chapter 1453. The route exports no quotient Real equality, selected dense enumeration, countable-choice schedule, host dense subset, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the seed-status surface of Definition 1810.12. It identifies $\mathsf{RealSeparability}^{\uparrow}$ as a child-route family, so the hub itself contributes no theorem body and no independent density object.

Read the classifier and approximation rows next. The Cauchy-equivalence setoid row fixes the comparison boundary, while the dyadic, StreamName, RegSeqRat, and Real rows display the finite tolerance, observation, readback, and seal route that a dense-name consumer must traverse.

Finally pass through the regular-Cauchy dense embedding boundary. This keeps completion-facing density attached to the same finite seed route, leaving no coordinate for quotient Real equality, selected enumeration, choice, host dense subsets, or ambient completeness. □

Theorem 1810.82 (RealSeparability public closure handoff)**.** *Every public* $\mathsf{RealSeparability}^{\uparrow}$ *countable-dense read is exported through the displayed L10 source route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

inside the separability packet. The handoff may expose dyadic tolerances, finite stream windows, regular rational readback, terminal Real seals, transport, replay, provenance, and local naming, but it does not expose host enumerations of completed reals, selected dense points, quotient real equality, countable choice, completed-real compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the countable dense route of Definition 1810.39 and the public status route of Definition 1810.74. Together they force the density consumer to pass through the displayed finite density rows before any public Real-facing read is available.

The dyadic tolerance row is the first public source row. It controls the approximation window and keeps the density read inside the finite $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rather than inside a host enumeration.

The stream and regular-rational rows then expose the inspected finite windows and the $\mathsf{RegSeqRat}^{\uparrow}$ readback. Only after those rows are displayed may the consumer inspect the terminal $\mathsf{Real}^{\uparrow}$ seal.

Thus the public handoff is the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Since no row contains a selected dense point, host enumeration, quotient equality, countable-choice selector, compactness theorem, or ambient completeness principle, those objects cannot be exported by the public separability surface. □

Theorem 1810.83 (RealSeparability public density)**.** *Every public countable dense* $\mathsf{RealSeparability}^{\uparrow}$ *read factors through*

$$\mathsf{CountableDenseSubset}^{\uparrow}, \quad \mathsf{DyadicDensityReal}^{\uparrow}, \quad \mathsf{RationalDensityReal}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSe}$$

before any Real-facing seal is exported. The public density surface exposes only the countable-dense boundary, dyadic and rational density routes, dyadic tolerance rows, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming. It exports no selected nearest point, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 1810.82. It already forces any public separability read through the displayed L10 route before the Real-facing public seal can be inspected.

Next read the countable-dense route of Definition 1810.39. That route places the $\mathsf{CountableDenseSubset}^{\uparrow}$ boundary downstream of finite stream windows, regular rational readback, dyadic tolerance data, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally combine the density routes of Definition 1809.6 and Definition 1809.12. They expose the $\mathsf{DyadicDensityReal}^{\uparrow}$ and $\mathsf{RationalDensityReal}^{\uparrow}$ rows before the public density read reaches $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The resulting public density export is therefore the displayed finite route through the countable-dense, dyadic-density, rational-density, dyadic-rational, stream, regular-rational, and Real rows. Since none of these routes contains a selected nearest point, quotient real equality, countable-choice selector, or ambient completeness coordinate, the public density theorem exports none of them. □

Chapter 1811

A Concrete Naming Certificate for $\mathsf{NestedDyadicCauchy}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the interval computations of Moore–Kearfott–Cloud, the $\mathsf{NestedDyadicCauchy}^{\uparrow}$ packet records the finite data by which a nested chain of dyadic intervals becomes a regular rational Cauchy name before the terminal real seal is consumed. It refines the finite-chain surface of chapter 328, the ambient interval discipline of chapter 320, the dyadic endpoint core of chapter 291, the finite schedule interface of chapter 126, the regular rational handoff of chapter 301, and the seal boundary of chapter 38. The packet is a finite-means Cauchy route for L10 real and completion work; it is not a completed intersection point, quotient stream equality, host real equality, countable choice, or ambient completeness.

Definition 1811.1 (Nested dyadic Cauchy carrier)**.** *A* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested dyadic interval window. It records a nonempty finite prefix of dyadic intervals, their endpoint rows through* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the displayed refinement relation inherited from* $\mathsf{NestedDyadicInterval}^{\uparrow}$*.*

2. *B is the shrinking-width dyadic budget. It assigns each displayed tolerance request to a prefix index whose interval width is bounded by the requested dyadic scale.*

3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite interval-prefix entries and endpoint observations that may be queried before regular rational readback.*

4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row formed from the selected endpoint or midpoint observations, the shrinking-width budget, and the stream schedule.*

5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, B, S, R have been displayed.*

6. *H records componentwise* hsame *transport for interval prefixes, dyadic budgets, stream schedules, regular rational readback, real seals, replay rows, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a finite interval-window request through B, S, R, E and then through the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{NestedDyadicInterval}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{NestedDyadicCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine displayed rows. It has no coordinate for completed intersections, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking.

↪ variant `BEDC.Derived.NestedDyadicCauchyUp.NestedDyadicCauchyTasteGate single carrier alignment`

Theorem 1811.2 (Nested dyadic Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier*

$$K = (I, B, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedDyadicCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the nested dyadic interval prefix, shrinking-width budget, stream schedule, regular rational handoff, real seal, transport, replay, provenance, and local naming row;*
2. *nested-prefix exposure, requiring each interval read to be one of the displayed prefix rows of I;*
3. *dyadic-width exactness, requiring every Cauchy tolerance request to be discharged by a width comparison stored in B and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the interval-prefix and endpoint observations used by B and R;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to be formed only after the prefix, budget, and schedule rows have been projected;*
6. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring E to be consumed only after R and the structural rows have fixed the finite route.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1811.1. The projection exposes one finite nested dyadic interval prefix, one shrinking-width dyadic budget, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Nested-prefix exposure is forced by I. A consumer may inspect only interval rows already present in the finite prefix, and each such row carries its endpoints through the DyadicRatCore surface named by the packet.

Dyadic-width exactness is then forced by B. Each tolerance request is answered by a displayed prefix index and a displayed dyadic comparison of the corresponding interval width against that tolerance.

The schedule and handoff rows are downstream. The row S records the finite prefix and endpoint observations that may be opened, and R repacks exactly those observations as regular rational Cauchy data.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 1811.3 (Nested dyadic Cauchy regularity-readback obligation)**.** *For every accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier* $K = (I, B, S, R, E, H, C, P, N)$*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer*

may read regularity only after it has displayed the $\mathsf{StreamName}^{\uparrow}$ *schedule row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The readback route is exactly*

$$S \longmapsto R \longmapsto E$$

together with I, B, H, C, P, N *as structural support; it exports no completed intersection, quotient stream equality, host real equality, countable choice, or ambient completeness.*

Proof. Project the carrier rows. The schedule row S is the only source of endpoint or midpoint observations available to a regular rational consumer, so regularity cannot be read before the schedule is displayed.

Apply Definition 1811.6. The handoff theorem forces every regular rational read through the finite interval prefix I, the shrinking-width budget B, the schedule S, and then the handoff row R.

The Real-facing step is downstream. By Definition 1811.9, the seal row E is opened only after R has fixed the regular rational route.

Tail compatibility is stable under Definition 1811.7: two compatible carriers share the displayed finite route before either seal is consumed. Thus the regularity-readback obligation is exactly the carrier projection through S, R, E and the structural rows. □

Theorem 1811.4 (Nested dyadic Cauchy shrinking-width obligation)**.** *For every accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier* $K = (I, B, S, R, E, H, C, P, N)$*, each Cauchy tolerance request is discharged by a row of the shrinking-width budget* B *whose endpoint comparison is read through* $\mathsf{DyadicRatCore}^{\uparrow}$*. No* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, or completion-facing consumer may use the request until that dyadic width comparison and its prefix index have been displayed.*

Proof. The row B is the only shrinking-width coordinate of the carrier. It assigns each displayed tolerance request to a prefix index and to the dyadic width comparison for the corresponding interval.

The comparison is not external arithmetic. The endpoint rows of I and the width comparison stored in B are read through the $\mathsf{DyadicRatCore}^{\uparrow}$ surface named in the carrier provenance, so the request is answered by displayed dyadic data.

Apply Definition 1811.6. Since R is formed only after I, B, S are projected, the RegSeqRat handoff cannot consume a tolerance request without first opening the dyadic width row.

The same restriction persists through Definition 1811.7. Common-tail gluing compares two requests by a shared dyadic budget row B^* before any shared regular rational row is exported. □

Theorem 1811.5 (Nested dyadic Cauchy schedule-compatibility obligation)**.** *For every accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier* $K = (I, B, S, R, E, H, C, P, N)$*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S *exposes exactly the finite interval-prefix entries and endpoint observations used by* B *and* R*. Any consumer that reads* R *or* E *must therefore show the displayed schedule row first, and the structural rows* H, C, P, N *may transport only that scheduled route.*

Proof. Project S from the carrier. Its entries are the finite interval-prefix and endpoint observations that the packet permits downstream consumers to inspect.

The budget row B and the handoff row R are compatible with that same row. A budget comparison may cite only a scheduled prefix entry, and the regular rational handoff may repack only scheduled endpoint or midpoint observations.

Apply Definition 1811.6. The displayed route $I \mapsto B \mapsto S \mapsto R$ makes the schedule row a prerequisite for every RegSeqRat read.

Finally use Definition 1811.7. When two carriers are glued, the common schedule S^* restricts both reads before the shared handoff R^* is formed. Hence H, C, P, N can only transport, replay, source, and name the scheduled route already displayed. □

Theorem 1811.6 (Nested dyadic Cauchy RegSeqRat handoff)**.** *Let $K = (I, B, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of K factors through the finite route*

$$I \longmapsto B \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite nested dyadic interval prefix, a shrinking-width budget, and the scheduled endpoint observations before it exports the regular rational Cauchy row. Any $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *consumer of the same packet must therefore read the route through I, B, S, R before its completion-facing tail modulus, common-tail window, and terminal Real seal rows are available, as in chapter 1639.*

Proof. Start with the displayed interval prefix I. Its rows give the only endpoint data available to a regular rational consumer, and the refinement relation keeps later prefix rows inside earlier rows.

Use the budget row B to answer a displayed Cauchy tolerance request. The selected prefix index and the dyadic width comparison are part of the same finite packet, so no external modulus or choice of tail is needed.

The schedule row S then fixes which interval endpoints or midpoint observations are opened. The handoff row R is obtained by reading those scheduled observations under the budget discipline and repacking them as the regular rational Cauchy surface.

The rows H, C, P, N transport, replay, source, and name that handoff. Since the carrier has no additional tail selector or quotient coordinate, every RegSeqRat read factors through the displayed route.

Apply the Bishop regular Cauchy completion carrier route of chapter 1639. Its $E, S, R, D, W, H, C, P, N$ rows cannot be opened for this packet until the NestedDyadicCauchy handoff has supplied the finite interval prefix I, dyadic width budget B, StreamName schedule S, and RegSeqRat row R. Thus the completion consumer adds no quotient stream equality, selected limit, countable choice, host real equality, or ambient Real completeness beyond the displayed finite handoff. □

Theorem 1811.7 (Nested dyadic Cauchy tail gluing)**.** *Let $K = (I, B, S, R, E, H, C, P, N)$ and $K' = (I', B', S', R', E', H', C', P', N')$ be accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carriers. Suppose their finite interval prefixes and dyadic budgets admit a displayed common refinement through the StreamName schedules: there are rows I^*, B^*, and S^* such that I^* refines the displayed tails of I and I', B^* compares both dyadic tolerance budgets against that common prefix through chapter 291, and S^* restricts both scheduled reads through chapter 126. Then every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read of K and K' factors through one common finite route*

$$I^* \longmapsto B^* \longmapsto S^* \longmapsto R^*$$

before either $\mathsf{Real}^{\uparrow}$ *seal row E or E' is available. Here R^* is the shared regular rational handoff row supplied by the* $\mathsf{RegSeqRat}^{\uparrow}$ *surface of chapter 301, and the terminal seal boundary remains the* $\mathsf{Real}^{\uparrow}$ *boundary of chapter 38.*

Lean4 ✓ `BEDC.Derived.NestedDyadicCauchyUp.NestedDyadicCauchyTasteGate single carrier alignment`

Proof. Project both accepted carriers by Definition 1811.1. The projections expose only the finite interval-prefix rows, shrinking-width budgets, StreamName schedule rows, RegSeqRat handoff rows, Real seal rows, and structural transport, replay, provenance, and naming rows.

Use the assumed displayed common refinement to choose the common prefix row I^*. The nested-prefix rows identify the tail entries of I and I' that are read by the two consumers, and the common prefix refines both of them before any downstream handoff row is opened.

Next use B^* to compare the two tolerance budgets against the same prefix. The comparisons are dyadic endpoint and width comparisons in the sense of chapter 291, so no external tail selector or ambient completeness principle is needed to align the two requests.

The schedule row S^* restricts both reads to the same finite endpoint observations. By the StreamName discipline of chapter 126, those observations are exactly the endpoint or midpoint rows that the two regular rational consumers may inspect.

Apply Definition 1811.6 to each carrier and compare the two handoffs through the shared rows I^*, B^*, S^*. The RegSeqRat interface of chapter 301 repacks those shared finite observations as one row R^*, so both reads factor through $I^* \mapsto B^* \mapsto S^* \mapsto R^*$ before the Real seal boundary of chapter 38 is consumed.

The construction exports no completed intersection point, quotient stream equality, host real equality, countable-choice selector, or ambient completeness. It only glues two compatible finite tails through the common route available before E or E'. □

Theorem 1811.8 (Nested dyadic Cauchy common-tail uniqueness)**.** *Let $K = (I, B, S, R, E, H, C, P, N)$ and $K' = (I', B', S', R', E', H', C', P', N')$ be accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carriers. Suppose the two packets admit a displayed common refinement I^*, B^*, S^* and that the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R^* is the same displayed route for both packets. Then every* $\mathsf{Real}^{\uparrow}$*-facing read of either packet reaches the same terminal seal boundary through*

$$I^* \longmapsto B^* \longmapsto S^* \longmapsto R^*,$$

without quotient stream equality, selected intersection point, host real equality, countable choice, or ambient completeness.

Proof. Apply tail gluing, Definition 1811.7. The displayed common refinement I^*, B^*, S^* forces both accepted packets through one regular-rational route before either Real seal is available.

Use the RegSeqRat handoff theorem Definition 1811.6 for each carrier. Since the handoff row R^* is the same displayed route for both packets, the two reads share the same finite route $I^* \mapsto B^* \mapsto S^* \mapsto R^*$.

Finally apply the Real seal boundary theorem Definition 1811.9. A Real-facing consumer can inspect a terminal seal only after the regular rational handoff has been displayed, so both packets reach the same terminal boundary through the common route.

The carrier inventory supplies the refusals. None of the cited theorems introduces quotient stream equality, a selected intersection point, host real equality, countable choice, or ambient completeness; they only compare the displayed finite tail route. □

Theorem 1811.9 (Nested dyadic Cauchy Real seal boundary)**.** *For every accepted* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *carrier $K = (I, B, S, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the regular rational handoff row R before the seal row E is available. The consumer receives the finite interval prefix, shrinking-width budget, StreamName schedule, RegSeqRat handoff, Real seal, and structural rows, but receives no completed intersection point, quotient stream equality, host real equality, countable-choice selector, or ambient completeness principle.*

Proof. Project the accepted carrier. The only real-facing coordinate is the seal row E, and E is downstream of the prefix, budget, schedule, and handoff rows by Definition 1811.1.

Apply Definition 1811.6. The regular rational handoff has already forced every read through I, B, S, R, H, C, P, N, so a Real-facing consumer cannot bypass the displayed Cauchy route.

The seal row E packages that handoff as the terminal Real boundary. Because the carrier contains no separate coordinate for an intersection point, a quotient stream, host real equality, a choice-selected tail, or ambient completeness, those objects cannot be exported by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedDyadicCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedDyadicCauchy}^{\uparrow}$ packet is generated from finite nested dyadic interval windows, a shrinking-width dyadic budget, a StreamName schedule, a RegSeqRat handoff, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedDyadicCauchy}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1811.1, Definition 1811.2, Definition 1811.3, Definition 1811.4, Definition 1811.5, Definition 1811.6, Definition 1811.7, and Definition 1811.9 close the finite nested dyadic Cauchy obligation surface from interval prefixes to RegSeqRat readback and the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedDyadicCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed intersections, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires Lean-checked carrier admission, nested-prefix exposure, dyadic-width exactness, schedule compatibility, RegSeqRat handoff, and Real seal nonescape for BEDC.Derived.NestedDyadicCauchyUp.

Chapter 1812

A Concrete Naming Certificate for $\mathsf{DyadicIntervalNesting}^{\uparrow}$

Following Bishop and Bridges' constructive real analysis, the $\mathsf{DyadicIntervalNesting}^{\uparrow}$ packet names the finite interval-nesting route that turns dyadic endpoint data into a regular rational real-name boundary. It sits between the endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational handoff of chapter 301, the terminal seal of chapter 38, and the finite nested-chain sibling of chapter 328. The packet records a constructive nesting route for L10 Real and Completion work; it does not assert an infinite intersection point, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1812.1 (DyadicIntervalNesting carrier)**.** *A* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (D, S, R, E, I, H, C, P, N)$$

with five displayed NameCert source rows and four structural rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and width ledger for the displayed dyadic intervals, including lower endpoint, upper endpoint, and dyadic comparison reads.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation schedule naming the interval-prefix windows that may be opened by a consumer.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from scheduled endpoint or midpoint reads after the dyadic width ledger has answered the current tolerance request.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R and the nesting row have been displayed.*
5. *I is the existing* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *sibling row, carrying the finite decreasing-chain witness and adjacent refinement ledger.*
6. *H stores componentwise* hsame *transport for the dyadic endpoint ledger, stream schedule, regular rational handoff, real seal, nested-chain row, continuation row, provenance row, and local naming row.*
7. *C stores the* Cont *replay from a finite interval-prefix request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalNesting}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalNesting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, I, H, C, P, N$. The carrier has no coordinate for completed intersections, quotient real names, host real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalNestingUp.DyadicIntervalNestingTasteGate single carrier alignment`

Theorem 1812.2 (DyadicIntervalNesting NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier $J = (D, S, R, E, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalNesting}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *dyadic endpoint admission through D, requiring every interval endpoint and width comparison to be read from* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
2. *finite observation scheduling through S, requiring every public interval-prefix read to be one of the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows;*
3. *regular rational handoff through R, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row to be formed only after the endpoint ledger and finite schedule have been projected;*
4. *real seal nonescape through E, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through D, S, R and the nested-chain row I;*
5. *sibling nesting compatibility through I, requiring the displayed interval chain to be the finite* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *refinement surface before any regular rational or real-name consumer reads it.*

The structural rows H, C, P, N transport, replay, source, and name these five rows and add no further mathematical coordinate.

Proof. Project the carrier of Definition 1812.1. The five mathematical source rows are precisely D, S, R, E, I, and each is named by a concrete sibling chapter in the L10 Real and Completion path.

The dyadic endpoint row supplies the lower endpoint, upper endpoint, and width comparison data. The stream row restricts all public reads to finite interval-prefix windows, so no hidden tail can be inspected.

The regular rational handoff is downstream of those two rows. It repacks scheduled endpoint or midpoint observations only after the dyadic tolerance ledger has selected the displayed comparison used by the current request.

The nested-chain row I supplies the adjacent refinement ledger already exposed by $\mathsf{NestedDyadicInterval}^{\uparrow}$. The real seal E is reached after this finite route, and the structural rows only preserve the same route under hsame transport and Cont replay. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 1812.3 (DyadicIntervalNesting regular name route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier factors through the concrete route*

$$\mathsf{NestedDyadicInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the consumer reads a finite nested dyadic chain, its dyadic endpoint and width ledger, the scheduled finite windows, the regular rational handoff, and finally the real seal. It does not receive an infinite intersection point, quotient stream equality, host real equality, selected limit, countable-choice selector, or ambient completeness theorem.

Proof. Start with the sibling nesting row I. It supplies a finite decreasing dyadic chain and adjacent refinement rows, so every downstream read begins with displayed interval data rather than with a completed point.

Read D next. The endpoint and width comparisons used by the nesting route are dyadic rational rows, and all tolerance comparisons are made inside that displayed ledger.

The schedule row S then fixes the finite interval windows available to the consumer. The handoff row R repacks exactly those scheduled reads as a regular rational name, and the seal row E exposes the corresponding $\mathsf{Real}^{\uparrow}$ boundary only after the handoff has occurred.

The rows H, C, P, N transport, replay, source, and name this route. They do not add quotient equality, host equality, choice, a selected limit, or completeness, so every regular-name and real-name consumer remains inside the displayed chain. □

Theorem 1812.4 (DyadicIntervalNesting width monotonicity)**.** *Let*

$$J = (D, S, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier. When a later interval-prefix window is read from the same* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *row I, the dyadic width ledger in D is no larger than the earlier displayed width, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R remains downstream of that monotone ledger. The route uses only I, D, S, R, E and introduces no completed intersection, host real equality, selected limit, or ambient completeness principle.*

Proof. Start with the nested-chain row I. It is the only carrier row that names the finite decreasing interval chain and its adjacent refinement relation, so a later interval-prefix window must be a later displayed read of the same sibling row.

Read the dyadic ledger D. Its endpoint and width comparison entries record the earlier and later displayed widths, and the later prefix is admitted only through the refinement data supplied by I.

Apply Definition 1812.3. Every regular-name consumer reads the nested row, then the dyadic endpoint and width ledger, then the scheduled finite windows before reaching the RegSeqRat handoff.

Thus the later width is no larger than the earlier displayed width inside the dyadic ledger, and R remains downstream of that monotone ledger. The seal row E is reached only after this route, so the argument never uses a completed intersection or host real equality. □

Theorem 1812.5 (DyadicIntervalNesting obligation scope)**.** *For an accepted* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier $J = (D, S, R, E, I, H, C, P, N)$, the obligation scope is exactly the* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *row I, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and width ledgers in D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows in S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, the* $\mathsf{Real}^{\uparrow}$ *seal E, the ambient* BHist *packet, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row N. No completed intersection, quotient stream equality, host real equality, selected limit, countable choice, or ambient completeness coordinate lies in the scope.*

Proof. Project the carrier rows $I, D, S, R, E, H, C, P, N$ from Definition 1812.1. The nested interval row, endpoint-width ledger, scheduled windows, regular handoff, and seal are exactly the mathematical source rows, while H, C, P, N preserve and name the same packet inside BHist.

Apply Definition 1812.2. It identifies the local NameCert clauses with dyadic endpoint admission, finite observation scheduling, regular rational handoff, real seal nonescape, and sibling nesting compatibility.

Apply Definition 1812.3 and Definition 1812.4. These keep every regular or Real consumer downstream of I, D, S, R, E and keep width reads inside the dyadic ledger. Since the carrier has no further coordinate, the listed rows exhaust the obligation scope. □

Theorem 1812.6 (DyadicIntervalNesting Real seal handoff)**.** *Every accepted* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier*

$$J = (D, S, R, E, I, H, C, P, N)$$

reaches a $\mathsf{Real}^{\uparrow}$ *boundary only through the dyadic endpoint ledger* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *observations* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name route* R*, the width-monotonicity row carried by* D *and* I*, and the sibling* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *chain packet* I*. Thus the Real seal* E *is a finite nesting-to-real route and not an infinite-intersection selector, quotient stream equality, host real equality, selected limit, countable-choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 1812.3. It sends every regular-name or Real consumer through the sibling nested chain, the dyadic endpoint-width ledger, finite stream windows, and the RegSeqRat handoff before the seal is read.

Next use Definition 1812.4. The later interval windows remain inside the same dyadic ledger and the same sibling chain, so the route to R carries monotone displayed width data rather than a completed intersection point.

Finally apply Definition 1812.5. The scope theorem lists exactly $I, D, S, R, E, H, C, P, N$ and excludes any extra host coordinate. Therefore the Real seal is reached only through the finite nesting route, with no quotient equality, host equality, selected limit, choice principle, or ambient completeness theorem. □

Theorem 1812.7 (DyadicIntervalNesting terminal seal boundary)**.** *For every accepted* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *carrier*

$$J = (D, S, R, E, I, H, C, P, N),$$

each $\mathsf{Real}^{\uparrow}$*-facing consumer must read exactly the finite nesting route* $I, D, S, R, E, H, C, P, N$*. The route begins with the nested-chain row* I*, then the dyadic endpoint and width ledger* D*, the finite observation schedule* S*, the regular rational handoff* R*, and the terminal Real seal* E*, with* H, C, P, N *only transporting, replaying, sourcing, and naming the same packet. It cannot be replaced by a completed intersection, quotient stream equality, selected limit, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 1812.1. The rows I, D, S, R, E are the only mathematical source rows, and H, C, P, N are the only structural rows available to a consumer.

Apply Definition 1812.2. It forces endpoint admission through D, finite observation through S, regular rational handoff through R, Real-seal nonescape through E, and sibling nesting compatibility through I.

Use Definition 1812.3 and Definition 1812.4. These keep the regular-name route downstream of the finite nested-chain row and keep every width comparison inside the dyadic ledger rather than inside a completed intersection.

Finally apply Definition 1812.5 and Definition 1812.6. The scope theorem exhausts the readable rows, and the handoff theorem makes E terminal. Since the excluded intersection, quotient, selected-limit, choice, host-equality, and completeness data have no carrier coordinate, no Real-facing consumer can substitute them for the finite terminal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalNesting}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalNesting}^{\uparrow}$ packet is generated from a finite NestedDyadicInterval row, DyadicRatCore endpoint and width ledgers, StreamName windows, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNesting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1812.1, Definition 1812.2, Definition 1812.3, and Definition 1812.4 seed the finite dyadic interval nesting route from endpoint ledgers and scheduled windows to regular rational readback and the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNesting}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DyadicIntervalNestingUp.DyadicIntervalNestingTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close infinite interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full Lean verification for every obligation row, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint ledger exactness, finite-window scheduling, regular rational handoff, sibling nesting compatibility, and Real seal nonescape for BEDC.Derived.DyadicIntervalNestingUp.

Chapter 1813

A Concrete Naming Certificate for $\mathsf{DyadicExponentShift}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicExponentShift}^{\uparrow}$ packet records the finite exponent-shift normalization route used before dyadic data is handed to regular rational and real-name consumers. It sits between the dyadic core boundary of chapter 291, the precision-scale packet of chapter 1768, the canonical normal-form surface of chapter 1613, the finite-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a BEDC-native finite normalization ledger for shifting dyadic exponents; it is not quotient equality of dyadics, host arithmetic on powers of two, or an appeal to ambient real completeness.

Definition 1813.1 (Dyadic exponent-shift carrier)**.** *A* $\mathsf{DyadicExponentShift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, U, K, S, D, T, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the signed mantissa row, read through the finite integer and rational surfaces already admitted by the dyadic core.*
2. *U is the unary exponent row attached to M, recording the current dyadic denominator scale before any shift is applied.*
3. *K is the shift amount row, recording a finite signed shift request as BEDC data rather than as host exponent arithmetic.*
4. *S is the common-scale row, displaying the single finite scale at which the shifted mantissa and shifted exponent are compared.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row for the mantissa-exponent pair before and after shifting.*
6. *T is the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *handoff row, recording the precision-scale ledger that downstream regular rational and real-name consumers may inspect.*
7. *F is the* $\mathsf{DyadicNormalForm}^{\uparrow}$ *handoff row, recording the canonical finite normal-form surface reached after the common-scale comparison.*
8. *H records componentwise* hsame *transport for the mantissa, exponent, shift amount, common scale, dyadic readback, tolerance-scale handoff, normal-form handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the input dyadic packet through shift inspection, common-scale comparison, dyadic readback, tolerance-scale handoff, normal-form handoff, transport, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicExponentShift}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{DyadicNormalForm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicExponentShift}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, K, S, D, T, F, H, C, P, N$. It has no coordinate for quotient dyadic equality, host powers of two, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

↪variant BEDC.Derived.DyadicExponentShiftUp.DyadicExponentShiftTasteGate single carrier alignment

Theorem 1813.2 (Dyadic exponent-shift NameCert obligations)**.** *For every accepted* $\mathsf{DyadicExponentShift}^{\uparrow}$ *carrier $E = (M, U, K, S, D, T, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicExponentShift}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the signed mantissa, unary exponent, shift amount, common scale, dyadic readback, tolerance-scale handoff, normal-form handoff, transport, replay, provenance, and local naming rows;*

2. *shift-ledger exactness, requiring K to be consumed as the only shift request and requiring S to record the finite common scale before any shifted readback is exported;*

3. *common-scale classifier stability, requiring accepted comparisons to preserve $M, U, K, S, D, T, F, H, C, P, N$ componentwise under* hsame *transport and displayed* Cont *replay;*

4. *normalization handoff, requiring* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *and* $\mathsf{DyadicNormalForm}^{\uparrow}$ *rows to be exposed before* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumers read the shifted dyadic;*

5. *Real-and-Completion nonescape, requiring P and N to export no quotient dyadic equality, host powers of two, selected limits, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or public bridge component.*

No exponent-shift NameCert obligation is stored outside these rows.

Lean4 ✓ BEDC.Derived.DyadicExponentShiftUp.DyadicExponentShiftTasteGate single carrier alignment

Proof. Carrier admission is projection from Definition 1813.1. The finite packet exposes exactly the mantissa row, unary exponent row, shift row, common-scale row, dyadic readback row, two normalization handoff rows, and structural rows H, C, P, N.

Shift-ledger exactness is the role of K and S. Since K is the only row carrying a shift amount and S is the only row carrying the common comparison scale, a shifted readback cannot be named before both rows have been displayed.

Classifier stability is componentwise through H and replayed through C. These rows preserve the route from M, U, K into S, then into the DyadicRatCore readback D, and then into the tolerance-scale and normal-form rows T and F.

The normalization handoff follows from the placement of T and F. A stream, regular rational, or real-name consumer reaches the shifted dyadic only after those two rows have been exposed, so the consumer reads a displayed finite normalization route rather than an implicit exponent manipulation.

The nonescape row is immediate from the carrier inventory. Quotient dyadic equality, host powers of two, selected limits, trichotomy, countable choice, ambient real completeness, and bridge

components are absent from the tuple and are not produced by transport, replay, provenance, or local naming. □

Theorem 1813.3 (Dyadic exponent-shift normalization handoff)**.** *Let* $E = (M, U, K, S, D, T, F, H, C, P, N)$ *be an accepted* $\mathsf{DyadicExponentShift}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an exponent-shifted dyadic read factors through the finite route*

$$M, U, K \longmapsto S \longmapsto D \longmapsto T, F \longmapsto H, C, P, N$$

over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{DyadicNormalForm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. Consequently the shifted dyadic is exported only as a normalized finite packet, not through quotient dyadic equality, host exponent arithmetic, selected limits, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a regular rational or real-name consumer of the shifted dyadic. By Definition 1813.1, the consumer can reach dyadic readback only at the row D.

The readback row D is downstream of the visible route M, U, K, S. Thus the mantissa, unary exponent, requested shift, and common-scale comparison must all be displayed before the shifted dyadic is available.

The rows T and F then route the same readback through the tolerance-scale and normal-form surfaces. These rows are the only downstream normalization interface presented to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers.

Finally, H, C, P, N transport, replay, package, and name that same route. Since no excluded coordinate appears in the packet, the consumer receives only the displayed finite normalization route over the listed BEDC rows. □

Theorem 1813.4 (Dyadic exponent-shift canonical window)**.** *Let* $E = (M, U, K, S, D, T, F, H, C, P, N)$ *be an accepted* $\mathsf{DyadicExponentShift}^{\uparrow}$ *packet. The packet exposes the same canonical finite observation window through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{DyadicNormalForm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*: exponent shifting changes only the displayed normalization ledger* K, S, D, T, F*, not the downstream* $\mathsf{Real}^{\uparrow}$ *seal route through* H, C, P, N*.*

Proof. Project the carrier rows from Definition 1813.1. The rows M, U, K, S, D, T, F display the mantissa, unary exponent, shift request, common-scale comparison, dyadic readback, tolerance-scale handoff, and normal-form handoff before any downstream consumer reads the packet.

Apply the normalization handoff of Definition 1813.3. It forces every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read through the same finite route from M, U, K into S, D, T, F and then into the structural rows.

Finally read the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows componentwise through H and replay them through C. The exponent shift therefore changes the displayed normalization ledger only; the downstream real-name seal remains the same transported and replayed finite window. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicExponentShift}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicExponentShift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1813.1, Definition 1813.2, and Definition 1813.3 seed the finite exponent-shift route from mantissa and unary exponent data through common-scale comparison, DyadicRatCore readback, tolerance-scale handoff, and normal-form handoff into regular rational and real-name consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicExponentShift}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient dyadic equality, host powers of two, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, shift-ledger exactness, common-scale classifier stability, normalization handoff, and Real-and-Completion nonescape for BEDC.Derived.DyadicExponentShiftUp.

Constructive story: A DyadicExponentShift$^{\uparrow}$ packet is generated from a signed mantissa row, unary exponent row, shift amount row, common-scale row, DyadicRatCore readback, DyadicToleranceScale and DyadicNormalForm handoff rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1814

A Concrete Naming Certificate for $\mathsf{CauchyRateDominance}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRateDominance}^{\uparrow}$ packet records the finite certificate by which one displayed Cauchy-modulus schedule is dominated by another before a Real-facing or completion-facing read consumes the resulting seal. It sits over the explicit modulus surface of chapter 292, the Real-facing modulus boundary of chapter 1423, the finite-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the domination-test consumer of chapter 1459. The packet gives later Real and Completion consumers a reusable finite domination row instead of requiring each consumer to repeat the modulus comparison inside its own carrier.

Definition 1814.1 (Cauchy rate dominance carrier)**.** *A* $\mathsf{CauchyRateDominance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule. It records the precision requests, source thresholds, and monotone reuse rows whose domination is being certified.*
2. *D is the displayed dominating modulus row. It records the target thresholds, comparison witnesses, and finite ledger entries showing that each accepted source request is bounded by the dominating schedule on the same displayed precision surface.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened by the dominated schedule and inspected only at requests listed in M and D.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from those windows, thresholds, and dyadic tolerance entries.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after M, D, S, Q have all been displayed.*
6. *H records componentwise* hsame *transport for the source modulus schedule, dominating row, finite windows, regular readback, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through M, D, S, Q, E and then through the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyRateDominance}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRateDominance}^{\uparrow}}$ *row.*

The classifier accepts only packets whose reads pass through these nine rows. It has no coordinate for quotient stream equality, a selected limit, host real comparison, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRateDominanceUp.CauchyRateDominanceTasteGate single carrier alignment`

Theorem 1814.2 (Cauchy rate dominance NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateDominance}^{\uparrow}$ *carrier*

$$R = (M, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRateDominance}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, dominating modulus row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*

2. *dominance ledger exactness, requiring each accepted precision request to read the source threshold in M and the displayed dominating threshold in D before a window or readback can be consumed;*

3. *componentwise transport, requiring H to preserve the source schedule, dominating row, selected windows, regular readback, terminal seal, replay, provenance, and naming rows together;*

4. *selected-window stability, requiring every window opened by S to be one of the windows licensed by the displayed domination ledger D for the source schedule M;*

5. *non-escape, requiring E, P, N to export no quotient stream equality, selected limit, host real comparison, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No dominance obligation is stored outside these rows.

Proof. Project the carrier of Definition 1814.1. The projection exposes exactly one source modulus schedule, one displayed dominating row, one finite window family, one regular rational readback, one terminal seal, and the structural transport, replay, provenance, and naming rows.

Dominance ledger exactness is forced before any analytic read occurs. A precision request first cites its source threshold in M, then reads the dominating threshold and comparison evidence in D. Only after both rows are displayed may the request open a StreamName window.

Selected-window stability follows from the order of the route. The window row S is downstream of M and D, so any window consumed by Q is a window licensed by the domination ledger for the same precision request.

Finally H, C, P, N only transport, replay, source, and name the displayed route, while E is the unique terminal seal row. Since the carrier has no additional analytic coordinate, the local NameCert surface cannot export quotient stream equality, selected limits, host comparison, choice, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Theorem 1814.3 (Cauchy rate dominance Real seal handoff)**.** *Every Real-facing read through the dominated modulus in an accepted* $\mathsf{CauchyRateDominance}^{\uparrow}$ *carrier factors through the same finite route*

$\mathsf{CauchyModulus}^{\uparrow}$, D, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

Equivalently, the read first consumes the source schedule M, the dominating row D, the selected window row S, and the regular readback Q, and only then reaches the terminal seal E and the structural rows H, C, P, N.

Proof. Begin with a Real-facing read admitted by the carrier. By Definition 1814.2, the read has no direct route to E; it must first read the source schedule M and the displayed domination ledger D.

The finite window and readback rows are then fixed. The row S supplies exactly the StreamName windows licensed by D, while the dyadic tolerance entries named in D determine the regular rational readback Q.

The terminal seal is downstream of that readback. Thus E is reached only through the route M, D, S, Q, and the remaining rows H, C, P, N transport, replay, source, and name the same displayed packet. This gives the stated factorization through the CauchyModulus, dominating row, StreamName, DyadicRatCore, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert surfaces. □

Falsifiable prediction: An accepted $\mathsf{CauchyRateDominance}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first reading the source $\mathsf{CauchyModulus}^{\uparrow}$ schedule, the displayed dominating row, the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: cauchymodulus, realcauchymodulus, streamname, dyadicratcore, regseqrat, regular-cauchy-comparison-test, real: no listed sibling supplies the whole nine-row packet $R = (M, D, S, Q, E, H, C, P, N)$, because each sibling contributes only schedule, window, tolerance, readback, comparison-test, or seal data while this chapter binds explicit domination, transport, replay, provenance, and local naming into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRateDominance}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRateDominance}^{\uparrow}$ packet is generated from a source CauchyModulus schedule, a displayed dominating modulus row, finite StreamName windows, DyadicRatCore tolerance entries, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRateDominance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1814.1, Definition 1814.2, and Definition 1814.3 seed the finite domination surface for explicit Cauchy-modulus schedules through the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRateDominance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real comparison, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dominance ledger exactness, componentwise transport, selected-window stability, non-escape, and Real seal handoff for BEDC.Derived.CauchyRateDominanceUp.

Chapter 1815

A Concrete Naming Certificate for $\mathsf{UniformHomeomorphism}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{UniformHomeomorphism}^{\uparrow}$ packet presents a uniform homeomorphism as a bidirectional uniform-continuity certificate between two $\mathsf{UniformSpace}^{\uparrow}$ rows. It is grounded by the uniform-space surface of chapter 339, the modulus discipline of chapter 391, the graph and pointwise route of chapter 130, the embedding boundary of chapter 1651, and the completion consumer surface of chapter 1473. The chapter records the L10 equivalence route used by completion comparisons without exposing quotient completion equality, selected representatives, host equality, countable choice, or ambient completeness.

Definition 1815.1 (UniformHomeomorphism carrier)**.** *A* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, f, g, F, G, M, N, H, C, P, L)$$

with the following displayed rows:

1. *X and Y are the source and target* $\mathsf{UniformSpace}^{\uparrow}$ *rows, including only the entourage requests and refinement ledgers visible to the certificate.*
2. *f and g are the forward and inverse graph rows, read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface and carrying no host function object beyond the displayed graph data.*
3. *F and G are the forward and inverse uniform-continuity rows, each exposing the source tolerance request, the target tolerance request, and the corresponding finite modulus route.*
4. *M and N are the forward and inverse modulus rows, respectively, so that each direction has its own displayed tolerance transformer before any completion consumer may read the route.*
5. *H records inverse-route compatibility: the composites $g \circ f$ and $f \circ g$ are accepted only through displayed graph rows, displayed uniform-continuity rows, and componentwise* hsame *transport.*
6. *C records* Cont *replay from a source or target entourage request through the appropriate graph row, the matching modulus row, inverse-route compatibility, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, f, g, F, G, M, N, H, C, P, L$. The carrier contains no quotient completion equality, selected representative, host equality of points or maps, countable-choice selector, ambient completeness datum, or hidden completion object.

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismCarrier field projection round trip`

Theorem 1815.2 (UniformHomeomorphism NameCert obligations)**.** *For every accepted* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *carrier $U = (X, Y, f, g, F, G, M, N, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source and target* $\mathsf{UniformSpace}^{\uparrow}$ *rows, forward and inverse graph rows, forward and inverse uniform-continuity rows, both modulus rows, inverse-route compatibility, replay, provenance, and local naming;*
2. *classifier bidirectionality, requiring rowwise comparison to preserve both directions at once rather than accepting a one-sided uniform-continuity certificate;*
3. *stability of both moduli, requiring M and N to transport with their matching graph and uniform-continuity rows under componentwise* hsame*;*
4. *inverse-route exactness, requiring the two composites to be read only through H after f, g, F, G, M, N have fixed the displayed bidirectional route;*
5. *ledger non-escape, requiring C, P, L to replay, source, and name no row from which quotient completion equality, selected representatives, host equality, countable choice, ambient completeness, or a hidden completion object can be exported.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1815.1. The packet displays the two uniform-space rows, the two graph rows, the two uniform-continuity rows, both modulus rows, inverse-route compatibility, replay, provenance, and local naming.

Classifier bidirectionality follows because the classifier reads the whole tuple $X, Y, f, g, F, G, M, N, H, C, P, L$. A packet cannot be accepted by comparing only f, F, M or only g, G, N; both directions are part of the same displayed row comparison.

Stability of both moduli is the componentwise transport clause. The forward modulus row M travels with f and F, while the inverse modulus row N travels with g and G, and both transports are recorded in H and replayed through C.

Inverse-route exactness is forced after the two directed routes have been fixed. The row H is the only displayed location where the composites $g \circ f$ and $f \circ g$ are named, so a consumer cannot introduce a separate host inverse or quotient-completion equality witness.

Finally, ledger non-escape is exhausted by C, P, L. These rows replay, source, and name only the displayed route, and none of them contains selected representatives, host equality, countable choice, ambient completeness, or a hidden completion object. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismNameCertObligations`

Theorem 1815.3 (UniformHomeomorphism bidirectional modulus route)**.** *Every accepted* $\mathsf{UniformHomeomorphism}$ *consumer route factors through both displayed moduli M and N along the finite route*

$$X, Y \longmapsto f, g \longmapsto F, G \longmapsto M, N \longmapsto H \longmapsto C, P, L.$$

Consequently the packet cannot read quotient completion equality, selected representatives, host equality, countable choice, or ambient completeness.

Proof. Start with a consumer route for an accepted packet and project the carrier rows. The source and target uniformities are visible only as X and Y, and the directed graphs are visible only as f and g.

The route must then read the two uniform-continuity rows F and G. The forward read exposes the modulus row M, and the inverse read exposes the modulus row N; omitting either one would leave only a one-sided continuity route rather than a uniform homeomorphism packet.

After both moduli have been read, the inverse-route row H records the displayed composites. This is the only route by which the consumer sees bidirectionality, so quotient completion equality, selected representatives, and host equality are not available as alternate witnesses.

The structural rows C, P, L close the consumer route by replay, provenance, and local naming. Since these rows name only $X, Y, f, g, F, G, M, N, H$, the packet exports no countable-choice selector, ambient completeness datum, or hidden completion object. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismBidirectionalModulusRoute`

Theorem 1815.4 (UniformHomeomorphism classifier bidirectionality)**.** *For every accepted* UniformHomeomorphism *carrier* $U = (X, Y, f, g, F, G, M, N, H, C, P, L)$*, rowwise classifier agreement preserves the forward graph row* f*, inverse graph row* g*, forward uniform-continuity row* F*, inverse uniform-continuity row* G*, forward modulus row* M*, and inverse modulus row* N *simultaneously. In particular, an agreement that preserves only* f, F, M *or only* g, G, N *is not a* UniformHomeomorphism$^{\uparrow}$ *classifier agreement.*

Proof. Project the classifier surface from Definition 1815.1. The accepted packet is compared through the full tuple $X, Y, f, g, F, G, M, N, H, C, P, L$, and Definition 1815.2 lists classifier bidirectionality as a local obligation.

The displayed route of Definition 1815.3 then forces both directed graph/modulus chains to remain visible before the inverse-route row H and the structural rows C, P, L can be read. A one-sided comparison omits one of the directed chains and therefore fails to compare the accepted carrier rows. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismClassifierBidirectionality`

Theorem 1815.5 (UniformHomeomorphism inverse-route exactness)**.** *For every accepted* UniformHomeomorphism *carrier* $U = (X, Y, f, g, F, G, M, N, H, C, P, L)$*, the composites* $g \circ f$ *and* $f \circ g$ *are readable only through the displayed graph rows* f, g*, both uniform-continuity rows* F, G*, both modulus rows* M, N*, and the inverse-route row* H*. No consumer may replace this route by a host inverse, quotient completion equality, selected representative, or ambient equality of maps.*

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismCarrier inverse route exactness`

Proof. Use the carrier definition to isolate the only rows that mention the directed maps and their inverse route. The graph rows are f, g, the uniform-continuity rows are F, G, the modulus rows are M, N, and the composite-read row is H.

The NameCert obligations of Definition 1815.2 require inverse-route exactness after both directed routes have been fixed. The bidirectional modulus route of Definition 1815.3 gives the order

$$X, Y \longmapsto f, g \longmapsto F, G \longmapsto M, N \longmapsto H.$$

Since the carrier has no additional coordinate for a host inverse, quotient completion equality, selected representative, or ambient equality of maps, the two composites can be read only through that displayed route. □

Theorem 1815.6 (UniformHomeomorphism completion consumer boundary)**.** *Any* UniformCompletion$^{\uparrow}$ *consumer reading an accepted* UniformHomeomorphism$^{\uparrow}$ *packet may use it only as the bidirectional modulus route through* $X, Y, f, g, F, G, M, N, H, C, P, L$*. The consumer may not read quotient completion equality, selected completion representatives, host equality, countable choice, or ambient completeness from the packet.*

Proof. Start with the completion-facing provenance row P in Definition 1815.1. It names UniformCompletion$^{\uparrow}$ only as a downstream consumer of the displayed uniform-space, graph, uniform-continuity, modulus, inverse-route, replay, provenance, and local naming rows.

Apply the NameCert obligation surface and the bidirectional modulus route. They expose exactly the two directed moduli and the inverse-route row before any completion-facing read is available.

Finally use the carrier exclusions. Because no row stores quotient completion equality, selected representatives, host equality, countable choice, ambient completeness, or a hidden completion object, a UniformCompletion$^{\uparrow}$ consumer can import only the finite bidirectional modulus route. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismCompletionConsumerBoundary`

Theorem 1815.7 (UniformHomeomorphism bidirectional modulus nonescape)**.** *Every accepted* UniformHomeomorphism$^{\uparrow}$ *carrier read that exposes either directed modulus row must expose the same displayed route through* UniformSpace$^{\uparrow}$*,* UniformContinuity$^{\uparrow}$*,* ContinuousMap$^{\uparrow}$*,* DenseUniformEmbedding$^{\uparrow}$*,* UniformCompletion$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The read may use the forward modulus* M *only together with* X, Y, f, F *and the inverse modulus* N *only together with* Y, X, g, G*, and both routes must pass through* H, C, P, L *before any completion-facing consumer can inspect them. No selected inverse, quotient completion equality, host function equality, countable-choice selector, or ambient completeness datum is exported by either direction.*

Proof. Project the carrier of Definition 1815.1. The forward route displays X, Y, f, F, M, and the inverse route displays Y, X, g, G, N; neither modulus is a free-standing row.

Apply the bidirectional modulus route of Definition 1815.3. It forces both directed chains to pass through the inverse-route compatibility row H and then through the structural rows C, P, L.

The completion consumer boundary of Definition 1815.6 is reached only after those rows have been displayed. Since the carrier has no coordinate for a selected inverse, quotient completion equality, host function equality, countable-choice selector, or ambient completeness datum, no such datum can escape from either modulus route. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismBidirectionalModulusNonescape`

Theorem 1815.8 (UniformHomeomorphism completion classifier stability)**.** *Completion-facing classifier comparisons for accepted* UniformHomeomorphism$^{\uparrow}$ *carriers are stable only along the displayed forward and inverse modulus rows. If two carriers are compared by a* UniformCompletion$^{\uparrow}$ *consumer, then the comparison must preserve* X, Y, f, F, M *and* Y, X, g, G, N *before it reads* H, C, P, L*; a comparison that identifies completion endpoints while dropping one directed modulus is not a* UniformHomeomorphism$^{\uparrow}$ *classifier comparison.*

Proof. Start with a completion-facing comparison. By Definition 1815.6, the consumer sees the packet only as the finite route $X, Y, f, g, F, G, M, N, H, C, P, L$.

Use classifier bidirectionality from Definition 1815.4. It requires the forward graph, inverse graph, both uniform-continuity rows, and both modulus rows to be preserved simultaneously.

It remains to exclude completion-only identifications. The carrier contains no quotient completion equality or host function equality row, and Definition 1815.7 keeps both directed modulus routes visible before H, C, P, L are consumed. Therefore completion-facing stability is exactly stability along the displayed forward and inverse modulus rows. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismCompletionClassifierStability`

Theorem 1815.9 (UniformHomeomorphism scoped L10 route)**.** *Every L10 completion-facing read of an accepted* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *packet factors through* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before any completion consumer inspects it. The route may expose the displayed bidirectional modulus and inverse-route compatibility rows, but it never exposes quotient completion equality, selected representatives, countable choice, host map equality, or ambient completeness.*

Proof. Start with the carrier of Definition 1815.1. Its source and target uniformities, directed graph rows, directed uniform-continuity rows, modulus rows, inverse-route compatibility, replay, provenance, and local naming are the only rows available to a completion-facing read.

Apply the bidirectional modulus route of Definition 1815.3. It forces a consumer to read both directed moduli before the inverse-route row can be inspected.

Use inverse-route exactness from Definition 1815.5. The composites are readable only through the displayed graph, continuity, modulus, and compatibility rows, so no host inverse or quotient-completion equality can be substituted.

Finally apply the completion consumer boundary and completion classifier stability of Definition 1815.6 and Definition 1815.8. They place every L10 completion-facing comparison downstream of the same finite route through $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, while selected representatives, countable choice, host map equality, and ambient completeness remain outside the packet. □

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismScopedRoute`

Theorem 1815.10 (UniformHomeomorphism public NameCert export)**.** *The carrier, NameCert obligations, bidirectional modulus route, classifier bidirectionality, inverse-route exactness, completion consumer boundary, bidirectional modulus nonescape, completion classifier stability, and scoped L10 route assemble the public* $\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}$ *surface over* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. The exported surface preserves the exclusions of quotient completion equality, selected representatives, countable choice, host map equality, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.UniformHomeomorphismUp.UniformHomeomorphismPublicExport`

Proof. Start from the carrier of Definition 1815.1 and its obligation list in Definition 1815.2. These two sites supply the displayed source and target uniform spaces, forward and inverse graph rows, forward and inverse uniform-continuity rows, both modulus rows, inverse-route compatibility, replay, provenance, and local naming.

The directed modulus chain is fixed by Definition 1815.3. Classifier bidirectionality from Definition 1815.4 then keeps the forward and inverse graph, continuity, and modulus rows visible together, while inverse-route exactness from Definition 1815.5 prevents a host inverse or ambient map equality from replacing the displayed compatibility row.

The completion-facing boundary is supplied by Definition 1815.6, refined by the nonescape clause of Definition 1815.7, and stabilized by Definition 1815.8. The scoped L10 route of Definition 1815.9 repacks those rows as the public completion-facing surface.

Because each cited site keeps quotient completion equality, selected representatives, countable choice, host map equality, and ambient completeness outside the displayed carrier rows, their composite public export keeps the same exclusions. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformHomeomorphism}^{\uparrow}$ packet is generated from two UniformSpace rows, forward and inverse graph rows, forward and inverse UniformContinuity rows, two displayed modulus rows, inverse-route compatibility, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1815.1, Definition 1815.2, Definition 1815.3, Definition 1815.4, Definition 1815.5, Definition 1815.6, Definition 1815.7, Definition 1815.8, and Definition 1815.9 close the carrier, NameCert obligations, bidirectional modulus route, completion consumer boundary, completion classifier stability, and scoped L10 route for finite completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformHomeomorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public-object surface and Lean verification for the bidirectional modulus, classifier stability, inverse-route exactness, and ledger non-escape rows of BEDC.Derived.UniformHomeomorphismUp.

Chapter 1816

A Concrete Naming Certificate for $\mathsf{RealExponential}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealExponential}^{\uparrow}$ packet records the exponential function by the displayed power series with coefficients $1/n!$ and by uniform Cauchy control on bounded real windows. It is a finite NameCert route through the $\mathsf{RealPowerSeries}^{\uparrow}$ carrier of chapter 1583, the shared tail discipline of $\mathsf{UniformCauchySeries}^{\uparrow}$ in chapter 1736, the series-product handoff of $\mathsf{CauchyProduct}^{\uparrow}$ in chapter 464, the arithmetic seal of $\mathsf{CauchyRealField}^{\uparrow}$ in chapter 1717, the classifier boundary of $\mathsf{RealEquality}^{\uparrow}$ in chapter 1636, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names exponential as a uniformly Cauchy real power-series packet; it does not import host exp, host transcendental-function laws, analytic continuation, quotient real equality, selected infinite sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1816.1 (RealExponential carrier)**.** *A* $\mathsf{RealExponential}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, F, B, U, M, K, P, S, R, Q, T, C, L, N)$$

with the following displayed rows:

1. *A is the coefficient ledger fixing the exponential power series by the finite readback of the coefficient rule $a_n = 1/n!$.*
2. *F is the factorial and reciprocal dyadic budget row, recording the inspected natural-number factorial windows, reciprocal dyadic enclosures, and denominator-growth bounds used by the coefficient ledger.*
3. *B is the bounded real-window row on which the packet accepts a request for evaluation.*
4. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *modulus row showing that the displayed coefficient windows and powers form a uniformly Cauchy series on B.*
5. *M is the majorant and tail-budget row used to discharge the uniform convergence request without selecting a host infinite sum.*
6. *K is the* $\mathsf{CauchyProduct}^{\uparrow}$ *law-route row that records the Cauchy-product passage used for the addition law handoff.*
7. *P is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *evaluation row, exposing the coefficient ledger, argument window, partial sums, and endpoint seal only as power-series data.*

8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal reached after the coefficient ledger, dyadic budget, uniform Cauchy modulus, product-law route, and power-series evaluation rows have all been displayed.*
9. *R is the* $\mathsf{RealEquality}^{\uparrow}$ *classifier row used to compare accepted exponential readbacks through the displayed real-equality boundary.*
10. *Q is the* $\mathsf{CauchyRealField}^{\uparrow}$ *arithmetic row used for finite addition, multiplication, and reciprocal-budget accounting inside the route.*
11. *T stores componentwise* hsame *transport for the coefficient ledger, factorial budget, bounded window, uniform modulus, majorant, product-law route, power-series row, real seal, equality classifier, arithmetic row, continuation, provenance, and local naming rows.*
12. *C stores displayed* Cont *replay from coefficient and factorial reads to partial sums, from partial sums to uniform Cauchy control, from the uniform route to the* $\mathsf{RealPowerSeries}^{\uparrow}$ *endpoint, from Cauchy product rows to the addition-law handoff, and from the endpoint to the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealEquality}^{\uparrow}$ *consumers.*
13. *L is the* Pkg *provenance over* $\mathsf{RealExponential}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{CauchyRealField}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{RealExponential}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, F, B, U, M, K, P, S, R, Q, T, C, L, N$. It has no coordinate for a host transcendental function, analytic continuation, quotient real equality, selected infinite sum, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1816.2 (RealExponential NameCert obligations)**.** *For every accepted* $\mathsf{RealExponential}^{\uparrow}$ *carrier $E = (A, F, B, U, M, K, P, S, R, Q, T, C, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealExponential}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier exposure for the displayed coefficient ledger, factorial and reciprocal budget, bounded real window, uniform Cauchy modulus, majorant, Cauchy-product law route, power-series evaluation row, real seal, real-equality classifier, arithmetic row, transport, continuation, provenance, and local naming rows;*
2. *classifier exposure through R, requiring every accepted comparison to preserve the displayed* $\mathsf{RealEquality}^{\uparrow}$ *route and no hidden host equality;*
3. *uniform Cauchy convergence through U and M, requiring every endpoint-facing read to use the displayed tail modulus and majorant budget before the endpoint seal is read;*
4. *product and addition law handoff through K and Q, requiring the exponential addition law to be read only through the* $\mathsf{CauchyProduct}^{\uparrow}$ *and* $\mathsf{CauchyRealField}^{\uparrow}$ *rows;*
5. *non-escape through T, C, L, N, requiring transport, replay, provenance, and local naming to preserve the same finite route and to export no host* $\exp$*, analytic-continuation datum, quotient real equality, selected infinite sum, countable-choice selector, or ambient completeness witness.*

Proof. Carrier exposure is projection from Definition 1816.1. The accepted packet displays exactly the rows $A, F, B, U, M, K, P, S, R, Q, T, C, L, N$, so there is no detached coordinate from which a consumer could read a host exponential function.

The classifier exposure is the row R. Since R is declared as the $\mathsf{RealEquality}^{\uparrow}$ boundary and the transport row T is componentwise, accepted comparisons can preserve only the displayed real-equality route attached to the packet.

Uniform convergence is read through U and M. The coefficient ledger and factorial budget first produce finite partial-sum data; the shared tail modulus and majorant budget then place those partial sums inside the $\mathsf{UniformCauchySeries}^{\uparrow}$ route before P or S can be consumed.

The product and addition handoff is read through K and Q. The Cauchy-product row supplies the series-product route, while the Cauchy-real-field row supplies the finite arithmetic surface that the addition law may inspect.

Finally, T, C, L, N transport, replay, source, and name the same displayed rows. Because all endpoint, equality, and arithmetic reads are already forced through the listed rows, none of the excluded host or quotient principles is exported by the local $\mathsf{NameCert}_{\mathsf{RealExponential}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.RealExponentialUp.RealExponentialTasteGate single carrier alignment`

Theorem 1816.3 (RealExponential series route)**.** *Every public read of an accepted* $\mathsf{RealExponential}^{\uparrow}$ *packet factors through*

$$\mathsf{RealPowerSeries}^{\uparrow},\quad \mathsf{UniformCauchySeries}^{\uparrow},\quad \mathsf{CauchyProduct}^{\uparrow},\quad \mathsf{CauchyRealField}^{\uparrow},\quad \mathsf{RealEquality}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

before any exponential value is consumed. Consequently the public route names the exponential series by finite coefficient, modulus, product, arithmetic, equality, and real-seal data, not by a host transcendental primitive.

Proof. Start with a public exponential read. The coefficient ledger A and factorial budget F identify the displayed $1/n!$ coefficients, while the bounded window B fixes the finite evaluation scope.

The read then enters the real power-series route through P. The power-series packet exposes the coefficient stream, selected powers, partial sums, and endpoint request without selecting a host infinite sum.

Uniform convergence is supplied next by U and M. These rows force the partial sums to pass through $\mathsf{UniformCauchySeries}^{\uparrow}$ and its displayed tail budget before any endpoint-facing real seal is available.

For law-facing reads, K and Q provide the only product and addition handoff. The Cauchy-product route supplies the multiplication of series windows, and the Cauchy-real-field route supplies the finite real-arithmetic operations that compare the result.

The final public comparison reads R and S. Thus equality is mediated by $\mathsf{RealEquality}^{\uparrow}$, and value consumption is mediated by the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows T, C, L, N preserve this route as transport, replay, provenance, and local naming, so no host transcendental function or ambient completeness principle can be read. □

Falsifiable prediction: Every $\mathsf{RealExponential}^{\uparrow}$ public read factors through a coefficient ledger for $1/n!$, factorial and reciprocal dyadic budgets, a bounded real-window row, a uniform Cauchy-series modulus, a majorant tail budget, a Cauchy-product law route, a Cauchy-real-field arithmetic row, a RealPowerSeries evaluation row, a RealEquality classifier row, a RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: realpowerseries, uniform-cauchy-series, cauchyproduct, cauchy-real-field, real-equality, real: $\mathsf{RealExponential}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the fixed exponential coefficient ledger, factorial reciprocal budget, bounded-window uniform convergence route, Cauchy-product addition-law handoff, arithmetic seal, equality classifier, endpoint real seal, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealExponential}^{\uparrow}}$.

Constructive story: A RealExponential$^{\uparrow}$ packet is generated from the coefficient ledger $a_n = 1/n!$, factorial and reciprocal dyadic budgets, a bounded real-window row, a uniform Cauchy-series modulus, a majorant tail budget, a Cauchy-product law route, Cauchy-real-field arithmetic rows, a RealPowerSeries evaluation row, a RealEquality classifier row, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealExponential}^{\uparrow}}$, seed)

Scope closed: Definition 1816.1, Definition 1816.2, and Definition 1816.3 seed the finite exponential power-series route through existing BEDC real-series and Cauchy-series infrastructure.

Formal verification: FormalStatus(NameCert$_{\text{RealExponential}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.RealExponentialUp`

Bridge status: none

Not claimed: This chapter does not close host transcendental functions, analytic continuation, quotient real equality, selected infinite sums, countable choice, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, uniform Cauchy convergence, product and addition law handoff, nonescape, and TasteGate field faithfulness for BEDC.Derived.RealExponentialUp.

Chapter 1817

A Concrete Naming Certificate for $\mathsf{ExpLogBisection}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ExpLogBisection}^{\uparrow}$ packet records the finite bisection route that makes logarithm a constructive inverse read for exponential on positive real data. It consumes the exponential packet of chapter 1816, the logarithm packet of chapter 2315, the dyadic bracket ledger of chapter 291, the finite window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the inverse route by finite brackets and comparison rows, not by a host exponential, host logarithm, quotient real equality, selected infinite bisection branch, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1817.1 (ExpLogBisection carrier)**.** *An* $\mathsf{ExpLogBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, I, B, E, L, W, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the positive* $\mathsf{Real}^{\uparrow}$ *input row whose logarithm is being named.*
2. *I is the finite dyadic initial bracket row for the inverse search.*
3. *B is the retained bisection ledger, recording midpoint comparisons and selected subintervals.*
4. *E is the* $\mathsf{RealExponential}^{\uparrow}$ *comparison row used to evaluate the displayed midpoint endpoints.*
5. *L is the* $\mathsf{RealLogarithm}^{\uparrow}$ *endpoint row read only after the bisection ledger and exponential comparisons are displayed.*
6. *W records the* $\mathsf{StreamName}^{\uparrow}$ *finite windows for the retained dyadic endpoints.*
7. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *width, midpoint, and comparison tolerances used by the bisection ledger.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the dyadic endpoint windows.*
9. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row for the inverse endpoint and its exponential comparison with X.*
10. *H records componentwise* hsame *transport for all displayed inverse-route rows.*
11. *C records displayed* Cont *replay from positive input and brackets through exponential comparison, regular readback, logarithm row, and real seal.*

12. *P is the* Pkg *provenance over* $\mathsf{ExpLogBisection}^{\uparrow}$, $\mathsf{RealExponential}^{\uparrow}$, $\mathsf{RealLogarithm}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ExpLogBisection}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, I, B, E, L, W, D, R, Q, H, C, P, N$. It has no coordinate for host analytic functions, quotient real equality, selected infinite branches, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ExpLogBisectionUp`

Theorem 1817.2 (ExpLogBisection NameCert obligations)**.** *For every accepted* $\mathsf{ExpLogBisection}^{\uparrow}$ *carrier $G = (X, I, B, E, L, W, D, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ExpLogBisection}^{\uparrow}}$ *surface consists exactly of positive input exposure, finite initial bracket exposure, retained bisection rows,* $\mathsf{RealExponential}^{\uparrow}$ *comparison rows,* $\mathsf{RealLogarithm}^{\uparrow}$ *endpoint routing,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the accepted carrier. The positive input and bracket data are exactly X, I, B, so the inverse search begins with a displayed finite bracket ledger.

The comparison and window rows are E, W, D, R. Exponential comparisons are evaluated through E, while the dyadic widths, midpoint tolerances, finite windows, and regular readback are exposed through D, W, R.

The endpoint and seal rows are L, Q. They identify the logarithm endpoint and the real equality-facing seal only after the bisection comparison rows have been displayed.

Finally H, C, P, N preserve the same rows under transport, replay, provenance, and naming. Since the carrier has no host analytic-function or selected-branch coordinate, the listed rows exhaust the local certificate. □

Theorem 1817.3 (ExpLogBisection inverse handoff)**.** *Every public inverse read of an accepted* $\mathsf{ExpLogBisection}^{\uparrow}$ *carrier factors through the finite route*

$$X \longmapsto I, B \longmapsto E, D, W \longmapsto R \longmapsto L \longmapsto Q.$$

Thus the consumer of $\exp(\log(X)) \sim_{\mathsf{Real}^{\uparrow}} X$ *receives a positive real input, dyadic brackets, exponential comparison rows, StreamName windows, RegSeqRat readback, logarithm endpoint row, and Real seal before any inverse conclusion is inspected.*

Proof. Start with the carrier projection. The inverse route has no access to a completed host logarithm; it first displays the positive input X and the finite bracket rows I, B.

The retained bracket is justified through E, D, W, R. These rows provide the exponential comparisons, dyadic width budgets, finite endpoint windows, and regular rational readback that make the bisection endpoint visible.

The logarithm and real-seal handoff is then L, Q. The endpoint row records the logarithm packet, and the real seal records the equality-facing inverse comparison with the original input.

The structural rows transport and replay exactly that route. No quotient equality, selected infinite branch, countable-choice schedule, or ambient completeness theorem is exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ExpLogBisection}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ExpLogBisection}^{\uparrow}$ packet is generated from a positive RealUp input, dyadic initial and retained bracket rows, RealExponential comparison rows, a RealLogarithm endpoint row, StreamName windows, DyadicRatCore

tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ExpLogBisection}\uparrow}$, seed)

Scope closed: Definition 1817.1, Definition 1817.2, and Definition 1817.3 seed the finite bisection inverse route linking logarithm and exponential over positive RealUp data.

Formal verification: FormalStatus(NameCert$_{\text{ExpLogBisection}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.ExpLogBisectionUp`

Bridge status: none

Not claimed: This chapter does not close host exponential or logarithm functions, quotient real equality, selected infinite bisection branches, countable choice, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-domain exposure, dyadic bracket exactness, exponential comparison routing, StreamName and RegSeqRat readback, logarithm endpoint handoff, Real seal nonescape, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.ExpLogBisectionUp.

Chapter 1818

A Concrete Naming Certificate for $\mathsf{CauchyRateLattice}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRateLattice}^{\uparrow}$ packet records the finite meet and join surface for Cauchy-rate schedules before any Real or completion consumer may read a terminal seal. It sits over the displayed domination route of chapter 1814, the shared-bound interface of chapter 462, the uniform schedule surface of chapter 1741, the finite-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives later Real and Completion certificates one finite lattice carrier for comparing and combining displayed Cauchy-rate schedules.

Definition 1818.1 (Cauchy rate lattice carrier)**.** *A* $\mathsf{CauchyRateLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, M, J, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two source Cauchy-rate schedule rows whose precision requests, source thresholds, and monotone reuse entries are visible to the packet.*
2. *M is the meet or shared-bound row. It records the finite threshold cells that both source schedules may use as a common Cauchy window before a downstream read consumes either source.*
3. *J is the displayed join or dominating-rate row. It records the finite threshold cells that dominate both A and B on the same precision surface.*
4. *D is the pair of* $\mathsf{CauchyRateDominance}^{\uparrow}$ *ledgers witnessing that M is readable from the two sources and that J dominates both source schedules through displayed comparison rows.*
5. *S is the selected* $\mathsf{StreamName}^{\uparrow}$ *window family opened only at requests certified by A, B, M, J, D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the selected windows and the visible dyadic tolerance entries.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source schedules, meet row, join row, dominance ledgers, selected windows, and regular readback have all been displayed.*
8. *H records componentwise* hsame *transport for the two source schedules, meet row, join row, dominance ledgers, selected windows, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through A, B, M, J, D, S, R, E and then through the structural rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRateLattice}^{\uparrow}$, $\mathsf{CauchyRateDominance}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRateLattice}^{\uparrow}}$ *row.*

The classifier accepts only packets whose reads pass through these twelve rows. It has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRateLatticeUp.CauchyRateLatticeTasteGate single carrier alignment`

Theorem 1818.2 (Cauchy rate lattice NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateLattice}^{\uparrow}$ *carrier*

$$L = (A, B, M, J, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRateLattice}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two source schedules, meet row, join row, dominance ledgers, selected windows, regular readback, terminal seal, transport, replay, provenance, and local naming rows;*

2. *meet ledger exactness, requiring M to be read as the displayed shared-bound row licensed by the source schedules and the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *surface;*

3. *join ledger exactness, requiring J to be read as the displayed dominating-rate row whose comparisons to A and B pass through the* $\mathsf{CauchyRateDominance}^{\uparrow}$ *ledgers in D;*

4. *uniform-window compatibility, requiring selected windows in S to be licensed by the same finite precision surface used by M, J, and the* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *schedule row;*

5. *componentwise transport, requiring H to preserve $A, B, M, J, D, S, R, E, C, P, N$ together;*

6. *non-escape, requiring the certificate to export no quotient stream equality, selected host limit, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No lattice obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyRateLatticeUp.CauchyRateLatticeCarrier namecert obligations`

Proof. Project the carrier of Definition 1818.1. The projection exposes exactly two source schedules, one shared-bound row, one dominating-rate row, the dominance ledgers, the selected windows, the regular rational readback, the terminal seal, and the structural rows.

The meet obligation is read first from A and B. A precision request cites both source thresholds, then reads M as the common row supplied by the CauchyModulusMeet surface. No downstream window is opened until this shared-bound row is visible.

The join obligation is read through J and D. The dominance ledgers in D display the comparisons from both source schedules to the same dominating row, so a consumer cannot replace J by a detached rate selector.

Uniform-window compatibility follows from the displayed route. The selected windows in S are downstream of M, J, D, and the uniform schedule row fixes the finite precision surface on which the meet and join are consumed. The readback row R and terminal seal E therefore see the same schedule surface.

Finally, H, C, P, N only transport, replay, source, and name the displayed packet. Since the carrier has no additional analytic coordinate, the local NameCert cannot export quotient stream equality, selected host limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Theorem 1818.3 (Cauchy rate lattice meet-join stability)**.** *Let*

$$L = (A, B, M, J, D, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyRateLattice}^{\uparrow}$ *carrier. Any Real-facing or completion-facing consumer that reads the meet row M or the join row J must factor through the same displayed source pair A, B, dominance ledger row D, selected-window row S, regular readback row R, and structural rows H, C, P, N. Thus the meet and join operations are stable under componentwise* hsame *transport and displayed* Cont *replay inside the packet.*

Proof. Begin with a consumer of M. By Definition 1818.2, the meet row is not an independent tail selector; it is read only after the source pair A, B has been displayed and only through the shared-bound ledger.

Now consider a consumer of J. The join row is likewise downstream of the same source pair, and its dominance evidence is stored in D. Hence the join read has no route that bypasses A, B, D.

The selected-window and readback rows are common to both reads. Since S is opened only after the meet, join, and dominance ledgers are visible, and since R reads only those selected windows, both operations reach the endpoint through the same finite window and readback route.

Transport stability is componentwise. The row H preserves all carrier coordinates together, and C replays only the displayed order from precision request to seal. Therefore both meet and join reads remain stable under the permitted hsame and Cont structure. □

Theorem 1818.4 (Cauchy rate lattice Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read out of an accepted* $\mathsf{CauchyRateLattice}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyRateDominance}^{\uparrow},\ \mathsf{CauchyModulusMeet}^{\uparrow},\ \mathsf{UniformCauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqR}$$

Equivalently, the read first consumes the two source schedules A, B, the meet row M, the join row J, the dominance ledgers D, the selected windows S, and the regular readback R, and only then reaches the terminal seal E and the structural rows H, C, P, N.

Proof. Take an endpoint-facing read admitted by the carrier. Projection of the carrier gives no direct coordinate from a precision request to E; the only endpoint route is through the displayed rows A, B, M, J, D, S, R.

The meet and join rows determine the lattice surface. The meet row reads the common Cauchy window supplied by the shared-bound surface, while the join row reads the dominating schedule supplied by the dominance ledgers. The uniform modulus row fixes the common finite precision surface used by both.

The selected windows and regular readback are then forced. The row S opens only windows licensed by the displayed lattice rows, and R reads those windows through the dyadic tolerance ledger before a $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Thus E is reached only through the stated sequence of concrete surfaces. The remaining rows H, C, P, N transport, replay, source, and name the same route, and no quotient stream, selected host limit, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checker can be inserted. □

Falsifiable prediction: An accepted $\mathsf{CauchyRateLattice}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first reading the source Cauchy-rate schedules, the shared meet row, the displayed join row, the dominance ledgers, the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: cauchy-rate-dominance, cauchymodulusmeet, uniform-cauchy-modulus, streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole twelve-row packet $L = (A, B, M, J, D, S, R, E, H, C, P, N)$, because each sibling contributes only domination, shared-bound, uniform-schedule, window, tolerance, readback, or seal data while this chapter binds meet, join, transport, replay, provenance, and local naming into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRateLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRateLattice}^{\uparrow}$ packet is generated from two source Cauchy-rate schedules, a displayed meet row, a displayed join row, dominance ledgers, selected StreamName windows, DyadicRatCore tolerance entries, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRateLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1818.1, Definition 1818.2, Definition 1818.3, and Definition 1818.4 seed the finite meet and join surface for Cauchy-rate schedules through the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRateLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, meet ledger exactness, join ledger exactness, uniform-window compatibility, componentwise transport, non-escape, meet-join stability, and Real route factorization for BEDC.Derived.CauchyRateLatticeUp.

Chapter 1819

A Concrete Naming Certificate for $\mathsf{EntourageBase}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on uniform structures, metric entourages, and constructive completion, the $\mathsf{EntourageBase}^{\uparrow}$ packet records the finite basis interface used by the L10 completion route before Cauchy filters or quotient completions are allowed to read it. It is anchored in the uniform entourage surface of chapter 339, the metric-ball naming surface of chapter 1510, and the finite observation windows of chapter 126. The packet names a displayed entourage-basis row and its dyadic radius ledger; it is not a quotient completion, not a selected limit, not an open-cover compactness argument, not countable choice, and not ambient completeness.

The finite basis route consumes the $\mathsf{UniformSpace}^{\uparrow}$ source row of chapter 339, the $\mathsf{Met}^{\uparrow}$ ball row of chapter 57, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301 before any completion-facing consumer may inspect the packet.

Definition 1819.1 (EntourageBase carrier)**.** *An* $\mathsf{EntourageBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, M, B, R, W, D, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, exposing only the finite entourage data and its displayed containment and refinement witnesses.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row from which metric-ball entourage requests may be read before any completion-facing consumer is present.*
3. *B is the finite entourage-basis row. It lists the basis entourages accepted by the packet, their finite-intersection refinement witnesses, and the containment route back to U.*
4. *R is the dyadic radius ledger, recording the admitted radii, the smaller-radius relation, and the monotone route from each radius request to the row B.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by finite completion-route consumers that need named observations rather than host-level points.*
6. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W and to the dyadic radius comparisons in R.*
7. *H records componentwise* hsame *transport for the uniform source, metric source, basis row, radius ledger, finite windows, readback row, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a requested entourage scale through* $U, M, B, R, W, D, H, P, N$.
9. *P is the* Pkg *provenance over* $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EntourageBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $U, M, B, R, W, D, H, C, P, N$. *The carrier has no coordinate for quotient completion, selected limits, open-cover compactness, countable-choice selectors, ambient completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.EntourageBaseUp.EntourageBaseTasteGate single carrier alignment`

Theorem 1819.2 (EntourageBase NameCert obligations)**.** *For every accepted* $\mathsf{EntourageBase}^{\uparrow}$ *carrier*

$$E = (U, M, B, R, W, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EntourageBase}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed UniformSpace source, MetricSpace source, entourage-basis row, dyadic radius ledger, StreamName window row, RegSeqRat readback, transport, replay, provenance, and local naming row;*
2. *basis containment, requiring every basis entourage in B to carry a displayed containment witness into the UniformSpace entourage row U;*
3. *finite-intersection refinement, requiring every accepted pair of basis rows to refine through a displayed row of B before any completion-route consumer may inspect it;*
4. *radius monotonicity, requiring every smaller-radius request recorded by R to factor through the same displayed basis row B and not through an ambient metric completion;*
5. *transport, requiring H to preserve the source rows, basis row, radius ledger, finite windows, readback, replay, provenance, and local naming componentwise under* hsame*;*
6. *replay, requiring C to repeat the route from a requested entourage scale through U, M, B, R, W, D before any named consumer is exposed;*
7. *provenance, requiring P to source only the listed rows and to export no quotient completion, selected limit, open-cover compactness, countable choice, or ambient completeness principle;*
8. *local naming, requiring N to name exactly this finite surface and no external completion object.*

No local NameCert obligation is stored outside these rows.

Theorem 1819.3 (EntourageBase finite radius refinement)**.** *Let $E = (U, M, B, R, W, D, H, C, P, N)$ be an accepted* $\mathsf{EntourageBase}^{\uparrow}$ *carrier. Every accepted smaller-radius request in R factors through the same displayed route*

$$U, M \longmapsto B \longmapsto R \longmapsto W, D \longmapsto H, C, P, N.$$

In particular, the refinement is witnessed by the finite entourage-basis row and dyadic ledger of the packet. It does not factor through quotient completion, selected limits, open-cover compactness, countable choice, or ambient completeness.

Theorem 1819.4 (EntourageBase UniformSpace dependency route)**.** *Every accepted* $\mathsf{EntourageBase}^{\uparrow}$ *completion-facing consumer must first display the same* $\mathsf{UniformSpace}^{\uparrow}$ *source row,* $\mathsf{Met}^{\uparrow}$ *ball row,*

$\mathsf{StreamName}^{\uparrow}$ *window row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carried by* U, M, W, D*. The consumer then reaches the basis row* B*, radius ledger* R*, transport* H*, replay* C*, provenance* P*, and local name* N *through that finite dependency route, and not through an ambient completion object.*

Closure status for $\mathsf{NameCert}_{\mathsf{EntourageBase}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EntourageBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1819.1, Definition 1819.2, Definition 1819.3, and Definition 1819.4 seed the finite uniform-basis interface through which UniformSpace and MetricSpace entourage data reaches StreamName and RegSeqRat completion-route consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EntourageBase}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.EntourageBaseUp.EntourageBaseTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, open-cover compactness, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis containment, finite-intersection refinement, radius monotonicity, transport, replay, provenance, and local naming for BEDC.Derived.EntourageBaseUp.

Constructive story: An $\mathsf{EntourageBase}^{\uparrow}$ packet is generated from one UniformSpace source row, one MetricSpace source row, a finite entourage-basis row, a dyadic radius ledger, StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

$\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ is consumed by chapter 301 and chapter 1809 through regular-rational classifier transport and dense readback; the seed closurestatus is carried by the child namecert construction file, while this hub only routes RegSeqRat and Real classifier dependencies.

Chapter 1820

A Concrete Naming Certificate for $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ packet records the finite classifier surface by which two regular Cauchy names may be compared before the $\mathsf{Real}^{\uparrow}$ seal exposes any equality-facing consumer. It sits on the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a non-quotient equality surface for the L10 Real and Completion route; it is not quotient stream equality, host real equality, a selected limit, countable choice, or ambient completeness.

The same classifier is consumed by chapter 1809 and chapter 1847 as the finite comparison route that must be displayed before density or Cauchy-space reads are exported.

The setoid dependency lattice also consumes the finite regular-rational readback of chapter 301, the Cauchy-name comparison surface of chapter 1412, and the terminal Real seal route of chapter 38; those sibling rows are displayed before the setoid relation becomes public to any Real or Completion consumer.

It is also a horizontal dependency of chapter 301 and the regular-Cauchy uniqueness route before any $\mathsf{Real}^{\uparrow}$-facing seal is read. A consumer first reads the finite classifier row T, the open-tail route through $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks R_0, R_1, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D; only then may regular-Cauchy uniqueness consume the comparison. The route refuses quotient stream equality, so representative independence remains a displayed classifier handoff rather than a host quotient.

Definition 1820.1 (CauchyEquivalenceSetoid carrier)**.** *A* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows. Each row lists only the visible observation windows that a classifier request may inspect.*

2. *R_0 and R_1 are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows. They expose the regular rational values attached to the stream windows before any real-name seal is consumed.*

3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the admitted dyadic precision requests, comparison witnesses, and refinement rows used to compare the two regular names.*

4. *T is the setoid-test row. It stores reflexivity, symmetry, and transitivity checks only as finite classifier rows over S_0, S_1, R_0, R_1, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-boundary row reached after the stream windows, readback rows, dyadic ledger, and setoid-test row have been displayed.*
6. *H records componentwise* hsame *transport for the two stream rows, the two readback rows, the dyadic ledger, the setoid-test row, the seal row, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from an equality-facing tolerance request through $S_0, S_1, R_0, R_1, D, T, E, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidCarrier semantic name certificate`

The regular-sequence classifier route of chapter 301 supplies the readback side of the setoid test, while the terminal seal discipline of chapter 38 fixes where equality-facing consumers may leave the comparison surface. Thus $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ is a displayed classifier over those sibling rows, not a quotient object; every public read keeps the two $\mathsf{RegSeqRat}^{\uparrow}$ presentations and the downstream $\mathsf{Real}^{\uparrow}$ seal visible before completion or equality consumers inspect the packet.

Theorem 1820.2 (CauchyEquivalenceSetoid obligation surface)**.** *For every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N),$$

the obligation surface consists exactly of carrier admission, regular-rational classifier transport, tail-stability of the displayed setoid tests, the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *readback boundary, and ledger non-escape through $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$. No obligation may be discharged by quotient stream equality, host real equality, a selected representative, countable choice, or ambient completeness.*

Proof. Carrier admission is the projection of Definition 1820.1. The projection supplies the two stream windows, two regular-rational readbacks, dyadic tolerance ledger, setoid-test row, Real seal boundary, and structural rows.

Regular-rational classifier transport is read from the rows R_0, R_1, T, H, C. The displayed transport row H and replay row C carry the same classifier tests over the two $\mathsf{RegSeqRat}^{\uparrow}$ presentations, so the comparison never becomes a host quotient relation.

Tail-stability is supplied by the classifier-law rows and by the regular-Cauchy handoff of Definition 1820.3 and Definition 1820.6. These force reflexive, symmetric, transitive, and uniqueness-facing reads to remain on $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$.

Finally the RegSeqRat and Real dependency routes of Definition 1820.20 and Definition 1820.8 place R_0, R_1 before the Real seal E. Since the carrier has no coordinate for any excluded equality, selection, choice, or completeness object, every accepted obligation is a ledger projection from the displayed packet. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidCarrier obligation surface`

Theorem 1820.3 (CauchyEquivalenceSetoid classifier laws)**.** *For every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N),$$

the classifier row T *supplies exactly the reflexive, symmetric, and transitive finite tests visible to the local* $\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}$ *surface:*

1. *reflexivity tests compare a stream window with itself through the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row and the dyadic zero-tolerance entries of* D*;*
2. *symmetry tests reverse the two displayed stream-readback sides and reuse the same dyadic comparison ledger* D *with no second equality relation;*
3. *transitivity tests concatenate two displayed comparison witnesses through a common readback side and discharge the resulting tolerance request by the refinement rows of* D*;*
4. *every test is replayed by* C*, transported componentwise by* H*, sourced by* P*, and named by* N *before the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is consumed.*

No classifier law is stored outside the finite rows of Q*.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidClassifierLaws`

Proof. Project the carrier of Definition 1820.1. The projection exposes two finite StreamName windows, two RegSeqRat readback rows, one DyadicRatCore tolerance ledger, one setoid-test row, the Real seal boundary, and the structural rows.

For reflexivity, use the same stream row and the same readback row on both sides. The dyadic ledger supplies the displayed zero-tolerance and refinement entries, so the test is a row of T rather than a quotient assertion.

For symmetry, exchange the two stream-readback sides. The comparison witness remains in the same ledger D, and T records the reversed finite row as the visible classifier test.

For transitivity, concatenate the two displayed comparison rows through their shared middle readback side. The resulting tolerance request is discharged by the refinement entries already listed in D.

Finally H, C, P, N transport, replay, source, and name these finite rows, while E is available only after the rows have been displayed. Since Q has no quotient or host-equality coordinate, the local certificate contains exactly the listed classifier laws. □

Theorem 1820.4 (CauchyEquivalenceSetoid transport)**.** *Let* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier. Every* hsame *transport of an equality-facing classifier read is componentwise over*

$$S_0, S_1, R_0, R_1, D, T, E, C, P, N.$$

Thus transport preserves the StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal boundary, displayed replay, package provenance, and local NameCert rows before any equality consumer may inspect the result.

Proof. Start with a classifier read and its displayed hsame witness in H. By the carrier definition, H has no global equality coordinate; it stores only componentwise transports for the rows of Q.

Apply the transport row to $S_0, S_1, R_0, R_1, D, T, E$ in order. The stream windows remain finite, the readback rows remain the same regular rational interface, the tolerance ledger remains the same dyadic comparison surface, and the seal row remains downstream of those rows.

The replay, provenance, and local naming rows are transported last. Since C, P, N only replay, source, and name the displayed route, the transported read still factors through the same finite classifier surface before any equality-facing consumer can inspect it. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidTransport`

Theorem 1820.5 (CauchyEquivalenceSetoid NameCert surface)**.** *For every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *carrier admission for the two StreamName finite-window rows, two RegSeqRat readback rows, DyadicRatCore tolerance ledger, setoid-test row, Real seal boundary, componentwise transport, replay, provenance, and local naming row;*
2. *StreamName window exactness, requiring every equality-facing observation to be one of the displayed windows in* S_0 *or* S_1*;*
3. *RegSeqRat readback exactness, requiring every rational comparison to pass through* R_0 *and* R_1 *before it reaches the dyadic ledger;*
4. *DyadicRatCore tolerance exactness, requiring every accepted equality test to be discharged by an entry of* D*;*
5. *classifier-law stability, requiring reflexivity, symmetry, and transitivity to be exactly the finite tests stored in* T*;*
6. *Real seal nonescape, requiring* E *to be consumed only after the window, readback, tolerance, and classifier-law rows have been displayed;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, C, P, N*.*

The surface exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness witness, Lean verification, or bridge check.

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidNameCertSurface`

Proof. Carrier admission is the displayed tuple of Definition 1820.1. It gives exactly the stream, readback, dyadic, classifier, seal, transport, replay, provenance, and naming rows.

Window exactness and readback exactness are immediate from the source rows. Every observation is first a finite StreamName window in S_0 or S_1, and every rational comparison then reads the corresponding RegSeqRat row R_0 or R_1.

Tolerance exactness is supplied by D. A classifier request can only use dyadic precision entries and refinement witnesses present in that ledger.

Use Definition 1820.3 for the setoid tests and Definition 1820.4 for the transport discipline. These place the law rows and transported reads inside the same finite packet.

The Real seal row E is downstream of the displayed classifier route, and C, P, N only replay, source, and name that route. Therefore the local NameCert surface is exhausted by the listed obligations and cannot export any of the excluded completion or equality objects. □

Theorem 1820.6 (CauchyEquivalenceSetoid regular-Cauchy uniqueness handoff)**.** *Any regular-Cauchy uniqueness consumer comparing two* $\mathsf{Real}^{\uparrow}$*-facing regular rational names through an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ *must first read the two* $\mathsf{StreamName}^{\uparrow}$ *windows* S_0, S_1*, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_0, R_1*, the* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance ledger D, the setoid-test row T, the Real$^{\uparrow}$ *seal boundary E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N. Representative independence is exported only through this non-quotient classifier route.*

Proof. Project the carrier of Definition 1820.1. The two regular rational presentations are visible only through the two finite StreamName windows, the two RegSeqRat readbacks, the dyadic tolerance ledger, and the setoid-test row.

Apply the classifier laws of Definition 1820.3. Reflexivity, symmetry, and transitivity remain finite tests in T over S_0, S_1, R_0, R_1, D, so the uniqueness consumer receives classifier evidence rather than quotient stream equality.

Use the transport theorem and NameCert surface, Definition 1820.4 and Definition 1820.5. They keep the comparison stable under componentwise hsame, replay the same displayed route through C, and source and name it through P, N before the Real seal can be consumed.

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient completeness. Thus representative independence is a displayed handoff through $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$ and not an appeal to any excluded equality or limit principle. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRegularCauchyUniquenessHandoff`

Theorem 1820.7 (CauchyEquivalenceSetoid RealEquality consumer route)**.** *Every* RealEquality$^{\uparrow}$ *consumer of an accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *packet $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ must read the two* StreamName$^{\uparrow}$ *windows S_0, S_1, the two* RegSeqRat$^{\uparrow}$ *readbacks R_0, R_1, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, the setoid-test row T, the* Real$^{\uparrow}$ *seal boundary E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N before it reaches the* RealEquality$^{\uparrow}$ *classifier boundary of chapter 1636. The consumer route has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRealEqualityConsumerRoute`

Proof. Project the carrier of Definition 1820.1. The visible inputs are exactly the two stream windows, two regular-rational readbacks, one dyadic ledger, the setoid-test row, the real seal, and the structural support rows.

Apply the classifier laws of Definition 1820.3. They require every reflexive, symmetric, or transitive setoid read to remain a finite test over S_0, S_1, R_0, R_1, D before the seal row is consumed.

Use Definition 1820.4 for the componentwise handoff and Definition 1820.5 for local certification. The rows H, C, P, N transport, replay, source, and name the same route, while E remains the downstream Real$^{\uparrow}$ boundary feeding the RealEquality$^{\uparrow}$ classifier.

Since the accepted packet lists no quotient, host-equality, selected-limit, choice, or ambient-completeness coordinate, a RealEquality$^{\uparrow}$ consumer can inspect only the displayed finite route before reaching the sibling equality classifier. □

Theorem 1820.8 (CauchyEquivalenceSetoid Real seal forward route)**.** *Every accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *read reaches a* Real$^{\uparrow}$ *consumer only after StreamName finite windows, RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the classifier row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row are visible. Concretely, the Real-facing route is*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto H, C, P, N \longmapsto E,$$

where E is the terminal $\mathsf{Real}^{\uparrow}$ *seal and no quotient stream equality, host real equality, selected representative, countable-choice selector, or ambient completeness row is exported.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRealSealForwardRoute`

Proof. Project the carrier of Definition 1820.1. The projection displays the StreamName windows S_0, S_1, RegSeqRat readbacks R_0, R_1, DyadicRatCore ledger D, classifier row T, Real seal E, and structural rows H, C, P, N.

Apply the classifier laws and NameCert surface, Definition 1820.3 and Definition 1820.5. They keep every comparison test inside the finite windows, readbacks, tolerance ledger, and classifier row before the Real seal can be consumed.

Use the transport theorem and RealEquality consumer route, Definition 1820.4 and Definition 1820.7. The transport row keeps the route componentwise stable, while the equality consumer route confirms that the Real-facing seal is reached through the same displayed packet rather than through quotient equality or host selection principles. □

Theorem 1820.9 (CauchyEquivalenceSetoid downstream equality dependency)**.** *Let $Q = (S_0, S_1, R_0, R_1, D, T, E,$ be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier. Every* RealClassifier *or* $\mathsf{MetricCompletion}^{\uparrow}$ *equality-facing consumer of Q reads the setoid surface only through the route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before any completion-facing read is available. In particular, the consumer first inspects $\mathsf{StreamName}^{\uparrow}$ *windows, then* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and only then the* $\mathsf{Real}^{\uparrow}$ *seal boundary that feeds Real equality or completion consumers.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidDownstreamEqualityDependency`

Proof. Start from the NameCert surface of Definition 1820.5. It says that every equality-facing observation is one of the displayed windows in S_0 or S_1, every rational comparison passes through R_0 and R_1, every accepted test is discharged by D, and the $\mathsf{Real}^{\uparrow}$ seal row E is downstream of those rows.

Use Definition 1820.3 for the finite equality tests stored in T. Reflexivity, symmetry, and transitivity therefore remain classifier rows over the same windows, readback rows, and dyadic tolerance ledger rather than a detached host equality.

Use Definition 1820.4 for the componentwise handoff to downstream readers. The sibling dependency paragraph below the surface theorem places this same route next to the StreamName, RegSeqRat, DyadicRatCore, and Real chapters, so a RealClassifier or $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives only the routed packet $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$ before any completion-facing read. □

Theorem 1820.10 (CauchyEquivalenceSetoid psame RealClassifier bridge)**.** *Let $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C$ be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier packet. Any accepted classifier row consumed as a* psame *comparison reaches the* RealClassifier *boundary only through*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E, H, C, P, N.$$

Conversely, any RealClassifier*-facing read backed by exactly those displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, setoid-test row, Real seal boundary, componentwise transport, replay, provenance, and local naming rows is a legitimate* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *consumer route. The bridge exports no quotient stream equality, host real equality, selected limit, countable choice, or ambient completeness.*

Lean4 ✓ BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidPsameRealClassifierBridge

Proof. For the forward direction, begin with the classifier laws of Definition 1820.3. A psame comparison can use only the reflexive, symmetric, and transitive finite tests in T over S_0, S_1, R_0, R_1, D.

Use the transport theorem, Definition 1820.4, to carry the comparison componentwise through H while preserving the same StreamName windows, RegSeqRat readbacks, dyadic ledger, classifier row, seal boundary, replay, provenance, and local naming rows.

Apply the NameCert surface and RealEquality consumer route, Definition 1820.5 and Definition 1820.7. They place the Real-facing classifier boundary downstream of the displayed finite route and exclude any detached quotient or host-equality coordinate.

For the converse direction, suppose a RealClassifier-facing read is backed by the rows $S_0, S_1, R_0, R_1, D, T, E, H, C$ in the displayed order. The NameCert surface admits exactly those rows as the local certificate surface, and the downstream equality dependency theorem, Definition 1820.9, identifies the same route as the equality-facing consumer route. Therefore the read is a legitimate $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ consumer route. □

Theorem 1820.11 (CauchyEquivalenceSetoid separated-completion forward link)**.** *Every* RegularCauchyCompletio *or* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P,$ *first reads the two* $\mathsf{StreamName}^{\uparrow}$ *windows* S_0, S_1*, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_0, R_1*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the setoid-test row* T*, the* $\mathsf{Real}^{\uparrow}$ *seal boundary* E*, and the structural rows* H, C, P, N*. The route feeds the separated-completion corridor of chapter 1513, the sequence-equivalence boundary of chapter 1412, and the separated-metric classifier of chapter 1411; it exposes no quotient stream equality, selected representative, host real equality, countable choice, or ambient completion.*

Proof. Begin with the downstream equality dependency of Definition 1820.9. It orders every equality-facing completion read through the two stream windows, regular rational readbacks, dyadic tolerance ledger, classifier row, real seal, and structural rows.

Use the classifier laws of Definition 1820.3. They say that reflexive, symmetric, and transitive comparison data remain finite tests in T over S_0, S_1, R_0, R_1, D, which is the same comparison route consumed by the sequence-equivalence boundary of chapter 1412.

Apply the NameCert surface of Definition 1820.5 and the transport theorem Definition 1820.4. These keep the separated-completion and separated-metric consumers inside E, H, C, P, N after the classifier route, matching the corridor of chapter 1513 and chapter 1411.

No carrier row remains from which a quotient equality, selected representative, host equality, countable-choice schedule, or ambient completion can be read. Thus every separated-completion or separated-metric consumer first traverses the displayed setoid route. □

Lean4 ✓ BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidSeparatedCompletionForwardLink

Theorem 1820.12 (CauchyEquivalenceSetoid separated metric factorization)**.** *Every* $\mathsf{SeparatedMetric}^{\uparrow}$ *or* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet factors its equality-facing read through the displayed route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before the separated metric classifier is available. Thus the consumer first reads StreamName windows, RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the classifier row, and the RealUp seal, and only then reaches the separated metric classifier boundary.

Proof. Project the carrier of Definition 1820.1. The projection exposes exactly $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$, so every consumer starts from the two StreamName windows, two RegSeqRat readbacks, DyadicRatCore ledger, classifier row, Real seal, and structural rows.

Apply the NameCert surface and downstream equality dependency, Definition 1820.5 and Definition 1820.9. These force equality-facing reads through the windows, readbacks, tolerance ledger, classifier row, and Real seal before a completion-facing read can be inspected.

Apply the separated-completion forward link, Definition 1820.11. It sends $\mathsf{SeparatedMetric}^{\uparrow}$ and $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ consumers through the same displayed route before the separated metric classifier of chapter 1411 is reached.

No row of the carrier stores quotient stream equality, a selected representative, host equality, countable choice, or ambient completion. Therefore the separated metric factorization is exhausted by the displayed packet and cannot be replaced by any of those excluded objects. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidSeparatedMetricFactorization`

Theorem 1820.13 (CauchyEquivalenceSetoid RealSeparability backward link)**.** *Let $Q = (S_0, S_1, R_0, R_1, D, T, E, H$ be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier packet whose displayed rows include the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R_0, R_1 and the* $\mathsf{Real}^{\uparrow}$ *seal row E. Then the* $\mathsf{RealSeparability}^{\uparrow}$ *dense-route consumer can read Q through the same finite classifier surface*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

without importing quotient equality of Cauchy names, host real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1820.1. The rows available to a dense-route consumer are precisely the StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, setoid-test row, Real seal, componentwise transport, replay, provenance, and local naming.

Apply the NameCert surface and classifier laws, Definition 1820.5 and Definition 1820.3. They keep every comparison used by the dense route inside S_0, S_1, R_0, R_1, D, T before the seal boundary is reached.

Use the downstream equality dependency of Definition 1820.9. The same finite route is already the path supplied to Real-facing consumers, and the opening sibling route to chapter 1809 reads it as classifier data rather than as quotient equality.

Since Q contains no row for quotient Cauchy-name equality, host real equality, selected limits, countable choice, or ambient completeness, the $\mathsf{RealSeparability}^{\uparrow}$ consumer receives only the displayed dense-route classifier packet. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRealSeparabilityBackwardLink`

Theorem 1820.14 (CauchyEquivalenceSetoid RealSeparability stable-density handoff)**.** *Let $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier packet. Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-route consumer of Q preserves the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently any two Cauchy-equivalent $\mathsf{RegSeqRat}^{\uparrow}$ *presentations accepted by the same packet feed the same rational density window to the* $\mathsf{RealSeparability}^{\uparrow}$ *consumer through that route, without quotient stream equality, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRealSeparabilityStableDensity`

Proof. Start with the NameCert surface of Definition 1820.5. It exhausts the accepted packet by the two stream windows, two regular-rational readbacks, dyadic tolerance ledger, classifier row, real seal, transport, replay, provenance, and local naming rows.

Apply the classifier laws of Definition 1820.3. Reflexive, symmetric, and transitive comparisons are finite tests in T over S_0, S_1, R_0, R_1, D, so a Cauchy-equivalent pair of regular rational presentations reaches the density consumer through the displayed classifier surface.

Use the downstream equality dependency of Definition 1820.9. It orders every Real-facing consumer read through the same route before the seal row E is available, so the rational density window cannot be chosen from a detached quotient equality or host real equality.

Finally apply the $\mathsf{RealSeparability}^{\uparrow}$ backward link of Definition 1820.13. The dense-route consumer already reads the classifier packet as finite route data; therefore the handoff preserves the same rational density window and excludes selected representatives, countable choice, and ambient completeness. □

Theorem 1820.15 (CauchyEquivalenceSetoid RealSeparability forward anchor)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-read consumer that uses an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must pass through the displayed classifier route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before it reads the separability surface of chapter 1809. Thus the density-facing handoff reaches $\mathsf{RealSeparability}^{\uparrow}$ *only through the two* $\mathsf{StreamName}^{\uparrow}$ *windows, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, dyadic tolerance ledger, classifier row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidRealSeparabilityForwardAnchor`

Proof. Project the accepted packet of Definition 1820.1. The only available dense-read data are the two stream windows, two regular-rational readbacks, dyadic ledger, classifier row, Real seal, and structural rows.

Apply the stable-density handoff and the backward link, Definition 1820.14 and Definition 1820.13. They identify the route consumed by a $\mathsf{RealSeparability}^{\uparrow}$ reader and place it before the downstream separability surface is inspected.

The local dependency route has no quotient equality, selected representative, countable-choice schedule, host real equality, or ambient completeness coordinate. Therefore the forward anchor into chapter 1809 is exactly the displayed classifier route. □

Theorem 1820.16 (CauchyEquivalenceSetoid tail transitivity)**.** *Let accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *tests share compatible* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers through the displayed classifier row* T*. Any downstream* $\mathsf{RealClassifier}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *equality-facing read receives the composed finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before any seal boundary is available. The composition is a finite classifier route through $S_0, S_1, R_0, R_1, D, T, E, H, C$ *not quotient stream equality, host real equality, a selected limit, countable choice, or ambient completeness.*

Proof. Use the classifier laws of Definition 1820.3. The transitivity row in T concatenates compatible finite comparison witnesses through the shared middle readback side, and the dyadic refinement rows in D discharge the resulting tolerance request.

Next apply the transport theorem Definition 1820.4. It keeps the two stream windows, the two regular-rational readbacks, the dyadic ledger, the classifier row, and the seal row componentwise stable under hsame handoff.

Finally use the downstream equality dependency theorem. It orders every RealClassifier or MetricCompletion$^{\uparrow}$ equality-facing read through the displayed stream, readback, dyadic, classifier, seal, transport, replay, provenance, and naming rows before any completion-facing boundary is reached. The carrier has no coordinate for quotient equality or host selection principles, so the composed tail-transitivity read remains inside the finite route. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidTailTransitivity`

Theorem 1820.17 (CauchyEquivalenceSetoid completion-tail composition)**.** *Let two compatible accepted equality-facing* CauchyEquivalenceSetoid$^{\uparrow}$ *tests share their* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks, and* DyadicRatCore$^{\uparrow}$ *tolerance ledgers through the displayed classifier row. Their composed read reaches any completion-facing classifier only through*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before any RealClassifier *or* MetricCompletion$^{\uparrow}$ *consumer may inspect the seal. The composition is a finite classifier route over the shared rows, not quotient stream equality, host real equality, a selected limit, countable choice, or ambient completeness.*

Proof. Use Definition 1820.3. The compatible tests compose by the transitivity row in T, and their reflexive and symmetric boundary reads remain finite classifier rows over the same windows, readbacks, and dyadic tolerance ledger.

Apply Definition 1820.4. It keeps the shared StreamName windows, RegSeqRat readbacks, DyadicRatCore ledger, classifier row, and seal boundary componentwise stable under the displayed hsame handoff.

Now use Definition 1820.16. It orders the composed finite route through $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$ before any downstream seal boundary is available.

Finally apply Definition 1820.9. Every RealClassifier or MetricCompletion$^{\uparrow}$ consumer receives only that displayed route, so completion-facing inspection cannot bypass the shared windows, readbacks, tolerance ledger, or classifier row. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidCompletionTailComposition`

Theorem 1820.18 (CauchyEquivalenceSetoid finite-chain composition)**.** *Any finite displayed chain of compatible* CauchyEquivalenceSetoid$^{\uparrow}$ *packets composes through repeated tail transitivity into one classifier route over the shared* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks,* DyadicRatCore$^{\uparrow}$ *tolerance ledgers, the terminal* Real$^{\uparrow}$ *seal row, componentwise transport, displayed replay, provenance, and local* NameCert *rows.*

The composed route is a finite classifier surface for downstream Real equality and completion consumers. It is not quotient equality of Cauchy streams, host real equality, a selected representative, a selected limit, countable choice, or ambient completeness.

Proof. Induct over the displayed finite chain. In the empty or singleton case, the route is the classifier row supplied by Definition 1820.3, transported componentwise by Definition 1820.4.

For the successor step, assume the initial segment has been composed into one classifier route over the displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming rows. Compose that route with the next compatible packet using Definition 1820.16.

Apply Definition 1820.17 to order the extended route before any completion-facing consumer inspects the seal. Since each step stays on the displayed classifier surface, no quotient equality, host equality, selected representative, selected limit, countable choice, or ambient completeness coordinate is introduced. □

Theorem 1820.19 (CauchyEquivalenceSetoid regular-chain induction)**.** *Any finite chain of accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier comparisons factors through repeated displayed rows*

$$S_i, R_i, D_i, T_i, E_i, H_i, C_i, P_i, N_i.$$

Its composite comparison remains a finite classifier route for Real equality and completion consumers. The induction never exports quotient stream equality, a selected representative, a selected limit, host real equality, countable choice, or ambient completeness.

Proof. Induct over the finite chain of accepted classifier comparisons. In the base case, the empty or singleton chain is the reflexive classifier row supplied by Definition 1820.3, with the carrier rows transported componentwise by Definition 1820.4.

For the successor step, assume the initial chain has already been factored through displayed rows $S_i, R_i, D_i, T_i, E_i, H_i, C_i, P_i, N_i$ and has produced one finite classifier route. The next accepted comparison contributes the same kind of rows, and the shared regular side is matched componentwise through the StreamName, RegSeqRat, and DyadicRatCore entries.

Apply the tail-transitivity and completion-tail composition theorems, Definition 1820.16 and Definition 1820.17. They compose the accumulated route with the next comparison while preserving the displayed windows, readbacks, tolerance ledgers, classifier rows, Real seal rows, transport, replay, provenance, and local naming.

Finally use the Real seal nonescape supplied by the downstream equality dependency and finite-chain composition theorems. The composite comparison remains a routed classifier packet before any Real equality or completion consumer may inspect it, so none of the excluded quotient, selection, host-equality, choice, or completeness objects can appear. □

Theorem 1820.20 (CauchyEquivalenceSetoid RegSeqRat route)**.** *Every completion-tail comparison exported by an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must pass through the sibling* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *routes of chapter 301 and chapter 38. The exported comparison is the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

rather than quotient stream equality, host real equality, a selected limit, countable choice, or ambient completeness.

Proof. Start from the classifier laws of Definition 1820.3. They force reflexive, symmetric, and transitive comparison reads to stay on the displayed S_0, S_1, R_0, R_1, D, T surface.

Use Definition 1820.4. It preserves the same StreamName windows, RegSeqRat readbacks, dyadic ledger, classifier row, Real seal, replay, provenance, and local naming under componentwise hsame comparison.

Apply Definition 1820.9 and Definition 1820.17. The first identifies the Real-facing equality consumer route, and the second orders completion-tail reads through the composed classifier surface before any completion consumer can inspect the seal.

Thus every exported completion-tail comparison must use the sibling RegSeqRat readback and Real seal routes. Since no carrier row records quotient equality, host real equality, selected limits, countable choice, or ambient completeness, the route cannot leave the finite packet. □

Theorem 1820.21 (CauchyEquivalenceSetoid finite sibling route)**.** *Every equality-facing consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must pass through the finite sibling route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyModulus}^{\uparrow},\ \mathsf{Completion}^{\uparrow}$$

as displayed regular-Cauchy readback, finite tolerance and modulus rows, terminal Real seal, completion-facing classifier, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}$ *row. The route is concrete over the carrier rows* $S_0, S_1, R_0, R_1, D, T, E, H, C, P,$ *and exports no quotient equality, host equality, selected representative, selected limit, countable choice, or ambient completeness.*

Proof. Start from the NameCert surface of Definition 1820.5. It forces every equality-facing observation through the displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, setoid-test row, Real seal boundary, transport, replay, provenance, and local naming rows.

Use the classifier laws and transport theorem, Definition 1820.3 and Definition 1820.4. The comparison remains a finite classifier route over $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$, and hsame can move only those displayed coordinates.

Apply the RegSeqRat route of Definition 1820.20. It places the regular-Cauchy readback and terminal Real seal before any completion-tail consumer can inspect the comparison, so the route reads $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ as sibling rows rather than as a quotient carrier.

Finally use the no-quotient boundary of Definition 1820.22. Since the accepted packet has no coordinate for quotient equality, host equality, selected representatives, selected limits, countable choice, or ambient completeness, the completion-facing consumer receives only the displayed finite sibling route through $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, replay, provenance, and local naming. □

Theorem 1820.22 (CauchyEquivalenceSetoid no-quotient boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet reads equality-facing data through the displayed classifier laws, componentwise transport, completion-tail composition, and finite-chain composition. The consumer receives the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

and cannot replace that route by quotient equality of Cauchy streams, selected representatives, host real equality, selected limits, countable choice, or ambient completion.

Proof. Project the carrier and apply Definition 1820.3. The equality-facing read begins with the two $\mathsf{StreamName}^{\uparrow}$ windows, the two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the dyadic tolerance ledger, and the classifier-law row.

Use Definition 1820.4. Componentwise hsame transport preserves the same displayed rows before any downstream Real-facing seal is available.

Apply Definition 1820.17 and Definition 1820.18. These order every completion-tail and finite-chain read through the classifier surface before the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can inspect the terminal seal.

The carrier has no coordinate for quotient equality, selected representatives, host real equality, selected limits, countable choice, or ambient completion. Therefore a downstream consumer cannot replace the displayed route by any such datum. □

Lean4 ✓ `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidNoQuotient`

The forward dependency into $\mathsf{RealSeparability}^{\uparrow}$ is the density-facing use of the Real seal route. Every $\mathsf{RealSeparability}^{\uparrow}$ consumer of an accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ packet must read the displayed comparison surface

$$S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$$

through the downstream $\mathsf{Real}^{\uparrow}$ seal of Definition 1820.8. Thus the density or completion-facing consumer reaches chapter 1809 only after the two stream windows, two regular rational readbacks, dyadic tolerance ledger, classifier row, Real seal, componentwise transport, replay, provenance, and local naming row are all visible. The route exports no quotient equality of Cauchy streams, selected representative, countable-choice schedule, host real equality, or ambient completeness witness.

The setoid-test row is consumed through the finite-window surface of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. Downstream Cauchy locatedness and selection-free real consumers therefore read the equality-facing classifier through those concrete sibling edges rather than through a detached kernel-only equality object.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ packet is generated from two StreamName finite-window rows, two RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a finite classifier-law row, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: The scoped surface binds the displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, Real seal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows behind the non-quotient classifier route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyEquivalenceSetoid}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyEquivalenceSetoidUp.CauchyEquivalenceSetoidNameCertSurface`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked classifier-law stability, componentwise transport, replay, provenance, and local naming beyond the displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ NameCert surface.

The downstream $\mathsf{RealClassifier}^{\uparrow}$ consumer of chapter 1620 reads $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ only after the finite comparison surface of chapter 1412 and the regular rational readback rows of chapter 301 have exposed their visible classifier data. Thus the setoid packet supplies the equality-facing sibling lattice route into the Real classifier without becoming a detached quotient equality, a selected limit, or a host real-equality oracle. The Real classifier route of chapter 1620 treats chapter 1820 as a visible sibling dependency, not as a hidden quotient boundary. Its consumer first exposes the regular rational readback discipline of chapter 301, then opens the StreamName windows and DyadicRatCore tolerance rows that make the Cauchy setoid finite before the Real-facing classifier seal is read.

Theorem 1820.23 (Cauchy equivalence setoid Real classifier forward dependency)**.** *Every* $\mathsf{RealClassifier}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance rows before any Real equality-facing seal or classifier boundary is consumed; it supplies no selected representative, quotient equality oracle, countable-choice schedule, ambient Real completeness witness, Lean verification, or bridge check.

Proof. Start from the Cauchy setoid packet and the Real classifier consumer. The packet exposes equality only through finite StreamName windows and the regular rational rows that are read on those windows.

Read the RegSeqRat and DyadicRatCore data next. These rows fix the rational readback and tolerance ledger before the classifier can ask for a Real-facing boundary.

Finally pass the visible setoid route to the Real classifier. Since the classifier receives only the displayed finite route, no quotient oracle, selected representative, choice schedule, ambient completeness datum, Lean proof, or bridge coordinate is available. □

Theorem 1820.24 (Cauchy equivalence setoid Real classifier consumer)**.** *Every* $\mathsf{Real}^{\uparrow}$ *classifier consumer of the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route must pass through the Cauchy equivalence carrier of Definition 1820.1, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the Real classifier dependency route before it can read the terminal Real classifier boundary of chapter 38. The consumer receives the two finite* $\mathsf{StreamName}^{\uparrow}$ *windows, regular rational readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, setoid-test row, Real seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, but it receives no quotient stream equality, host real equality, selected limit, countable choice, trichotomy, ambient completeness theorem, or detached Real classifier oracle.*

Proof. Project the carrier of Definition 1820.1. Any equality-facing consumer first sees the displayed stream windows, regular rational readbacks, dyadic tolerance ledger, setoid-test row, Real seal boundary, and structural rows.

Use the local Real classifier dependency route. That route sends downstream Real classifier reads through the finite comparison surface and the regular rational readback rows before chapter 38 can be consumed.

The structural rows then transport, replay, source, and name the same path. Since the carrier has no quotient, host-equality, selected-limit, choice, trichotomy, ambient-completeness, or detached-classifier coordinate, every $\mathsf{Real}^{\uparrow}$ classifier consumer remains on the displayed setoid route. □

Theorem 1820.25 (CauchyEquivalenceSetoid RegSeqRat sibling route)**.** *Every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *equality-facing read consumes the finite comparison surface of* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *from chapter 1412, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before exposing the* $\mathsf{Real}^{\uparrow}$ *seal. Completion-facing consumers must read this whole route before any equality read is public, so the setoid packet is horizontally linked to those sibling certificates rather than being a detached equality object, a quotient stream, or a host real-equality relation.*

Proof. Begin with the carrier of Definition 1820.1. Its equality-facing route starts with stream-window rows and regular rational readback rows before the dyadic tolerance, classifier-law, and Real seal rows are visible.

Apply the classifier laws and the NameCert surface. These theorems force reflexivity, symmetry, transitivity, readback exactness, and tolerance exactness to remain finite rows over the same comparison packet.

Use the downstream equality dependency theorem. It identifies the route through the Cauchy comparison surface, $\mathsf{RegSeqRat}^{\uparrow}$ readback, dyadic tolerance ledger, classifier row, and terminal $\mathsf{Real}^{\uparrow}$ seal before any completion-facing consumer can read the result.

The completion-facing boundary is therefore not a separate equality service. A $\mathsf{Real}^{\uparrow}$ or completion consumer first sees $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows, then the classifier laws and terminal seal; only after that finite dependency route has been displayed can the public equality read be consumed.

Therefore the sibling route is substantive and non-quotient: the setoid packet exposes equality only after the RegSeqRat and CauchySequenceEquivalence dependencies have been consumed, and no detached host equality coordinate is present. □

The completion-facing dependency lattice for $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ routes equality reads through the regular-Cauchy classifier before any metric-completion consumer sees them. In particular, chapter 301 supplies the regular rational readback rows that make the setoid comparison visible as finite stream data, and chapter 1506 consumes that comparison only after the metric-completion carrier has exposed its tolerance and completion rows. Thus the setoid packet is a child dependency of the regular-Cauchy and metric-completion route, not a free-standing quotient equality or detached host equivalence relation.

Theorem 1820.26 (RegSeqRat completion classifier route)**.** *Every completion-facing* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *equality read first factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows of chapter 301 and only then through the* $\mathsf{MetricCompletion}^{\uparrow}$ *tolerance and completion rows of chapter 1506. Thus a downstream completion consumer receives the stream-window comparison, regular rational readback, dyadic tolerance ledger, setoid test, and completion-facing handoff in that order; it receives no detached quotient equality, selected representative, host real equality, or independent completion oracle.*

Proof. Start with an accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. Its equality-facing rows expose two stream windows, their regular rational readbacks, the dyadic tolerance ledger, the setoid-test row, and the structural transport, replay, provenance, and naming rows.

The first completion-facing classifier available to a consumer is the $\mathsf{RegSeqRat}^{\uparrow}$ readback route. Only after those regular rational rows and the dyadic tolerance ledger have been displayed can the $\mathsf{MetricCompletion}^{\uparrow}$ tolerance and completion rows read the comparison.

Since the carrier contains no quotient equality coordinate, selected representative, host real equality, or independent completion oracle, every completion-facing equality read follows the stated route. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier is consumed only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback route has exposed the regular rational observation and before the $\mathsf{Real}^{\uparrow}$ seal comparison is read, so the setoid row remains an L10 dependency between chapter 301 and chapter 38 rather than an isolated quotient or host-equality surface. The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier route depends substantively on the regular rational readback of chapter 301 and the terminal seal of chapter 38. The completion and Real classifier child routes already display how those dependencies are consumed before any downstream equality-facing reader sees the setoid packet, so the dependency lattice remains a routed finite comparison surface rather than quotient stream equality, host real equality, a selected limit, or ambient completeness. The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ packet is consumed by the regular-rational to real-name seal route: a $\mathsf{RegSeqRat}^{\uparrow}$ readback supplies the displayed Cauchy representative boundary of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ classifier of chapter 38 can then read equality only through that setoid boundary. This route keeps the setoid as a finite dependency row for the Real seal rather than as host quotient equality, selected representatives, countable choice, or ambient real completeness. Every $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier consumer that serves $\mathsf{MetricCompletion}^{\uparrow}$ or separated-completion readers first reads the regular-rational comparison route of chapter 301 and the terminal Real seal route of chapter 38. The setoid classifier is therefore consumed only through displayed regular-rational windows, finite $\mathsf{StreamName}^{\uparrow}$ observations, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ seal rows before completion-facing data is public. Quotient stream equality and selected representatives are excluded from the route, since

no completion consumer receives a classifier except through those displayed rows and their hsame, Cont, Pkg, and NameCert handoff.

Theorem 1820.27 (CauchyEquivalenceSetoid RegSeqRat–Real dependency anchor)**.** *Every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier read consumed by chapter 301 or chapter 38 routes through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and dyadic tolerance ledgers before any terminal Real-facing equality boundary is exposed. Thus the setoid surface supplies a displayed dependency anchor for regular rational readback and Real sealing, not a quotient-stream object, selected representative, host equality relation, or ambient completeness principle.*

The $\mathsf{RegSeqRat}^{\uparrow}$ consumer edge of chapter 301 reads $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ only as a displayed finite classifier. The route is forced through the setoid carrier, the open-tail classifier, and the regular-Cauchy uniqueness boundary before any regular rational readback is exported.

Theorem 1820.28 (RegSeqRat forward link from Cauchy equivalence setoid)**.** *Every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier read used by a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer factors through the finite classifier of Definition 1820.1, the open-tail route of Definition 1820.32, and the regular-Cauchy uniqueness route of Definition 1820.55. Thus a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer receives stream windows, regular rational readback rows, the dyadic tolerance ledger, the setoid-test row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming as one finite route, not as quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Proof. Project the accepted carrier $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ from Definition 1820.1. The only visible comparison surface begins with the two $\mathsf{StreamName}^{\uparrow}$ windows and their two $\mathsf{RegSeqRat}^{\uparrow}$ readback rows.

Apply the open-tail classifier route. It places the dyadic tolerance ledger and setoid-test row after those regular rational readbacks and before the terminal $\mathsf{Real}^{\uparrow}$ seal, so the consumer cannot replace the route by a detached equality of streams.

Finally apply the regular-Cauchy uniqueness route. That route consumes the same displayed classifier rows before exporting any uniqueness-facing regular Cauchy readback, and therefore gives the forward link into chapter 301 without selected representatives, host equality, or an ambient completion principle. □

Theorem 1820.29 (Cauchy equivalence setoid RegSeqRat classifier gate)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must pass through the displayed regular-Cauchy classifier row before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The consumer may then use the forward link to chapter 301 and the seal boundary of chapter 38, but it receives no quotient stream equality, selected representative, host real equality, countable-choice selector, or ambient completion principle outside the displayed classifier route.*

Proof. Project the setoid classifier row from the carrier of Definition 1820.1. This is the only public row that compares two regular Cauchy presentations before a Real-facing read is allowed.

Next apply the RegSeqRat forward link, Definition 1820.28. It sends the consumer through the stream windows, regular rational readback rows, dyadic tolerance ledger, and setoid-test row before any regular-rational data are exported.

Finally read the Real-seal nonescape boundary along the same route. Since the terminal seal is downstream of the displayed classifier and the RegSeqRat handoff, a consumer cannot bypass those rows by using a quotient stream, selected representative, host equality, choice selector, or ambient completion witness. □

The forward equality route for $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ is a finite dependency path through chapter 301, chapter 291, and chapter 38. It keeps the sibling edge outside the hub and records that equality-facing reads are downstream of regular rational and dyadic tolerance data.

Theorem 1820.30 (Cauchy equivalence setoid RegSeqRat–Real forward route)**.** *Every equality-facing read exported by* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *first consumes finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, and only then reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the setoid route exposes regular rational observations and dyadic comparison rows before any Real-facing equality handoff, and it exports no selected representatives, quotient stream object, host real equality, or ambient completeness principle.*

Proof. Project the accepted Cauchy-equivalence carrier from Definition 1820.1. Its comparison surface begins with finite stream windows and regular rational readback rows.

Apply the dyadic tolerance route. The tolerance ledger is read before the Real seal, so a Real-facing equality handoff cannot bypass the dyadic comparison cells.

Finally apply the existing Real classifier dependency route for $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$. It reaches $\mathsf{Real}^{\uparrow}$ only after the regular rational and dyadic rows have been displayed, which gives the stated forward route without selected representatives, quotient stream objects, host real equality, or ambient completeness. □

Theorem 1820.31 (Cauchy equivalence setoid RegSeqRat sibling forward route)**.** *Every* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier read consumed by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing route factors through the displayed sibling rows of* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any Real seal is read. Concretely, the consumer first follows the RegSeqRat sibling route of Definition 1820.25, then the forward link of Definition 1820.28, and finally the RegSeqRat–Real forward route of Definition 1820.30; no quotient stream object, selected representative, host real equality, or detached completion oracle is available outside that finite route.*

Proof. Project the accepted carrier of Definition 1820.1. Its comparison surface already begins with finite stream windows and regular rational readback rows rather than a quotient object.

Apply the sibling route of Definition 1820.25. This forces every equality-facing read to expose the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before the terminal seal can be consumed.

Now use the forward link of Definition 1820.28. The link identifies the same displayed rows as the route read by RegSeqRat-facing consumers, so a completion-facing consumer cannot replace the dependency by selected representatives or host equality.

Finally apply Definition 1820.30. The Real-facing handoff occurs only after the regular rational and dyadic rows have been displayed, which proves the sibling forward route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any Real seal is read. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ packet is also read in reverse from the regular-Cauchy and Real completion side: consumers in chapter 301 and chapter 38 cite its equality-facing classifier only after the displayed regular rational readback, dyadic tolerance ledger, and terminal Real seal have all been exposed. This records the horizontal dependency edge without turning the setoid into quotient stream equality, selected representatives, host real equality, or ambient completeness. When a $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ comparison is restricted to bounded regular Cauchy packets, its equality route consumes the bounded tail-modulus and regular-readback surface of chapter 1697. The comparison first reads the finite threshold row of Definition 1697.6, then keeps the two compared names on the same displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$ route before any setoid classifier may be applied.

Theorem 1820.32 (Open-tail Cauchy equivalence classifier)**.** *Every open-tail classifier read from an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet is the exact sibling route consumed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *completion readback and the terminal* $\mathsf{Real}^{\uparrow}$ *classifier boundary. It first exposes the two* $\mathsf{StreamName}^{\uparrow}$ *finite windows, then the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and setoid-test row, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. Completion-facing consumers may read that route through chapter 1506, but they receive no quotient stream equality, selected representative, host real equality, or detached completion oracle.*

Proof. Project the carrier of Definition 1820.1. An open-tail read begins with the two visible stream windows and their regular rational readback rows.

Use the RegSeqRat completion classifier route of Definition 1820.26. That route places the regular rational readbacks before the metric-completion tolerance and completion rows, so the comparison is already a displayed finite classifier before any completion consumer can inspect it.

Finally use the Real classifier consumer of Definition 1820.24. The terminal Real boundary is reached only after the dyadic tolerance ledger and setoid-test row are visible, and the packet has no coordinate for quotient equality or selected representatives. □

Theorem 1820.33 (Cauchy equivalence setoid open-tail forward link)**.** *Every accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet that is consumed by an open-tail classifier route sends its setoid comparison forward through the displayed route of Definition 1820.32. The consumer first reads the two* $\mathsf{StreamName}^{\uparrow}$ *finite windows, then the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback rows, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and local setoid-test row, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *completion seal. Thus the open-tail route is a child dependency of the setoid packet rather than a detached completion oracle.*

Proof. Project the accepted carrier from Definition 1820.1. Its visible comparison data are the two stream names, their regular-rational readbacks, the dyadic tolerance ledger, the local setoid-test row, transport, replay, provenance, and local naming.

Apply the open-tail classifier route of Definition 1820.32. That route already orders the finite windows before the $\mathsf{RegSeqRat}^{\uparrow}$ rows and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before the terminal $\mathsf{Real}^{\uparrow}$ seal.

Consequently a consumer that asks for the open-tail classifier consumes the same setoid comparison surface. Since the carrier has no coordinate for quotient stream equality, selected representatives, host real equality, or a detached completion point, the forward link is exactly the displayed child route. □

Theorem 1820.34 (Open-tail Cauchy equivalence transitivity route)**.** *Every open-tail classifier route from an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet composes Cauchy-equivalence transitivity with the* $\mathsf{Real}^{\uparrow}$ *completion readback as a finite NameCert route. If two displayed comparisons share the middle regular-Cauchy read, then the consumer first reads the two* $\mathsf{StreamName}^{\uparrow}$ *window pairs, then the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and transitivity row, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *completion seal of chapter 38. The route is available to completion consumers through chapter 1506, but it exports no quotient stream equality, selected representative, host real equality, or detached completion point.*

Proof. Project the accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. The two open-tail comparisons expose their finite stream windows and regular rational readbacks before the setoid classifier can be consumed.

Use the open-tail classifier route of Definition 1820.32. Each comparison is already constrained to the same StreamName, RegSeqRat, DyadicRatCore, and RealUp route, so the shared middle read is a displayed row rather than a quotient representative.

Now compose the two displayed tolerance ledgers by the transitivity row carried by the setoid packet. The resulting comparison remains in the same BHist surface and is transported by the packet hsame row and replayed by its Cont row.

Finally pass the composed classifier to the Real completion readback. Since the terminal seal is downstream from the displayed windows, readbacks, dyadic ledger, transitivity row, transport, replay, provenance, and local naming, no host equality or detached completion point is introduced. □

Theorem 1820.35 (Cauchy equivalence setoid tail transitivity choice-free)**.** *Composing two open-tail comparisons in an accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *packet with a shared middle read uses only the displayed finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks,* DyadicRatCore$^{\uparrow}$ *tolerance transitivity,* Real$^{\uparrow}$ *completion readback, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows. The composite exports no selected representative, quotient stream equality, host real equality, detached completion point, countable-choice schedule, or ambient completeness row.*

Proof. Start with the open-tail route of Definition 1820.34. The two comparisons are already displayed as finite StreamName windows and RegSeqRat readbacks with one shared middle read.

Next read the DyadicRatCore tolerance rows attached to those two comparisons. Their transitivity row composes the displayed tail bounds inside the same BHist packet, so no representative of a quotient stream is selected.

Now transport the composite through the packet hsame row and replay it through the displayed Cont row. The Pkg provenance and local NameCert rows keep the composite attached to the same CauchyEquivalenceSetoid surface.

Finally send the composed comparison to the Real completion readback named in the open-tail route. Since the terminal Real seal consumes only the displayed windows, readbacks, dyadic transitivity, transport, replay, provenance, and local naming rows, it cannot add quotient equality, host real equality, detached completion points, choice data, or ambient completeness. □

Theorem 1820.36 (CauchyEquivalenceSetoid tail stability)**.** *Let* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ *be an accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *carrier. Replacing both compared regular rational windows by later displayed tails preserves the local* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier whenever the later windows are read through the same* StreamName$^{\uparrow}$ *schedules,* RegSeqRat$^{\uparrow}$ *readbacks, dyadic tolerance ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

The preserved classifier is still the finite row T *over the displayed tails. It exports no quotient stream equality, selected representatives, host real equality, countable choice, hidden cofinal tail, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 1820.1. The classifier can inspect only the two StreamName$^{\uparrow}$ finite windows, the two RegSeqRat$^{\uparrow}$ readbacks, the DyadicRatCore$^{\uparrow}$ tolerance ledger, the setoid-test row, the Real seal boundary, and the structural rows.

Pass to later displayed tails by finite tail projection on S_0 and S_1. The corresponding readbacks remain rows of R_0 and R_1, and every admitted comparison still uses the same dyadic tolerance ledger D.

Transport the projected windows componentwise through H and replay the read order through C. The rows P and N keep the tail comparison attached to the same package provenance and local NameCert surface.

Thus the setoid-test row T is preserved over the later displayed tails. Since no carrier row names quotient stream equality, selected representatives, host real equality, countable choice, hidden

cofinal tails, or ambient completeness, tail stability is exactly the displayed finite classifier route. □

Theorem 1820.37 (CauchyEquivalenceSetoid uniform completion consumer)**.** *Every* $\mathsf{UniformSpaceCompletion}^{\uparrow}$*-facing read from an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet factors through the displayed regular-Cauchy classifier, the completion dependency lattice, the* $\mathsf{RegSeqRat}^{\uparrow}$ *completion classifier route, and the* $\mathsf{Real}^{\uparrow}$ *classifier consumer before it can be consumed by chapter 3560. Thus the consumer receives stream-window comparison, regular rational readback, dyadic tolerance, setoid-test, completion handoff, Real classifier boundary, transport, replay, provenance, and local naming rows; it cannot replace those classifier rows by host quotient equality or by a selected representative.*

Proof. Start with an accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. The completion dependency lattice forces the equality read through the regular-Cauchy classifier before any completion-facing consumer can see it.

Next use the $\mathsf{RegSeqRat}^{\uparrow}$ completion classifier route. This route exposes the regular rational readback and dyadic tolerance ledger before the comparison reaches a completion handoff, so the uniform-completion consumer cannot receive a detached quotient equality.

Finally use the $\mathsf{Real}^{\uparrow}$ classifier consumer. It sends the same finite comparison through the Real classifier boundary and then repacks the result through the packet projection, transport, replay, provenance, and local NameCert rows. Since none of these rows contains a selected representative or host quotient coordinate, the $\mathsf{UniformSpaceCompletion}^{\uparrow}$ read remains on the displayed classifier route. □

Theorem 1820.38 (Cauchy equivalence setoid Real separability route)**.** *Let* $Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$ *be an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *carrier. Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer that exports a* $\mathsf{Real}^{\uparrow}$ *read from* Q *factors through the displayed Cauchy equivalence row, the regular rational readback rows* R_0, R_1*, the terminal Real seal row* E*, and the finite density route of chapter 1809. In particular, the consumer may inspect only*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D, T \longmapsto E \longmapsto H, C, P, N$$

before it reaches the Real-separability density read.

Proof. Start with an accepted consumer of Q that exports a Real-separability read. By Definition 1820.1, the only equality-facing rows available to that consumer are the two StreamName windows, the two RegSeqRat readback rows, the dyadic tolerance ledger, the setoid-test row, the Real seal boundary, and the structural rows.

Apply Definition 1820.3 and Definition 1820.5. These force the Cauchy equivalence row to be read as finite classifier data over S_0, S_1, R_0, R_1, D, T, with no quotient-equality or host-equality coordinate.

Next use the sibling route through chapter 301, chapter 38, and chapter 1809. The regular rational readback is inspected before E, and the finite density route of $\mathsf{RealSeparability}^{\uparrow}$ is available only after that Real seal has been displayed.

This is the forward dependency that moves the density surface of chapter 1809 through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier before $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are consumed.

Finally, Definition 1820.4 keeps the route componentwise under H, while C, P, N replay, source, and name the same rows. Thus every Real-separability consumer factors through the displayed Cauchy equivalence, RegSeqRat readback, Real seal, and density route. □

Theorem 1820.39 (Cauchy equivalence setoid Real-separability forward link)**.** *The* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier route is the forward source consumed by the* RealSeparability$^{\uparrow}$ *RegSeqRat dependency lattice. Any consumer using chapter 1809 together with the regular rational surface of chapter 301 must first read the displayed Cauchy-equivalence classifier rows, the two RegSeqRat readback rows, the dyadic tolerance ledger, and the Real seal boundary supplied by the accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *packet.*

Consequently the RealSeparability density surface receives a finite Cauchy/RegSeqRat comparison route rather than a quotient stream equality, selected representative, host real equality, countable-choice selector, or ambient completeness row.

Proof. Begin with the accepted CauchyEquivalenceSetoid$^{\uparrow}$ classifier route. Its visible source rows are the two StreamName windows, the two RegSeqRat readback rows, the dyadic tolerance ledger, the setoid-test row, the Real seal boundary, and the hsame, Cont, Pkg, and local NameCert support.

Apply Definition 1820.38. That route places the RealSeparability consumer after the Cauchy-equivalence classifier, the RegSeqRat readback rows, and the Real seal boundary, so the density read cannot bypass the displayed setoid comparison.

Now read the RegSeqRat dependency through chapter 301. The same regular rational rows that feed the Cauchy-equivalence classifier are the rows consumed by the RealSeparability lattice, and chapter 1809 receives them as finite classifier-facing data.

The route is consumed by chapter 1809 because the Cauchy-equivalence setoid classifier rows provide the dense-read equality surface used by RealSeparability$^{\uparrow}$.

The excluded objects have no source row in this route. Quotient stream equality, selected representatives, host real equality, countable-choice selectors, and ambient completeness data are not among the displayed classifier, readback, tolerance, seal, transport, continuation, package, or naming rows, so they cannot serve as a second forward dependency. □

The backward dependency from RealSeparability$^{\uparrow}$ to CauchyEquivalenceSetoid$^{\uparrow}$ is the classifier-facing half of the finite density route. Before a separability packet exports a countable dense display as in chapter 1809, it reads the Cauchy-equivalence classifier to keep equivalent regular names on the same displayed density window. The dependency is therefore a finite comparison and density handoff, not quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness.

Proposition 1820.40 (RealSeparability backward dependency)**.** *Every* RealSeparability$^{\uparrow}$ *consumer that exports a countable dense display through chapter 1809 reads the accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier before the dense display is exposed. Consequently the exported density row is stable under the displayed Cauchy-equivalence comparison, and the route exports no quotient stream, selected representative, countable-choice selector, host real equality, or ambient completeness row.*

Proposition 1820.41 (Cauchy equivalence setoid dense-readback consumer route)**.** *The* CauchyEquivalenceSetoid$^{\uparrow}$ *packet supplies the classifier boundary consumed by the dense-readback routes of chapter 1809. In particular, every dense* RealSeparability$^{\uparrow}$ *read that identifies a rational or regular-rational approximation through Cauchy-tail agreement must keep the equivalence-setoid row upstream of the* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*, and* Real$^{\uparrow}$ *readback rows, so the dense consumer receives a finite classifier boundary rather than quotient stream equality, host real equality, or a selected completion representative.*

Proof. Project the CauchyEquivalenceSetoid$^{\uparrow}$ carrier through the existing real-classifier and uniform-completion routes. Those routes expose the Cauchy-tail classifier before any regular rational or Real-facing seal is consumed.

The dense-readback packet of chapter 1809 uses that same boundary when it names approximating rationals. Since the setoid row is already upstream of the StreamName, RegSeqRat, DyadicRatCore, and Real rows, the dense consumer cannot replace it by quotient stream equality or by a host-selected representative. □

Theorem 1820.42 (CauchyEquivalenceSetoid RealSeparability forward scope)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-modulus consumer that reads through an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must first pass through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *schedule of chapter 5728, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before exporting density through chapter 1809. The route exports no quotient equality, selected representative, countable choice, or ambient completeness principle.*

Proof. Project the local CauchyEquivalenceSetoid carrier of Definition 1820.1. Its visible rows begin with two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the setoid-test row, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Next route the dense-modulus request through chapter 5728. The bridge supplies the explicit Cauchy-modulus schedule before the RealSeparability consumer may export density.

Finally read the separability endpoint of chapter 1809. Because the carrier and bridge expose only the displayed finite rows, the route cannot appeal to quotient equality, selected representatives, countable choice, or ambient completeness. □

Theorem 1820.43 (CauchyEquivalenceSetoid RealSeparability route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-readback consumer of* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *first reads the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks of chapter 301, dyadic tolerance data, the displayed setoid classifier, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local naming rows. Thus the downstream route to chapter 1809 is a finite dependency row through the Cauchy-equivalence carrier, not quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Theorem 1820.44 (Cauchy equivalence setoid Real-separability sibling route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-route consumer that reads an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must first traverse the finite sibling route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RealSeparability}^{\uparrow}.$$

Concretely, the consumer reads the two $\mathsf{StreamName}^{\uparrow}$ *windows, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the setoid-test row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and then the componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows before density is public through chapter 1809. The route exports no quotient stream equality, selected representative, host real equality, countable-choice selector, or ambient completeness row.*

Proof. Start with the carrier and surface theorems Definition 1820.1 and Definition 1820.5. They list exactly the two stream windows, two regular-rational readbacks, dyadic ledger, setoid-test row, Real seal, transport, replay, provenance, and local naming rows.

Apply the classifier laws and transport discipline, Definition 1820.3 and Definition 1820.4. These keep the setoid-test row finite over the displayed StreamName, RegSeqRat, and DyadicRatCore rows before the Real seal is consumed.

Now use the existing Real-separability routes Definition 1820.38, Definition 1820.39, and Definition 1820.14. They place the dense-route consumer of chapter 1809 after the same classifier and Real-seal surface.

Thus the public density read is available only after the sibling route has displayed every row in order. Since none of the cited carrier rows contains quotient equality, selected representatives, host equality, choice, or ambient completeness, the Real-separability consumer receives only the finite sibling edge. □

Theorem 1820.45 (Cauchy equivalence setoid Real-separability forward lattice repair)**.** *Every downstream* $\mathsf{RealSeparability}^{\uparrow}$ *dense-route consumer that cites chapter 1809 from the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *side must first read the displayed sibling rows*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CauchyEquivalenceSetoid}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Thus the RealSeparability citation is a horizontal sibling edge after the finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, CauchyEquivalenceSetoid test row, and RealUp seal have all been displayed.

Proof. Apply Definition 1820.44. It already forces the dense-route consumer through the StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and RealUp rows before any $\mathsf{RealSeparability}^{\uparrow}$ read is public.

The explicit endpoint is the sibling chapter chapter 1809. Therefore the citation to RealSeparability is not a self-reference inside the CauchyEquivalenceSetoid packet, but a finite lattice edge whose source rows have already been displayed. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier is the forward lattice edge used when $\mathsf{RealSeparability}^{\uparrow}$ reads Cauchy-tail agreement as dense-readback data. It is placed before the stream, regular-sequence, dyadic, and real readback rows are treated as a dense route.

Theorem 1820.46 (Cauchy equivalence setoid Real-separability forward lattice)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense-readback consumer that uses Cauchy-tail agreement must read the displayed* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier before the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readback rows can be treated as a dense route. The consumer receives a finite classifier edge from the accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet to chapter 1809; it receives no quotient stream equality, selected representative, countable-choice selector, host real equality, or ambient completeness row.*

Proof. Start with the carrier surface of Definition 1820.1. Its displayed rows expose the two stream windows, two regular-rational readbacks, dyadic tolerance ledger, setoid-test row, terminal Real seal, componentwise transport, continuation replay, provenance, and local naming data.

The dense-readback consumer may use Cauchy-tail agreement only after the setoid-test row has been inspected. Therefore the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier is the row that turns the surrounding $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readbacks into a route toward $\mathsf{RealSeparability}^{\uparrow}$.

Finally apply the existing Real-separability sibling and route statements, Definition 1820.44 and Definition 1820.38. They place chapter 1809 after the same finite classifier boundary, so the forward lattice edge adds no quotient equality, selected representative, countable-choice selector, host real equality, or ambient completeness claim. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ family also supplies the forward classifier route consumed by $\mathsf{RealSeparability}^{\uparrow}$ dense-read and setoid-modulus schedules. The route in Definition 1820.44 keeps the two $\mathsf{StreamName}^{\uparrow}$ windows, the two $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the Cauchy-equivalence classifier, and the terminal $\mathsf{Real}^{\uparrow}$ seal visible before the dense consumer reaches chapter 1809. Thus the separability lattice receives a finite classifier boundary

rather than quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness.

Theorem 1820.47 (Cauchy equivalence setoid Real-separability reverse route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *dense read that uses regular Cauchy representatives must preserve the same* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier before any dense-seal comparison is exported. Thus a consumer returning from chapter 1809 to the Cauchy-equivalence surface must keep the two StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, setoid-test row, terminal Real seal, transport, replay, provenance, and local naming rows visible.*

Proof. Start with the accepted Cauchy-equivalence carrier and local classifier route. The route in Definition 1820.38 sends a Real-separability consumer through the displayed StreamName, RegSeqRat, DyadicRatCore, setoid-test, and Real-seal rows before density is public.

Now read the dense-seal comparison back through chapter 1809. A Real-separability dense read supplies a countable dense surface only after its regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows have been displayed.

The reverse route therefore preserves the original classifier row. If the consumer dropped it, the returned dense-seal comparison would be a quotient stream equality, selected representative, countable-choice selector, host real equality, or ambient completeness claim, none of which is present in the accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. □

Theorem 1820.48 (Cauchy equivalence setoid Real-separability backlink)**.** *The* $\mathsf{RealSeparability}^{\uparrow}$ *dense surface consumes the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier through the regular Cauchy and real-name routes. Concretely, any citation from chapter 1809 back to the setoid packet must first display the regular rational readback of chapter 301, the Cauchy equivalence classifier row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38; only then may the dense surface read the setoid route as a horizontal dependency.*

Proof. Start with the accepted $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. Its classifier row is not a free equality principle; it is read through StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, the setoid test row, and the terminal Real seal.

The RealSeparability surface can therefore consume the setoid packet only after those same rows have been displayed. The regular Cauchy route supplies the readback discipline, the RealUp route supplies the name seal, and the dense surface records the resulting edge without selecting representatives or quotienting completed streams. □

Theorem 1820.49 (CauchyEquivalenceSetoid RegSeqRat Real classifier bridge)**.** *Every equality-facing comparison accepted by* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *displays two* $\mathsf{StreamName}^{\uparrow}$ *windows, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier before any* $\mathsf{Real}^{\uparrow}$ *seal or separated-completion consumer may read equality. Thus the bridge from regular rational readback to Real-facing and completion-facing equality is a finite classifier route, not quotient stream equality, selected representatives, host real equality, countable choice, or ambient Real completeness.*

Proof. Start with the carrier and local surface of Definition 1820.1 and Definition 1820.5. They expose exactly the two stream windows, two regular-rational readback rows, dyadic tolerance ledger, setoid-test row, Real seal boundary, transport, replay, provenance, and local naming.

Apply the RegSeqRat–Real route of Definition 1820.30. It orders finite $\mathsf{StreamName}^{\uparrow}$ observations before $\mathsf{RegSeqRat}^{\uparrow}$ readback and places the dyadic comparison ledger before the terminal $\mathsf{Real}^{\uparrow}$ seal.

Use the separated-completion route of Definition 1820.56. A completion-facing reader receives equality only after the same displayed classifier rows have been consumed.

Since the carrier contains no quotient stream, selected representative, host equality, choice, or ambient-completeness coordinate, the composed bridge exports only the finite classifier route. □

Theorem 1820.50 (CauchyEquivalenceSetoid concrete RegSeqRat Real route)**.** *Every completion-facing consumer that uses the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier as a RegSeqRat-to-Real equality route must first read the regular rational comparison surface of chapter 301 and then the terminal seal boundary of chapter 38. The consumed packet is the displayed route through* $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$*, not quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Proof. Start with the carrier and NameCert surface of Definition 1820.1 and Definition 1820.5. They display the two StreamName windows, two RegSeqRat readback rows, dyadic tolerance ledger, setoid-test row, Real seal boundary, and structural rows before any equality-facing consumer may inspect the result.

Apply the RegSeqRat Real classifier bridge of Definition 1820.49. It orders the regular rational readback through chapter 301 before the Real-facing seal route of chapter 38.

Finally use the Real seal forward route of Definition 1820.8. The downstream consumer receives the same finite classifier route and no excluded quotient, selected representative, host equality, choice, or ambient-completeness object. □

The Cauchy-space route for $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ is a child dependency of the finite regular-rational comparison surface. A consumer in chapter 1847 reads the setoid only after the regular rational windows of chapter 301 have exposed the comparison rows, and before the completion-facing seals of chapter 1506 or chapter 38 may consume them.

Theorem 1820.51 (CauchySpace route for Cauchy-equivalence setoids)**.** *Every* $\mathsf{CauchySpace}^{\uparrow}$ *consumer that uses a* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison must read it through the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison route before any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is available. Thus the setoid supplies a routed comparison row for Cauchy-space and metric-completion consumers, not a detached quotient equality or a host representative selector.*

Proof. Read the setoid comparison as a regular-rational route. The sibling surface of chapter 301 supplies the finite windows through which two Cauchy names become comparable.

The Cauchy-space consumer of chapter 1847 can then import that comparison as one row in its finite filter-uniform route. It has not yet reached a metric-completion seal or a terminal real seal.

Only downstream of that route may chapter 1506 and chapter 38 consume the comparison. Because the route stores no quotient equality, selected representative, or host equality test, the setoid remains a finite dependency edge in the L10 completion lattice. □

The $\mathsf{CauchySpace}^{\uparrow}$ consumers of chapter 1847 read $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ from chapter 1820 only after the $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, setoid-test row, terminal $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, and NameCert rows are visible. Thus the setoid packet reaches Cauchy-space as a routed finite comparison surface, not as a detached quotient representative or host equality selector.

Theorem 1820.52 (Completion and real dependency readback)**.** *Every* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *read consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchySpace}^{\uparrow}$*,* $\mathsf{UniformSpaceCompletion}^{\uparrow}$*, or* $\mathsf{RealSeparability}^{\uparrow}$

is available only through the displayed classifier and readback rows of the accepted packet. More precisely, a consumer may inspect the two StreamName$^{\uparrow}$ *windows, the two* RegSeqRat$^{\uparrow}$ *readback rows of chapter 301, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the setoid-test classifier, the terminal* Real$^{\uparrow}$ *seal of chapter 38, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The completion-facing consumers of chapter 3560 and the density-facing consumers of chapter 1809 receive exactly that route, so the setoid remains a child dependency of the Real-completion lattice rather than a top-level quotient stream, selected representative, countable-choice selector, host real equality, or ambient completeness principle.*

Proof. Start with an accepted CauchyEquivalenceSetoid$^{\uparrow}$ carrier. Its public coordinates are the two stream windows, the two regular-rational readback rows, the dyadic tolerance ledger, the setoid-test classifier, the Real seal boundary, transport, replay, provenance, and local naming.

The RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers read these coordinates in the order already exposed by the classifier route. The CauchySpace$^{\uparrow}$ consumer of chapter 1847 receives the same comparison row only after the regular-rational readback and Real seal have been displayed.

For completion and separability consumers, apply the uniform-completion and real-separability routes. They consume the displayed comparison after the same readback and classifier rows, and neither route adds a quotient equality, selected representative, countable-choice selector, host real equality, or ambient completeness coordinate. Hence every listed sibling reads the setoid only through the displayed dependency route. □

The CauchyEquivalenceSetoid$^{\uparrow}$ equality surface is consumed by chapter 1569 and chapter 1506 only through the completion-filter route that first exposes StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, the DyadicRatCore$^{\uparrow}$ tolerance ledger, the terminal Real$^{\uparrow}$ seal, and then the displayed BHist, hsame, Cont, Pkg, and NameCert rows. The route supplies equality inspection for completion consumers without exporting quotient representatives, selected limits, ambient metric completeness, countable choice, or host real equality. The CauchyEquivalenceSetoid$^{\uparrow}$ completion reads consume the finite Cauchy-filter route of chapter 333 before the regular-sequence and real-name consumers identify tail-equivalent regular Cauchy names. In this route, the filter base fixes the displayed tail packets and Cauchy-modulus rows, chapter 301 reads them as regular rational sequence evidence, and chapter 38 seals the same data as a terminal real-name consumer without adding quotient filters, selected limits, or ambient completeness.

Theorem 1820.53 (CauchyEquivalenceSetoid sibling route)**.** *Every setoid-classifier read exported by an accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *packet consumes the finite sibling route through chapter 126, chapter 301, chapter 291, and chapter 38 before any* RealEquality$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer may inspect it. After the* RealEquality$^{\uparrow}$ *boundary is displayed,* MetricCompletion$^{\uparrow}$ *and* SeparatedCompletion$^{\uparrow}$ *consumers routed through chapter 1612 may consume the classifier only after the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *and* RealEquality$^{\uparrow}$ *rows are displayed. The route reads finite stream windows, regular rational readbacks, the dyadic tolerance ledger, and the terminal real-name seal as displayed rows; it does not export host real equality, quotient setoid classes, selected representatives, countable choice, or ambient completion.*

Proof. Project the accepted setoid packet to its classifier route. The sequence-facing entry is a displayed StreamName$^{\uparrow}$ row, so a consumer first reads finite windows rather than a completed stream or selected representative.

The regular rational readback is then consumed through the RegSeqRat$^{\uparrow}$ sibling route. Its tolerance comparisons are read only through the DyadicRatCore$^{\uparrow}$ ledger, which supplies the finite dyadic budget used by the classifier.

Only after those rows are fixed can the terminal $\mathsf{Real}^{\uparrow}$ seal be inspected. The $\mathsf{RealEquality}^{\uparrow}$ consumer of chapter 1636 reads the setoid classifier only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows have been fixed.

The completion consumers are downstream of that equality boundary. $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{SeparatedCompletion}^{\uparrow}$ may consume the classifier only after the RealEquality row is displayed, so they receive a routed setoid classifier over displayed rows, not host real equality or a quotient completion object. □

Theorem 1820.54 (CauchyEquivalenceSetoid quotient-boundary completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet must read quotient-boundary refusal through chapter 1708 and completion readiness through chapter 3452 before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is exposed. The setoid route therefore reaches Real readback only after the quotient boundary, regular Cauchy completion criterion, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed; it does not export quotient classes, selected representatives, host real equality, countable choice, or ambient completion.*

Proof. Project the accepted setoid packet to its completion-facing classifier rows. The quotient-boundary chapter supplies the refusal surface, so the consumer first learns that the route is not a quotient-class construction.

Next read the regular Cauchy completion criterion. It exposes the finite completion readiness rows before any Real seal can be inspected, and it keeps the route on displayed regular-Cauchy data rather than a selected representative.

The structural rows then transport, replay, source, and name the same route. Thus the terminal Real readback is downstream of quotient-boundary refusal and completion readiness, not a replacement for them. □

The $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ seal route of chapter 3390 may consume the finite classifier supplied by $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ before it reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. This makes the setoid packet a horizontal dependency for regular Cauchy uniqueness rather than an isolated equality-facing classifier.

Theorem 1820.55 (RegularCauchyUniqueness CauchyEquivalenceSetoid route)**.** *Every* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *seal read that consumes a* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet first traverses the finite classifier route of Definition 1820.1, the classifier laws of Definition 1820.3, and the NameCert surface of Definition 1820.5. Thus the uniqueness consumer reads* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the setoid-test row, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, transport, replay, provenance, and local naming before it treats the regular Cauchy seal as independent of representative choice.*

Proof. Project the local $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier. Its visible route is the pair of stream windows, pair of regular readback rows, dyadic tolerance ledger, setoid-test row, Real seal boundary, and structural rows.

Apply the classifier laws and NameCert surface. Reflexivity, symmetry, transitivity, tolerance exactness, seal nonescape, transport, replay, provenance, and local naming are all supplied by the same finite rows, so the uniqueness consumer receives classifier data rather than quotient stream equality.

Finally compare with chapter 3390. The $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ carrier already reads paired $\mathsf{RegSeqRat}^{\uparrow}$ names, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data, a comparison row, and a terminal $\mathsf{Real}^{\uparrow}$ seal. The setoid packet supplies that comparison row through the displayed finite

classifier route, with no selected representative, host real equality, countable choice, or ambient completeness. □

Theorem 1820.56 (CauchyEquivalenceSetoid separated-completion forward route)**.** *Every* $\mathsf{SeparatedCompletion}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *packet consumes the setoid boundary through chapter 1612 after the displayed* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been exposed. The route is a finite comparison handoff into separated completion, not quotient completion equality, selected representatives, host real equality, countable choice, or ambient Real completeness.*

Proof. Start with the CauchyEquivalenceSetoid carrier of Definition 1820.1. It exposes two finite StreamName windows, two RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the setoid-test row, and the Real seal boundary.

Use the downstream equality dependency and completion dependency routes already displayed in this chapter. They place completion-facing consumers behind the same finite comparison data rather than behind a quotient of Cauchy names.

Now read the separated-completion carrier. Its Cauchy-equivalence source row consumes the displayed CauchySequenceEquivalence, RegSeqRat, StreamName, DyadicRatCore, and Real rows before separated comparison is available. Hence the forward route into $\mathsf{SeparatedCompletion}^{\uparrow}$ is exactly the finite setoid boundary and not a quotient-completion equality. □

Theorem 1820.57 (SeparatedCompletion displayed setoid dependency)**.** *Every* $\mathsf{SeparatedCompletion}^{\uparrow}$ *read that cites the Cauchy-equivalence component of its carrier reads it only as displayed classifier evidence from the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *surface of Definition 1820.1. Thus the route through chapter 1612 consumes the finite setoid rows* $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$ *before separated-completion equality is exported, and it does not replace those rows by quotient classes, selected representatives, host real equality, or ambient completeness.*

Proof. Project the separated-completion carrier through its Cauchy-equivalence source row. The row is a consumer of displayed classifier evidence, so it must read the local $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ carrier before the separated-completion export is available.

The carrier of Definition 1820.1 lists exactly the two stream windows, two regular-rational readbacks, dyadic tolerance ledger, setoid-test row, real seal boundary, componentwise transport, replay, provenance, and local naming rows. These are the rows read by the separated-completion route.

Since no quotient class, selected representative, host real equality, or ambient-completeness witness appears in that carrier, the reverse dependency records only the displayed classifier route into chapter 1612. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier is consumed by separated-completion and metric-completion readers only after the regular rational stream rows and terminal real-name rows have been displayed. The route reads chapter 301 for regular-Cauchy comparison data, chapter 38 for the Real seal that preserves the same comparison window, and chapter 1506 for the completion-facing tolerance consumer.

Route statement. A separated-completion or metric-completion consumer may use $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ as a sibling lattice edge through the sequence

$$\mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{MetricCompletion}^{\uparrow},$$

but it receives no quotient real equality, selected representative, ambient completion theorem, or host equivalence relation beyond the displayed classifier rows. The equality-facing reads of $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ are also consumed by the cut-to-stream comparison route of chapter 2312. Before the setoid route is compared with a located lower–upper cut packet, the exposed cut rows must display $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and the $\mathsf{Real}^{\uparrow}$ seal boundary, so the comparison remains a finite L10 dependency rather than quotient equality or a selected limit.

Theorem 1820.58 (Cauchy equivalence setoid Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *lattice must route through the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The setoid boundary may identify regular Cauchy names only after those sibling rows are displayed, and it exports no isolated quotient token that can bypass the L10 lattice.*

Proof. Start from the existing Cauchy-equivalence setoid packet and read its classifier route through the sibling dependency lattice. The displayed equality surface is attached to finite stream observations, regular rational readback, and dyadic tolerance comparisons before any real-facing consumer can inspect a seal.

The $\mathsf{StreamName}^{\uparrow}$ windows determine which finite observations are compared. The $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational source names, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance ledger that makes the Cauchy comparison meaningful.

Only after those rows have been retained may the $\mathsf{Real}^{\uparrow}$ seal be read. Therefore the setoid cannot export a detached quotient credential, selected representative, host real equality, or ambient completeness row; every Real-facing read stays on the displayed StreamName, RegSeqRat, DyadicRatCore, and Real route. □

The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ row feeds the Cauchy–Dedekind gap-router comparison of chapter 5906 only after the finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ classifier rows have been displayed. This keeps the equality-facing setoid as an L10 dependency route into the router rather than a quotient stream, selected representative, host real equality, or ambient completeness surface.

Theorem 1820.59 (Cauchy setoid modulus extraction route)**.** *Every* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *consumer that needs an explicit representative-tail schedule must route the tail read through* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *before it asks* $\mathsf{RegSeqRat}^{\uparrow}$ *for finite-window readback or* $\mathsf{Real}^{\uparrow}$ *for terminal seal rows. The extraction route is*

$$\mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{CauchyModulusBridge}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the setoid interface remains a finite schedule route for displayed representative tails, not a quotient-only sink and not a source of selected representatives, quotient Real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ consumer to the representative-tail rows it actually reads. An explicit tail schedule is not a bare setoid verdict: it contains a displayed request for the point at which the two representative reads are compared.

Route that request through chapter 5728. The $\mathsf{CauchyModulusBridge}^{\uparrow}$ ledger is the finite surface that mediates the schedule before any regular rational readback can be consumed.

After the bridge row is visible, the consumer may read the RegSeqRat$^{\uparrow}$ finite windows and then the terminal Real$^{\uparrow}$ seal rows. Since no step introduces a quotient representative, a selected limit, a choice schedule, or an ambient completeness coordinate, the setoid cannot be used as a quotient-only sink. □

The CauchyEquivalenceSetoid$^{\uparrow}$ lattice reads CauchyModulus$^{\uparrow}$ bridge data before any Real$^{\uparrow}$ seal consumer may treat tail equivalence as a usable completion classifier. The sibling dependency on chapter 5728 keeps representative-tail schedules visible as finite modulus rows, so downstream completion reads pass through displayed tail thresholds, regular rational windows, and the terminal Real seal rather than through an unrecorded quotient-equivalence sink.

Theorem 1820.60 (CauchyEquivalenceSetoid RealModulusExtraction forward link)**.** *Every* RealModulusExtractio *consumer that treats a regular-Cauchy witness as a stable real-facing modulus must first read the* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier rows of Definition 1820.1. The required route exposes two* StreamName$^{\uparrow}$ *windows, two* RegSeqRat$^{\uparrow}$ *readbacks, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the setoid-test row, the* Real$^{\uparrow}$ *seal boundary,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row before the downstream chapter 3848 consumer may name the modulus as stable.*

Proof. Project the carrier of Definition 1820.1. Its displayed coordinates include the paired stream windows and paired regular rational readbacks whose comparison is measured by the dyadic tolerance ledger and the setoid-test row.

The RealModulusExtraction$^{\uparrow}$ consumer reads a regular-Cauchy witness only as real-facing data. Therefore the route must pass through the same Real$^{\uparrow}$ seal boundary and preserve the comparison by the componentwise hsame transport and displayed Cont replay rows.

When the downstream modulus is read as an extracted Cauchy threshold, the same forward link also factors through chapter 641 before the Real-facing modulus row is named.

Finally, the provenance and local naming rows keep this as a CauchyEquivalenceSetoid$^{\uparrow}$ classifier dependency rather than a host equality or selected representative. The downstream chapter 3848 chapter can then consume a stable modulus route only after the listed classifier rows have been displayed. □

Theorem 1820.61 (CauchyEquivalenceSetoid located completion forward link)**.** *Every* LocatedCompactCompletio *or completion-facing consumer that reads a regular-Cauchy stream as a stable located real route must first consume the* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier side of Definition 1820.1. The route passes through the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located compact completion handoff of chapter 6172. It exposes paired stream windows, paired* RegSeqRat$^{\uparrow}$ *tails, the* Real$^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before the downstream completion packet may treat the classifier as stable.*

Proof. Project the classifier rows from Definition 1820.1. The setoid side compares two regular-Cauchy names by paired stream windows and paired regular rational tails, so a located completion consumer cannot read a single representative without first displaying the comparison rows.

The RegSeqRat and Real sibling chapters provide the forward handoff. The regular rational rows are read through chapter 301, and the terminal seal is read through chapter 38; the located compact completion consumer then receives the same classifier route through chapter 6172.

Transport, replay, provenance, and local naming keep the route inside the displayed CauchyEquivalenceSetoid$^{\uparrow}$ classifier. Thus the forward link supplies the classifier side for located completion consumers without selecting representatives, identifying quotient completions, choosing limits, or asserting host real equality. □

The CauchyEquivalenceSetoid$^{\uparrow}$ lattice reads RegSeqRat comparison rows through chapter 301 and terminal Real classifier rows through chapter 38. When the located dyadic real route of chapter 6192 is present, it supplies the finite located tolerance handoff between those rows without adding quotient stream equality, selected limits, or ambient Real completeness. The compact-metric continuous-image route reads CauchyEquivalenceSetoid$^{\uparrow}$ only through the displayed RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ classifier rows before any image-net or compactness consumer is reached. In particular, the finite image-net handoff of chapter 3605 and the total-bounded image carrier of chapter 3924 consume Cauchy equivalence as a regular-rational comparison surface with Real-seal readback, not as quotient stream equality, selected limits, host real equality, or ambient completeness. The CauchyEquivalenceSetoid$^{\uparrow}$ route is consumed by the Real$^{\uparrow}$ completion classifier of chapter 38. A regular Cauchy name routed through RegSeqRat$^{\uparrow}$ reaches the Real seal only after equality of regular Cauchy names has been read through the displayed setoid; the classifier exported by the Real completion surface therefore depends on this sibling row rather than on host quotient equality or a selected representative. The CauchyEquivalenceSetoid$^{\uparrow}$ route is consumed by the RealSeparability$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ classifier routes. A dense Real-name read in chapter 1809 and a regular-rational readback in chapter 301 both use this displayed setoid boundary before any equality-facing classifier can pass to a Real$^{\uparrow}$ seal; neither route receives host quotient equality, a selected representative, or an ambient equality theorem.

Theorem 1820.62 (Cauchy equivalence setoid seed closure for Real separability)**.** *Every* RealSeparability$^{\uparrow}$ *dense-read packet that consumes a Cauchy-name classifier reads the* CauchyEquivalenceSetoid$^{\uparrow}$ *route before exporting dense real rows. The consumed data are the displayed stream comparison, regular rational readback, metric-completion boundary, componentwise* hsame *transport,* Cont *replay, provenance, and local* NameCert *rows of this hub; the export does not acquire quotient real equality, selected representatives, countable choice, or ambient* Real$^{\uparrow}$ *completeness from the setoid classifier.*

Proof. Read the hub through its regular-rational and Real-separability sibling routes. They expose the Cauchy classifier as finite comparison data before the dense real consumer receives any exported row.

The dense read therefore factors through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, MetricCompletion$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, and NameCert support already displayed by the setoid packet. Since none of those rows stores quotient real equality, a chosen representative, countable choice, or ambient completeness, the RealSeparability consumer cannot export such data from this dependency. □

The CauchyEquivalenceSetoid$^{\uparrow}$ hub records its substantive classifier dependencies through the regular rational readback of chapter 301, the terminal seal discipline of chapter 38, and the Cauchy-name comparison boundary of chapter 1412. These sibling chapters supply the visible rows that make the setoid a finite comparison route rather than a detached quotient or host equality object.

Theorem 1820.63 (CauchyEquivalenceSetoid forward dependency)**.** *Every* Real$^{\uparrow}$ *or completion-facing equality consumer of an accepted* CauchyEquivalenceSetoid$^{\uparrow}$ *classifier must expose the* StreamName$^{\uparrow}$ *finite windows, the* RegSeqRat$^{\uparrow}$ *readback rows, the* DyadicRatCore$^{\uparrow}$ *tolerance rows, and the terminal* Real$^{\uparrow}$ *seal before it consumes the setoid classifier. The route is the sibling-facing dependency surface of chapter 126, chapter 301, chapter 291, and chapter 38; it exports no quotient stream equality, selected representative, countable-choice schedule, host real equality, or ambient completion principle.*

Proof. Project the carrier of Definition 1820.1. Its equality-facing rows begin with two StreamName windows, two RegSeqRat readbacks, and the DyadicRatCore tolerance ledger before the setoid-test row is available.

Apply the classifier-law and NameCert-surface theorems, Definition 1820.3 and Definition 1820.5. They keep reflexivity, symmetry, transitivity, tolerance exactness, transport, replay, provenance, and local naming inside the displayed packet.

Use the Real seal forward route of Definition 1820.8. It places the terminal $\mathsf{Real}^{\uparrow}$ seal after the visible stream, readback, tolerance, classifier, transport, replay, provenance, and naming rows.

Thus any Real or completion-facing equality consumer reads the classifier only after those sibling rows have been exposed. Since the carrier has no quotient, selected-representative, choice, host-equality, or ambient-completion coordinate, none of those objects can replace the displayed dependency route. □

Chapter 1821

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$

Following Bishop and Bridges constructive regular-Cauchy completion, the $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$ packet isolates the finite limit-seal surface consumed by the L10 completion route. It reads the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It also points to the sequential-completeness route of chapter 1794, the uniqueness boundary of chapter 1782, and the universal route of chapter 1425. The packet names only the displayed finite handoff from regular rational Cauchy data into a Real-facing seal; it does not assert quotient streams, selected host limits, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1821.1 (Bishop regular Cauchy limit seal carrier)**.** *A* $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, M, E, U, V, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to ask finite regular-Cauchy precision questions.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the tolerance ledger.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row exposed inside the displayed windows.*
4. *M is the regular tail-control row witnessing that each dyadic request reads a finite threshold before inspecting S and R.*
5. *E is the displayed* $\mathsf{Real}^{\uparrow}$ *limit seal reached from D, S, R, M.*
6. *U is the* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *handoff row that records the finite route from regular sequence data to the displayed seal.*
7. *V is the completion comparison row, read through* $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$ *and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *after the seal row E has been exposed.*
8. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, tail-control row, seal row, sequential-completeness handoff, completion comparison row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a limit-seal request through D, S, R, M, E, U, V.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, M, E, U, V, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected host limits, countable-choice selectors, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, or bridge credentials.*

Theorem 1821.2 (Bishop regular Cauchy limit seal NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$ *carrier*

$$L = (D, S, R, M, E, U, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance ledger, stream-window row, regular rational readback row, regular tail-control row, Real limit seal, sequential-completeness handoff, completion comparison row, transport, replay, provenance, and local naming row;*
2. *regular-tail discipline, requiring every tolerance request to obtain its threshold from M before it reads the finite rows D, S, R;*
3. *seal handoff, requiring the displayed* $\mathsf{Real}^{\uparrow}$ *row E to be reached only after the regular route D, S, R, M has been replayed;*
4. *sequential-completeness compatibility, requiring U to consume the same D, S, R, M, E coordinates and no separate completion carrier;*
5. *uniqueness and universal compatibility, requiring V to compare completion-facing uses only after the displayed seal row and the common finite regular-Cauchy route have been fixed;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient stream equality, selected host limit, countable-choice selector, host real equality, ambient Real completeness theorem, metric-completeness datum, or bridge credential.*

No NameCert obligation is stored outside these rows.

```
Lean4 ✓  BEDC.Derived.BishopRegularCauchyLimitSealUp.BishopRegularCauchyLimitSealTasteGate
single carrier alignment
```

Proof. Carrier admission is projection from Definition 1821.1. The accepted packet displays the dyadic ledger, finite windows, regular readback, tail-control row, seal row, sequential-completeness handoff, completion comparison row, and the structural rows H, C, P, N.

The regular-tail discipline is forced by the order of the replay row. A tolerance request first reads M, then inspects the corresponding dyadic, window, and regular rational rows D, S, R.

The seal handoff is downstream of that same route. The row E is the only displayed $\mathsf{Real}^{\uparrow}$ limit seal, so a consumer cannot obtain a Real-facing endpoint before D, S, R, M have been exposed.

Sequential-completeness compatibility follows because U is a row over the displayed route, not an independent completion object. The completion comparison row V is likewise read after E and can compare only the already displayed finite route.

Finally, H, C, P, N preserve and name the listed rows. Since the carrier contains none of the excluded coordinates, the local certificate cannot export quotient stream equality, selected host

limits, choice, host real equality, ambient Real completeness, metric-completeness data, or bridge credentials. □

Theorem 1821.3 (Bishop regular Cauchy limit seal nonescape)**.** *Every Real-facing or completion-facing read of an accepted* $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchySequentialCompleteness}^{\uparrow},\ \mathsf{RegularCauchyCompletionUni}$$

The exported limit seal is the displayed row E reached from D, S, R, M and then consumed by U, V, H, C, P, N. It exports no quotient stream equality, selected host limit, countable-choice selector, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness datum, or bridge credential.*

Proof. Project the accepted carrier. A Real-facing or completion-facing read can access only the rows $D, S, R, M, E, U, V, H, C, P, N$.

The read first follows the regular-Cauchy data route. The dyadic tolerance ledger D opens the finite windows S, the row R supplies regular rational readback, and M supplies the finite tail-control threshold for the same request.

Only after this route is displayed can the read reach E as the $\mathsf{Real}^{\uparrow}$ limit seal. The rows U and V then record sequential-completeness and completion comparison uses of that same seal, rather than selecting a host limit or a quotient representative.

The structural rows close the route by componentwise transport, replay, provenance, and local naming. Because no excluded coordinate occurs in the packet, every accepted read remains inside the finite limit-seal surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, a RegSeqRat regular rational readback row, a regular tail-control row, a displayed RealUp limit seal, RegularCauchySequentialCompleteness handoff, RegularCauchyCompletionUniqueness and RegularCauchyCompletionUniversal comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1821.1, Definition 1821.2, and Definition 1821.3 seed the finite L10 limit-seal surface from regular rational Cauchy data into the displayed $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, metric-completeness data, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding carrier admission, regular-tail discipline, seal handoff, sequential-completeness compatibility, uniqueness and universal compatibility, and ledger non-escape to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Chapter 1822

A Concrete Naming Certificate for $\mathsf{CompactMetricProduct}^{\uparrow}$

Following Bishop and Bridges constructive metric compactness and Kelley-style product metrics, the $\mathsf{CompactMetricProduct}^{\uparrow}$ packet records binary finite-product compactness for L10 compact metric spaces as a displayed BEDC certificate. It reads the product-metric ledger of chapter 424, the compact metric source rows of chapter 129, the finite-net surface of chapter 127, the complete-limit surface of chapter 128, the finite epsilon-net rows of chapter 1767, and the binary product carrier of chapter 34. The packet names the standard constructive route: build finite product nets componentwise, pair complete-limit witnesses componentwise, and expose the resulting compact-metric package only through the displayed product metric.

Definition 1822.1 (Compact metric product carrier)**.** *A* $\mathsf{CompactMetricProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, M, P, T, L, H, C, Q, N)$$

with the following displayed rows:

1. *X is the first compact metric source row. It exposes its* $\mathsf{CompactMetric}^{\uparrow}$ *packet only through the associated* $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *and* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *rows.*
2. *Y is the second compact metric source row, with the same displayed compact-metric boundary for the second component.*
3. *M is the* $\mathsf{ProductMetric}^{\uparrow}$ *row on the binary product carrier. It stores the two projection routes, the component distance reads, and the product-distance ledger.*
4. *P is the* $\mathsf{Prod}^{\uparrow}$ *pairing row carrying the product points inspected by M, together with the two displayed projection histories.*
5. *T is the finite epsilon-net product witness. A tolerance request is split into component tolerances, the component* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witnesses are read from X and Y, and their paired centers form the product finite-net row.*
6. *L is the paired complete-limit witness row. A regular Cauchy stream in the product metric is projected through M to the two component* $\mathsf{CompleteMetric}^{\uparrow}$ *witnesses, then repacked through P as the displayed product limit row.*
7. *H records componentwise* hsame *transport for the two compact metric sources, the product metric row, the product carrier row, the finite-net product witness, the paired limit witness, replay, provenance, and local name.*

8. *C records displayed* Cont *replay from a compactness request through*

$$X, Y \longmapsto M, P \longmapsto T, L \longmapsto H, Q, N.$$

9. *Q is the* Pkg *provenance over* $\mathsf{CompactMetricProduct}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, M, P, T, L, H, C, Q, N$. The carrier has no coordinate for open-cover compactness, sequential compactness, quotient product equality, selected limits, countable choice, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompactMetricProductUp.TasteGate.CompactMetricProductTasteGate single carrier alignment`

Theorem 1822.2 (Compact metric product NameCert obligations)**.** *For every accepted* $\mathsf{CompactMetricProduct}^{\uparrow}$ *carrier*

$$K = (X, Y, M, P, T, L, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricProduct}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *carrier admission for the two compact metric sources, product metric row, product carrier row, finite-net product witness, paired complete-limit witness, transport, replay, provenance, and local name;*
2. *product-metric exactness, requiring every product distance and projection read to pass through the displayed* $\mathsf{ProductMetric}^{\uparrow}$ *row M and* $\mathsf{Prod}^{\uparrow}$ *row P;*
3. *finite-net product coverage, requiring T to be assembled from the two component* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *rows and the product-distance ledger of M;*
4. *complete-limit pairing, requiring L to project every product Cauchy stream to the two component* $\mathsf{CompleteMetric}^{\uparrow}$ *witnesses before repacking the limit through P;*
5. *non-escape provenance, requiring H, C, Q, N to preserve the displayed rows and to export no open-cover compactness, sequential compactness, quotient product equality, selected limit, countable-choice selector, or external compactness theorem.*

No local NameCert obligation is stored outside these five rows.

Lean4 ✓ `BEDC.Derived.CompactMetricProductUp.CompactMetricProductTasteGate single carrier alignment`

Proof. The carrier row already lists the only admissible coordinates. Carrier admission is therefore the tuple inspection of $X, Y, M, P, T, L, H, C, Q, N$, while product-metric exactness is the projection and distance replay inherited from M and P.

For total boundedness, read the positive tolerance through the component tolerance split recorded by T. The two component compact metric sources expose their finite epsilon-net rows, and the product row pairs the chosen centers through P. The product-distance ledger in M then gives the displayed coverage comparison.

For completeness, project a product Cauchy stream through the two projection routes of M. The component complete-limit rows in X and Y supply the two limits, and L repacks those limits through the binary product carrier P.

Finally, H, C, Q, N only replay and name the rows already displayed. Since no listed coordinate stores an open-cover argument, sequential compactness theorem, quotient equality, selected limit, or countable-choice selector, none can be exported by the local NameCert surface. □

Theorem 1822.3 (Compact metric product component handoff)**.** *Let $K = (X, Y, M, P, T, L, H, C, Q, N)$ be an accepted* $\mathsf{CompactMetricProduct}^{\uparrow}$ *carrier. Every consumer read of compactness for the product factors through the two component* $\mathsf{CompactMetric}^{\uparrow}$ *rows X, Y and the* $\mathsf{ProductMetric}^{\uparrow}$ *projection ledger M. In particular, the only compactness data visible to the consumer are the component finite-net rows, the component complete-limit rows, their paired transport through P, and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows of K.*

Lean4 ✓ `BEDC.Derived.CompactMetricProductUp.CompactMetricProductComponentHandoff`

Proof. Start with an arbitrary product compactness consumer. The carrier has no compactness coordinate except T and L, so the consumer must ask for finite coverage or complete-limit data through those rows.

The finite-coverage request reaches T. That row is defined by reading the finite epsilon-net witnesses from X and Y, then pairing the selected centers through P and measuring coverage through M.

The complete-limit request reaches L. That row is defined by projecting the product Cauchy stream through M, invoking the component complete-limit witnesses carried by X and Y, and repacking the two limits through P.

Thus every compactness read is componentwise before it is product-facing. The remaining rows H, C, Q, N transport, replay, source, and name this same route without adding any external compactness principle. □

Theorem 1822.4 (CompactMetric package for binary products)**.** *Every accepted* $\mathsf{CompactMetricProduct}^{\uparrow}$ *carrier*

$$K = (X, Y, M, P, T, L, H, C, Q, N)$$

supplies a $\mathsf{CompactMetric}^{\uparrow}$ *package for the binary product named by P and metrized by M. Its total-bounded component is the finite epsilon-net product witness T, and its complete component is the paired complete-limit witness L. The package is exposed only through the displayed rows $X, Y, M, P, T, L, H, C, Q, N$.*

Proof. The product metric row M supplies the metric carrier for the binary product row P. This gives the target metric surface on which a $\mathsf{CompactMetric}^{\uparrow}$ package can be read.

The total-bounded half is T. For each admitted tolerance, T reads finite epsilon-net witnesses from the component compact metric rows, pairs their centers, and uses the product-distance ledger to prove product coverage.

The complete half is L. A product Cauchy stream is projected to the two component streams, the component complete-limit witnesses produce component limits, and the binary product row repacks those limits as the product limit.

Combining these two rows gives the compact metric package for the product. The package has no route to open-cover compactness, sequential compactness, quotient product equality, selected limits, countable choice, Lean verification, or bridge checking, because those data are absent from the carrier and from its replay and provenance rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricProduct}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1822.1, Definition 1822.2, Definition 1822.3, and Definition 1822.4 seed the constructive finite-product compactness certificate for L10 compact metric spaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, quotient product equality, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-metric exactness, finite-net product coverage, complete-limit pairing, component handoff, provenance non-escape, and local naming for BEDC.Derived.CompactMetricProductUp.

Constructive story: A CompactMetricProduct$^{\uparrow}$ packet is generated from two CompactMetricUp sources, one ProductMetricUp row, one ProdUp product carrier, finite epsilon-net product witnesses, paired CompleteMetricUp limit witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1823

A Concrete Naming Certificate for $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$ packet records the standard passage from a displayed convergent real sequence to a displayed Cauchy criterion as finite BEDC route data. It sits over the displayed limit row of chapter 1413, the criterion row of chapter 1509, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic triangle ledger of chapter 291, and the terminal seal boundary of chapter 38.

Definition 1823.1 (Convergent sequence Cauchy carrier)**.** *A* $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, W, D, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row containing the displayed source sequence, candidate limit, tail-window schedule, dyadic tolerance ledger, and convergence classifier.*
2. *W is the paired finite tail-window schedule. For each requested dyadic tolerance it stores two tail observations of the displayed sequence and the matching observation windows of the displayed limit row.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *triangle ledger. It records the two sequence-to-limit comparisons from L and the finite triangle comparison routing the two tail observations through the displayed limit.*
4. *K is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row obtained from the same paired tail-window schedule and dyadic triangle ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled sequence observations and the displayed limit observations used by L, W, D, K.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the displayed limit row, paired tail windows, dyadic ledger, criterion row, and regular rational readback have been exposed.*
7. *H records componentwise* hsame *transports for L, W, D, K, R, E and the structural rows.*
8. *C records displayed* Cont *replay from a Cauchy request through the limit row, paired tail windows, dyadic ledger, criterion handoff, regular rational readback, and terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConvergentSequenceCauchy}^{\uparrow}}$ *row.*

The carrier stores a finite route from displayed convergence data to displayed Cauchy data. It contains no host sequence convergence theorem, selected limit, quotient stream equality, countable-choice selector, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.ConvergentSequenceCauchyUp.ConvergentSequenceCauchyTasteGate single carrier alignment`

Theorem 1823.2 (Convergent sequence Cauchy NameCert obligations)**.** *For every accepted* ConvergentSequenceCa *carrier $Q = (L, W, D, K, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConvergentSequenceCauchy}^{\uparrow}}$ *surface consists exactly of the following six obligation rows:*

1. *carrier admission for the displayed* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row, paired tail-window schedule, dyadic triangle ledger,* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local name;*
2. *limit-source exposure, requiring every tail comparison to read the displayed convergence classifier stored in L;*
3. *paired-window synchronization, requiring the two sequence observations and the two limit observations to be taken from the same tolerance request in W;*
4. *triangle-ledger exactness, requiring the Cauchy comparison to be assembled only from the two sequence-to-limit comparisons recorded in D;*
5. *criterion handoff, requiring the row K to reuse the same finite windows and dyadic ledger rather than introducing a second sequence representative;*
6. *seal boundary, requiring every terminal* $\mathsf{Real}^{\uparrow}$ *read to remain downstream of L, W, D, K, R and the structural rows.*

No obligation is stored outside these rows.

Proof. Project the carrier of Definition 1823.1. Its visible coordinates are exactly the displayed limit row, paired tail-window schedule, dyadic triangle ledger, criterion row, regular rational readback, terminal seal, transport, replay, provenance, and local naming row.

The limit-source and paired-window obligations are forced by L and W. A Cauchy request first selects one tolerance request, then W exposes two tail observations together with the matching limit observations certified by the displayed convergence row L.

The triangle-ledger obligation is read from D. The ledger contains the two sequence-to-limit comparisons and the finite triangle route comparing the two tail observations through the displayed limit, so no detached comparison row is available.

The criterion handoff is the projection to K. Since K is part of the same packet and reuses W, D, R, the local certificate names the Cauchy criterion without adding a second stream representative or a selected host limit.

The seal boundary follows from the ordering of the rows. The terminal seal E can be consumed only after the displayed limit, paired windows, dyadic ledger, criterion handoff, and regular rational readback have been exposed, while H, C, P, N transport, replay, source, and name the same finite route. □

Theorem 1823.3 (Convergent sequence Cauchy tail-window factorization)**.** *Let $Q = (L, W, D, K, R, E, H, C, P, N$ be an accepted* $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *consumer*

of Q factors through the finite route

$$L \longmapsto W \longmapsto D \longmapsto K$$

before it can inspect the regular rational readback R, the terminal $\mathsf{Real}^{\uparrow}$ *seal E, or the structural rows H, C, P, N. The route compares two tail observations only by routing each observation through the displayed limit row and then through the dyadic triangle ledger.*

Proof. Begin with a criterion-facing consumer of Q. Carrier admission gives the consumer no sequence source except the displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ row L.

The request then passes to the paired window schedule W. This schedule supplies two tail observations for the same dyadic tolerance request, together with the limit-side observation windows needed to read the convergence classifier in L.

Next read the dyadic triangle ledger D. The ledger is the only row comparing the two tail observations, and it does so by composing the two sequence-to-limit comparisons through the displayed limit.

The handoff to K now has exactly the data required by the $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ surface: finite windows, dyadic tolerances, and a regular rational readback route. Only after this handoff may the consumer inspect R, E, H, C, P, N, so the criterion read factors through L, W, D, K. □

Theorem 1823.4 (Convergent sequence Cauchy Real-seal boundary)**.** *For an accepted* $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$ *carrier $Q = (L, W, D, K, R, E, H, C, P, N)$, every terminal* $\mathsf{Real}^{\uparrow}$*-facing read is downstream of the displayed convergence row L, the paired tail-window schedule W, the dyadic triangle ledger D, the criterion row K, and the regular rational readback R. The read exports only the finite NameCert route from displayed convergence to displayed Cauchy data, not host sequence convergence, a selected limit, quotient stream equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Start from the accepted packet. The terminal seal row E is not a source coordinate; it is listed after the displayed limit row, paired window schedule, dyadic ledger, criterion row, and regular rational readback.

A terminal consumer must therefore traverse L, W, D, K, R in order. The rows L, W, D supply the finite convergence-to-Cauchy triangle route, while K names the Cauchy criterion handoff and R supplies the regular rational observations used by that handoff.

The structural rows preserve the same route. Transport H is componentwise, replay C follows the displayed request path, provenance P records the same dependencies, and N names the local certificate.

Since the carrier has no coordinate for host sequence convergence, selected limits, quotient stream equality, countable choice, trichotomy, ambient real completeness, Lean verification, or bridge checking, the terminal seal read exports none of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConvergentSequenceCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConvergentSequenceCauchy}^{\uparrow}$ packet is generated from a displayed RealSequenceLimit row, paired finite tail-window schedule, DyadicRatCore triangle ledger, CauchyConvergenceCriterion handoff, RegSeqRat readback, terminal RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvergentSequenceCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1823.1, Definition 1823.2, Definition 1823.3, and Definition 1823.4 seed the finite route from displayed convergence data to displayed Cauchy criterion data through paired tail windows and a dyadic triangle ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvergentSequenceCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence convergence, selected limits, quotient stream equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, limit-source exposure, paired-window synchronization, triangle-ledger exactness, criterion handoff, and Real-seal boundary for the same displayed packet.

Chapter 1824

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$ packet records the finite endpoint handoff by which regular Cauchy completion data may be read by public $\mathsf{Real}^{\uparrow}$ and Completion consumers without importing a quotient stream, a selected representative, or an ambient completeness principle. It sits after the regular-completion carrier of chapter 1639, the limit-seal route of chapter 386, the exact-boundary row of chapter 1120, the source-to-endpoint unit of chapter 1527, and the terminal real-name seal of chapter 38. The packet is an endpoint boundary: it names the handoff surface consumed by later Real and Completion routes, not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1824.1 (Regular Cauchy completion endpoint carrier)**.** *A* $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (B, L, X, U, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *row containing the regular rational sequence route, dyadic tail modulus, common-tail window, and completion-facing carrier boundary.*
2. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route that seals the displayed regular Cauchy handoff before any endpoint consumer reads it.*
3. *X is the* RealCompletionExactBoundaryUp *exact-boundary row binding the StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, and terminal Real faces into one finite completion route.*
4. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *source-to-endpoint row, recording how the displayed source name enters the endpoint boundary without selecting a representative.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after B, L, X, U have been displayed.*
6. *H records componentwise* hsame *transport for the regular-completion row, limit-seal route, exact-boundary row, unit row, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an endpoint request through B, L, X, U, R and then through the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, RealCompletionExactBoundaryUp, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}}$ *row.*

The classifier accepts only packets read through $B, L, X, U, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyCompletionEndpointUp.RegularCauchyCompletionEndpointUp`
Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEndpointUp.RegularCauchyCompletionEndpointTasteGate`
`single carrier alignment`

Theorem 1824.2 (Regular Cauchy completion endpoint NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$ *carrier $E = (B, L, X, U, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCor}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the regular-completion row, limit-seal route, exact-boundary row, source-to-endpoint unit, terminal Real seal, transport, replay, provenance, and local naming row;*
2. *classifier transport, requiring H to preserve B, L, X, U, R, C, P, N componentwise and requiring C to replay the same endpoint route;*
3. *endpoint seal handoff, requiring every endpoint-facing read to pass through B, L, X, U before exposing R;*
4. *unit and embedding compatibility, requiring the unit row U to reuse the displayed source route already admitted by B and sealed by L, X;*
5. *nonescape, requiring the packet to export no quotient stream equality, selected representative, countable choice, host real equality, or ambient Real completeness.*

No endpoint obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEndpointUp.RegularCauchyCompletionEndpointCarrier`
`namecert obligations`

Proof. Project the carrier of Definition 1824.1. The projection exposes exactly the regular-completion row, limit-seal route, exact-boundary row, unit row, terminal seal, and structural rows.

Carrier admission is therefore rowwise. The completion-facing source is admitted through B, the seal route through L, the exact endpoint boundary through X, the unit handoff through U, and the terminal Real surface through R.

Classifier transport is componentwise. The row H preserves each visible coordinate, while C replays the ordered route from an endpoint request through B, L, X, U, R.

The endpoint seal handoff and unit compatibility are forced by the placement of R downstream of B, L, X, U. A consumer cannot read the terminal $\mathsf{Real}^{\uparrow}$ seal before the displayed regular-completion source, limit-seal route, exact boundary, and unit row have all been exposed.

Finally, the carrier inventory contains no excluded coordinate. Since quotient stream equality, selected representatives, countable choice, host real equality, and ambient Real completeness are absent from the tuple and from the replay route, the nonescape obligation is exhausted by $B, L, X, U, R, H, C, P, N$. □

Theorem 1824.3 (Regular Cauchy completion endpoint Real-seal handoff)**.** *Let $E = (B, L, X, U, R, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or Completion endpoint consumer of E factors through the displayed route*

$$B \longmapsto L \longmapsto X \longmapsto U \longmapsto R$$

together with the structural rows H, C, P, N. Consequently the consumer receives only the regular-completion carrier, CauchyLimitSeal route, RealCompletionExactBoundary row, CauchyCompletionUnit handoff, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert rows, and receives no quotient stream equality, selected representative, countable choice, host real equality, or ambient Real completeness.

Proof. Begin with an endpoint consumer of the accepted packet. By carrier projection, its only completion-facing source is B, the displayed $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ row.

The consumer next reads L and X. The row L supplies the Cauchy-limit seal for the same regular-completion route, while X binds that sealed route to the exact Real-completion boundary before an endpoint row is public.

The source-to-endpoint step is U. This row records the unit handoff from the displayed source route into the endpoint boundary and does not add a second representative or a hidden selector.

Only after B, L, X, U have been read may the terminal seal R be exposed. The rows H, C, P, N transport, replay, source, and name the same ordered route, so every endpoint consumer factors through the listed packet.

The excluded principles have no carrier slot and no replay insertion point. Hence the consumer receives no quotient stream equality, selected representative, countable choice, host real equality, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}$ packet is generated from a BishopRegularCauchyCompletion row, CauchyLimitSeal route, RealCompletionExactBoundary row, CauchyCompletionUnit source-to-endpoint row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1824.1, Definition 1824.2, and Definition 1824.3 seed the endpoint handoff from regular Cauchy completion packets to public RealUp and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEndpoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires future Lean work under BEDC.Derived.RegularCauchyCompletionEndpointUp for carrier admission, classifier transport, endpoint seal handoff, unit and embedding compatibility, and nonescape.

Chapter 1825

A Concrete Naming Certificate for $\mathsf{CauchyEstimate}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyEstimate}^{\uparrow}$ packet records finite Cauchy error-estimate data for regular rational real names. It consumes the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy threshold discipline of chapter 292. The packet gives the L10 Real and Completion route one visible estimate ledger before any $\mathsf{Real}^{\uparrow}$-facing consumer can read a completed seal.

Definition 1825.1 (Cauchy estimate carrier)**.** *A* $\mathsf{CauchyEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, W, D, L, M, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row containing the regular rational name whose estimates are being read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It lists exactly the observation windows of R that an estimate request may inspect.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic scale, comparison arithmetic, and tolerance conversions used by the estimate ledger.*
4. *L is the finite estimate ledger. Each row pairs a requested tolerance with the two scheduled rational observations, the dyadic comparison witnessing their distance bound, and the local row in which the bound is stored.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning every admitted tolerance request to the window threshold used by W and L.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, W, D, L, M have been displayed.*
7. *H records componentwise* hsame *transport for the source row, finite windows, dyadic tolerance row, estimate ledger, modulus row, real seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from an estimate request through $R, W, D, L, M, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyEstimate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient real equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyEstimateUp.CauchyEstimateTasteGate single carrier alignment`

Theorem 1825.2 (Cauchy estimate NameCert obligations)**.** *For every accepted* $\mathsf{CauchyEstimate}^{\uparrow}$ *carrier*

$$E = (R, W, D, L, M, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyEstimate}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, estimate ledger,* $\mathsf{CauchyModulus}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *seal row, transport, replay, provenance, and local name;*
2. *estimate-window exactness, requiring every ledger entry in L to use only the finite windows displayed by W for the admitted tolerance request;*
3. *dyadic tolerance stability, requiring every estimate comparison to be read through the dyadic scale and comparison arithmetic stored in D;*
4. *classifier transport, requiring H and C to preserve the source, window, tolerance, ledger, modulus, seal, provenance, and local naming rows componentwise under* hsame *and displayed replay;*
5. *ledger non-escape, requiring the packet to export no estimate row outside $R, W, D, L, M, S, H, C, P, N$.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1825.1. The projection exposes one regular rational source, one finite-window schedule, one dyadic tolerance row, one estimate ledger, one modulus row, one terminal real seal, and the structural rows.

Carrier admission is therefore exactly admission of those displayed coordinates. Since the source row R and the window row W are the only observation coordinates, an estimate request cannot read a rational observation outside the finite windows named by W.

The dyadic tolerance obligation is read from D. Each ledger row in L cites the dyadic scale and comparison arithmetic stored there, so stability of the bound is a property of the displayed tolerance row rather than of an ambient real-comparison principle.

Transport and replay are structural. The row H transports the same displayed coordinates componentwise, and the row C repeats the route from an estimate request through the source, windows, dyadic tolerance row, ledger, modulus, seal, provenance, and local name.

The remaining non-escape clause follows from the coordinate list. The packet has no additional estimate surface and no coordinate for real completeness, quotient real equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking. □

Theorem 1825.3 (Cauchy estimate Real seal handoff)**.** *Let $E = (R, W, D, L, M, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyEstimate}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing estimate read factors through the finite route*

$$W \longmapsto R \longmapsto D \longmapsto M \longmapsto L$$

before the real seal row S is visible. The read exports only the displayed StreamName windows, RegSeqRat observations, DyadicRatCore tolerance comparisons, CauchyModulus threshold row, estimate ledger, real seal, and structural rows, not $\mathsf{Real}^{\uparrow}$ *completeness, quotient real equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking.*

Proof. Start with a real-facing estimate consumer of the accepted packet. The only real-facing coordinate is S, and it is listed downstream of the regular rational source, finite windows, dyadic tolerance row, estimate ledger, and modulus row.

The consumer first reads the finite windows W and the source observations R. These rows determine which rational observations can participate in an estimate request.

Next the consumer reads D and M. The row D supplies the dyadic tolerance arithmetic, while M supplies the threshold discipline saying which windows discharge the admitted tolerance.

Only then can the estimate ledger L be inspected. The ledger binds the selected windows, regular rational observations, dyadic comparisons, and modulus threshold into the displayed estimate row.

Thus the seal row S is visible only after the finite StreamName, RegSeqRat, DyadicRatCore, modulus, and ledger rows have been read. Since the carrier has no coordinate for completeness, quotient equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking, none of those principles can be exported by the real-facing read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyEstimate}^{\uparrow}$ packet is generated from one RegSeqRat source row, one StreamName finite-window row, one DyadicRatCore tolerance row, a finite estimate ledger, one CauchyModulus threshold row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1825.1, Definition 1825.2, and Definition 1825.3 seed the finite error-estimate ledger route from regular rational observations through dyadic tolerances and a Cauchy modulus before the Real seal is consumed.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyEstimate}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyEstimateUp`

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient real equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, estimate-window exactness, dyadic tolerance stability, classifier transport, ledger non-escape, and Real-seal handoff for BEDC.Derived.CauchyEstimateUp.

Chapter 1826

A Concrete Naming Certificate for $\mathsf{DiagonalSubsequence}^{\uparrow}$

Following Cantor's diagonal method and Bishop–Bridges constructive analysis, the $\mathsf{DiagonalSubsequence}^{\uparrow}$ packet records the finite-window diagonal subsequence extraction route used by the L10 Real and Completion spine. It sits over the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the regular Cauchy extraction route of chapter 1773, and the downstream diagonal-limit seal of chapter 1800. The packet names diagonal subsequence extraction as displayed BEDC route data, not as a quotient stream, a countable-choice selector, a host limit, trichotomy, or an ambient completeness theorem.

Definition 1826.1 (Diagonal subsequence carrier)**.** *A* $\mathsf{DiagonalSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, W, J, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-sequence window row. It exposes only finite* $\mathsf{StreamName}^{\uparrow}$ *windows of the displayed family from which the diagonal subsequence is read.*
2. *W is the finite diagonal window ledger. For each requested finite diagonal stage it stores the source window, target window, tolerance budget, and compatibility check visible at that stage.*
3. *J is the monotone unary selector row. It records a displayed finite selector trace whose successive entries are strictly later source positions and whose order is checked inside the packet.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the windows selected by S, W, J.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the dyadic radii, slack entries, and comparison budgets used by W, J, R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source windows, diagonal ledger, selector row, regular rational readback, and dyadic tolerance ledger have been displayed.*
7. *H records componentwise* hsame *transport for S, W, J, R, Q, E and the structural rows.*
8. *C records displayed* Cont *replay from a finite diagonal request through $S, W, J, R, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DiagonalSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, J, R, Q, E, H, C, P, N$. It has no coordinate for a quotient stream, countable-choice selector, host limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DiagonalSubsequenceUp.TasteGate.DiagonalSubsequenceTasteGate single carrier alignment`

Theorem 1826.2 (Diagonal subsequence NameCert obligations)**.** *For every accepted* $\mathsf{DiagonalSubsequence}^{\uparrow}$ *carrier*

$$D = (S, W, J, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiagonalSubsequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source-sequence windows, finite diagonal window ledger, monotone unary selector row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *finite-window diagonal compatibility, requiring each diagonal stage in W to expose only the source and target windows selected from S for the same displayed tolerance request;*
3. *selector monotonicity, requiring J to witness that later diagonal stages read strictly later source positions by a finite unary trace;*
4. *readback exactness, requiring R to be assembled only from the selected windows and tolerance entries recorded in S, W, J, Q;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring E to be downstream of the finite source-window, diagonal-ledger, selector, readback, and tolerance route;*
6. *componentwise* hsame *transport through H for all displayed analytic and structural rows;*
7. *displayed* Cont *replay through C for every finite diagonal request;*
8. Pkg *provenance through P for the same dependency surface;*
9. *local naming through N and refusal of quotient streams, countable-choice selectors, host limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as certificate data.*

No diagonal subsequence obligation is stored outside these rows.

Proof. Project the carrier of Definition 1826.1. The visible analytic rows are exactly the source windows S, finite diagonal ledger W, monotone selector row J, regular rational readback R, dyadic tolerance ledger Q, and terminal real seal E.

Finite-window diagonal compatibility is read from S and W. A diagonal request chooses one finite stage, and the ledger exposes only the source and target windows assigned to that same displayed tolerance request.

Selector monotonicity is read from J. Since J is a finite unary trace inside the packet, the local certificate can check that each later diagonal stage uses a later source position without importing a countable-choice schedule.

Readback exactness is the projection to R and Q. The regular rational row is assembled from the selected windows and dyadic tolerance entries already displayed by S, W, J, Q, so no quotient stream or detached representative is available.

The seal, transport, replay, provenance, and naming rows preserve the same route. The terminal seal E is downstream of S, W, J, R, Q, while H, C, P, N transport, replay, record, and name only the listed packet rows. □

Theorem 1826.3 (Diagonal subsequence regular readback route)**.** *Every accepted* $\mathsf{DiagonalSubsequence}^{\uparrow}$ *packet*

$$D = (S, W, J, R, Q, E, H, C, P, N)$$

routes each $\mathsf{Real}^{\uparrow}$*-facing diagonal-subsequence read through the finite chain*

$$S \longmapsto W \longmapsto J \longmapsto R \longmapsto Q \longmapsto E$$

before any structural row is consumed. Consequently the read exposes source windows, a finite diagonal window ledger, a monotone unary selector trace, a $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it exports no quotient stream, countable-choice selector, host limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing consumer of the accepted packet. The only source data visible before a seal read are the finite windows in S.

The diagonal ledger W then binds the consumer to one finite diagonal stage. It supplies the source and target windows for that stage and records the tolerance budget that the later readback must respect.

The selector row J is next. It certifies that the selected source positions form a monotone unary trace, so the consumer can read a subsequence route without selecting an infinite function outside the packet.

The rows R and Q assemble the regular rational readback and the dyadic tolerance ledger from the same displayed windows and selector trace. Thus the terminal seal E is reached only after S, W, J, R, Q have been consumed.

Since the carrier contains no quotient stream, countable-choice selector, host limit, trichotomy row, or ambient completeness theorem, the displayed route exhausts every real-facing diagonal-subsequence read. □

Theorem 1826.4 (Diagonal subsequence Cauchy-window extraction)**.** *Every accepted* $\mathsf{DiagonalSubsequence}^{\uparrow}$ *packet*

$$D = (S, W, J, R, Q, E, H, C, P, N)$$

extracts each $\mathsf{RegSeqRat}^{\uparrow}$ *readback window from the finite source window row* S*, diagonal ledger* W*, monotone selector row* J*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Q*. The terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is downstream of that extracted Cauchy window and cannot be read from a quotient stream or from a countable-choice selector.*

Proof. Project the carrier of Definition 1826.1. The source windows S, diagonal ledger W, selector trace J, readback row R, tolerance ledger Q, and seal E are the only analytic rows available to a real-facing diagonal-subsequence consumer.

Use Definition 1826.2. Its readback exactness clause requires R to be assembled only from the selected windows and tolerance entries recorded in S, W, J, Q.

Now apply Definition 1826.3. The ordered route places E after S, W, J, R, Q, so the terminal seal is reached only after the extracted Cauchy window has been displayed. Since the carrier has no quotient-stream or countable-choice coordinate, no consumer can bypass that finite extraction route. □

Bounded-sequence compactness consumers read this diagonal route through chapter 1254 and chapter 1415 when a retained finite-window subsequence is repacked as a cluster witness or compactness witness. The diagonal packet therefore supplies the finite extraction surface consumed by the L10 bounded-sequence lattice rather than floating only as a kernel-facing route.

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{DiagonalSubsequence}^{\uparrow}$ packet is generated from source-sequence windows, a finite diagonal window ledger, a monotone unary selector row, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1826.1, Definition 1826.2, and Definition 1826.3 seed the finite-window diagonal subsequence extraction route through source windows, diagonal ledgers, monotone selector traces, regular readback, dyadic tolerances, and a terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, countable-choice selectors, host limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and TasteGate field faithfulness for BEDC.Derived.DiagonalSubseque

Chapter 1827

A Concrete Naming Certificate for $\mathsf{CesaroConvergence}^{\uparrow}$

Following Hardy's classical treatment of Cesaro summability, the $\mathsf{CesaroConvergence}^{\uparrow}$ packet records ordinary convergence of the displayed Cesaro means as a BEDC finite-window certificate over regular real-sequence data. It consumes the finite averaging surface of chapter 1765, keeps the quotient-tail comparison discipline of chapter 1439 available as a sibling route, routes every transformed read through the regular rational interface of chapter 301, and reaches the terminal real-name seal only through chapter 38. The chapter names the carrier that a convergence consumer may inspect; it does not import a host convergence theorem or an ambient limit object.

Definition 1827.1 (Cesaro convergence carrier)**.** *A* $\mathsf{CesaroConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, M, A, L, R, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the source real-sequence row, exposed only through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows requested by the current convergence tolerance.*
2. *M is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row carrying the displayed prefix sums, unary denominator rows, dyadic division budgets, and finite Cesaro mean windows generated from S.*
3. *A is the finite averaging ledger, recording for each inspected tolerance the source windows, prefix rows, denominator rows, and dyadic error budgets used by the displayed Cesaro means.*
4. *L is the convergence-window ledger, containing the finite tail requests that classify the Cesaro mean rows as a regular real sequence.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from M, A, L before any completed real-name seal is read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source, Cesaro mean, averaging ledger, convergence-window ledger, and regular handoff rows have been displayed.*
7. *H stores componentwise* hsame *transports for the sequence source, Cesaro mean rows, averaging ledger, convergence ledger, regular handoff, real seal, continuation rows, provenance, and local naming.*

8. *T stores displayed* Cont *routes from source-window reads to Cesaro mean rows, from Cesaro mean rows to convergence-window classification, from that classification to R, and from R to E.*

9. *P is the* Pkg *provenance over* $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{StolzCesaro}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CesaroConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, A, L, R, E, H, T, P, N$. It has no coordinate for ordinary pointwise convergence of the source sequence, a host limit, quotient stream equality, a choice-selected subsequence, trichotomy, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CesaroConvergenceUp.TasteGate.CesaroConvergenceTasteGate single carrier alignment`

Theorem 1827.2 (Cesaro convergence NameCert obligations)**.** *For every accepted* $\mathsf{CesaroConvergence}^{\uparrow}$ *carrier $C = (S, M, A, L, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CesaroConvergence}^{\uparrow}}$ *surface consists exactly of the following six finite obligation rows:*

1. *carrier admission for the displayed source row, Hardy–Cesaro mean row, averaging ledger, convergence-window ledger, regular handoff, real seal, transport, continuation, provenance, and naming rows;*

2. *mean-window classification, requiring each accepted Cesaro mean read to be generated by M from the finite source windows and averaging ledger A;*

3. *stability, requiring the displayed* hsame *transports H and* Cont *routes T to preserve the same source, averaging, convergence-window, regular handoff, and real-seal rows;*

4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring every accepted convergence read to pass through R after M, A, L have been displayed;*

5. $\mathsf{Real}^{\uparrow}$ *seal factorization, requiring the seal row E to consume only the regular handoff obtained from the displayed Cesaro averaging route;*

6. *ledger non-escape, excluding ordinary pointwise convergence of S, host limits, quotient stream equality, choice-selected subsequences, and any detached real-completeness coordinate.*

Proof. Project the carrier of Definition 1827.1. Carrier admission is exactly the displayed packet $S, M, A, L, R, E, H, T, P, N$, so the certificate has no free coordinate for a source-sequence limit or an external convergence oracle.

Mean-window classification is supplied by the order of the rows. The source windows in S feed the $\mathsf{HardyCesaroMean}^{\uparrow}$ row M, and A records the finite averaging ledger that produced each displayed Cesaro mean from prefix sums, denominator rows, and dyadic budgets.

The convergence side is then forced through L and R. The ledger L records the finite tail requests witnessing regularity of the Cesaro mean sequence, while R is the only $\mathsf{RegSeqRat}^{\uparrow}$ handoff reachable from those requests before any real seal is visible.

Finally, E is downstream of R, and H, T, P, N merely transport, replay, source, and name the same route. Since no listed row stores ordinary pointwise convergence, a host limit, quotient stream equality, a selected subsequence, or ambient completeness, the six obligations exhaust the local NameCert surface. □

Theorem 1827.3 (Cesaro convergence RegSeqRat handoff)**.** *Every accepted* $\mathsf{CesaroConvergence}^{\uparrow}$ *read reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *through the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row and the displayed averaging ledger before the* $\mathsf{Real}^{\uparrow}$ *seal is available. More precisely, for every accepted packet* $C = (S, M, A, L, R, E, H, T, P, N)$*, a completion-facing consumer can reach* E *only along the route*

$$S \longmapsto M \longmapsto A \longmapsto L \longmapsto R \longmapsto E \longmapsto (H, T, P, N).$$

The sibling $\mathsf{StolzCesaro}^{\uparrow}$ *route may certify compatible quotient-tail estimates in* P*, but it does not bypass* M, A, L, R *for the Cesaro-convergence read.*

Proof. Begin with a completion-facing read of C. By Definition 1827.1, the read first exposes the source row S only as finite stream windows.

The next analytic surface is M. This is the $\mathsf{HardyCesaroMean}^{\uparrow}$ packet of chapter 1765; it supplies the finite prefix-sum, denominator, dyadic-division, and Cesaro mean rows. The averaging ledger A records the same rows as the local route consumed by the convergence classifier.

The tail classifier then reads L and only then reaches the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R. The sibling $\mathsf{StolzCesaro}^{\uparrow}$ edge named in P can provide quotient-tail compatibility data, but the displayed route for this carrier still passes through the Cesaro mean row and averaging ledger before R.

The $\mathsf{Real}^{\uparrow}$ seal E is downstream of R. The structural rows H, T, P, N preserve and name the route, so a consumer that reaches E has already consumed S, M, A, L, R and receives no ordinary pointwise convergence witness, host limit, quotient stream equality, selected subsequence, or ambient completeness principle. □

Falsifiable prediction: Every $\mathsf{CesaroConvergence}^{\uparrow}$ Real-facing read factors through source sequence windows, a HardyCesaroMean row, a finite averaging ledger, a convergence-window ledger, RegSeqRat handoff, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: hardycesaromean, stolzcesaro, streamname, regseqrat, dyadicratcore, real: $\mathsf{CesaroConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source sequence row, Hardy–Cesaro mean rows, an averaging ledger, a convergence-window ledger, RegSeqRat handoff, Real seal, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CesaroConvergence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CesaroConvergence}^{\uparrow}$ packet is generated from a source real-sequence row, finite HardyCesaroMean averaging rows, an averaging ledger, convergence-window ledger, RegSeqRat handoff, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CesaroConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1827.1, Definition 1827.2, and Definition 1827.3 seed the finite Cesaro-convergence surface from regular real-sequence windows to the Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CesaroConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ordinary pointwise convergence, host limits, quotient stream equality, choice-selected subsequences, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, mean-window classification, stability, RegSeqRat handoff, RealUp seal factorization, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.CesaroConvergenceUp.

Chapter 1828

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocationWitness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocationWitness}^{\uparrow}$ packet records the finite location witness by which a regular Cauchy rational name may be consumed as a located real-name route. It sits over the dyadic tolerance ledger of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the sequence-level located Cauchy surface of chapter 340, and the filter-level located witness rows of chapter 1661. The certificate supplies the missing sequence-level location surface for later $\mathsf{Real}^{\uparrow}$ consumers without asserting Dedekind cuts, quotient streams, selected limits, countable choice, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1828.1 (Regular Cauchy location witness carrier)**.** *A* $\mathsf{RegularCauchyLocationWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, S, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular source row, namely the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name whose finite windows are being located.*
2. *S is the finite window schedule, namely the* $\mathsf{StreamName}^{\uparrow}$ *row that exposes exactly the inspected windows of R.*
3. *D is the dyadic tolerance ledger, recording requested radii, comparison budgets, endpoint approximants, and window tolerances.*
4. *W is the location-witness row, recording for each displayed dyadic cut request a finite left-or-right locatedness witness over the windows selected by S and the tolerances in D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, reachable only after R, S, D, W have been displayed.*
6. *H records componentwise* hsame *transport for the regular source, schedule, dyadic ledger, location witness, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a location request through R, S, D, W, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocationWitness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedCauchy}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocationWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, D, W, E, H, C, P, N$. The carrier contains no Dedekind cut, quotient stream equality, real trichotomy branch, countable-choice selector, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge checking datum.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocationWitnessUp.TasteGate.RegularCauchyLocationWitnessTasteGate single carrier alignment`

Theorem 1828.2 (Regular Cauchy location witness NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocationWitness}^{\uparrow}$ *carrier*

$$L = (R, S, D, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocationWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular source row, finite window schedule, dyadic tolerance ledger, location-witness row,* $\mathsf{Real}^{\uparrow}$ *seal boundary, transport, replay, provenance, and local name;*
2. *regular-source exposure, requiring every location request to read the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R only through the displayed schedule S;*
3. *dyadic-budget exactness, requiring each locatedness comparison to consume the radius, endpoint, and tolerance data stored in D before the witness row W is inspected;*
4. *witness routing, requiring W to record only finite left-or-right locatedness rows over the windows selected by S and the dyadic budget supplied by D;*
5. *seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *read to remain downstream of R, S, D, W;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name exactly the displayed route and no off-packet completeness or choice object.*

No local NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier from Definition 1828.1. The analytic rows are exactly the regular rational source, the finite schedule, the dyadic tolerance ledger, the location witness, and the terminal seal boundary.

Regular-source exposure is forced by the schedule row. A location request cannot inspect R directly; it must pass through the finite windows named by S.

The dyadic-budget and witness rows are then read together. The ledger D supplies the radius, endpoint, and tolerance data for the displayed cut request, and W records the finite locatedness witness over those same scheduled windows.

Finally, seal non-escape and structural stability are componentwise. The seal row E is reached only after R, S, D, W, while H, C, P, N preserve, replay, source, and name that same route. Since no excluded object is a coordinate of the packet, the local certificate has no place from which to export Dedekind cuts, quotient streams, trichotomy, choice, selected limits, ambient completeness, Lean verification, or bridge checking. □

Theorem 1828.3 (Regular Cauchy location witness regular readback)**.** *Let*

$$L = (R, S, D, W, E, H, C, P, N)$$

be an accepted RegularCauchyLocationWitness$^{\uparrow}$ *carrier. Every location read of L factors through the displayed regular-Cauchy route*

$$R \longmapsto S \longmapsto D \longmapsto W$$

before any Real$^{\uparrow}$ *seal or structural row is inspected.*

Proof. Begin with a location read. Carrier admission supplies R as the only regular rational source row, so no second stream representative or quotient stream can be selected.

The read then passes through S. This schedule determines the finite windows on which the regular source is inspected, and it is the only window source available to the packet.

Next the read consumes D and W. The dyadic ledger fixes the tolerance and endpoint budget, while the witness row records the finite locatedness decision over the scheduled windows.

Only after this route is displayed can the read reach E or the structural rows H, C, P, N. Thus every location read is a regular-Cauchy readback route rather than a host-level located real construction. □

Theorem 1828.4 (Regular Cauchy location witness Real seal non-escape)**.** *For every accepted* RegularCauchyLocationWitness$^{\uparrow}$ *carrier $L = (R, S, D, W, E, H, C, P, N)$, the exported* Real$^{\uparrow}$ *seal E is read only as the terminal boundary of the displayed finite route through R, S, D, W, H, C, P, N. It exports no Dedekind cuts, quotient stream equality, real trichotomy, countable-choice selector, selected limit, ambient Real completeness theorem, Lean verification, or bridge checking datum.*

Proof. Project the seal row from the carrier. The row E is listed after the regular source, schedule, dyadic ledger, and witness rows, so a seal-facing consumer has no direct entry to E.

Use Definition 1828.3. Any seal-facing location route first reads R, S, D, W, and those rows exhaust the finite analytic data available to the packet.

The structural rows preserve only this route. Transport H, replay C, provenance P, and local naming N do not add new analytic coordinates; they keep the same displayed packet available under componentwise comparison and continuation.

The excluded principles are absent from the carrier inventory and from the provenance row. Therefore the terminal seal remains a finite located regular-Cauchy boundary, not a proof of Dedekind completeness, quotient equality, trichotomy, choice, selected limits, Lean verification, or bridge checking. □

Closure status for NameCert$_{\text{RegularCauchyLocationWitness}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyLocationWitness}^{\uparrow}}$, seed)

Scope closed: Definition 1828.1, Definition 1828.2, Definition 1828.3, and Definition 1828.4 seed the finite location-witness route from regular rational source rows through StreamName windows, DyadicRatCore tolerances, displayed locatedness witnesses, and the terminal Real seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyLocationWitness}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularCauchyLocationWitnessUp.TasteGate.RegularCauchyLocationWitnessTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient streams, real trichotomy, countable choice, selected limits, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-source exposure, dyadic-budget exactness, witness routing, regular readback, Real-seal non-escape, and structural stability for BEDC.Derived.RegularCauchyLocationWitnessUp.

Constructive story: A RegularCauchyLocationWitness$^{\uparrow}$ packet is generated from a RegSeqRat regular source row, finite StreamName windows, a DyadicRatCore tolerance ledger, displayed locatedness witnesses, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1829

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$

Following Mac Lane's monad multiplication terminology together with Bishop–Bridges and Kelley completion language, the $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ packet records the finite BEDC join route that flattens a completion of completion into the displayed completion boundary. It sits after the monad surface of chapter 378, the idempotence row of **??**, and the associativity ledger of chapter 1635; its public L10 face is read through chapter 126, chapter 301, chapter 291, and chapter 38. The packet names monad multiplication as finite carrier data; it is not a quotient completion, selected representative, host equality comparison, countable-choice construction, ambient completeness principle, or completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1829.1 (Cauchy completion multiplication carrier)**.** *A* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, O, I, A, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *transformer row that records the completion endofunctor, unit, and bind surface consumed by the join.*
2. *O is the outer completion row, presenting the completion-of-completion input before flattening.*
3. *I is the* $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$ *row that identifies a completed completion boundary with the displayed completion boundary through finite certificate data.*
4. *A is the* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ *ledger that keeps nested bind and flattening routes in the same displayed order.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed only after the nested completion route has passed through M, O, I, A.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same flattened stream windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the flattened readback and terminal seal.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the displayed StreamName, RegSeqRat, and DyadicRatCore faces have been fixed.*
9. *H records componentwise* hsame *transports for the monad, outer-completion, idempotence, associativity, window, readback, tolerance, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an outer completion request through the flattening route and then through S, R, D, E.*
11. *P is the* Pkg *provenance over* CauchyCompletionMultiplication$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, CauchyCompletionIde CauchyCompletionAssociativity$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CauchyCompletionMultiplication}^{\uparrow}}$ *row.*

The classifier of accepted packets compares only these twelve displayed rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, ambient Real completeness, completeness of Real$^{\uparrow}$*, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.TasteGate.CauchyCompletionMultiplicationTasteGate single carrier alignment`

Theorem 1829.2 (Cauchy completion multiplication NameCert obligations)**.** *For every accepted* CauchyCompletionMultiplication$^{\uparrow}$ *carrier $K = (M, O, I, A, S, R, D, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyCompletionI}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed monad transformer, outer completion, idempotence, associativity, stream-window, readback, tolerance, real-seal, transport, replay, provenance, and local naming rows;*
2. *outer-to-inner flattening, requiring every completion-of-completion request to pass through M, O, I, A before any public L10 row is exposed;*
3. *shared window, readback, and seal routing, requiring S, R, D, E to be read as one flattened route rather than as detached representatives;*
4. *componentwise transport, requiring H to preserve the twelve displayed coordinates and no additional completion witness;*
5. *replay, requiring C to reproduce the same route from outer completion request through M, O, I, A, S, R, D, E;*
6. *provenance, requiring P to name only the cited monad, idempotence, associativity, stream, regular rational, dyadic, Real, and BEDC structural sources;*
7. *ledger nonescape, requiring N and the classifier to export no quotient completion, selected representative, countable choice, host equality, ambient Real completeness,* Real$^{\uparrow}$ *completeness theorem, Lean verification claim, or bridge credential.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1829.1. The tuple lists exactly the monad transformer, outer completion, idempotence, associativity ledger, public L10 rows, transport, replay, provenance, and local name.

The outer-to-inner flattening obligation is forced by the tuple order. A request addressed to the outer completion first reads M and O, then uses I to display the boundary as a single completion row, and uses A to keep the nested bind route coherent.

Shared routing is the projection to S, R, D, E. These rows are downstream of M, O, I, A, so the packet cannot expose a stream window, regular rational readback, dyadic tolerance, or Real seal detached from the displayed flattening route.

Componentwise transport and replay are read through H and C. The transport row identifies accepted packets coordinate by coordinate, while the continuation row reproduces the same request path from the outer completion through the public L10 face.

Finally, provenance and nonescape are exhausted by P, N and by the classifier. Since the carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge credentials, none of these can be exported by a local obligation. □

Theorem 1829.3 (Cauchy completion multiplication flattening route)**.** *Every accepted* CauchyCompletionMultiplica *packet flattens the outer completion through the route*

$$M \longmapsto O \longmapsto I \longmapsto A$$

before exposing the public L10 face

$$S \longmapsto R \longmapsto D \longmapsto E.$$

Thus a completion-of-completion consumer can read the StreamName window, RegSeqRat readback, DyadicRatCore tolerance, and Real seal only after the monad transformer, outer completion row, idempotence row, and associativity ledger have been displayed.

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplication flattening route`

Proof. Start with an accepted packet $K = (M, O, I, A, S, R, D, E, H, C, P, N)$. Projection gives the monad transformer M and the outer completion row O before any public L10 coordinate is available.

The idempotence row I supplies the displayed route from the completed completion boundary back to the single completion boundary. The associativity ledger A records that nested bind and flattening reads follow the same route.

Only after M, O, I, A have been read does the carrier expose S, R, D, E. The continuation row C replays this order, and componentwise transport by H preserves it for transported packets.

Consequently every public read from an accepted packet factors through the stated flattening route before the StreamName, RegSeqRat, DyadicRatCore, and Real-seal rows can be consumed. □

Theorem 1829.4 (Cauchy completion multiplication Real seal nonescape)**.** *Let $K = (M, O, I, A, S, R, D, E, H, C,$ be an accepted* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of K receives only the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N after the flattening route through M, O, I, A.*

In particular, the consumer receives no quotient completion, selected representative, countable-choice selector, host equality comparison, ambient Real completeness datum, or completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationRealSealNonescape`
↪ variant `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationCarrier real seal nonescape`

Proof. Project the accepted packet. A $\mathsf{Real}^{\uparrow}$-facing read reaches the terminal seal only through the flattened public face S, R, D, E.

The structural rows H, C, P, N do not add data to that face. They transport it componentwise, replay the displayed route, record the cited sources, and name the local certificate.

The excluded objects are absent from the carrier and from the classifier. There is no coordinate from which a quotient completion, selected representative, countable-choice selector, host equality comparison, ambient Real completeness datum, or $\mathsf{Real}^{\uparrow}$ completeness theorem could be read.

Therefore the Real-facing consumer receives exactly the displayed rows listed in the statement, downstream of the flattening route through M, O, I, A. □

Theorem 1829.5 (Cauchy completion multiplication obligation closure package)**.** *For every accepted* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *carrier* $K = (M, O, I, A, S, R, D, E, H, C, P, N)$*, the obligation surface named by* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMultiplication}^{\uparrow}}$ *is the package obtained by projecting exactly the rows* $M, O, I, A, S, R, D, E, H, C, P, N$*, applying Definition 1829.2 for carrier admission and local obligation exhaustion, applying Definition 1829.3 for the outer-to-inner route, and applying Definition 1829.4 for the terminal Real-facing boundary.*

The package has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, ambient Real completeness, a completeness theorem for $\mathsf{Real}^{\uparrow}$*, Lean verification status, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationCarrier obligation closure package`

Proof. Project the accepted carrier. The rows M, O, I, A provide the monad transformer, outer-completion, idempotence, and associativity data; the rows S, R, D, E provide the displayed StreamName, RegSeqRat, DyadicRatCore, and Real-seal face; and H, C, P, N provide transport, replay, provenance, and local naming.

Apply Definition 1829.2. It lists the local carrier admission, flattening, shared routing, transport, replay, provenance, and ledger nonescape obligations and says that no local obligation is stored outside those rows.

Apply Definition 1829.3 to bind the order M, O, I, A before S, R, D, E. Apply Definition 1829.4 to show that the terminal Real-facing consumer receives only the displayed L10 face and structural rows.

The excluded objects are absent from the carrier and from all three cited obligation routes, so the projected package is exactly the local obligation surface. □

Theorem 1829.6 (Cauchy completion multiplication outer-inner replay)**.** *Let* $K = (M, O, I, A, S, R, D, E, H, C, P,$ *be an accepted* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *carrier. Every displayed* Cont *replay in* C *factors an outer-completion request through*

$$M \longmapsto O \longmapsto I \longmapsto A$$

before it reads

$$S \longmapsto R \longmapsto D \longmapsto E.$$

The replay then returns through H, C, P, N *as structural transport, displayed continuation, provenance, and local naming, and it never exposes a detached completion-of-completion representative.*

Proof. Project K and read the replay row C together with the transport row H. The carrier order gives the monad transformer M and outer completion row O before any public L10 row can be inspected.

Use Definition 1829.3. It forces the idempotence row I and associativity ledger A to mediate the route from the outer completion to the displayed completion boundary before the route reaches S, R, D, E.

Use Definition 1829.2 for replay as a local NameCert obligation. The replay obligation names the same route and no hidden representative.

Finally, Definition 1829.4 prevents the terminal read from exporting quotient completion equality, selected representatives, countable choice, host equality, or ambient completeness data. Thus every replay is the stated outer-inner route. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationCarrier outer inner replay`

Theorem 1829.7 (Cauchy completion multiplication provenance exhaustion)**.** *For every accepted* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *carrier* $K = (M, O, I, A, S, R, D, E, H, C, P, N)$*, the provenance row* P *and local naming row* N *source only* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*. Any accepted consumer of* K *that reaches provenance or local naming has already passed through the carrier admission, flattening, replay, and Real-seal nonescape obligations.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMultiplicationUp.CauchyCompletionMultiplicationProvenanceExhaustio`

Proof. Project the carrier to P and N. By Definition 1829.1, P names only the displayed monad, idempotence, associativity, stream, regular rational, dyadic, Real, and BEDC structural sources, while N names the local certificate row.

Apply Definition 1829.2. Its provenance and ledger-nonescape clauses require the local surface to source only these rows and to export no additional completion witness.

Apply Definition 1829.3 and Definition 1829.4. The first forces provenance-facing reads to pass through the displayed outer-to-inner route, and the second prevents the terminal seal from adding Real-completeness or selected-representative data.

Therefore P, N exhaust the cited sources and no provenance-facing consumer receives data outside the listed carrier rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMultiplication}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMultiplication}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1829.1, Definition 1829.2, Definition 1829.3, Definition 1829.4, Definition 1829.5, Definition 1829.6, and Definition 1829.7 enumerate the displayed carrier admission, outer-to-inner flattening, componentwise transport, replay, provenance, and Real-seal nonescape obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMultiplication}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits or representatives, host equality, countable choice, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, outer-to-inner flattening, componentwise transport, replay, provenance, and Real-seal nonescape obligations for BEDC.Derived.CauchyCompletionMultiplicationUp.

Constructive story: A $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ packet is generated from a CauchyCompletionMonad transformer row, an outer completion row, idempotence and associativity rows, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1830

A Concrete Naming Certificate for $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ packet records uniformly Cauchy real-valued function data as a finite BEDC route rather than as host function equality or a completed function space. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the uniform Cauchy modulus surface of chapter 1741, and the terminal real-name seal of chapter 38. The packet gives later uniform-limit and compact-continuity consumers one named route for real-valued function families before any quotient stream, selected pointwise limit, countable-choice schedule, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 1830.1 (Real-function uniform Cauchy carrier)**.** *A* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, S, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the real-valued function source row. It stores only the displayed argument window, the displayed function-value row, and the local classifier for the finite function observation.*
2. *S is the finite source-window ledger. For each accepted tolerance request it records the finite argument windows and the paired value-observation rows that will be compared.*
3. *M is the* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *row. It assigns one displayed modulus request to all source-window rows in S and never selects a host-level pointwise limit.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested tolerance, the smaller dyadic tolerance supplied by M, and the finite descent route used by the paired value comparisons.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational observations exposed by S, M, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source windows, uniform modulus row, dyadic tolerance ledger, and regular rational readback have been exposed.*
7. *H records componentwise* hsame *transport for the function source row, source-window ledger, modulus row, dyadic ledger, readback row, seal row, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a uniform Cauchy request through $A, S, M, D, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealFunctionUniformCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $A, S, M, D, R, E, H, C, P, N$. The carrier has no coordinate for host function equality, quotient streams, selected pointwise limits, countable-choice selectors, ambient real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RealFunctionUniformCauchyUp.TasteGate.RealFunctionUniformCauchyTasteGate single carrier alignment`

Theorem 1830.2 (Real-function uniform Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *carrier*

$$F = (A, S, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealFunctionUniformCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real-valued function row, finite source-window ledger, uniform Cauchy modulus row, dyadic tolerance ledger, regular rational readback, terminal real seal, transport, replay, provenance, and local name;*
2. *finite-window stability, requiring every comparison of function values to be read from the windows listed in S;*
3. *uniform-modulus transport, requiring the same modulus row M to serve all accepted source-window rows for the requested tolerance;*
4. *dyadic tolerance descent, requiring the comparison tolerance used by the value rows to be obtained from the dyadic ledger D;*
5. *regular rational readback, requiring every numeric observation consumed by the packet to pass through R before the terminal seal is inspected;*
6. *Real-seal non-escape, requiring E to remain downstream of A, S, M, D, R and the structural rows;*
7. *provenance exhaustion, requiring P to source only the listed rows and to export no host function equality, quotient stream, selected pointwise limit, countable-choice schedule, or ambient real completeness principle;*
8. *local naming, requiring N to name exactly this finite surface and no external function-space object.*

No local NameCert obligation is stored outside these rows.

Theorem 1830.3 (Real-function uniform Cauchy Real-completion handoff)**.** *Let $F = (A, S, M, D, R, E, H, C, P, N$ be an accepted* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read of F factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as exposed by the source windows S, the readback row R, the tolerance ledger D, and the terminal seal E. In particular, a completion-facing consumer can inspect real-valued function data only

through the displayed finite windows, regular rational observations, dyadic tolerance descent, uniform modulus transport, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It cannot read host function equality, quotient streams, countable choice, selected pointwise limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealFunctionUniformCauchy}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient streams, countable choice, selected pointwise limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window stability, uniform-modulus transport, dyadic tolerance descent, regular rational readback, Real-seal non-escape, provenance exhaustion, and local naming for BEDC.Derived.RealFunctionUniformCauchyUp.

Constructive story: A $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ packet is generated from one real-valued function source row, finite source-window rows, one UniformCauchyModulus row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1831

A Concrete Naming Certificate for $\mathsf{DyadicIntervalRefinement}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Moore–Kearfott–Cloud interval analysis, the $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ packet isolates one finite dyadic subdivision step before any infinite nested route is read. It sits over the dyadic endpoint core of chapter 291, the interval surface of chapter 306, the midpoint selector of chapter 1712, the finite nesting discipline of chapter 328, the Cauchy handoff of chapter 1811, the finite schedule interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a one-step finite-means carrier for L10 real and completion work; it is not an open-cover compactness theorem, a selected branch, a quotient stream equality, a trichotomy principle, countable choice, ambient real completeness, a Lean theorem, or a bridge check.

Definition 1831.1 (Dyadic interval refinement carrier)**.** *A* $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, J_0, J_1, E, R, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the parent* $\mathsf{DyadicInterval}^{\uparrow}$ *row. It exposes the ordered dyadic endpoints through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and the parent containment ledger read by later interval consumers.*

2. *J_0 and J_1 are the two child* $\mathsf{DyadicInterval}^{\uparrow}$ *rows produced by the displayed midpoint row. Their outer endpoints are reused from I, and their shared endpoint is the midpoint supplied by* $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$*.*

3. *E is the endpoint-reuse ledger. It records that the lower endpoint of J_0 is the lower endpoint of I, the upper endpoint of J_1 is the upper endpoint of I, and the upper endpoint of J_0 is the lower endpoint of J_1.*

4. *R is the refinement-containment ledger. It records both child intervals as dyadic subintervals of I, and records that any retained child row is a finite step admissible for the* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *surface.*

5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It names only the parent endpoint observations, child endpoint observations, midpoint observation, and retained-child flag opened by this one refinement step.*

6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It repacks the scheduled dyadic observations from S as regular rational data for downstream Cauchy consumers.*

7. *H records componentwise* hsame *transport for the parent interval, child intervals, endpoint-reuse ledger, refinement-containment ledger, stream window, regular rational readback, replay rows, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a refinement request through $I, J_0, J_1, E, R, S, Q, H, P, N$ without adding a branch selector, quotient stream, or completed real point.*
9. *P is the* Pkg *provenance over* DyadicIntervalRefinement$^\uparrow$, DyadicRatCore$^\uparrow$, DyadicInterval$^\uparrow$, LocatedIntervalMidpoi NestedDyadicInterval$^\uparrow$, NestedDyadicCauchy$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DyadicIntervalRefinement}^\uparrow}$ *row.*

The classifier compares accepted packets only through these eleven displayed rows. The carrier has no coordinate for open-cover compactness, selected infinite branches, quotient stream equality, trichotomy, countable choice, ambient Real$^\uparrow$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalRefinementUp.DyadicIntervalRefinementTasteGate single carrier alignment`

Theorem 1831.2 (Dyadic interval refinement NameCert obligations)**.** *For every accepted* DyadicIntervalRefinement *carrier*

$$K = (I, J_0, J_1, E, R, S, Q, H, C, P, N),$$

the local NameCert$_{\text{DyadicIntervalRefinement}^\uparrow}$ *surface consists exactly of carrier admission, parent dyadic interval exposure, two child dyadic interval exposures, endpoint-reuse exactness, dyadic containment and retained-step exactness, finite StreamName window exposure, RegSeqRat readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. No local NameCert obligation is stored outside those rows.*

Proof. Project the carrier of Definition 1831.1. The projection exposes one parent interval row, two child interval rows, one endpoint-reuse row, one refinement-containment row, one stream window, one regular rational readback, and the structural rows.

The parent and child exposure obligations are forced by I, J_0, J_1. Endpoint-reuse exactness is forced by E, and containment exactness is forced by R; a consumer can inspect no other interval or containment object through the classifier.

The downstream read rows are S and Q. The StreamName row lists exactly the finite observations opened by this subdivision step, while the RegSeqRat row repacks only those observations as regular rational data.

Finally H, C, P, N transport, replay, source, and name the same displayed rows. Since the carrier has no extra coordinate, the listed rows exhaust the NameCert surface. □

Theorem 1831.3 (Dyadic interval refinement window handoff)**.** *Let $K = (I, J_0, J_1, E, R, S, Q, H, C, P, N)$ be an accepted* DyadicIntervalRefinement$^\uparrow$ *carrier. Every* NestedDyadicInterval$^\uparrow$, StreamName$^\uparrow$, *or* RegSeqRat$^\uparrow$ *consumer of the refinement factors through the finite route*

$$I, J_0, J_1 \longmapsto E \longmapsto R \longmapsto S \longmapsto Q \longmapsto H, C, P, N.$$

Thus the consumer receives a parent interval, two displayed child intervals, endpoint reuse, finite containment, the scheduled observation window, and regular rational readback, but receives no infinite branch selector or quotient stream equality.

Proof. Start with the interval rows. The parent row I and child rows J_0, J_1 provide the only endpoint data available to any nested-window consumer.

Use E to identify the reused endpoints and shared midpoint. Then use R to read the finite containment relation that makes either child an admissible retained step for a nested dyadic interval prefix.

The schedule row S fixes which endpoint, midpoint, and retained-child observations may be opened. The readback row Q then repacks those finite observations for regular rational consumers.

The structural rows H, C, P, N only transport, replay, source, and name this route. They do not add an infinite branch, a quotient stream, or an external real point, so every listed consumer factors through the displayed finite handoff. □

Theorem 1831.4 (Dyadic interval refinement Real boundary)**.** *For every accepted* $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ *carrier* $K = (I, J_0, J_1, E, R, S, Q, H, C, P, N)$*, every* $\mathsf{NestedDyadicCauchy}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing read must pass through the finite StreamName window* S *and the RegSeqRat readback* Q *before any real-completion consumer can inspect the row. The refinement exports a finite dyadic subdivision boundary, not open-cover compactness, a selected infinite branch, quotient stream equality, trichotomy, countable choice, ambient real completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier. The only schedule coordinate is S, and the only regular rational readback coordinate is Q.

Apply Definition 1831.3. A NestedDyadicCauchy or Real-facing consumer must first read the displayed parent and child intervals, endpoint reuse, containment, and scheduled observations before the readback row is available.

The readback row Q is therefore the boundary through which real-completion consumers see the refinement. Because the carrier contains no open-cover, selected-branch, quotient, trichotomy, choice, completeness, Lean, or bridge coordinate, none of those objects can be exported by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ packet is generated from one parent dyadic interval, two child dyadic intervals, endpoint reuse, dyadic containment and retained-step rows, finite StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1831.1, Definition 1831.2, Definition 1831.3, and Definition 1831.4 seed the finite one-step dyadic refinement route from interval subdivision to StreamName, RegSeqRat, NestedDyadicCauchy, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, quotient stream equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-reuse exactness, containment and retained-step exactness, finite window exposure, RegSeqRat readback, Real-boundary nonescape, provenance exhaustion, and local naming for BEDC.Derived.DyadicIntervalRefinementUp.

Chapter 1832

A Concrete Naming Certificate for $\mathsf{RegularCauchyMinimum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMinimum}^{\uparrow}$ packet records the finite Bishop-style route for the lower member of two regular Cauchy real names without importing a host minimum operation or an ambient order-completeness principle. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located comparison modulus of chapter 1627, and the Archimedean comparison budget of chapter 430. The certificate gives downstream real-order and completion-facing chapters one finite route for binary lower-bound formation before quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness is available.

Definition 1832.1 (Regular Cauchy minimum carrier)**.** *A* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, T, L, D, A, B, W, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* $\mathsf{Real}^{\uparrow}$ *rows presented by regular Cauchy names. Each row exposes only its finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, dyadic tolerance ledger, and terminal real seal.*

2. *T is the dyadic comparison tolerance row. It stores the requested output tolerance, the comparison tolerance used to separate the two names when a side is selected, and the smaller dyadic budget consumed by the exported lower-bound row.*

3. *L is the* $\mathsf{LocatednessModulus}^{\uparrow}$ *row. It records the finite located comparison request for the two displayed regular Cauchy names and never supplies a host trichotomy or a global order decision.*

4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for the two readbacks, the comparison tolerance, and the lower dyadic approximation chosen for the output name.*

5. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *budget row, used only to align dyadic comparison scale, regular Cauchy tail scale, and the requested output tolerance.*

6. *B is the finite branch ledger. It records whether the displayed located comparison routes the lower-bound output through the left name, through the right name, or through the overlap tolerance when the two windows are indistinguishable at the requested scale.*

7. *W is the exported regular Cauchy output row. Every window of W is copied from X or Y under the branch ledger B and the tolerance rows T, L, D, A.*

8. *H records componentwise* hsame *transport for the two input names, tolerance, locatedness, dyadic arithmetic, Archimedean budget, branch, output, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a lower-bound request through $X, Y, T, L, D, A, B, W, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMinimum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMinimum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the tuple $X, Y, T, L, D, A, B, W, H, C, P, N$. The carrier has no coordinate for a host minimum function, trichotomy, quotient stream equality, selected limits, countable-choice schedules, ambient real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyMinimumUp.RegularCauchyMinimumTasteGate single carrier alignment`

Theorem 1832.2 (Regular Cauchy minimum NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carrier*

$$M = (X, Y, T, L, D, A, B, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMinimum}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, tolerance row, locatedness row, dyadic arithmetic ledger, Archimedean budget, branch ledger, output row, transport, replay, provenance, and local name;*

2. *input regularity, requiring every exported output window to be copied from the displayed regular Cauchy windows of X or Y at the scale fixed by T, D, A;*

3. *located comparison, requiring the side ledger B to be read only after the locatedness row L and the dyadic tolerance row T have been displayed;*

4. *left-bound exactness, requiring a left-routed branch to expose an output window no larger than the displayed window of X at the requested tolerance;*

5. *right-bound exactness, requiring a right-routed branch to expose an output window no larger than the displayed window of Y at the requested tolerance;*

6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, L, D, A, B, W, C, P, N$ to preserve the accepted lower-bound route;*

7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no host minimum, trichotomy, quotient stream equality, selected limit, countable choice, ambient Real completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1832.1. Its displayed rows are exactly the two regular Cauchy real inputs, the dyadic tolerance row, locatedness row, dyadic arithmetic ledger, Archimedean budget, branch ledger, output row, and structural rows.

Input regularity follows because W has no independent numeric coordinate. Each exported window is copied from X or Y after the tolerance, locatedness, dyadic, and Archimedean rows fix the scale.

The left-bound and right-bound rows are then read from B. A left-routed branch consumes the left input window and the overlap tolerance; a right-routed branch consumes the right input window and the same displayed tolerance surface.

Classifier stability and non-escape are ledger exhaustion. The only permitted transports and replays are H and C, and the provenance and naming rows P, N cite no excluded host or quotient object. □

Theorem 1832.3 (Regular Cauchy minimum left bound)**.** *Let $M = (X, Y, T, L, D, A, B, W, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carrier. Every finite window exported by W is a displayed lower-bound window for the left input row X at the tolerance recorded in T. The witness is read entirely from the branch ledger B, the locatedness row L, the dyadic arithmetic ledger D, the Archimedean budget A, the* hsame *transport H, and the replay row C.*

Proof. Project the displayed output window from W and inspect the corresponding branch row in B.

In a left-routed branch, the output window is copied from X, so the claimed left-bound row is the reflexive displayed comparison transported by H and replayed by C.

In a right-routed or overlap branch, the locatedness row L supplies the finite comparison certificate at the dyadic scale fixed by T, D, A. The output window is copied from Y only under that certificate, so the same ledger gives the displayed lower-bound comparison against X.

No other comparison source exists in the carrier. The proof is therefore exhausted by B, L, T, D, A, H, C. □

Lean4 ✓ `BEDC.Derived.RegularCauchyMinimumUp.RegularCauchyMinimumLeftBound`

Theorem 1832.4 (Regular Cauchy minimum right bound)**.** *Let $M = (X, Y, T, L, D, A, B, W, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carrier. Every finite window exported by W is a displayed lower-bound window for the right input row Y at the tolerance recorded in T. The witness is read entirely from the branch ledger B, the locatedness row L, the dyadic arithmetic ledger D, the Archimedean budget A, the* hsame *transport H, and the replay row C.*

Proof. Project the displayed output window from W and inspect its branch row in B.

In a right-routed branch, the output window is copied from Y, so the claimed right-bound row is the reflexive displayed comparison transported by H and replayed by C.

In a left-routed or overlap branch, the locatedness row L supplies the finite comparison certificate at the dyadic scale fixed by T, D, A. The output window is copied from X only under that certificate, so the same ledger gives the displayed lower-bound comparison against Y.

The carrier contains no independent host order proof. Thus the right-bound witness is exactly the local projection of B, L, T, D, A, H, C. □

Theorem 1832.5 (Regular Cauchy minimum classifier stability)**.** *If two accepted* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carriers*

$$M = (X, Y, T, L, D, A, B, W, H, C, P, N)$$

and

$$M' = (X', Y', T', L', D', A', B', W', H', C', P', N')$$

are componentwise hsame *on the two input names, tolerance, locatedness, dyadic arithmetic, Archimedean budget, branch ledger, output row, replay, provenance, and local naming row, then their classifiers agree. In particular, every accepted lower-bound window in W is transported to the corresponding accepted lower-bound window in W' without adding a host minimum or quotient-stream equality.*

Proof. Unfold the classifier described in Definition 1832.1. It reads only $X, Y, T, L, D, A, B, W, H, C, P, N$.

The assumed componentwise hsame rows identify each coordinate with its primed counterpart. Transport along those rows preserves the side ledger, the copied output window, and the displayed dyadic comparison scale.

Since neither classifier has a hidden coordinate, there is no remaining source from which disagreement could arise. The transported packet is accepted exactly when the original packet is accepted. □

Theorem 1832.6 (Regular Cauchy minimum non-escape)**.** *Every accepted* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *carrier exports only the finite lower-bound route described by Definition 1832.1. No consumer of the packet can recover a host minimum function, trichotomy of real names, quotient stream equality, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean verification, or bridge checking credential.*

Proof. Read the carrier coordinate by coordinate. Numeric data are confined to the two input rows, the tolerance row, the locatedness row, the dyadic ledger, the Archimedean budget, the branch ledger, and the output row.

Transport and replay are confined to H and C. Provenance and local naming are confined to P and N, and those rows cite only the finite BEDC names listed in the carrier.

The excluded principles have no coordinate, no provenance entry, and no replay edge. Therefore a consumer can inspect the displayed lower-bound certificate but cannot escape to any host or quotient object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMinimum}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinimum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1832.1, Definition 1832.2, Definition 1832.3, Definition 1832.4, Definition 1832.5, and Definition 1832.6 seed a finite lower-bound route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinimum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host minimum, trichotomy, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, input regularity, located comparison, left-bound exactness, right-bound exactness, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyMinimumUp.

Constructive story: A $\mathsf{RegularCauchyMinimum}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a dyadic comparison tolerance, a LocatednessModulus row, a DyadicRatCore arithmetic ledger, an ArchimedeanReal budget, a branch ledger, an output regular Cauchy row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1833

A Concrete Naming Certificate for $\mathsf{RegularCauchyMaximum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMaximum}^{\uparrow}$ packet records the constructive upper member of two regular rational Cauchy real names by reducing the public route to already displayed regular Cauchy arithmetic. It reads the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic surface of chapter 291, the absolute-value lift of chapter 1499, the addition surface of chapter 417, the subtraction surface of chapter 429, the sibling lower-bound packet of chapter 1832, and the terminal real-name seal of chapter 38. The certificate gives downstream $\mathsf{Real}^{\uparrow}$ consumers a finite maximum route without assuming quotient streams, selected limits, trichotomy, countable choice, or ambient completeness.

Definition 1833.1 (Regular Cauchy maximum carrier)**.** *A* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, W_X, W_Y, D, S, A, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* $\mathsf{Real}^{\uparrow}$ *rows presented by regular Cauchy names; each exposes only its finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, dyadic tolerance ledger, and terminal real seal.*

2. *W_X and W_Y are aligned finite observation windows for the two names at the requested output tolerance.*

3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *subtraction ledger for the displayed difference $X - Y$ read through W_X and W_Y.*

4. *S is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row repacking the pointwise dyadic subtraction route as a regular Cauchy difference name.*

5. *A is the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *row applied to the displayed difference route S.*

6. *U is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row adding the two source names and the absolute-difference row on the shared observation scale.*

7. *R is the final regular Cauchy readback row for the half-sum maximum route, with the dyadic division-by-two ledger displayed inside the same finite tolerance budget.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R has been exposed.*

9. *H records componentwise* hsame *transport for the two inputs, windows, dyadic subtraction, difference row, absolute-difference row, sum row, half-sum readback, real seal, provenance, and local name.*

10. *C records displayed* Cont *replay from a maximum request through $X, Y, W_X, W_Y, D, S, A, U, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMaximum}^{\uparrow}$, $\mathsf{RegularCauchyMinimum}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMaximum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W_X, W_Y, D, S, A, U, R, E, H, C, P, N$. The carrier has no coordinate for a host maximum function, trichotomy, quotient stream equality, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMaximumUp.RegularCauchyMaximumTasteGate single carrier alignment`

Theorem 1833.2 (Regular Cauchy maximum NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *carrier*

$$M = (X, Y, W_X, W_Y, D, S, A, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMaximum}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, aligned stream windows, dyadic subtraction ledger, difference row, absolute-difference row, sum row, half-sum readback, real seal, transport, replay, provenance, and local name;*

2. *aligned-window exposure, requiring every output request to display matching* $\mathsf{StreamName}^{\uparrow}$ *windows for X and Y before any dyadic subtraction, absolute value, sum, or seal row is consumed;*

3. *arithmetic route exactness, requiring D, S, A, U, R to be read in the order subtraction, regular Cauchy difference, regular Cauchy absolute value, regular Cauchy sum, and dyadic half-sum readback;*

4. *classifier stability, requiring componentwise* hsame *transport of $X, Y, W_X, W_Y, D, S, A, U, R, E, C, P, N$ to preserve the accepted maximum route;*

5. *non-escape, requiring H, C, P, N to transport, replay, source, and name no host maximum, trichotomy, quotient stream equality, selected limit, countable choice, ambient Real completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1833.1. Its displayed rows are exactly the two regular Cauchy real inputs, aligned stream windows, dyadic subtraction ledger, regular Cauchy difference row, absolute-difference row, sum row, half-sum readback, real seal, and structural rows.

Aligned-window exposure follows because D has no independent source coordinate. The subtraction ledger can read endpoints only through W_X and W_Y, so the later rows S, A, U, R, E remain downstream of the displayed finite windows.

Arithmetic route exactness is ledger order. The difference row S consumes D, the absolute-difference row A consumes S, the sum row U consumes X, Y, A, and the readback row R records the dyadic division by two before E seals the result as a real name.

Classifier stability and non-escape are coordinate exhaustion. The only permitted transports and replays are H and C, and the provenance and naming rows P, N cite no excluded host or quotient object. □

Theorem 1833.3 (Regular Cauchy maximum abs-sum route)**.** *Let*

$$M = (X, Y, W_X, W_Y, D, S, A, U, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the maximum row reaches the seal E only through the constructive route*

aligned windows for X and Y,
dyadic subtraction $X - Y$,
regular Cauchy difference S,
absolute difference A,
regular Cauchy sum of X, Y, A,
dyadic half-sum readback R,
final real seal E.

Equivalently, the packet presents the maximum of X and Y by the displayed finite route for $(X + Y + |X - Y|)/2$, and it exposes no quotient stream equality, selected limit, trichotomy, countable choice, host maximum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a real-facing read of the carrier. By the obligation rows of Definition 1833.2, the read cannot reach the seal E before it has consumed the half-sum readback row R.

The row R is downstream of the sum row U. The sum row consumes the two source names together with the absolute-difference row A, and the row A is downstream of the regular Cauchy difference row S formed from the dyadic subtraction ledger D.

The ledger D is read only after the aligned windows W_X and W_Y are displayed. Thus the route is the listed sequence of aligned windows, dyadic subtraction, regular Cauchy difference, absolute difference, sum, half-sum readback, and real seal.

No excluded principle has a coordinate in the carrier. The provenance and replay rows merely name and transport this finite route, so the consumer receives the abs-sum maximum certificate and nothing outside it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMaximum}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMaximum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1833.1, Definition 1833.2, and Definition 1833.3 seed a finite upper-member route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMaximum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host maximum, trichotomy, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, aligned-window exposure, arithmetic route exactness, classifier stability, non-escape, and the abs-sum RealUp handoff for BEDC.Derived.RegularCauchyMaximumUp.

Constructive story: A $\mathsf{RegularCauchyMaximum}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, aligned StreamName windows, a DyadicRatCore subtraction ledger, RegularCauchyDifference, RegularCauchyAbs, and RegularCauchySum rows, a dyadic half-sum readback, a RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1834

A Concrete Naming Certificate for $\mathsf{ImplicitFunction}^{\uparrow}$

Following the classical implicit function theorem tradition of Dieudonne and Rudin, the $\mathsf{ImplicitFunction}^{\uparrow}$ packet records the local-solution data that a constructive BEDC consumer may inspect when an equation row is solved by a displayed derivative and an invertible linear approximation. The packet consumes the derivative source of chapter 122, the linear approximation surface of chapter 48, the finite coordinate ledger of chapter 49, the completeness boundary of chapter 128, the Picard contraction route of chapter 395, and the terminal real-name seal of chapter 38. It is not a host-level theorem asserting differentiability of an ambient function space or selecting a solution germ; it is a finite NameCert route from displayed analytic rows to a local graph window.

Definition 1834.1 (Implicit function carrier)**.** *An* $\mathsf{ImplicitFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, B, D, L, M, Q, G, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the displayed equation row. It stores the finite source variables, target variable, equation-value history, and local classifier for the read $F(x, y) = 0$.*
2. *B is the base-point row. It records the displayed point (x_0, y_0), the equation read at that point, and the finite neighbourhood name in which all later rows are interpreted.*
3. *D is the* $\mathsf{Derivative}^{\uparrow}$ *row for the equation source at B, including the displayed partial-derivative histories consumed by the linear approximation.*
4. *L is the invertible* $\mathsf{LinMap}^{\uparrow}$ *approximation row attached to the target-variable derivative, together with its finite inverse-witness ledger.*
5. *M is the* $\mathsf{Mat}^{\uparrow}$ *coordinate row that displays the same approximation and inverse witness in finite component form for comparison and tolerance bookkeeping.*
6. *Q is the* $\mathsf{PicardContraction}^{\uparrow}$ *local-solution row. It records the displayed fixed-point map, contraction budget, iterate ledger, and local nonescape side condition obtained from D, L, M.*
7. *G is the local graph and window row. It records the source window, target window, graph readback, and uniqueness window exported by the Picard route.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the equation, base point, derivative, linear approximation, matrix ledger, Picard route, and graph window have been displayed.*

9. *H records componentwise* hsame *transport for the equation row, base-point row, derivative row, linear approximation row, matrix row, Picard local-solution row, graph-window row, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from an equation request through $E, B, D, L, M, Q, G, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{ImplicitFunction}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, B, D, L, M, Q, G, R, H, C, P, N$. The carrier has no coordinate for host differentiability, quotient function spaces, selected solution germs, the classical inverse-function theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionTasteGate single carrier alignment`

Theorem 1834.2 (Implicit function root equation carrier)**.** *Every accepted* $\mathsf{ImplicitFunction}^{\uparrow}$ *root packet must display the equation row, base point row, derivative row, linear map row, matrix row, Picard row, graph row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}$ *row. No root-equation consumer may read a local solution window before those rows are all visible in the same finite* BHist *packet.*

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionRootEquationCarrier`

Proof. Project the accepted packet through Definition 1834.1. The carrier inventory is exactly $E, B, D, L, M, Q, G, R, H, C, P, N$, so the displayed equation, base point, derivative, linear approximation, matrix ledger, Picard route, graph window, Real seal, transport, replay, provenance, and local name are the only rows available.

A root-equation read must therefore open E and B before any analytic route is interpreted. The rows D, L, M, Q, G then expose the derivative, linearization, component ledger, contraction route, and graph window in carrier order.

The terminal rows R, H, C, P, N seal, transport, replay, source, and name that same route. Since the carrier contains no second equation row or detached solution object, no local solution window can be consumed before the displayed rows have been read. □

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionCarrier root equation carrier`

Theorem 1834.3 (Implicit function linearization Picard route)**.** *The local graph route of an accepted* $\mathsf{ImplicitFunction}^{\uparrow}$ *packet can be consumed only after the* $\mathsf{Derivative}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *and* $\mathsf{PicardContraction}^{\uparrow}$ *rows are visible through D, L, M, Q and the completeness boundary named by the Picard row. Thus the graph row G is a contraction-route endpoint, not a host differentiability theorem or selected solution germ.*

Proof. Read the linearization rows from the carrier. The derivative row D supplies the equation source data, the linear-map row L supplies the invertible approximation, and the matrix row M supplies the finite component ledger for the same approximation and inverse witness.

The Picard row Q is the only fixed-point coordinate in the packet. It names the complete-metric boundary and the contraction budget before any graph endpoint is exported.

The graph row G is downstream of D, L, M, Q. Consequently a consumer of the local graph must pass through the displayed derivative, linear map, matrix, complete-metric, and Picard rows, and cannot extract host differentiability or a selected germ from an absent carrier coordinate. □

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionLinearizationPicardRoute`

Theorem 1834.4 (Implicit function local graph seal handoff)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal* R *of an accepted* $\mathsf{ImplicitFunction}^{\uparrow}$ *packet is a boundary for the displayed graph window* G*. It exports the equation, base point, derivative, linearization, matrix ledger, Picard route, graph window, transport, replay, provenance, and local name, but exports no host differentiability, selected solution germ, quotient function space, or ambient completeness principle.*

Proof. Apply the root equation carrier theorem above to expose the finite packet rows. The Real seal R is listed after the equation, base point, derivative, linearization, matrix, Picard, and graph-window rows.

Use the linearization Picard route theorem. It places G downstream of the derivative, linear map, matrix, complete-metric, and Picard data, so the seal reads only the displayed contraction endpoint.

The structural rows H, C, P, N then transport, replay, source, and name the sealed graph window. The excluded host differentiability, selected germ, quotient function space, and ambient completeness principles have no coordinate in Definition 1834.1, so the seal cannot export them. □

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionLocalGraphSealHandoff`

Theorem 1834.5 (Implicit function NameCert obligations)**.** *For every accepted* $\mathsf{ImplicitFunction}^{\uparrow}$ *carrier*

$$I = (E, B, D, L, M, Q, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed equation row, base-point row, derivative row, linear approximation row, matrix row, Picard row, graph-window row, Real seal, transport, replay, provenance, and local name;*
2. *derivative and invertibility ledger compatibility, requiring* D, L, M *to display the same target-variable approximation and inverse witness;*
3. *Picard local-solution handoff, requiring* Q *to be the only fixed-point route available to the packet;*
4. *graph-window transport, requiring* G *to expose local reads only through the source and target windows named by* B *and certified by* Q*;*
5. *Real-seal non-escape, requiring every read of* R *to remain downstream of* E, B, D, L, M, Q, G *and the structural rows;*
6. *provenance exactness, requiring* P *and* N *to name only the listed rows and no host differentiability theorem, quotient function space, selected solution germ, classical inverse-function theorem, or ambient completeness principle.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.ImplicitFunctionUp.ImplicitFunctionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1834.1. The finite packet lists the equation, base point, derivative source, invertible approximation, matrix ledger, Picard route, graph window, Real seal, transport, replay, provenance, and local name.

The derivative and invertibility obligations are local to D, L, M. The derivative row supplies the displayed partial-derivative histories, the linear-map row records the inverse witness, and the matrix row exposes the same witness in component form for finite tolerance comparison.

The local solution is then routed through Q. Since Q is the only Picard coordinate of the carrier, any fixed-point read must use the displayed contraction budget, iterate ledger, and nonescape row recorded there.

The graph-window and seal obligations are downstream. The row G reads the local graph only inside the carried source and target windows, and the row R is reached only after the equation, derivative, invertibility, Picard, and graph-window rows have been opened. The structural rows H, C, P, N transport, replay, source, and name this same route without adding a host solution object. □

Theorem 1834.6 (Implicit function Picard local-solution route)**.** *Every accepted* $\mathsf{ImplicitFunction}^{\uparrow}$ *carrier factors each local-solution read through the route*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{Mat}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{PicardContraction}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by D, L, M, Q, R *and the graph-window row* G*. In particular, the* $\mathsf{Real}^{\uparrow}$ *seal is consumed only after the derivative row of chapter 122, the linear-map row of chapter 48, the matrix row of chapter 49, the complete-metric boundary of chapter 128, the Picard contraction route of chapter 395, and the real-name seal of chapter 38 have been displayed.*

Proof. Read the carrier coordinates. The equation and base-point rows E, B provide only the local problem statement and the neighbourhood in which the route is interpreted.

The analytic source then passes through D, L, M. The derivative row D supplies the local derivative data, the linear-map row L supplies the invertible approximation, and the matrix row M supplies finite componentwise comparisons for the same approximation and inverse witness.

The completeness and fixed-point part is exposed only by Q. Its contraction budget and nonescape side condition are the carried route to the complete-metric boundary and Picard local-solution ledger, so no alternate selected solution germ is available.

Finally G repacks the Picard endpoint as a local graph-window read, and R provides the terminal $\mathsf{Real}^{\uparrow}$ seal. Because R is downstream of D, L, M, Q, G, every Real-facing local-solution read factors through the listed chapters before the seal is consumed. □

Falsifiable prediction: Every $\mathsf{ImplicitFunction}^{\uparrow}$ local-solution read factors through one displayed equation row, one base-point row, one Derivative row, one invertible LinearMap approximation row, one Matrix component ledger, one PicardContraction local-solution row, one local graph-window row, one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: derivative, linearmap, matrix, completemetric, picardcontraction, real: $\mathsf{ImplicitFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries equation data, base-point data, derivative data, an invertible linear approximation, matrix coordinates, a Picard local-solution route, a local graph window, and a terminal Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1834.1, Definition 1834.5, Definition 1834.6, Definition 1834.3, and Definition 1834.4 bind the scoped BEDC primitives for derivative-window exposure, local inverse approximation, Picard local-solution routing, graph-window transport, Real-seal nonescape, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ImplicitFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability, quotient function spaces, selected solution germs, the classical inverse-function theorem, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires checked carrier admission, derivative and invertibility ledger compatibility, Picard local-solution handoff, graph-window transport, Real-seal non-escape, provenance exactness, and local naming for BEDC.Derived.ImplicitFunctionUp.

Constructive story: An ImplicitFunction$^{\uparrow}$ packet is generated from one displayed equation row, one base-point row, one Derivative row, one invertible LinearMap approximation row, one Matrix component ledger, one PicardContraction local-solution row, one local graph-window row, one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1835

A Concrete Naming Certificate for $\mathsf{UniformBoundedness}^{\uparrow}$

Following the Banach–Steinhaus theorem as presented in Bourbaki and Kreyszig, the $\mathsf{UniformBoundedness}^{\uparrow}$ packet records the finite certificate surface by which a pointwise bounded family of displayed bounded linear operators exposes a uniform bound on a displayed Baire-complete source window. It consumes the operator carrier of chapter 1644, the prefix-bar completeness handoff of chapter 1602, the norm rows of chapter 89, the functional-analysis consumer face of chapter 94, the stream scheduler of chapter 126, and the regular rational readback surface of chapter 301. The packet is a NameCert reconstruction of the traditional theorem's visible route; it is not an unrestricted host-level Banach–Steinhaus principle.

Definition 1835.1 (Uniform boundedness carrier)**.** *A* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, W, B, N, R, S, Q, H, C, P, L)$$

with the following displayed rows:

1. *F is a finite family ledger of* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows* $\mathsf{BanachBLOp}(X, Y_i, T_i, K_i, \Lambda_i)$ *sharing the displayed source carrier X and carrying target rows Y_i.*
2. *W is the pointwise boundedness window. For each carried source endpoint x inspected by the schedule, it records a* $\mathsf{Norm}^{\uparrow}$ *bound row for the finite family of target reads $T_i(x)$ and the local rational budget used for that inspection.*
3. *B is the* $\mathsf{BaireMetric}^{\uparrow}$ *bar and complete-metric handoff row on the source-side observation space. It records the displayed bar of windows on which pointwise boundedness is visible and the complete-metric route used to pass from local windows to a source neighbourhood.*
4. *N is the* $\mathsf{Norm}^{\uparrow}$ *envelope ledger. It records the source norm window, the target norm rows, and the candidate uniform operator-bound endpoint.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of the rational bound budget used to compare the local pointwise windows with the single displayed uniform bound.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule controlling which source endpoints, operator rows, norm rows, and rational comparisons may be inspected.*
7. *Q records componentwise* hsame *transport for the operator family, pointwise windows, Baire handoff, norm envelope, regular-rational readback, stream schedule, continuation, provenance, and local name.*

8. *H is the visible history row binding the operator-family reads, pointwise-boundedness witnesses, Baire bar handoff, norm-envelope rows, and readback comparisons into one* BHist *packet.*
9. *C records displayed* Cont *replay from a requested family-bound read through $F, W, B, N, R, S, Q, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformBoundedness}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformBoundedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the listed rows. It has no coordinate for host function extensionality, choice-selected uniform constants, quotient operator equality, a hidden operator space, or the unrestricted classical Banach–Steinhaus theorem.

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessUpTasteGate single carrier alignment`

Theorem 1835.2 (Uniform boundedness NameCert obligations)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier*

$$U = (F, W, B, N, R, S, Q, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{UniformBoundedness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the shared-source family of* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, pointwise boundedness windows, Baire bar handoff, norm envelope, regular-rational readback, stream schedule, transport, history, replay, provenance, and local naming;*
2. *family coherence, requiring every operator row in F to share the displayed source carrier and to expose its endpoint action and norm bound through Definition 1644.1;*
3. *pointwise boundedness admission, requiring W to give only scheduled source endpoints and scheduled operator reads;*
4. *Baire handoff compatibility, requiring B to be the only route from pointwise windows to a source neighbourhood;*
5. *norm-envelope exactness, requiring N and R to display the same rational budget and the same uniform operator-bound endpoint;*
6. *ledger refusal, excluding host function extensionality, choice-selected uniform constants, quotient operator equality, hidden operator-space completion, and an unrestricted classical Banach–Steinhaus theorem.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessPacket namecert obligations`
↪ variant `BEDC.Derived.UniformBoundednessUp.UniformBoundednessTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1835.1. The tuple lists the finite operator family, pointwise boundedness window, Baire handoff, norm envelope, regular-rational readback, stream schedule, transport, history, replay, provenance, and local name.

Family coherence is read from F. Each member is a $\mathsf{BoundedLinearOperator}^{\uparrow}$ carrier over the same displayed source, so the endpoint actions, bound endpoints, and operator ledgers are exactly the rows admitted by Definition 1644.2.

Pointwise boundedness is local to W and S. The schedule chooses the finite source reads and the finite operator reads, while W records only the corresponding target-norm comparisons and rational budgets.

The passage from local pointwise windows to a source neighbourhood is routed through B. By Definition 1602.2, the handoff may inspect only displayed prefix windows, bar data, metric rows, transport, replay, provenance, and local naming.

Finally N and R bind the visible norm envelope to the regular-rational readback. Since the classifier sees only $F, W, B, N, R, S, Q, H, C, P, L$, none of the excluded host or quotient principles can be exported as a NameCert obligation. □

Theorem 1835.3 (Uniform boundedness carrier admission)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier*

$$U = (F, W, B, N, R, S, Q, H, C, P, L),$$

the admission surface is exactly the projection of the eleven displayed rows $F, W, B, N, R, S, Q, H, C, P, L$*. These rows expose the shared-source operator family, pointwise boundedness window, Baire handoff, norm envelope, regular-rational readback, stream schedule, componentwise transport, visible history, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundedness carrier admission`

Proof. Open Definition 1835.1. The tuple presentation lists precisely $F, W, B, N, R, S, Q, H, C, P, L$, so every admitted coordinate is one of those rows.

Conversely each listed row appears as a displayed coordinate of the same carrier. Thus carrier admission is neither an ambient Banach-space assertion nor an unrestricted theorem schema; it is the finite inventory read from the accepted packet. □

Theorem 1835.4 (Uniform boundedness family coherence)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier, each row of* F *shares the displayed source carrier and reads its endpoint action and norm bound through the existing* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *envelope. No family member may be read as a host function, quotient operator, or independently completed operator-space point.*

Proof. The row F is specified in Definition 1835.1 as a finite family ledger of $\mathsf{BoundedLinearOperator}^{\uparrow}$ rows over the same source carrier. Reading a member of the family is therefore a read of the bounded-operator packet, not a read of an external function object.

Apply Definition 1644.2 and Definition 1644.5. They confine endpoint action, bound endpoint, linearity ledger, norm ledger, history, replay, provenance, and local naming to the displayed operator envelope, which gives the required family coherence. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessFamilyCoherence`

Theorem 1835.5 (Uniform boundedness pointwise window)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier, the pointwise boundedness evidence is scheduled only through* W *and* S*. A source endpoint, operator row, target norm comparison, or rational pointwise budget is visible to the packet only when the stream schedule* S *names the read and the window* W *stores the corresponding boundedness row.*

Proof. The carrier definition gives S as the finite schedule and W as the pointwise boundedness window. Thus a pointwise read has two required coordinates: the schedule that permits the source and operator inspection, and the window that stores the target-norm comparison.

No other row in U has pointwise boundedness as its role. The Baire row consumes windows downstream, while N and R record the envelope and rational readback; hence unscheduled pointwise data cannot be read from the packet. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessPointwiseWindow`

Theorem 1835.6 (Uniform boundedness Baire handoff compatibility)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier, a source neighbourhood may be read only after the pointwise windows have passed through the* $\mathsf{BaireMetric}^{\uparrow}$ *row* B*. The handoff uses* B *as the unique route from scheduled pointwise data to a displayed Baire-complete source window.*

Proof. Start with the scheduled pointwise data supplied by W and S. These rows identify finite source inspections and finite operator reads, but they do not themselves expose a source neighbourhood.

The source-neighbourhood passage is stored in B. By Definition 1602.2 and Definition 1602.8, the Baire row supplies the displayed bar and complete-metric route; since no other coordinate carries that route, compatibility is forced through B. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessBaireHandoffCompatibility`

Theorem 1835.7 (Uniform boundedness norm-envelope exactness)**.** *For every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier, the norm-envelope row* N *and the regular-rational readback row* R *name the same uniform-bound endpoint and the same rational comparison budget. A consumer cannot read a bound endpoint from* N *while substituting an unrelated rational budget from outside* R*.*

Proof. The row N records the source norm window, the target norm rows, and the candidate uniform operator-bound endpoint. The row R is the regular-rational readback used to compare the local pointwise budgets with that single displayed endpoint.

Because both rows occur in one carrier and are replayed by the same C row, the comparison endpoint and the rational budget are tied to the same finite history H. Thus exactness is the shared readback of N and R, not a separately chosen bound. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessNormEnvelopeExactness`

Theorem 1835.8 (Uniform boundedness ledger refusal)**.** *Every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier refuses host function extensionality, choice-selected uniform constants, quotient operator equality, hidden operator-space completion, and unrestricted Banach–Steinhaus. These principles are not coordinates of* $F, W, B, N, R, S, Q, H, C, P, L$ *and cannot be reconstructed by transport, replay, provenance, or local naming.*

Proof. Inspect the carrier inventory from Definition 1835.3. The visible data are the finite family ledger, pointwise windows, Baire handoff, norm envelope, rational readback, schedule, transport, history, replay, provenance, and local name.

The structural rows Q, H, C, P, L preserve and replay that inventory. They do not add host function extensionality, a selected uniform constant, quotient equality of operators, an operator-space completion, or the unrestricted classical theorem, so the ledger refuses each listed endpoint. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessLedgerRefusal`

Theorem 1835.9 (Uniform boundedness Baire handoff)**.** *Every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier factors the passage from pointwise boundedness to a uniform source-window bound through the displayed route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{BaireMetric}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Norm}^{\uparrow}.$$

The stream schedule first names finite source and operator reads, the Baire row supplies the bar and complete-metric handoff, the regular-rational row reads the finite bound budget, and the norm row records the source and target bound comparisons. No completed host space or countable-choice selector is introduced by the route.

Proof. Read an accepted carrier as $U = (F, W, B, N, R, S, Q, H, C, P, L)$. A pointwise boundedness read must begin with S, because W has no unscheduled source endpoint or unscheduled operator coordinate.

The Baire step is then forced through B. It is the only carrier coordinate naming a bar and complete-metric handoff, and Definition 1602.23 confines such handoffs to displayed prefix, schedule, radius, metric, and ultrametric rows.

The rational and norm comparisons are downstream of that handoff. The row R reads the regular rational budget attached to the selected window, and N records the matching norm envelope and uniform-bound endpoint.

Thus the source-window bound is obtained only by replaying S, B, R, N with the structural rows Q, H, C, P, L. The carrier contains no coordinate for a completed ambient host space or a countable-choice selector, so neither can be read from the handoff. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessBaireHandoff`

Theorem 1835.10 (Uniform boundedness bounded-operator envelope)**.** *Let U be an accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *carrier. Every uniform operator-bound conclusion exported by U reads each family member through a* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *carrier row and reads the common bound through* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. In particular, the functional-analysis consumer face receives only the displayed operator ledgers, pointwise boundedness windows, Baire handoff, rational readback, and norm-envelope rows named in Definition 1835.1.*

Proof. Open the family row F. By construction its entries are $\mathsf{BoundedLinearOperator}^{\uparrow}$ packets sharing the source carrier, so Definition 1644.5 makes the endpoint action, bound endpoint, linearity ledger, norm ledger, history, replay, provenance, and local naming the only readable operator data.

The common envelope is not an additional operator-space object. It is the row N together with the rational readback R, so the comparison between individual operator bounds and the displayed uniform bound is carried by $\mathsf{Norm}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ evidence.

The $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer face therefore receives the same bounded-operator rows and the same norm-bound ledgers described in Definition 94.3. The uniform boundedness packet adds only the scheduled pointwise windows and the Baire handoff that justify reading one envelope from the finite family ledger. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessBoundedOperatorEnvelope`

Theorem 1835.11 (Uniform boundedness public boundary)**.** *Every accepted* $\mathsf{UniformBoundedness}^{\uparrow}$ *consumer factors through the displayed route*

$$\mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{BaireMetric}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{FunctionalAnalysis}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pk}$$

The public packet explicitly excludes host function extensionality, choice-selected uniform constants, quotient operator equality, hidden completion of an operator space, and an unrestricted classical Banach–Steinhaus theorem.

Proof. Let a consumer read an accepted carrier. By Definition 1835.1, the only visible coordinates are the operator family, pointwise window, Baire handoff, norm envelope, rational readback, stream schedule, componentwise transport, history, replay, provenance, and local name.

The operator data are confined by Definition 1835.10. The Baire passage is confined by Definition 1835.9, and the finite NameCert obligation surface is exactly the one listed in Definition 1835.2.

Combining these three readings gives the displayed public route and no other route. Since no carrier coordinate stores a host function-extensionality principle, a selected uniform constant, quotient equality of operators, hidden operator-space completion, or the full classical theorem, none of those objects can be exported by a public $\mathsf{UniformBoundedness}^{\uparrow}$ consumer. □

Lean4 ✓ `BEDC.Derived.UniformBoundednessUp.UniformBoundednessPublicBoundary`

Falsifiable prediction: Every accepted $\mathsf{UniformBoundedness}^{\uparrow}$ uniform-bound read factors through one finite family of $\mathsf{BoundedLinearOperator}^{\uparrow}$ rows, one pointwise boundedness window, one $\mathsf{BaireMetric}^{\uparrow}$ bar handoff, one $\mathsf{Norm}^{\uparrow}$ envelope, one $\mathsf{RegSeqRat}^{\uparrow}$ rational readback, one $\mathsf{StreamName}^{\uparrow}$ schedule, componentwise hsame transport, one BHist ledger, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: boundedlinearoperator, bairemetric, norm, functionalanalysis, streamname, regseqrat: $\mathsf{UniformBoundedness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a shared-source operator family, pointwise boundedness windows, a Baire bar handoff, a norm envelope, regular-rational readback, scheduling, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformBoundedness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformBoundedness}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1835.1, Definition 1835.2, Definition 1835.9, Definition 1835.10, and Definition 1835.11 seed the finite Banach–Steinhaus NameCert surface over displayed bounded-operator families, Baire handoffs, norm envelopes, scheduled pointwise windows, and regular-rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformBoundedness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, choice-selected uniform constants, quotient operator equality, hidden completion of an operator space, an unrestricted classical Banach–Steinhaus theorem, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires the displayed BoundedLinearOperator, BaireMetric, Norm, FunctionalAnalysis, StreamName, RegSeqRat, BHist, hsame, Cont, Pkg, and NameCert rows to be bound into one public UniformBoundednessUp consumer scope.

Constructive story: A $\mathsf{UniformBoundedness}^{\uparrow}$ packet is generated from a finite shared-source family of $\mathsf{BoundedLinearOperator}^{\uparrow}$ rows, scheduled pointwise boundedness windows, a $\mathsf{BaireMetric}^{\uparrow}$ bar and complete-metric handoff, $\mathsf{Norm}^{\uparrow}$ envelope rows, $\mathsf{RegSeqRat}^{\uparrow}$ rational readback, $\mathsf{StreamName}^{\uparrow}$ scheduling, componentwise transport, a visible history ledger, replay, provenance, and a local NameCert row.

Chapter 1836

A Concrete Naming Certificate for $\mathsf{RegularCauchyComposition}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyComposition}^{\uparrow}$ packet records the finite route by which one regular Cauchy name is read through another regular Cauchy name before any completed real equality or function-space object is consulted. It sits over the shared finite windows of chapter 126, the rational regularity rows of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the nested dyadic Cauchy route of chapter 1811, and the Cauchy-rate lattice discipline of chapter 1818. The packet gives Real and Completion consumers one named finite composition surface instead of forcing each consumer to reassemble the StreamName, RegSeqRat, DyadicRatCore, and Real rows separately.

Definition 1836.1 (Regular Cauchy composition carrier)**.** *A* $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, W, D, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row. It stores the displayed rational observations, the source regularity rate, and the source-side classifier used by the composed read.*
2. *T is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *row. It stores the displayed rational observations, the target regularity rate, and the target-side classifier reached after the source row has supplied its accepted window.*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger. It records the finite source windows, the finite target windows, and the handoff cells in which an accepted source observation licenses the target observation consumed next.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the outer tolerance request, the inner tolerance used to read S, the target tolerance used to read T, and the finite dyadic descent route binding these tolerances together.*
5. *K is the composition route. It records the displayed order S, W, D, T and the local compatibility checks saying that each target read is opened only after the matching source window and dyadic tolerance cells have been exposed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is reachable only after both regular rational rows, the shared window ledger, the dyadic tolerance ledger, and the composition route have all been displayed.*

7. *H records componentwise* hsame *transport for the source row, target row, shared window ledger, tolerance ledger, composition route, seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from an outer regular Cauchy request through $S, T, W, D, K, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyComposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NestedDyadicCauchy}^{\uparrow}$, $\mathsf{CauchyRateLattice}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $S, T, W, D, K, E, H, C, P, N$. The carrier has no coordinate for completed real equality, quotient stream equality, host-level function composition, selected limits, countable choice, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompositionUp.RegularCauchyCompositionTasteGate single carrier alignment`

Theorem 1836.2 (Regular Cauchy composition NameCert obligations)**.** *For every accepted* RegularCauchyCompos *carrier*

$$Q = (S, T, W, D, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular rational row, target regular rational row, shared stream-window ledger, dyadic tolerance ledger, composition route, terminal seal, transport, replay, provenance, and local naming row;*
2. *source-window exactness, requiring every source-side observation consumed by the composed read to be listed in S and opened through W;*
3. *target-window exactness, requiring every target-side observation to be opened from the handoff cells in W after the matching source observation has been accepted;*
4. *dyadic tolerance compatibility, requiring the outer request, source tolerance, target tolerance, and descent route to be the displayed cells of D;*
5. *composition-route determinacy, requiring K to name the displayed order S, W, D, T and to forbid any detached host-level composition map;*
6. *Real-seal non-escape, requiring E to remain downstream of S, T, W, D, K and the structural rows;*
7. *componentwise structural preservation, requiring H and C to transport and replay the whole packet without changing the handoff cells;*
8. *provenance exhaustion, requiring P and N to source and name exactly the displayed packet and no completed real equality, quotient stream equality, selected limit, countable-choice schedule, Lean verification, or bridge checker.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1836.1. The projection exposes exactly two regular rational rows, one shared stream-window ledger, one dyadic tolerance ledger, one composition route, one terminal seal, and the structural rows.

The source-window and target-window obligations are read from S, T, W. A source observation must first appear in the source row and in the shared window ledger. Only then may the corresponding handoff cell open the target observation.

The tolerance obligation is read from D. The outer request, the source-side tolerance, the target-side tolerance, and the dyadic descent cells are all visible in the same ledger, so a consumer cannot replace the route by an unrecorded modulus.

The composition route is then forced by K. It records the order S, W, D, T and therefore blocks any direct jump from a source rational observation to a completed real equality or a host-level composition map.

Finally, E, H, C, P, N only seal, transport, replay, source, and name the displayed packet. Since the carrier has no further analytic coordinate, the local NameCert exports exactly the listed finite obligations and no external completion principle. □

Theorem 1836.3 (Regular Cauchy composition stream handoff)**.** *Let*

$$Q = (S, T, W, D, K, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier. Every target-side* $\mathsf{StreamName}^{\uparrow}$ *read in the composed route is opened from a handoff cell of W whose source-side cell has already been accepted by S and whose tolerance cell is displayed in D. Thus the stream handoff is stable under componentwise* hsame *transport and displayed* Cont *replay inside the packet.*

Proof. Begin with a target-side stream read. The carrier gives no independent target-window selector; the only target-window coordinates are the handoff cells recorded in W.

The source row must be consumed first. The accepted source observation is listed in S, and the same finite window ledger W records the cell that authorizes the target read.

The tolerance ledger supplies the remaining compatibility condition. The cell in D displays the outer request and the inner tolerances used by both regular rational rows, so the handoff cannot be detached from the dyadic descent route.

Transport and replay preserve the handoff because H acts componentwise on $S, T, W, D, K, E, C, P, N$, while C replays only the displayed order. Therefore every target-side stream read remains downstream of the accepted source cell and the displayed tolerance cell. □

Definition 1836.4 (Regular Cauchy composition modulus carrier)**.** *A modulus-refined* $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q_\mu = (S_0, S_1, W, D, \mu, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose regular rational observations are composed.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule used by both regular rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, displaying the outer tolerance, the intermediate tolerance, and the endpoint tolerance consumed by the composition.*
4. *μ is the composed modulus row. It records the finite route from an outer precision request through the shared window schedule and both regular rational rows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after S_0, S_1, W, D, μ have all been displayed.*
6. *H records componentwise* hsame *transport for the two regular rows, shared schedule, tolerance ledger, composed modulus row, seal, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from an outer composed-modulus request through $S_0, S_1, W, D, \mu, E, H, P, N$.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyComposition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$ *row.*

The classifier compares modulus-refined packets only through the displayed tuple $S_0, S_1, W, D, \mu, E, H, C, P, N$. It has no coordinate for a host-level modulus function, quotient stream equality, selected limit, completed real equality, Lean verification, or bridge checking.

Theorem 1836.5 (Regular Cauchy composition modulus stability)**.** *Let*

$$Q_\mu = (S_0, S_1, W, D, \mu, E, H, C, P, N)$$

be an accepted modulus-refined $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier. Componentwise* hsame *transport of the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal preserves the composed modulus route μ. Hence every transported packet exposes the same finite outer-request to endpoint-read route through $S_0, S_1, W, D, \mu, E, H, C, P, N$.*

Proof. Project the modulus carrier of Definition 1836.4. The projection exposes the two regular rational rows, the shared window schedule, the tolerance ledger, the composed modulus row, and the terminal seal.

Transport is componentwise by the row H. It moves the displayed histories of $S_0, S_1, W, D, \mu, E, C, P, N$ together, so the composed modulus row cannot be separated from the two source regular rows or from the dyadic tolerance cells that justify it.

Replay is restricted by C. It repeats the displayed order from an outer composed-modulus request through the shared window schedule, both regular rows, the dyadic tolerance ledger, and the terminal seal.

Therefore the transported packet still exposes the same finite composed modulus route. No host-level modulus function, quotient stream equality, selected limit, or completed real equality is introduced by the transport. □

Theorem 1836.6 (Regular Cauchy composition modulus Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read out of an accepted modulus-refined* $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mu \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the shared schedule, the two regular rational rows, the dyadic tolerance ledger, the composed modulus row, and the terminal seal. Thus every Real and Completion consumer reads the composed name through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *$\mu$, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Take a Real-facing read admitted by the modulus-refined carrier. Projection of Q_μ gives no coordinate from an outer request directly to the terminal seal E.

The read first opens the shared StreamName schedule and the two regular rational rows. The schedule W fixes the finite windows, while S_0 and S_1 display the rational observations consumed at those windows.

The tolerance and modulus rows then determine the Real-facing handoff. The ledger D displays the outer, intermediate, and endpoint tolerances, and μ records the composed route through those cells.

Only after those rows are displayed can E be consumed. The structural rows H, C, P, N preserve, replay, source, and name the same route, so every Real-facing read factors through the stated finite packet. □

Theorem 1836.7 (Regular Cauchy composition Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read out of an accepted* $\mathsf{RegularCauchyComposition}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyComposition}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by W*,* S, T*,* D*,* K*, and* E*. Equivalently, a Real or Completion consumer can inspect the composed name only through the shared stream windows, the two regular rational rows, the dyadic tolerance ledger, the composition route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Take a Real-facing read admitted by the carrier. Projection of Q gives no coordinate from an outer request directly to the terminal seal E.

The read first passes through the shared stream windows and the two regular rational rows. The row W displays the source and target windows, while S and T display the regular rational observations consumed at those windows.

The dyadic tolerance ledger and composition route then determine the endpoint. The row D records the tolerance descent, and K records the order in which the source row, handoff cells, tolerance cells, and target row are read.

Only after those rows are displayed can the terminal seal E be consumed. The rows H, C, P, N preserve, replay, source, and name the same route, so no completed real equality, quotient stream equality, host-level function composition, selected limit, countable choice, Lean verification, or bridge checker can be inserted. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyComposition}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first reading the shared $\mathsf{StreamName}^{\uparrow}$ windows, both $\mathsf{RegSeqRat}^{\uparrow}$ rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the displayed composition route refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, nested-dyadic-cauchy, cauchy-rate-lattice, real: no listed sibling supplies the whole ten-row packet $Q = (S, T, W, D, K, E, H, C, P, N)$, because each sibling contributes only window, regularity, tolerance, nested route, rate discipline, or terminal seal data while this chapter binds source and target regular Cauchy name reads into one finite composition carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyComposition}^{\uparrow}$ packet is generated from source and target RegSeqRat rows, a shared StreamName window ledger, a DyadicRatCore tolerance ledger, a displayed composition route, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$, seed)

Scope closed: Definition 1836.1, Definition 1836.2, Definition 1836.3, and Definition 1836.7 seed the finite route for composing regular Cauchy name reads through StreamName, RegSeqRat, DyadicRatCore, and Real-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyComposition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed real equality, quotient stream equality, host-level function composition, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, target-window exactness, dyadic tolerance compatibility, composition-route determinacy, Real-seal non-escape, stream handoff stability, and Real seal factorization for BEDC.Derived.RegularCauchyCompositionUp.

Chapter 1837

A Concrete Naming Certificate for $\mathsf{RealRootExistence}^{\uparrow}$

Following Bishop and Bridges on constructive intermediate-value reasoning, the $\mathsf{RealRootExistence}^{\uparrow}$ packet turns a displayed sign-change bracket and its bisection-to-Cauchy seal into a public finite BEDC root-existence surface. It is grounded by the intermediate-value row of chapter 1402, the sign-change bracket of chapter 1786, the bisection seal of chapter 1798, the finite stream interface of chapter 126, the regular rational and dyadic readback of chapter 301 and chapter 291, and the terminal real-name boundary of chapter 38. The chapter names the public existence certificate; it does not select a root.

Definition 1837.1 (RealRootExistence carrier)**.** *A* $\mathsf{RealRootExistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, F, S, B, R, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval row. It records the lower and upper endpoint windows, endpoint order evidence, interval identity, and tolerance requests consumed by the public existence read.*
2. *F is the endpoint sign row. It stores the displayed opposite-sign endpoint data and the sign orientation used by the root-existence packet.*
3. *S is the continuity modulus row. It records the source tolerance demanded by each endpoint, midpoint, retained-window, and Real-facing read.*
4. *B is the* $\mathsf{IntermediateValue}^{\uparrow}$ *ledger row. It stores the finite intermediate-value obligation surface attached to the displayed interval, endpoint signs, and modulus data.*
5. *R is the* $\mathsf{RealRootBracket}^{\uparrow}$ *row. It records the finite bracket surface that keeps the sign-change interval visible as a BEDC certificate rather than as a host theorem.*
6. *Q is the* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *row. It records the finite bisection branch ledger, retained windows, regular Cauchy readback, and public seal handoff.*
7. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row. It contains the regular rational observations, dyadic tolerances, endpoint comparisons, branch radii, and rounding rows used by the seal.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is visible only after the sign-change bracket, bisection branch, retained windows, and regular readback have been exposed.*

9. *H records componentwise* hsame *transport for the interval, signs, modulus, intermediate-value ledger, bracket row, bisection seal, regular and dyadic readback, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a public root-existence request through located interval inspection, endpoint sign inspection, modulus use, intermediate-value admission, bracket exposure, bisection sealing, regular and dyadic readback, and Real-seal consumption.*

11. *P is the* Pkg *provenance over* $\mathsf{RealRootExistence}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{BisectionRootCauchySea}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealRootExistence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, S, B, R, Q, D, E, H, C, P, N$. It has no coordinate for a selected root, quotient stream equality, real trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host root equality.*

Lean4 ✓ `BEDC.Derived.RealRootExistenceUp.TasteGate.RealRootExistenceTasteGate single carrier alignment`

Theorem 1837.2 (RealRootExistence NameCert obligations)**.** *For every accepted* $\mathsf{RealRootExistence}^{\uparrow}$ *carrier*

$$X = (I, F, S, B, R, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealRootExistence}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the located interval, endpoint signs, continuity modulus, intermediate-value ledger, real-root bracket, bisection-root Cauchy seal, regular and dyadic readback, Real seal, transports, replay, provenance, and local naming;*

2. *sign-change stability, requiring I and F to expose the same located interval and opposite displayed endpoint signs before any public existence row is available;*

3. *continuity and modulus compatibility, requiring S to answer each bracket, bisection, and seal request by source precision consumed by the same finite route;*

4. *bisection branch regularity, requiring B, R, Q to keep the intermediate-value ledger, bracket row, branch prefix, midpoint sign rows, retained windows, and Cauchy readback attached to the displayed sign-change packet;*

5. *Real-seal non-escape, requiring D, E, H, C, P, N to export only the displayed existence route and no selected root, quotient real equality, real trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host root equality.*

No RealRootExistence obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealRootExistenceUp.RealRootExistenceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1837.1. The accepted packet displays exactly the located interval, endpoint signs, modulus row, intermediate-value ledger, bracket row, bisection seal, regular and dyadic readback, Real seal, and structural rows.

Sign-change stability is the entry stage. The rows I and F must be opened together, so the public existence read cannot replace the displayed interval and endpoint signs by an ambient real interval or by a host sign theorem.

Continuity and modulus compatibility is the precision stage. The row S supplies the source precision used by endpoint inspection, midpoint inspection, retained-window requests, and the terminal seal, so all later rows consume one displayed continuity route.

Bisection branch regularity is the middle stage. The row B admits the intermediate-value ledger, R exposes the bracket surface, and Q records the finite branch prefix, midpoint sign rows, retained windows, and regular Cauchy handoff.

Finally, D, E, H, C, P, N perform readback, sealing, transport, replay, provenance, and naming for the same route. Since selected roots, quotient real equality, real trichotomy, open-cover compactness, ambient Real completeness, and host root equality are absent from the carrier, none of the five obligation rows can export them. □

Theorem 1837.3 (RealRootExistence bisection seal handoff)**.** *Every accepted* $\mathsf{RealRootExistence}^{\uparrow}$ *read factors through* $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{BisectionRootCauchySeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any public root seal is visible. In row form the route is*

$$I, F, S \longmapsto B \longmapsto R \longmapsto Q \longmapsto D \longmapsto E, H, C, P, N.$$

The handoff exports a finite public existence certificate and a terminal seal boundary, not a selected root, quotient stream, trichotomy decision, or ambient Real-completeness principle.

Proof. Start with an accepted carrier $X = (I, F, S, B, R, Q, D, E, H, C, P, N)$. The only entry rows are the located interval, endpoint sign, and modulus rows I, F, S.

The intermediate-value and bracket stages are forced next. The row B records the $\mathsf{IntermediateValue}^{\uparrow}$ obligation surface attached to I, F, S, and the row R records the $\mathsf{RealRootBracket}^{\uparrow}$ surface that keeps the sign-change bracket visible as finite data.

The bisection seal stage is Q. It records the $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ branch ledger, retained windows, StreamName-facing observations, and regular Cauchy handoff, all downstream of the same intermediate-value and bracket rows.

The public seal stage is terminal. The row D reads the route as $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ data, the row E seals the resulting boundary as $\mathsf{Real}^{\uparrow}$ data, and H, C, P, N transport, replay, package, and name that same route.

Thus every accepted read factors through the listed siblings before the public seal is visible. Because the carrier has no coordinate for a selected root, quotient stream, trichotomy row, or ambient Real-completeness theorem, the handoff cannot export any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealRootExistence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealRootExistence}^{\uparrow}$ packet is generated from a located interval row, endpoint sign row, continuity modulus row, $\mathsf{IntermediateValue}^{\uparrow}$ ledger, $\mathsf{RealRootBracket}^{\uparrow}$ row, $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ row, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealRootExistence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1837.1, Definition 1837.2, and Definition 1837.3 seed the finite public sign-change root-existence route from located interval and endpoint sign rows through intermediate-value, bracket, bisection-seal, regular readback, dyadic readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealRootExistence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected roots, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, host root equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-change stability, bisection branch regularity, Cauchy-seal handoff, and Real-seal non-escape for BEDC.Derived.RealRootExistenceUp.

Chapter 1838

A Concrete Naming Certificate for BishopCompletionUniversalBoundary$^{\uparrow}$

Following Bishop and Bridges' constructive treatment of completion, the BishopCompletionUniversalBoundary$^{\uparrow}$ packet isolates the finite L10 boundary at which a Bishop regular Cauchy completion route can be consumed by a universal-property extension and uniqueness surface. It reads the completion carrier of chapter 1639, the extension and uniqueness face of chapter 397, and the regular-Cauchy universal seed of chapter 1425. Its source observations remain the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readback of chapter 301, the DyadicRatCore$^{\uparrow}$ tolerance ledger of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

The packet is only a boundary certificate. It names the finite rows that let a completion consumer move from regular Cauchy data to an extension route and a uniqueness ledger, while excluding quotient streams, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, and any bridge credential.

Definition 1838.1 (Bishop completion universal boundary carrier)**.** *A* BishopCompletionUniversalBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, R, D, A, U, E, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* BishopRegularCauchyCompletion$^{\uparrow}$ *row, exposing the regular Cauchy completion carrier and its common-tail route.*
2. *S is the* StreamName$^{\uparrow}$ *finite-window row read by the completion source and by downstream extension consumers.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the windows in S.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used by the regular Cauchy route, the extension request, and the uniqueness comparison.*
5. *A is the terminal* Real$^{\uparrow}$ *seal reached only after Q, S, R, D have been displayed.*
6. *U is the* CompletionUniversalProperty$^{\uparrow}$ *face restricted to the displayed Bishop regular Cauchy route.*
7. *E is the extension route row, read through U after the rows Q, S, R, D, A have fixed the source and seal surface.*

8. *L is the uniqueness ledger, a displayed* hsame *comparison between two extension rows over the same Q, S, R, D, A, U, E route.*
9. *H records componentwise* hsame *transport for the completion row, stream windows, regular readback, dyadic ledger, Real seal, universal-property face, extension route, uniqueness ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a completion-universal request through $Q, S, R, D, A, U, E, L, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, S, R, D, A, U, E, L, H, C, P, N$. The carrier contains no quotient stream, selected limit, countable-choice selector, host real equality row, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, or standard-bridge credential.*

Lean4 ✓ `BEDC.Derived.BishopCompletionUniversalBoundaryUp.BishopCompletionUniversalBoundaryTasteGate`
`single carrier alignment`

Theorem 1838.2 (Bishop completion universal extension route)**.** *Let $B = (Q, S, R, D, A, U, E, L, H, C, P, N)$ be an accepted* $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$ *carrier. Every extension read exported by E first displays the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *row Q, then the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal A, and only then reads the restricted* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *face U.*

Proof. Project the carrier of Definition 1838.1. The extension row E is downstream of the completion carrier Q, the finite source windows S, the regular rational readback R, the dyadic tolerance ledger D, the terminal seal A, and the universal-property face U.

The sibling completion chapters supply exactly these rows. The Bishop regular Cauchy completion packet fixes the completion-facing source, while the StreamName, RegSeqRat, DyadicRatCore, and Real chapters expose the finite observation route consumed by the universal-property face.

The continuation row C can replay only the displayed route, and the provenance row P names no selected limit, quotient stream, host real equality, choice schedule, or ambient completeness object. Therefore every extension read factors through Q, S, R, D, A, U before E is exported. □

Theorem 1838.3 (Bishop completion universal uniqueness ledger)**.** *Let*

$$B = (Q, S, R, D, A, U, E, L, H, C, P, N)$$

and

$$B' = (Q, S, R, D, A, U, E', L', H', C', P, N')$$

be accepted $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$ *carriers over the same completion row, stream windows, regular readback, dyadic ledger, Real seal, universal-property face, and provenance. Any comparison between the exported extension rows is exhausted by the displayed uniqueness ledgers L, L' together with their componentwise* hsame *transports and displayed* Cont *replays. No quotient-stream equality, selected limit, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum, or bridge credential can contribute to the comparison.*

Proof. The shared coordinates Q, S, R, D, A, U, P fix the completion source, finite windows, readback, tolerance ledger, terminal seal, universal-property face, and provenance available to both packets.

The only extension-sensitive coordinates are E, L, H, C, N and E', L', H', C', N'. The ledgers L and L' compare extension rows over the fixed displayed source route, while H, H' and C, C' provide the permitted transports and replays.

Since neither accepted carrier contains any excluded quotient, selected-limit, choice, host-equality, completeness, or bridge coordinate, the comparison cannot leave the displayed uniqueness surface. It is exactly the local hsame ledger over the Bishop regular Cauchy universal boundary. □

Theorem 1838.4 (Bishop completion universal NameCert obligations)**.** *For every accepted* BishopCompletionUnive *carrier* $B = (Q, S, R, D, A, U, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Bishop regular Cauchy completion row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, CompletionUniversalProperty face, extension route, uniqueness ledger, transport, replay, provenance, and local naming row;*
2. *source-route exactness, requiring every universal-property request to pass through* Q, S, R, D, A *before* U, E, L *can be inspected;*
3. *extension-route exactness, requiring* E *to be read only as the extension route attached to the displayed* Q, S, R, D, A, U *surface;*
4. *uniqueness-ledger exactness, requiring every comparison of extension rows to use* L *over the same displayed source, seal, universal-property, and extension coordinates;*
5. *regular-Cauchy compatibility, requiring the boundary to reuse the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *extension and uniqueness seed without adding a second completion carrier;*
6. *non-escape, requiring* H, C, P, N *to transport, replay, source, and name no row from which quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, or bridge credentials can be exported.*

No local obligation is stored outside these rows.

```
Lean4 ✓  BEDC.Derived.BishopCompletionUniversalBoundaryUp.BishopCompletionUniversalBoundaryCarrier
namecert obligations
```

Proof. Carrier admission is projection from Definition 1838.1. The accepted packet displays exactly the completion carrier, finite windows, readback, tolerance ledger, Real seal, universal-property face, extension route, uniqueness ledger, and structural rows.

Source-route exactness follows from the order of the carrier. A universal-property request first reads Q and then the finite observation route S, R, D, A before it can inspect the rows U, E, L.

Extension-route exactness is Definition 1838.2. The extension row E is attached to the displayed Bishop regular Cauchy source and cannot be read as a detached host completion map.

Uniqueness-ledger exactness is Definition 1838.3. The comparison is carried by the displayed ledgers L, L' and their transports and replays, over the same visible source and extension coordinates.

Regular-Cauchy compatibility is the provenance constraint in P. The packet cites the RegularCauchyCompletionU seed as a source for the extension and uniqueness shape, but it stores no second completion carrier beyond the displayed row Q.

Finally, non-escape is exhausted by H, C, P, N. These rows transport, replay, source, and name the displayed route only, and none contains quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, or bridge credentials. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1838.1, Definition 1838.2, Definition 1838.3, and Definition 1838.4 seed the finite L10 boundary from Bishop regular Cauchy completion data to extension and uniqueness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-route exactness, extension-route exactness, uniqueness-ledger exactness, regular-Cauchy compatibility, and non-escape proofs for BEDC.Derived.BishopCompletionUniversalBoundary

Constructive story: A $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$ packet is generated from a BishopRegularCauchyCompletion row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, a CompletionUniversalProperty face, an extension route, a uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1839

A Concrete Naming Certificate for $\mathsf{RealOscillation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealOscillation}^{\uparrow}$ packet records the finite oscillation interface by which a real-facing consumer reads tail variation, interval clamping, and squeeze enclosure before it treats a displayed name as Real or Completion data. It refines the tail ledger of chapter 448, the interval route of chapter 1810, and the envelope route of chapter 1772. Its numerical rows are grounded in the dyadic tolerance surface of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet is therefore a finite L10 interface for oscillation arguments, not an assertion of ambient Real completeness or host equality.

Every $\mathsf{RealOscillation}^{\uparrow}$ read consumes the clamped interval route of chapter 1810 and the squeeze envelope of chapter 1772 before the terminal $\mathsf{Real}^{\uparrow}$ seal is inspected.

Definition 1839.1 (Real oscillation carrier)**.** *A* $\mathsf{RealOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q_{\mathrm{osc}} = (X, O, C, S, D, W, R, H, T, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *seal whose oscillation-facing reads are being routed.*
2. *O is the* $\mathsf{CauchyOscillation}^{\uparrow}$ *row exposing the finite tail-variation ledger.*
3. *C is the* $\mathsf{RealClamping}^{\uparrow}$ *interval row recording the clamped bounded-window route.*
4. *S is the* $\mathsf{RegularCauchySqueeze}^{\uparrow}$ *envelope row recording the lower, middle, and upper regular Cauchy squeeze data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row supplying the dyadic radius and endpoint slack consumed by O, C, S.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened at the precision named by D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from X, O, C, S, D, W before any Real or Completion-facing oscillation conclusion is exposed.*
8. *H records componentwise* hsame *transport for the Real seal, oscillation ledger, clamp interval, squeeze envelope, dyadic tolerance, window, readback, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from each Real or Completion-facing oscillation request through $O, C, S, D, W, R, H, P, N$ before X is consumed as a terminal seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyOscillation}^{\uparrow}$, $\mathsf{RealClamping}^{\uparrow}$, $\mathsf{RegularCauchySqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, O, C, S, D, W, R, H, T, P, N$ and the displayed routes among those rows. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, host trichotomy, selected limits, countable choice, Lean verification, or bridge checking.*

Lean4 (definition) `BEDC.Derived.RealOscillationUp.RealOscillationCarrier`

Theorem 1839.2 (Real oscillation NameCert obligations)**.** *For every accepted* $\mathsf{RealOscillation}^{\uparrow}$ *carrier*

$$Q_{\mathrm{osc}} = (X, O, C, S, D, W, R, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealOscillation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Real seal, CauchyOscillation ledger, RealClamping interval, RegularCauchySqueeze envelope, dyadic tolerance, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming rows;*

2. *oscillation-ledger exposure, requiring O to be displayed before any Real or Completion-facing oscillation read can consume the seal X;*

3. *clamp interval exposure, requiring C, D, W, R to display the bounded interval route used by the oscillation packet;*

4. *squeeze-envelope compatibility, requiring S to consume the same tolerance, window, and regular rational readback route as the oscillation and clamp rows;*

5. *ledger nonescape, requiring H, T, P, N to export no ambient Real completeness, quotient stream equality, host trichotomy, selected limit, countable-choice schedule, Lean verification, standard bridge credential, or row outside Q_{osc}.*

No Real oscillation obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealOscillationUp.RealOscillationTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1839.1. The accepted packet displays exactly the Real seal, oscillation ledger, clamp interval, squeeze envelope, tolerance, finite window, readback, transport, replay, provenance, and local naming rows.

Oscillation-ledger exposure is forced by the row O. A consumer cannot inspect the terminal seal X as oscillation evidence before the CauchyOscillation ledger has displayed the tail-variation data attached to the same packet.

The clamp and squeeze obligations are the two bounded routes around that ledger. The clamp row C is read through D, W, R, while the squeeze row S uses the same tolerance, window, and readback route to align its envelope with the displayed oscillation ledger.

The structural rows H, T, P, N transport, replay, source, and name the same finite packet. Since the carrier inventory omits ambient completeness, quotient stream equality, host trichotomy, selected limits, countable choice, Lean verification, bridge credentials, and external rows, the listed obligations exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.RealOscillationUp.RealOscillationUpTasteGate single carrier alignment`

Theorem 1839.3 (Real oscillation clamped-window factorization)**.** *Let*

$$Q_{\mathrm{osc}} = (X, O, C, S, D, W, R, H, T, P, N)$$

be an accepted $\mathsf{RealOscillation}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read of the oscillation packet factors through the displayed route*

$$O \longmapsto C \longmapsto S \longmapsto D, W, R \longmapsto H, T, P, N \longmapsto X.$$

Consequently the read receives the CauchyOscillation tail ledger, RealClamping interval route, RegularCauchySqueeze envelope, dyadic tolerance, StreamName window, RegSeqRat readback, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it reaches the Real seal.*

Proof. Start with the accepted carrier and project the rows $X, O, C, S, D, W, R, H, T, P, N$. The terminal seal X is present in the packet, but the classifier exposes it to oscillation consumers only through the displayed rows that name the oscillation route.

The read first reaches the tail ledger O, then the clamp interval row C, and then the squeeze envelope row S. These rows supply tail variation, bounded interval routing, and lower-middle-upper enclosure as finite data.

The rows D, W, R provide the shared numerical route. They fix the dyadic tolerance, open the finite StreamName window, and repack the observations as RegSeqRat readback before any Real or Completion-facing conclusion is exposed.

The remaining rows H, T, P, N preserve the same route by transport, replay, provenance, and local naming. No coordinate in the packet can replace that route by ambient Real completeness, quotient stream equality, host trichotomy, a selected limit, or a standard bridge credential, so the displayed factorization is exhaustive. □

Falsifiable prediction: Every $\mathsf{RealOscillation}^{\uparrow}$ Real or Completion-facing read factors through one CauchyOscillation tail ledger, one RealClamping interval route, one RegularCauchySqueeze envelope, one DyadicRatCore tolerance row, one StreamName window, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local NameCert, and the terminal RealUp seal.

Independence witness: cauchyoscillation, real-clamping, regular-cauchy-squeeze, dyadicratcore, streamname, regseqrat, real: $\mathsf{RealOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Real seal, an oscillation ledger, a clamp interval route, a squeeze envelope, one shared dyadic-window-readback route, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealOscillation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealOscillation}^{\uparrow}$ packet is generated from one RealUp seal, one CauchyOscillation ledger, one RealClamping interval row, one RegularCauchySqueeze envelope, one DyadicRatCore tolerance row, one StreamName window, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealOscillation}^{\uparrow}}$, seed)

Scope closed: Definition 1839.1, Definition 1839.2, and Definition 1839.3 seed the finite Real and Completion-facing oscillation route through tail variation, clamping, squeeze enclosure, dyadic tolerance, finite windows, regular rational readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealOscillation}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.RealOscillationUp.RealOscillationCarrier`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, host trichotomy, selected limits, countable choice, Lean theorem checking, or standard bridge credentials.

Upgrade path: Obligation closure requires checked carrier admission, oscillation-ledger exposure, clamp interval exposure, squeeze-envelope compatibility, clamped-window factorization, and ledger nonescape for BEDC.Derived.RealOscillationUp.RealOscillation

Chapter 1840

A Concrete Naming Certificate for $\mathsf{MeanErgodic}^{\uparrow}$

Following von Neumann on Hilbert-space mean convergence and Birkhoff on orbit averages, the $\mathsf{MeanErgodic}^{\uparrow}$ packet records only the finite Cesaro-average ledger visible to a BEDC consumer. It consumes the measure-preserving transformation surface of chapter 196, the finite transition rows of chapter 195, the event and preservation rows of chapter 92, the finite transfer-row handoff of chapter 456, and the Cesaro averaging route of chapter 1765. The chapter names a finite averaging NameCert surface; it does not claim a host Hilbert projection, pointwise convergence theorem, invariant-function quotient, or ambient completed orbit space.

Definition 1840.1 (Mean ergodic carrier)**.** *A* $\mathsf{MeanErgodic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, D, W, T, H, A, P, R, C, Q, N)$$

with the following displayed rows:

1. *E is the measure-preserving* $\mathsf{Ergodic}^{\uparrow}$ *source row. It displays the carried transformation, the invariant-row ledger, the measure-preservation witness, and the finite dynamic and measure endpoints already visible through* $\mathsf{Ergodic}^{\uparrow}$*.*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *step row for the same transformation, recording the source point row, successor row, and finite iterate endpoints used by the orbit window.*
3. *W stores finite orbit windows $x, Tx, \ldots, T^{n-1}x$ together with the visible unary window length n.*
4. *T is the* $\mathsf{TransferOperator}^{\uparrow}$ *or transition-row handoff. It records the finite row by which each displayed step is transported into the averaging ledger when the packet is read through a transfer-style consumer.*
5. *H is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *averaging row. It stores the prefix sums, denominator row, and finite Cesaro division route for the orbit-window observations.*
6. *A stores the averaged endpoint rows exposed to downstream consumers, each obtained only after W, T, H have been displayed.*
7. *P is the* $\mathsf{Measure}^{\uparrow}$ *preservation row, recording that the same measure ledger is carried across the displayed transformation and its finite orbit-window reads.*
8. *R stores componentwise* hsame *transport for the ergodic source, dynamic steps, finite windows, transfer rows, Cesaro averages, averaged endpoints, measure preservation, replay, provenance, and local naming.*

9. *C stores displayed* Cont *replay from an orbit-window request through $E, D, W, T, H, A, P, R, Q, N$.*
10. *Q is the* Pkg *provenance over* $\mathsf{MeanErgodic}^{\uparrow}$, $\mathsf{Ergodic}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{TransferOperator}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MeanErgodic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, W, T, H, A, P, R, C, Q, N$. It has no coordinate for a host Hilbert-space projection, pointwise ergodic convergence, completed invariant subspace, quotient orbit space, spectral theorem, or ambient Banach-space limit.

Lean4 ✓ `BEDC.Derived.MeanErgodicUp.MeanErgodicTasteGate single carrier alignment`

Theorem 1840.2 (Mean ergodic NameCert obligations)**.** *For every accepted* $\mathsf{MeanErgodic}^{\uparrow}$ *carrier $M = (E, D, W, T, H, A, P, R, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MeanErgodic}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed ergodic source, dynamic step row, finite orbit windows, transfer handoff, Hardy–Cesaro averaging row, averaged endpoint rows, measure-preservation row, transport, replay, provenance, and local name;*
2. *orbit-window exactness, requiring every entry of W to be read from the displayed* $\mathsf{DynSystem}^{\uparrow}$ *step ledger and the measure-preserving* $\mathsf{Ergodic}^{\uparrow}$ *source row;*
3. *Cesaro-average exactness, requiring every exposed average in A to be computed by the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row from the displayed finite orbit window and denominator row;*
4. *preservation stability, requiring the* $\mathsf{Measure}^{\uparrow}$ *preservation row to be transported with the same* hsame *and* Cont *routes as the orbit-window source;*
5. *nonescape, requiring the packet to export no Hilbert projection, no pointwise convergence theorem, no invariant-function quotient, no completed orbit space, and no ambient spectral or Banach-space limit.*

Proof. Carrier admission is projection from Definition 1840.1. The visible packet lists exactly the ergodic source, dynamic steps, orbit windows, transfer rows, Cesaro averaging row, averaged endpoints, preservation row, transport rows, replay rows, provenance, and local name.

Orbit-window exactness is read from D and W. Each window entry is generated by replaying the displayed $\mathsf{DynSystem}^{\uparrow}$ step row over the transformation already carried by E, so there is no independent trajectory object.

Cesaro-average exactness is read from H and A. The averaging row consumes the finite window W, prefix sums, the visible denominator, and dyadic division data supplied by $\mathsf{HardyCesaroMean}^{\uparrow}$ before an averaged endpoint can be exposed.

Preservation stability is then read from P, R, C. The same measure-preservation row is transported along the displayed hsame and replay routes used by the orbit-window source, so a measure claim cannot detach from the carried transformation.

Finally, nonescape follows from the carrier inventory. Since none of the coordinates names a Hilbert projection, pointwise convergence theorem, invariant quotient, completed orbit space, spectral theorem, or Banach limit, the local NameCert obligations are exhausted by the finite rows above. □

Theorem 1840.3 (Mean ergodic Cesaro-average handoff)**.** *Every averaged endpoint exported by an accepted* $\mathsf{MeanErgodic}^{\uparrow}$ *packet factors through the route*

$$\mathsf{Ergodic}^{\uparrow} \longmapsto \mathsf{DynSystem}^{\uparrow} \longmapsto \mathsf{TransferOperator}^{\uparrow} \longmapsto \mathsf{HardyCesaroMean}^{\uparrow} \longmapsto \mathsf{Measure}^{\uparrow}$$

as instantiated by E, D, T, H, P and the finite orbit-window row W. Consequently, the consumer sees only the displayed transformation, finite orbit windows, transfer or step handoff rows, Hardy–Cesaro prefix averages, measure-preservation ledger, hsame *transport,* Cont *replay,* Pkg *provenance, and local naming before reading A.*

Proof. Start with an averaged-endpoint request. The request first opens E, so the transformation and preservation source are the carried $\mathsf{Ergodic}^{\uparrow}$ rows rather than a host measurable dynamical system.

The finite orbit is then read through D and W. These rows display the step ledger and the selected finite window length, so the consumer has only the requested finite prefix of the orbit.

If the packet is viewed through a transfer-style consumer, T records the handoff from the step rows into the finite transfer ledger. This handoff is still a finite row route and does not add an analytic transfer operator or a spectral datum.

The averaging itself is supplied by H. By chapter 1765, the prefix sum, denominator, and division rows are the only route from the finite window to a Cesaro mean.

The preservation row P is finally replayed along the same transported source. Thus every exported endpoint in A factors through the displayed finite route and no alternate host projection or convergence theorem can be read. □

Theorem 1840.4 (Mean ergodic nonescape boundary)**.** *An accepted* $\mathsf{MeanErgodic}^{\uparrow}$ *carrier exports no data beyond the finite rows $E, D, W, T, H, A, P, R, C, Q, N$. In particular, it does not export a Hilbert-space orthogonal projection onto invariant vectors, a pointwise almost-everywhere convergence theorem, an invariant-function quotient, an infinite orbit measure, a completed orbit closure, a spectral decomposition, or a Banach-space limit operator.*

Proof. Project the accepted carrier to the tuple of Definition 1840.1. The only readable coordinates are the displayed finite rows $E, D, W, T, H, A, P, R, C, Q, N$.

The first group E, D, W, T, H, A, P accounts for the mathematical content: carried ergodic source, displayed dynamic steps, finite windows, transfer handoff, Cesaro averaging, averaged endpoints, and measure preservation. Each row has a named sibling source and a finite replay route.

The second group R, C, Q, N accounts for transport, continuation replay, package provenance, and local naming. These structural rows preserve and name the same packet; they do not add a projection, quotient, completion, spectral, or Banach-space coordinate.

Therefore any downstream consumer is confined to the finite rows in the carrier. The listed host-level objects are not merely unproved; they are absent from the packet boundary. □

Falsifiable prediction: Every $\mathsf{MeanErgodic}^{\uparrow}$ averaged endpoint read factors through one ErgodicUp measure-preserving source row, one DynSystemUp finite step ledger, one finite orbit-window row, a TransferOperatorUp or step handoff row, one HardyCesaroMeanUp averaging row, one MeasureUp preservation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ergodic, dynsystem, transferoperator, hardycesaromean, measure: $\mathsf{MeanErgodic}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a measure-preserving ergodic source, finite orbit windows, transition handoff rows, Cesaro prefix averages, preservation stability, transport, replay, provenance, and local naming while excluding host projection and convergence coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{MeanErgodic}^{\uparrow}}$.

Constructive story: A MeanErgodic$^{\uparrow}$ packet is generated from an ErgodicUp measure-preserving source row, DynSystemUp finite step rows, finite orbit-window rows, TransferOperatorUp or step handoff rows, HardyCesaroMeanUp prefix-average rows, MeasureUp preservation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MeanErgodic}^{\uparrow}}$, seed)

Scope closed: Definition 1840.1, Definition 1840.2, Definition 1840.3, and Definition 1840.4 seed the finite Cesaro-average ergodic packet from measure-preserving orbit windows to averaged endpoint reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{MeanErgodic}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.MeanErgodicUp.MeanErgodicTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Hilbert-space projection, pointwise ergodic convergence, invariant-function quotients, infinite orbit measures, completed orbit closures, spectral decompositions, Banach-space limit operators, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, orbit-window exactness, Cesaro-average handoff, preservation stability, nonescape, and local naming for BEDC.Derived.MeanErgodicUp.

Chapter 1841

A Concrete Naming Certificate for $\mathsf{RegularCauchyBall}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyBall}^{\uparrow}$ packet records finite-window membership in a rational-radius ball around a displayed regular Cauchy real name. It sits over the finite observation windows of chapter 126, the regular rational readback rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later metric and completion consumers a local-neighbourhood surface before any ambient real ball, selected limit, quotient equality, trichotomy, countable choice, compactness principle, or $\mathsf{Real}^{\uparrow}$ completeness claim is available.

Definition 1841.1 (Regular Cauchy ball carrier)**.** *A* $\mathsf{RegularCauchyBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, C, R, W, D, Q, S, H, T, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row for the point being tested.*
2. *C is the* $\mathsf{RegSeqRat}^{\uparrow}$ *centre row for the displayed ball.*
3. *R is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, including the rational endpoint and dyadic scale used by the membership test.*
4. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger from which X and C are inspected.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the requested window and radius budget.*
6. *Q is the comparison row recording that the displayed window distance is inside the radius budget after the dyadic tolerance descent in D.*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after X, C, R, W, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for the point row, centre row, radius row, window ledger, tolerance row, comparison row, seal row, replay row, provenance row, and local naming row.*
9. *T records displayed* Cont *replay from a ball-membership request through $X, C, R, W, D, Q, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBall}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBall}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed tuple $X, C, R, W, D, Q, S, H, T, P, N$. The carrier has no coordinate for ambient real balls, quotient equality of real names, selected limits, trichotomy, countable-choice schedules, metric-space compactness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyBallUp.TasteGate.RegularCauchyBallTasteGate single carrier alignment`

Theorem 1841.2 (Regular Cauchy ball window stability)**.** *Let*

$$B = (X, C, R, W, D, Q, S, H, T, P, N)$$

be an accepted $\mathsf{RegularCauchyBall}^{\uparrow}$ *carrier. Every ball-membership read of B factors through the same finite route*

$$X, C, R \longmapsto W, D \longmapsto Q \longmapsto S, H, T, P, N.$$

Consequently any two reads transported by H and replayed by T use the same point row, centre row, radius row, finite window ledger, dyadic tolerance descent, comparison row, and seal boundary.

Proof. Project the accepted carrier. The point row X, centre row C, and radius row R are the only analytic inputs available to a membership request, and the request has no direct access to an ambient real ball.

The finite observation step is therefore forced through W and D. The window ledger W names the finite observations of X and C, while the tolerance row D supplies the dyadic descent needed to compare those observations against the radius row R.

The comparison row Q is read only after those finite rows are displayed. The seal boundary S is downstream of Q, so a Real-facing consumer receives a window-stable membership route rather than a host-level ball assertion.

Finally transport and replay are componentwise. The rows H and T preserve the same displayed inputs and the same route through W, D, Q, S, while P and N source and name that finite packet. Thus repeated reads cannot introduce a second window, hidden radius, selected limit, quotient equality, compactness principle, or $\mathsf{Real}^{\uparrow}$ completeness row. □

Theorem 1841.3 (Regular Cauchy ball NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBall}^{\uparrow}$ *carrier $B = (X, C, R, W, D, Q, S, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBall}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the point* $\mathsf{RegSeqRat}^{\uparrow}$ *row, centre* $\mathsf{RegSeqRat}^{\uparrow}$ *row, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger, dyadic tolerance row, comparison row,* $\mathsf{Real}^{\uparrow}$ *seal boundary, transport, replay, provenance, and local name;*
2. *finite-window exposure, requiring membership to be tested only on the windows displayed by W;*
3. *radius-budget exactness, requiring the radius row R and tolerance row D to be read before the comparison row Q;*
4. *comparison routing, requiring Q to bind the point and centre observations to the radius budget through the same dyadic ledger;*
5. *seal non-escape, requiring S to remain downstream of X, C, R, W, D, Q;*
6. *structural stability, requiring H, T, P, N to transport, replay, source, and name exactly the displayed route.*

No local NameCert obligation is stored outside these rows.

Proof. Read the carrier projection from Definition 1841.1. It exposes exactly the two regular rational names, one positive dyadic radius row, one finite window ledger, one dyadic tolerance row, one comparison row, one seal boundary, and the structural rows.

Finite-window exposure is the first obligation. A membership request can inspect X and C only through W, and the dyadic tolerance row D supplies the visible descent used with the radius row R.

The comparison row then records the local ball test. Since Q is downstream of R, W, D, it is a finite-window comparison row and not an ambient real-ball predicate.

The remaining obligations are structural. The seal row S cannot be read before the comparison route is displayed, while H, T, P, N only preserve, replay, source, and name the same finite packet. The excluded principles are absent because no carrier coordinate stores Real completeness, trichotomy, selected limits, countable choice, metric compactness, or quotient equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBall}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBall}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1841.1, Definition 1841.2, and Definition 1841.3 seed the finite-window ball-membership surface for two $\mathsf{RegSeqRat}^{\uparrow}$ rows, a positive $\mathsf{DyadicRatCore}^{\uparrow}$ radius row, shared $\mathsf{StreamName}^{\uparrow}$ windows, dyadic tolerance descent, comparison routing, and terminal $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBall}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, selected limits, countable choice, metric-space compactness, quotient equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, radius-budget exactness, comparison routing, seal non-escape, structural stability, and local naming for BEDC.Derived.RegularCauchyBallUp.

Constructive story: A $\mathsf{RegularCauchyBall}^{\uparrow}$ packet is generated from a point RegSeqRat row, a centre RegSeqRat row, a positive DyadicRatCore radius row, shared StreamName windows, a dyadic tolerance row, a comparison row, a terminal RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1842

A Concrete Naming Certificate for $\mathsf{PrecompactCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PrecompactCompletion}^{\uparrow}$ packet reads $\mathsf{PrecompactMetric}^{\uparrow}$ finite-net and filter rows through $\mathsf{CompletionEmbedding}^{\uparrow}$ and $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ without quotient completion, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits between the precompact-metric bridge of chapter 1531, the totally bounded completion route of chapter 1573, and the constructive metric completion route of chapter 1556; its role is to preserve the finite BEDC ledger that completion consumers inspect.

Definition 1842.1 (Precompact completion carrier)**.** *A* $\mathsf{PrecompactCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, N, F, E, C, S, H, R, Q, L)$$

with the following displayed rows:

1. *X is the source metric carrier row, including accepted point histories, metric-distance witnesses, and classifier transports already exposed by the* $\mathsf{PrecompactMetric}^{\uparrow}$ *packet.*
2. *N is the finite-net ledger inherited from* $\mathsf{PrecompactMetric}^{\uparrow}$*. For each positive tolerance it records the closed* $\mathsf{ProbeBundle}$ *of centers,* $\mathsf{InBundle}$ *membership rows, center histories, distance witnesses, rational comparison ledgers, and net-refinement reads.*
3. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *replay row generated from the same metric and finite-net data, including finite basis packets, common-refinement rows, regular tail windows, and dyadic neighbourhood witnesses.*
4. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that inserts source observations into the dense completion boundary while preserving the displayed finite-net and filter-basis ledgers.*
5. *C is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route through regular Cauchy names, dyadic tolerances, separated comparison, finite stream windows, regular rational readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *naming boundary.*
6. *S is the stream-and-real seal row. It records the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *reads that completion-facing consumers may inspect after F, E, C have been replayed.*
7. *H records componentwise* hsame *transport for the source metric, finite nets, filter-basis replay, embedding row, constructive completion route, stream-and-real seal, provenance, and local naming rows.*

8. *R is the route ledger of displayed* Cont *reads, requiring every consumer to pass through N, F, E, C, S in that order before it reaches H, Q, L.*
9. *Q is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{PrecompactMetric}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}$ *row naming the displayed packet and the permitted reads from it.*

The classifier on such packets is componentwise transport through H together with replay through the displayed route row R. No coordinate stores a quotient completion, a selected completed point, a choice schedule, an open-cover compactness argument, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PrecompactCompletionUp.PrecompactCompletionTasteGate single carrier alignment`

Theorem 1842.2 (PrecompactCompletion NameCert obligations)**.** *For every accepted* $\mathsf{PrecompactCompletion}^{\uparrow}$ *carrier $P = (X, N, F, E, C, S, H, R, Q, L)$, the local* $\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed source metric, finite-net ledger, Cauchy-filter basis, completion embedding, constructive completion route, stream-and-real seal, transport ledger, route ledger, provenance, and local naming row;*
2. *finite-net persistence, requiring every completion tolerance request to read the centers, membership constructors, distance witnesses, rational bounds, and refinement rows recorded in N;*
3. *filter-basis replay, requiring each completion-facing read to consume the finite basis packets, common-refinement rows, regular tail windows, and dyadic neighbourhood witnesses in F before it reaches the embedding row;*
4. *dense-embedding handoff, requiring source observations to pass through E before the constructive completion route C may be inspected;*
5. *constructive-completion non-escape, requiring the completed read to continue through C and S using only* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *naming rows exposed by the finite route;*
6. *ledger exactness, excluding quotient completion, selected limits, countable choice, open-cover compactness, detached* $\mathsf{Real}^{\uparrow}$ *completeness, and ambient completeness.*

No NameCert obligation is stored outside these displayed rows.

Proof. Carrier admission is projection from Definition 1842.1. The packet lists exactly the source metric, finite-net ledger, Cauchy-filter basis, dense embedding, constructive completion route, stream-and-real seal, transport ledger, route ledger, provenance, and local naming row.

Finite-net persistence is read from N. A tolerance request inspects the closed ProbeBundle, its InBundle constructors, center histories, metric witnesses, rational comparisons, and refinement rows; no later row can replace this ledger by an open cover or by a host finite set.

Filter-basis replay and dense-embedding handoff follow the route order in R. The basis row F consumes the displayed finite-net data, and the embedding row E receives only those basis reads before placing source observations in the dense completion boundary.

The constructive-completion read is then local to C and S. Regular Cauchy names, dyadic tolerances, separated comparison, finite stream windows, regular rational readbacks, and the terminal real-name seal are the only completion-facing rows exposed downstream.

Finally, H, Q, L record transport, provenance, and local naming for the same coordinates. Since the excluded principles have no carrier coordinate, no replay edge, and no provenance row, the local $\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}$ surface is exactly the listed obligation surface. □

Theorem 1842.3 (PrecompactCompletion density handoff)**.** *Let $P = (X, N, F, E, C, S, H, R, Q, L)$ be an accepted* $\mathsf{PrecompactCompletion}^{\uparrow}$ *packet. Every completion-facing consumer factors through*

$\mathsf{PrecompactMetric}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Re

Equivalently, the consumer reads the finite route

$$X, N \longmapsto F \longmapsto E \longmapsto C \longmapsto S \longmapsto H, R, Q, L$$

rather than a quotient completion class, a selected completed point, a choice schedule, an open-cover compactness proof, or an ambient completeness theorem.

Proof. Start with the source metric row X and the finite-net ledger N. These are precisely the precompact metric data of chapter 1531: point histories, distance witnesses, finite centers, membership constructors, rational bounds, and refinement reads.

The consumer next reaches the Cauchy-filter basis row F. This step keeps the handoff finite because the basis packets, common refinements, regular tail windows, and dyadic neighbourhood witnesses are generated from the same rows already exposed by $\mathsf{PrecompactMetric}^{\uparrow}$.

Density enters only through E. The $\mathsf{CompletionEmbedding}^{\uparrow}$ row receives source observations after the basis replay and places them in the completion boundary without adding quotient representatives or selected limits.

The constructive completion route C and seal row S complete the factorization. They expose the regular Cauchy, stream-name, regular-rational, and real-name reads of $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ while preserving the displayed route ledger.

Transport, provenance, and local naming through H, R, Q, L do not add new data; they preserve the same dependency order. Thus every completion-facing consumer factors through the named route and cannot inspect any of the excluded nonconstructive or ambient-completeness objects. □

Theorem 1842.4 (PrecompactCompletion ledger exactness)**.** *For every accepted* $\mathsf{PrecompactCompletion}^{\uparrow}$ *packet $P = (X, N, F, E, C, S, H, R, Q, L)$, every exported completion read remains inside the finite ledger*

$$X, N, F, E, C, S, H, R, Q, L.$$

It cannot export a quotient completion, a selected completed point, countable choice, open-cover compactness, detached $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completeness.*

Proof. Project an exported completion read from the carrier. By Definition 1842.1, the read has access only to the ten displayed coordinates and their componentwise transport rows.

Apply Definition 1842.2. Finite-net persistence keeps the read inside N, filter-basis replay moves it through F, dense-embedding handoff moves it through E, and constructive-completion non-escape moves it through C and S.

The remaining rows H, R, Q, L record transport, route order, provenance, and local naming for the same data. Every excluded object is absent from these rows, so no exported completion read can leave the displayed finite ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1842.1, Definition 1842.2, Definition 1842.3, and Definition 1842.4 seed the finite precompact-completion route from explicit precompact metric rows through dense constructive completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrecompactCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PrecompactCompletionUp.PrecompactCompletionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, open-cover compactness, full $\mathsf{Real}^{\uparrow}$ completeness, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-net persistence, filter-basis replay, dense-embedding handoff, constructive-completion non-escape, and ledger exactness for the same packet.

Constructive story: A $\mathsf{PrecompactCompletion}^{\uparrow}$ packet starts from a precompact metric source, attaches finite Cauchy-filter basis replay, routes source observations through a dense completion embedding and constructive metric completion, then exposes only stream-name, regular-rational, and Real naming rows to downstream consumers.

Chapter 1843

Compact Baire NameCert Construction

Beginning from the Baire category theorem for complete metric spaces, as developed by Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{CompactBaire}^{\uparrow}$ packet records the finite BEDC route by which a compact metric certificate may feed a dense-open Baire certificate without importing open-cover compactness or host intersections. It reads the compact metric carrier of chapter 129, the dense-open handoff of chapter 1542, the enumerated dense surface of chapter 1566, the complete-metric witness of chapter 128, the finite windows of chapter 126, and the regular rational readback of chapter 301. The chapter names the compact-metric Baire consequence as certificate composition, not as a host theorem about arbitrary intersections.

Definition 1843.1 (Compact Baire carrier)**.** *A* $\mathsf{CompactBaire}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, B, D, C, S, R, T, H, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *row, exposing the metric carrier, total-bounded finite-net data, and complete-limit route that will be inspected by the Baire argument.*
2. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open row, restricted to the displayed compact-metric source row X.*
3. *D is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *row used to enumerate the finite dense probes that a scheduled dense-open request may read.*
4. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row inherited from the compact metric certificate and presented as the only completion route visible to the Baire row.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule controlling which compact probes, dense-open rows, countable dense indices, and completion windows may be inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerance and radius comparisons used by the finite dense-open route.*
7. *T is the compact Baire trace ledger, recording the finite passage from compact-metric data through the complete-metric handoff and dense-open route to the displayed readback.*
8. *H records componentwise* hsame *transport for X, B, D, C, S, R, T and the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactBaire}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactBaire}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no open-cover compactness object, countable-choice selector, host set intersection, ambient Real completeness row, Lean verification credential, or standard bridge credential.

Lean4 ✓ `BEDC.Derived.CompactBaireUp.CompactBaireTasteGate single carrier alignment`

Theorem 1843.2 (Compact Baire NameCert obligations)**.** *For every accepted* $\mathsf{CompactBaire}^{\uparrow}$ *carrier* $K = (X, B, D, C, S, R, T, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactBaire}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric row, Baire dense-open row, countable dense row, complete-metric handoff, stream schedule, regular rational readback, trace ledger, transport, provenance, and local naming;*
2. *compact-source exposure, requiring every dense-open and finite-probe read to enter through the same* $\mathsf{CompactMetric}^{\uparrow}$ *row* X*;*
3. *complete-metric handoff, requiring the Baire row to consume the inherited* $\mathsf{CompleteMetric}^{\uparrow}$ *route* C *rather than an ambient completion principle;*
4. *dense-open finite routing, requiring the* $\mathsf{BaireCategory}^{\uparrow}$ *row* B *to use only the displayed schedule* S*, dense row* D*, readback row* R*, and trace ledger* T*;*
5. *nonescape, excluding open-cover compactness, countable choice, host set intersections, ambient Real completeness, Lean verification, and bridge checking.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1843.1. The accepted tuple displays exactly the compact metric row, Baire dense-open row, countable dense row, complete-metric handoff, stream schedule, regular rational readback, trace ledger, transport, provenance, and local name.

Compact-source exposure is forced by X. The dense-open row B, dense index row D, complete handoff C, schedule S, and readback R are all presented downstream of the same compact metric certificate.

The complete-metric handoff is the row C. Since C is inherited from the compact metric certificate, the packet has no coordinate from which an ambient completion theorem or separate Real-completeness principle can be selected.

Dense-open finite routing is read from B, S, R, T. The route names finite windows, regular rational comparisons, and the compact Baire trace ledger before any dense-open conclusion is exported.

Finally, H, P, N transport, source, and name only the displayed rows. Hence the carrier exports no open-cover compactness object, countable-choice selector, host set intersection, ambient Real completeness row, Lean verification credential, or bridge credential. □

Theorem 1843.3 (Compact Baire complete metric handoff)**.** *Let* $K = (X, B, D, C, S, R, T, H, P, N)$ *be an accepted* $\mathsf{CompactBaire}^{\uparrow}$ *carrier. Every Baire read exported by* K *reaches* $\mathsf{BaireCategory}^{\uparrow}$ *only after the compact metric row* X *has exposed its inherited* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff* C*.*

Proof. Read the carrier from its source row. The compact metric coordinate X is the first row that can supply the metric carrier, total-bounded finite-net surface, and complete-limit route.

The Baire row B is attached to that same source. Its complete-metric requirement is not stored independently; it is the displayed row C inherited from X.

Thus any Baire read accepted by the packet passes through X and C before consuming the dense-open rows. The remaining rows S, R, T, H, P, N only schedule, read back, trace, transport, source, and name that route. □

Theorem 1843.4 (Compact Baire dense-open finite route)**.** *Every dense-open request accepted by a* $\mathsf{CompactBaire}^{\uparrow}$ *carrier factors through the displayed finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{BaireCategory}^{\uparrow} \longmapsto \mathsf{CountableDenseSubset}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

The route records compact-source admission, completion handoff, dense-open refinement, countable dense probing, scheduled windows, and rational readback before the local name is exported.

Proof. Begin with a dense-open request. Carrier admission sends the request first to X, and Definition 1843.3 identifies the displayed completion row C as the only complete-metric route available to the Baire read.

The dense-open step is the row B. It is read with the countable dense row D, so the request sees only displayed finite probes rather than a choice-selected dense subset.

The schedule and readback are then supplied by S and R. The trace ledger T records the same compact-source, completion, dense-open, dense-probe, window, and rational-readback route, while H, P, N transport, source, and name it. □

Theorem 1843.5 (Compact Baire nonescape boundary)**.** *For an accepted* $\mathsf{CompactBaire}^{\uparrow}$ *carrier* $K = (X, B, D, C, S, R, T, H, P, N)$*, every exported comparison, replay, provenance read, and local name is exhausted by the displayed rows* $X, B, D, C, S, R, T, H, P, N$*. In particular, the packet exports no open-cover compactness object, countable-choice selector, host set intersection, ambient Real completeness theorem, Lean verification credential, or bridge credential.*

Proof. Project the accepted carrier. The classifier compares two packets only through the displayed compact metric, Baire, countable dense, complete-metric, stream, regular-rational, trace, transport, provenance, and local naming rows.

The possible escape points are exactly the compactness, density, completion, and dense-open interfaces. The compactness row X is read as the $\mathsf{CompactMetric}^{\uparrow}$ certificate of chapter 129; the complete row C is its displayed completion handoff; the dense row D is the finite index surface of chapter 1566; and the Baire row B is the dense-open route of chapter 1542.

None of these coordinates stores an open-cover compactness object, countable-choice selector, host set intersection, ambient Real completeness theorem, Lean verification credential, or bridge credential. The structural rows only replay and name the same route, so no exported read can leave the displayed boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactBaire}^{\uparrow}}$.

Scope closed: Definition 1843.1, Definition 1843.2, Definition 1843.3, Definition 1843.4, and Definition 1843.5 seed the compact-metric Baire certificate route over displayed compactness, completeness, countable dense probing, dense-open refinement, finite windows, and regular rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactBaire}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, host set intersections, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, complete-metric handoff, dense-open finite routing, trace exactness, and nonescape proofs for BEDC.Derived.CompactBaireUp.

Constructive story: A CompactBaire$^{\uparrow}$ packet is generated from a CompactMetric$^{\uparrow}$ row, a BaireCategory$^{\uparrow}$ dense-open row, a CountableDenseSubset$^{\uparrow}$ dense-probe row, an inherited CompleteMetric$^{\uparrow}$ handoff, StreamName$^{\uparrow}$ scheduling, RegSeqRat$^{\uparrow}$ readback, a trace ledger, componentwise transport, package provenance, and a local NameCert row.

Chapter 1844

A Concrete Naming Certificate for $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ packet records the finite four-object boundary at which rational approximants, stream names, regular rational sequences, and the terminal Real seal can be cited together without asserting a completeness theorem. It reads the dyadic endpoint and tolerance ledger of chapter 291, the finite-window stream surface of chapter 126, the regular-rational readback of chapter 301, the terminal seal of chapter 38, and the Bishop regular Cauchy completion carrier of chapter 1639.

The packet is an interface certificate. It names the rows that a completion-facing consumer may inspect when moving among the L10 rational, stream, regular-sequence, and Real surfaces, while excluding quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, and bridge checking.

Definition 1844.1 (Cauchy real completion interface carrier)**.** *A* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, S, R, B, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance row used by the rational boundary, stream-window requests, regular-sequence comparisons, and Real-seal reads.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the displayed windows that a completion consumer may replay.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational sequence row attached to the same dyadic tolerance and stream-window data.*
4. *B is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after D, S, R have fixed the rational, stream, and regular-sequence faces.*
5. *T is the completion-boundary tail ledger, recording the finite handoff from dyadic tolerances through stream windows and regular rational readback to the terminal Real seal.*
6. *H records componentwise* hsame *transports for the dyadic, stream, regular-sequence, Real-seal, tail-ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-boundary request through D, S, R, B, T, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealCompletionInterface}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, B, T, H, C, P, N$. The carrier contains no quotient stream equality, selected limit, countable-choice selector, host real equality row, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, or standard-bridge credential.*

Theorem 1844.2 (Cauchy real completion interface NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carrier $I = (D, S, R, B, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealCompletionInterface}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed DyadicRatCore endpoint and tolerance row, StreamName finite windows, RegSeqRat readback, Real seal, completion-boundary tail ledger, transport, replay, provenance, and local naming row;*
2. *dyadic endpoint exposure, requiring every interface read to project D before inspecting stream windows, regular rational readback, or the terminal Real seal;*
3. *stream-window exactness, requiring S to expose only finite windows tied to the displayed dyadic tolerance row;*
4. *regular-sequence handoff, requiring R to reuse the same D, S surface rather than selecting a second sequence representative;*
5. *Real-seal boundary, requiring every* $\mathsf{Real}^{\uparrow}$ *read to remain downstream of D, S, R and the tail ledger T;*
6. *non-escape, requiring H, C, P, N to transport, replay, source, and name no row from which quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, or bridge credentials can be exported.*

No local obligation is stored outside these rows.

```
Lean4 ✓  BEDC.Derived.CauchyRealCompletionInterfaceUp.CauchyRealCompletionInterfaceTasteGate
single carrier alignment
```

Proof. Carrier admission is projection from Definition 1844.1. The accepted packet displays exactly the dyadic endpoint and tolerance row, finite stream windows, regular-rational readback, terminal Real seal, completion-boundary tail ledger, and structural rows.

The dyadic exposure and stream-window exactness clauses are forced by the order of the carrier. A completion-boundary request first reads D, then obtains only the finite windows in S that are tied to that displayed tolerance row.

The regular-sequence handoff is the projection to R. Since R is stored after D, S, the interface has no coordinate from which a second stream representative or detached rational sequence can be selected.

The Real-seal boundary is carried by B and T. The terminal seal is read only after the rational, stream, and regular-sequence faces have been displayed, and the tail ledger records that same handoff.

Finally, non-escape is exhausted by H, C, P, N. These rows transport, replay, source, and name the displayed interface only, and none contains quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, or bridge credentials. □

Theorem 1844.3 (Cauchy real completion four-face handoff)**.** *Let $I = (D, S, R, B, T, H, C, P, N)$ be an accepted* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carrier. Every completion-facing read exported by I factors through the four displayed faces*

$$D \longmapsto S \longmapsto R \longmapsto B$$

before it can inspect the tail ledger T or the structural rows H, C, P, N.

Proof. Begin with a completion-facing read of I. Carrier admission provides no source row before the dyadic endpoint and tolerance ledger D.

The read then passes to the finite-window row S. These windows are the only stream observations exposed by the packet, so no quotient stream equality or host stream representative can enter the route.

Next the read projects the regular-rational row R. This row is attached to the displayed dyadic and stream data, and it does not select a second regular sequence.

The terminal Real seal B is therefore reached only after D, S, R. The tail ledger T and structural rows H, C, P, N replay the same route, so every exported completion-facing read factors through the four displayed faces in order. □

Lean4 ✓ `BEDC.Derived.CauchyRealCompletionInterfaceUp.CauchyRealCompletionInterfaceUpTasteGate`
`single carrier alignment`

Theorem 1844.4 (Cauchy real completion interface Real-seal route determinacy)**.** *Let $I = (D, S, R, B, T, H, C, P, N)$ and $I' = (D', S', R', B', T', H', C', P', N')$ be accepted* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carriers. Suppose the two packets expose componentwise matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. Then every completion-facing consumer read of I and every matching read of I' reaches the same terminal Real-seal route after the four-face handoff through D, S, R, B and D', S', R', B'. Any remaining exported comparison is exhausted by the shared T, H, C, P, N rows, so there is no second seal coordinate, quotient stream equality, selected limit, countable-choice selector, host real equality, ambient completeness datum, or bridge credential along which the two reads could diverge.*

Proof. Project both accepted carriers to their displayed rows. The componentwise matching assumptions identify the dyadic endpoint and tolerance rows, finite stream windows, regular-rational readbacks, and terminal Real seals as the only route data available to the two completion-facing reads.

Apply Definition 1844.3 to each carrier. Both reads must pass through the four displayed faces in order, so the matched D, S, R, B and D', S', R', B' rows force the same terminal Real-seal route before any tail-ledger or structural row can be inspected.

It remains to compare the residual rows. The carrier projection leaves only T, H, C, P, N for completion-boundary tail data, componentwise transport, replay, provenance, and local naming. These rows replay the already matched handoff and contain no second seal coordinate, quotient stream equality, selected limit, countable-choice selector, host real equality, ambient completeness datum, or bridge credential. Hence no further route choice remains. □

Theorem 1844.5 (Cauchy real completion interface non-escape)**.** *For an accepted* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carrier $I = (D, S, R, B, T, H, C, P, N)$, every exported comparison, replay, provenance read, or local name is exhausted by the displayed rows $D, S, R, B, T, H, C, P, N$. In particular, the packet exports no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, selected limit, countable-choice selector, host real equality, or bridge credential.*

Proof. Project the accepted packet. Its classifier compares carriers only through the displayed rows $D, S, R, B, T, H, C, P, N$.

The comparison-sensitive rows are T, H, C, P, N. The tail ledger records the finite handoff across D, S, R, B, transport is componentwise, replay follows the displayed request path, provenance names the same source chapters, and the local NameCert row names only this packet.

Since no accepted coordinate stores a quotient stream equality, selected limit, choice selector, host real equality, ambient Real-completeness datum, or bridge credential, no exported comparison or replay can use such a row. The packet therefore remains a boundary interface rather than a completeness assertion. □

Theorem 1844.6 (Cauchy real completion interface tail-ledger determinacy)**.** *Let $I = (D, S, R, B, T, H, C, P, N)$ and $I' = (D', S', R', B', T', H', C', P', N')$ be accepted* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *carriers. If the two packets expose matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows D, D', matching* $\mathsf{StreamName}^{\uparrow}$ *window rows S, S', matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows R, R', and matching terminal* $\mathsf{Real}^{\uparrow}$ *seal rows B, B', then every completion-boundary read through I and every matching read through I' is forced onto the same tail-ledger route through T, H, C, P, N and T', H', C', P', N'. The comparison exports no second Real seal, quotient stream equality, selected limit, host real equality, ambient completeness datum, or bridge credential.*

Proof. Project both carriers to the displayed rows of Definition 1844.1. The assumptions identify the four analytic faces D, S, R, B and D', S', R', B' as matching dyadic, stream, regular-rational, and terminal Real-seal data.

Apply the four-face handoff theorem, Definition 1844.3, to each packet. A completion-boundary read cannot inspect T, H, C, P, N or T', H', C', P', N' until the matched faces have already been displayed in order.

Use Real-seal route determinacy, Definition 1844.4. The terminal seal route is already fixed by the matched four faces, so any remaining comparison can only replay the tail ledger, componentwise transport, continuation, provenance, and local naming rows.

Finally invoke non-escape, Definition 1844.5. Those residual rows contain no second seal coordinate, quotient stream equality, selected limit, host real equality, ambient completeness datum, or bridge credential. Hence the tail-ledger route is determined by the matching D, S, R, B faces. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealCompletionInterface}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealCompletionInterface}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1844.1, Definition 1844.2, Definition 1844.3, Definition 1844.4, Definition 1844.5, and Definition 1844.6 bind the finite L10 interface obligations to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealCompletionInterface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, stream-window exactness, regular-sequence handoff, Real-seal boundary, four-face handoff, Real-seal route determinacy, and non-escape proofs for BEDC.Derived.CauchyRealCompletionInterfaceUp.

Constructive story: A $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ packet is generated from a DyadicRatCore endpoint and tolerance row, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal row, a completion-boundary tail ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1845

A Concrete Naming Certificate for $\mathsf{CauchyCompletionKleisli}^{\uparrow}$

Following Mac Lane's language of Kleisli categories for monads, and Bishop–Bridges and Kelley completion terminology for Cauchy completion interfaces, the $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ packet names the finite consumer boundary where unit and bind routes of the L10 completion monad are handed to downstream completion readers. It is downstream of the completion monad of chapter 378, the unit certificate of chapter 1527, the multiplication certificate of chapter 1829, the stream surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38.

The packet is a consumer boundary rather than a construction of selected limits. It records exactly the rows by which a downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ reader can inspect a unit source, a bind source, a reassociated bind source, the shared schedule-window-observation-readback route, and the terminal seal.

Definition 1845.1 (Cauchy completion Kleisli carrier)**.** *A* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, B, A, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the unit source row inherited from* $\mathsf{CauchyCompletionUnit}^{\uparrow}$*, displaying the constant regular-rational input packet before any bind consumer is read.*
2. *B is the bind source row inherited from* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*, displaying the source-family row used by a single Kleisli bind request.*
3. *A is the reassociated bind source row inherited from* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$*, displaying the source route for two successive bind requests after reassociation.*
4. *S is the shared unary schedule row used by U, B, A before any finite window, dyadic observation, readback, or seal coordinate is inspected.*
5. *W is the shared finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the schedule row.*
6. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation and tolerance row attached to the same finite window.*
7. *R is the shared diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
8. *E is the public* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, D, R have been displayed.*

9. *H records componentwise* hsame *transport for the unit source, bind source, reassociated bind source, schedule, window, dyadic observation, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a Kleisli consumer request through $U, B, A, S, W, D, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisli}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, B, A, S, W, D, R, E, H, C, P, N$. The carrier has no coordinate for quotient streams, selected limits, countable choice, host equality, hidden representatives, ambient completeness, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1845.2 (Cauchy completion Kleisli NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *carrier $K = (U, B, A, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisli}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the unit source, bind source, reassociated bind source, shared schedule, finite stream window, dyadic observation and tolerance row, diagonal readback, Real seal, transport, replay, provenance, and local naming row;*
2. *unit-source admission, requiring every left-unit or right-unit consumer read to pass through U before it can inspect S, W, D, R, E;*
3. *bind-source admission, requiring every single bind consumer read to pass through B before it can inspect the shared downstream rows;*
4. *reassociated-bind admission, requiring every two-step bind consumer read to pass through A and then the same S, W, D, R, E rows;*
5. *seal coherence, requiring the unit, bind, and reassociated bind routes to reach the same public* $\mathsf{Real}^{\uparrow}$ *seal row under componentwise* hsame *transport and displayed* Cont *replay;*
6. *non-escape, requiring P, N to source and name no quotient stream, selected limit, countable-choice selector, host equality, hidden representative, ambient completeness theorem,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential.*

No local obligation is stored outside these rows.

```
Lean4 ✓  BEDC.Derived.CauchyCompletionKleisliUp.TasteGate.CauchyCompletionKleisliUpTasteGate
single carrier alignment
```

Proof. Carrier admission is projection from Definition 1845.1. The accepted packet displays exactly the unit source, bind source, reassociated bind source, shared schedule, finite window, dyadic observation, diagonal readback, Real seal, and structural rows.

Unit-source admission is supplied by U and by the unit boundary of chapter 1527. A unit consumer reaches the downstream rows only after the constant source packet has been displayed.

Bind-source admission is supplied by B and by the bind route of chapter 378. The route fixes the source family before opening the shared schedule, window, dyadic observation, readback, and seal.

Reassociated-bind admission is supplied by A and by the multiplication boundary of chapter 1829. Two successive bind requests are exposed as one reassociated source route before the same downstream rows are read.

The seal coherence and non-escape clauses are structural. Componentwise transport H, continuation replay C, provenance P, and the local name N preserve and source only the displayed Kleisli packet, so no excluded completion coordinate is available. □

Theorem 1845.3 (Cauchy completion Kleisli source triangle)**.** *For every accepted* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *carrier* $K = (U, B, A, S, W, D, R, E, H, C, P, N)$*, the route that reads a unit source, then a bind source, and then a downstream completion consumer has the same displayed source triangle as the reassociated route. Both routes read only*

$$U, B, A \longmapsto S \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N*, and neither route inserts a second completion source between bind and consumer.*

Proof. Start with the unit source row U. It displays the constant regular-rational source before any bind-facing coordinate is read.

Next attach the bind source row B. Since the carrier admits no row between B and the shared schedule, every single-bind consumer proceeds through S, W, D, R, E.

Now compare with the reassociated bind source row A. The carrier stores A as the only source route for two successive bind requests, and it is followed by the same schedule, window, observation, readback, and seal rows.

The structural rows H, C, P, N transport, replay, source, and name this same route. Thus the unit-bind-consumer path and the reassociated consumer path have the same displayed source triangle. □

Theorem 1845.4 (Cauchy completion Kleisli seal coherence)**.** *In every accepted* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *carrier, the unit route, the single-bind route, and the reassociated-bind route reach the same public* $\mathsf{Real}^{\uparrow}$ *seal row* E *after componentwise* hsame *transport of the source, schedule, window, dyadic-observation, diagonal-readback, replay, provenance, and local naming rows. The Kleisli consumer boundary therefore has one seal-facing route for unit, bind, and reassociated bind reads.*

Proof. Read the unit, bind, and reassociated bind rows U, B, A. Each row is followed in the carrier by the same schedule, finite window, dyadic observation, diagonal readback, and seal coordinates.

The componentwise transport row H compares these routes without introducing a detached representative. Displayed replay C preserves the order in which the downstream consumer reads the shared rows.

The public seal coordinate is the single row E. Since provenance P and the local name N source the same packet, every unit, bind, or reassociated bind presentation reaches the same seal-facing route. □

Theorem 1845.5 (Cauchy completion Kleisli nonescape)**.** *Every consumer-facing read of an accepted* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *carrier* $K = (U, B, A, S, W, D, R, E, H, C, P, N)$ *is exhausted by the displayed rows* $U, B, A, S, W, D, R, E, H, C, P, N$*. Thus the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisli}^{\uparrow}}$ *boundary exports no quotient stream, selected limit, countable-choice selector, host equality, hidden representative, ambient completeness theorem,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential.*

Proof. Project the accepted carrier. The tuple $K = (U, B, A, S, W, D, R, E, H, C, P, N)$ lists every coordinate admitted by the local Kleisli consumer surface.

The source rows U, B, A and the shared analytic rows S, W, D, R, E give the whole consumer-facing route. They contain the unit source, bind source, reassociated bind source, schedule, finite stream window, dyadic observation, diagonal readback, and public Real seal.

The structural rows do not enlarge the boundary. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row only preserve, replay, source, and name the same displayed packet.

Since no excluded object occurs as a coordinate or replay target, no consumer-facing read can escape to quotient streams, selected limits, countable choice, host equality, hidden representatives, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking. □

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1845.1, Definition 1845.2, Definition 1845.3, Definition 1845.4, and Definition 1845.5 seed the finite Kleisli consumer boundary for the L10 completion monad.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host equality, countable choice, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-source admission, bind-source admission, reassociated-bind admission, source-triangle, seal-coherence, and non-escape proofs for BEDC.Derived.CauchyCompletionKleisliUp.

Constructive story: A $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ packet is generated from a unit source row, a bind source row, a reassociated bind source row, a shared schedule, finite StreamName windows, DyadicRatCore observations, RegSeqRat diagonal readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1846

A Concrete Naming Certificate for $\mathsf{CauchyPrecompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley constructive completion, the $\mathsf{CauchyPrecompletion}^{\uparrow}$ packet collects displayed regular Cauchy names before quotient, separated completion, or ambient completeness is read. It sits after the dyadic rational endpoint and tolerance surface of chapter 291, the finite stream windows of chapter 126, and the regular rational readback of chapter 301, while remaining upstream of the terminal Real seal of chapter 38, the completion-embedding interface of chapter 1512, the separated completion boundary of chapter 1612, and the constructive metric completion surface of chapter 1556.

The packet is a pre-separated collection boundary. It names the finite rows a completion consumer may inspect when assembling regular Cauchy data, but it does not quotient names, select representatives, invoke countable choice, identify host reals, assert ambient $\mathsf{Real}^{\uparrow}$ completeness, close compactness by open covers, or provide a standard bridge.

Definition 1846.1 (CauchyPrecompletion carrier)**.** *A* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, R, D, S, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the source window family, listing the finite* $\mathsf{StreamName}^{\uparrow}$ *requests whose displayed entries are admitted before any quotient or separated completion step.*
2. *R is the regular Cauchy readback row, carrying the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence read from those source windows.*
3. *D is the dyadic tolerance ledger, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints and tolerance budgets used by W and R.*
4. *S is the finite stream-observation row, exposing only the displayed stream entries attached to W, D, R.*
5. *E is the completion-embedding handoff row, naming the downstream* $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, *and* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *consumers without giving them a quotient, a selected representative, or a completeness proof.*
6. *H records componentwise* hsame *transport for the source-window, regular-readback, dyadic-ledger, stream-observation, handoff, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a precompletion request through W, R, D, S, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyPrecompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPrecompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, S, E, H, C, P, N$. The carrier contains no quotient completion row, selected representative, countable-choice schedule, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, open-cover compactness datum, Lean verification credential, or standard bridge.*

Lean4 ✓ `BEDC.Derived.CauchyPrecompletionUp.TasteGate.CauchyPrecompletionTasteGate single carrier alignment`

Theorem 1846.2 (CauchyPrecompletion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *carrier $Q = (W, R, D, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyPrecompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source window family, regular Cauchy readback, dyadic tolerance ledger, finite stream observations, completion-embedding handoff, transport, replay, provenance, and local naming row;*
2. *source-window locality, requiring every precompletion request to read only the displayed finite windows in W before it can inspect the regular Cauchy readback;*
3. *regular-readback attachment, requiring R to be tied to the same source windows and dyadic ledger rather than to a second stream name or host representative;*
4. *dyadic-tolerance exactness, requiring D to provide the endpoint and tolerance budget used by both the source windows and the readback row;*
5. *finite-observation exactness, requiring S to expose only displayed stream observations attached to W, R, D;*
6. *downstream handoff, requiring E to name only completion-embedding, separated-completion, and constructive-metric-completion consumers without exporting their quotient, representative, completeness, compactness, or bridge data;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no row outside $W, R, D, S, E, H, C, P, N$.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1846.1. The accepted packet displays exactly the source window family, regular Cauchy readback, dyadic tolerance ledger, finite stream observations, completion-embedding handoff, and structural rows.

Source-window locality and regular-readback attachment are forced by the order of the carrier. A precompletion request first reads W, then obtains the regular rational readback R attached to the same windows rather than to a second stream name or host representative.

Dyadic-tolerance and finite-observation exactness are supplied by D and S. The dyadic ledger records the endpoint and tolerance budget for both the source windows and the readback row, while S exposes only the displayed observations tied to that same data.

The downstream handoff is the row E. It names completion-embedding, separated-completion, and constructive-metric-completion consumers as later readers, but it has no coordinate from

which to export a quotient completion, selected representative, completeness theorem, open-cover compactness datum, or bridge credential.

Finally, non-escape is exhausted by H, C, P, N. These rows transport, replay, source, and name the displayed precompletion packet only, so no local obligation is stored outside $W, R, D, S, E, H, C, P, N$. □

Theorem 1846.3 (CauchyPrecompletion regular handoff)**.** *Every completion-facing read of an accepted* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *carrier* $Q = (W, R, D, S, E, H, C, P, N)$ *factors through the displayed regular Cauchy route*

$$W, D, S \longmapsto R \longmapsto E$$

before it can be replayed, transported, sourced, or locally named. Consequently the packet hands regular Cauchy names to completion interfaces without quotienting them, selecting representatives, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $Q = (W, R, D, S, E, H, C, P, N)$. The source window family W is the only row from which a completion-facing request may obtain stream entries.

The read then exposes the shared dyadic tolerance ledger D and the finite observation row S. These rows fix the endpoint budget and the displayed stream observations before any regular readback is used.

The regular Cauchy readback R is therefore reached through W, D, S. Since R is attached to the same displayed data, the packet has no coordinate for a second stream name, quotient class, selected representative, choice schedule, or host real equality.

The handoff row E names downstream completion consumers only after the regular route has been displayed. Transport, replay, provenance, and local naming preserve that same route, so the handoff remains a pre-separated regular Cauchy boundary rather than an ambient completeness assertion. □

Theorem 1846.4 (CauchyPrecompletion nonescape)**.** *Every exported comparison, replay, provenance read, or local name of an accepted* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *carrier* $Q = (W, R, D, S, E, H, C, P, N)$ *is exhausted by the displayed rows* $W, R, D, S, E, H, C, P, N$*. In particular, the packet exports no quotient completion, selected representative, countable-choice selector, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, open-cover compactness principle, Lean verification marker, or bridge credential.*

Proof. Project the accepted packet. Its classifier compares carriers only through the tuple $W, R, D, S, E, H, C, P, N$ named in Definition 1846.1.

The analytic rows are W, R, D, S, E. They display the source windows, regular readback, dyadic tolerance ledger, finite observations, and downstream handoff surface, without adding a quotient row or an ambient completeness coordinate.

The structural rows do not enlarge the boundary. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row only preserve, replay, source, and name the same displayed packet.

Since no excluded object appears as a coordinate or replay target, no exported comparison, provenance read, or local name can escape to quotient completion, selected representatives, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPrecompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyPrecompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1846.1, Definition 1846.2, Definition 1846.3, and Definition 1846.4 seed the finite pre-separated regular Cauchy collection boundary over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, SeparatedCompletion$^{\uparrow}$, and ConstructiveMetricCompletion$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyPrecompletion}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyPrecompletionUp.TasteGate.CauchyPrecompletionTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, ambient Real$^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window locality, regular-readback attachment, dyadic-tolerance exactness, finite-observation exactness, completion-embedding handoff, regular handoff, and non-escape proofs for BEDC.Derived.CauchyPrecompletionUp.

Constructive story: A CauchyPrecompletion$^{\uparrow}$ packet is generated from a source window family, regular Cauchy readback, DyadicRatCore tolerance ledger, finite StreamName observations, completion-embedding handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1847

A Concrete Naming Certificate for $\mathsf{CauchySpace}^{\uparrow}$

Following Kelley and Bishop and Bridges, the $\mathsf{CauchySpace}^{\uparrow}$ packet records the finite L10 interface at which filter Cauchy data, uniform entourage data, regular rational Cauchy names, and Real completion consumers can be read through one NameCert surface. It refines the filter route of chapter 333, the entourage route of chapter 339, and the regular rational readback of chapter 301, while remaining upstream of the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 and the pre-separated completion boundary of chapter 1846.

The packet is an interface certificate rather than a completion theorem. It names the finite rows that let later metric and completion chapters cite one displayed Cauchy-space boundary, without asking those chapters to reassemble the filter, uniform, regular-sequence, and Real-consumer handoff separately.

Definition 1847.1 (CauchySpace carrier)**.** *A* $\mathsf{CauchySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, U, R, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, listing the finite filter requests and finite stability witnesses that are allowed to be read by the Cauchy-space interface.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, listing the finite entourage requests, refinements, and composition witnesses used to test the same Cauchy data.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row attached to the displayed filter and entourage data.*
4. *Q is the precompletion row, pointing to the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *packet that accepts the displayed regular Cauchy name before quotienting or representative selection.*
5. *T is the Real-consumer row, naming the downstream* $\mathsf{Real}^{\uparrow}$ *completion consumers allowed to read F, U, R, Q without importing ambient completeness.*
6. *H records componentwise* hsame *transport for the filter, uniform, regular-name, precompletion, Real-consumer, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Cauchy-space request through F, U, R, Q, T, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchySpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyPrecompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}$ *row.*

The carrier contains no quotient completion row, selected representative, countable-choice schedule, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, open-cover compactness datum, Lean verification credential, or standard bridge.*

Lean4 (definition) `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier`
Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceTasteGate single carrier alignment`

Definition 1847.2 (CauchySpace classifier)**.** *Two accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carriers*

$$S = (F, U, R, Q, T, H, C, P, N) \quad \textit{and} \quad S' = (F', U', R', Q', T', H', C', P', N')$$

are classified as the same Cauchy-space packet exactly when the displayed component comparisons hold:

$$F\mathsf{hsame}F', \quad U\mathsf{hsame}U', \quad R\mathsf{hsame}R', \quad Q\mathsf{hsame}Q', \quad T\mathsf{hsame}T',$$
$$H\mathsf{hsame}H', \quad C\mathsf{hsame}C', \quad P\mathsf{hsame}P', \quad N\mathsf{hsame}N'.$$

No classifier branch may inspect quotient completions, selected representatives, countable-choice selectors, host real equality, ambient completeness, open-cover compactness, Lean verification, or bridge credentials.

Lean4 (definition) `BEDC.Derived.CauchySpaceUp.CauchySpaceClassifier`

Theorem 1847.3 (CauchySpace filter stability)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier* $S = (F, U, R, Q, T, H, C, P, N)$*, every exported filter comparison or replay factors through the displayed Cauchy-filter row F and is stable under the componentwise transport recorded by H. In particular, changing the surrounding uniform, regular-name, precompletion, or Real-consumer rows by displayed* hsame *transport cannot create a new filter obligation outside the carrier rows.*

Proof. Project the accepted carrier. The only row whose coordinates can answer a filter request is F, so carrier admission places every exported filter comparison inside the displayed Cauchy-filter boundary.

The transport row H is componentwise. Its filter component transports F to an hsame filter row while leaving the remaining rows available only as later readers, not as additional filter witnesses.

Replay by C follows the same displayed request route. Since C, P, N replay, source, and name the carrier S rather than an external filter object, no replay step can introduce a second filter obligation.

The remaining rows U, R, Q, T may consume the stabilized filter data, but none contains an independent filter classifier. Thus every exported filter comparison is exhausted by F and its displayed transport through H. □

Theorem 1847.4 (CauchySpace filter-uniform compatibility)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier* $S = (F, U, R, Q, T, H, C, P, N)$*, any consumer that compares filter Cauchy data with a uniform entourage test must first read F and U through the same componentwise* hsame *transport row H. Only after that shared transport may the consumer pass through R, Q, T, C, P, N before reaching any* $\mathsf{Real}^{\uparrow}$ *consumer. The route refuses quotient completion, selected representatives, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier filter uniform compatibility`

Proof. Use the carrier of Definition 1847.1 and the classifier of Definition 1847.2. The rows F and U are separate visible coordinates, but their comparison is classified only after the componentwise transport row H has carried both sides of the packet.

Apply the filter-stability result of Definition 1847.3. It keeps every filter read inside F and its H-transported copy, so an entourage test cannot introduce an independent filter witness.

The uniform read is then aligned with the same transported packet. The regular-name row R, precompletion row Q, Real-consumer row T, replay row C, provenance row P, and local naming row N are downstream readers of that aligned finite packet.

Since no carrier row stores a quotient completion, selected representative, countable-choice schedule, host real equality test, or ambient completeness datum, the shared filter-uniform comparison reaches $\mathsf{Real}^{\uparrow}$ consumers only through the displayed finite route. □

Theorem 1847.5 (CauchySpace uniform regular-sequence interface)**.** *Let $S = (F, U, R, Q, T, H, C, P, N)$ be an accepted $\mathsf{CauchySpace}^{\uparrow}$ carrier. Every regular rational name exported by S is read through the finite interface*

$$F, U \longmapsto R$$

where F supplies the Cauchy-filter stability data and U supplies the uniform entourage tests. The packet therefore exposes regular Cauchy names to completion consumers without selecting representatives or invoking countable choice.

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier uniform regseq interface`

Proof. Start with an exported regular-name read. Carrier admission exposes the filter row F and the uniform row U before the regular rational row R can be inspected.

The filter row supplies the finite stability witnesses, while the uniform row supplies the finite entourage requests and refinements. These two rows are the only analytic inputs allowed upstream of R.

The regular rational row is attached to the displayed pair F, U. Hence a downstream reader obtains R as a regular Cauchy name certified by finite filter and entourage data, not as a chosen representative of a quotient class.

Transport, replay, provenance, and local naming preserve the same route. Since no accepted row stores a choice schedule or representative selector, the interface from uniform Cauchy data to regular rational names remains constructive and finite. □

Theorem 1847.6 (CauchySpace Real completion consumer boundary)**.** *Every $\mathsf{Real}^{\uparrow}$ completion consumer named by an accepted $\mathsf{CauchySpace}^{\uparrow}$ carrier $S = (F, U, R, Q, T, H, C, P, N)$ reads only the displayed route*

$$F, U, R \longmapsto Q \longmapsto T$$

before structural replay, provenance, or local naming. Consequently the packet exports a Cauchy-space consumption boundary, not quotient completion, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier real completion consumer`

Proof. The consumer row T is downstream of the analytic rows. A $\mathsf{Real}^{\uparrow}$ completion consumer first reads the finite filter row F, the finite uniform row U, and the attached regular rational name row R.

The precompletion row Q is then the only permitted handoff into completion-facing data. It accepts the displayed regular Cauchy name while still excluding quotienting, representative selection, host equality, and ambient completeness.

The consumer row T names later $\mathsf{Real}^{\uparrow}$ readers of that precompletion handoff. It has no coordinate from which to export a real-equality theorem, a completeness theorem, an open-cover compactness principle, or a bridge credential.

Finally, H, C, P, N preserve, replay, source, and name this same finite route. Since each structural row is attached to F, U, R, Q, T, every exported completion-consumer read remains inside the displayed Cauchy-space boundary. □

Theorem 1847.7 (CauchySpace Real completion provenance route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *completion read exported by an accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier can be named only after the displayed route*

$$F, U \longmapsto R \longmapsto N \longmapsto P$$

has exposed the filter-uniform replay, regular rational readback, local naming row, and provenance row. Thus the Real completion consumer boundary feeds the local $\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}$ *provenance route, rather than a detached completion object or selected host representative.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier real completion provenance route`

Proof. Start with Definition 1847.6. It places the Real-facing read downstream of the displayed filter-uniform route and the regular rational readback.

The local naming row N is then the only accepted row that names this Real-facing read for the packet. The provenance row P records the source of that named read, so a consumer cannot replace the route by a quotient completion, selected representative, host equality, or ambient completeness datum.

Because H transports the same displayed packet and C replays only that route, the resulting provenance read remains attached to F, U, R, N, P and exports no external completion object. □

Theorem 1847.8 (CauchySpace filter-uniform Real consumer obligation)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier* $S = (F, U, R, Q, T, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *consumer named by* T *must first traverse the shared filter and uniform rows* F, U *together with the componentwise transport row* H*. Only after that shared route is displayed may the consumer read the regular-name row* R*, the precompletion row* Q*, the Real-consumer row* T*, and the structural replay, provenance, and naming rows* C, P, N*.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier filter uniform real consumer obligation`

Proof. Project the carrier in Definition 1847.1. The Real-consumer row T is not an independent analytic source; it is downstream of the finite filter row, the uniform entourage row, the regular rational row, and the precompletion row.

Use the filter-uniform compatibility result of Definition 1847.4. It forces any comparison between filter Cauchy data and uniform entourage data through F, U, H before a later row can consume the comparison.

Thus a Real-facing read reaches R, Q, T only after the shared filter-uniform transport has been displayed. The support rows C, P, N replay, source, and name this same route, so no Real consumer can bypass F, U, H. □

Theorem 1847.9 (CauchySpace precompletion nonescape obligation)**.** *Let $S = (F, U, R, Q, T, H, C, P, N)$ be an accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier. The precompletion row Q can export only the displayed handoff from the regular rational name R to the Real-consumer row T; it cannot export quotient completion, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read Q through Definition 1847.6. The theorem places Q between the regular-name row R and the Real-consumer row T, so Q is a handoff row rather than a completed quotient object.

The excluded principles are absent from the carrier inventory in Definition 1847.1. Since neither Q nor the structural rows H, C, P, N store those principles, replay and naming cannot introduce them.

Consequently any precompletion consumer receives only the finite route $F, U, R, Q, T, H, C, P, N$ and no stronger completion principle. □

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier precompletion nonescape obligation`

Theorem 1847.10 (CauchySpace regular-name handoff obligation)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *carrier $S = (F, U, R, Q, T, H, C, P, N)$, the row R is the sole* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff from finite filter and uniform data. Any completion-facing read must obtain its regular rational name through $F, U \longmapsto R$ before the rows Q and T can be inspected.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier regular name handoff obligation`

Proof. Use the uniform regular-sequence interface of Definition 1847.5. It states that exported regular rational names are attached to the displayed filter row F and uniform row U.

No second regular-name coordinate appears in the carrier. The rows Q and T are downstream consumers of R, while H, C, P, N only transport, replay, source, and name the existing route.

Therefore every completion-facing handoff reads R as the unique $\mathsf{RegSeqRat}^{\uparrow}$ row generated from the finite filter-uniform data, before any precompletion or Real-consumer row is exposed. □

Definition 1847.11 (CauchySpace local filter carrier)**.** *A* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier is a finite* BHist *subpacket*

$$L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$$

inside an accepted carrier $S = (F, U, R, Q, T, H, C, P, N)$ such that F_0 lists the local $\mathsf{CauchyFilter}^{\uparrow}$ *requests, F_1 lists their finite meet and tail-stability witnesses, U_0 lists the matching* $\mathsf{UniformSpace}^{\uparrow}$ *entourage requests, R_0 is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from those local requests, T_0 is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer handoff, H_0 records componentwise* hsame *transport for all displayed rows, C_0 records the* Cont *replay route, P_0 records* Pkg *provenance, and N_0 is the local* $\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}$ *row.*

Lean4 (definition) `BEDC.Derived.CauchySpaceUp.CauchySpaceLocalFilterCarrier`

Theorem 1847.12 (CauchySpace RegSeqRat uniform obligation)**.** *Let $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$ be a* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exported by R_0 is generated only after the local* $\mathsf{CauchyFilter}^{\uparrow}$ *rows F_0, F_1 and the* $\mathsf{UniformSpace}^{\uparrow}$ *row U_0 have been transported componentwise by H_0 and replayed through C_0. The route therefore exposes a regular rational Cauchy name from finite local-filter and uniform-entourage rows, not from quotient completion, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier regseqrat uniform obligation`

Proof. Project the local filter carrier. The rows F_0 and F_1 contain the finite filter requests, finite meets, and tail-stability data, while U_0 contains the matching uniform-entourage requests.

Transport these rows by the corresponding components of H_0. Since H_0 is componentwise, it moves the local filter data and uniform data together without adding a second filter object or a second uniform-space object.

Replay the transported route by C_0. The regular rational readback R_0 is reached only after this replay, so the resulting $\mathsf{RegSeqRat}^{\uparrow}$ row is generated from the displayed local Cauchy and uniform rows.

The remaining rows T_0, P_0, N_0 consume, source, and name the same route. None stores a quotient completion, selected representative, choice schedule, host equality test, or ambient completeness datum. □

Theorem 1847.13 (CauchySpace completion handoff obligation)**.** *For every* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$*, every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer named by* T_0 *receives the handoff*

$$F_0, F_1, U_0 \longmapsto R_0 \longmapsto T_0$$

through the displayed hsame *and* Cont *rows. The consumer receives no quotient-completion object, no selected Cauchy representative, no host real equality, no countable-choice selector, and no ambient completeness theorem from the Cauchy-space packet.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier completion handoff obligation`

Proof. Begin with the consumer row T_0. By Definition 1847.11, T_0 is downstream of the local filter rows, the uniform row, and the regular rational readback row.

Use Definition 1847.12 to obtain the generated $\mathsf{RegSeqRat}^{\uparrow}$ row R_0 from F_0, F_1, U_0 after componentwise transport and replay. This places R_0 between the local Cauchy-space data and any completion-facing consumer.

The displayed route then passes to T_0 and is recorded by P_0 and N_0. Since the carrier inventory contains no quotient-completion row, selected representative, choice schedule, host equality, or ambient completeness row, the completion handoff remains the finite route shown above. □

Theorem 1847.14 (CauchySpace filter-uniform completion nonescape)**.** *For every* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$*, every completion-facing CauchySpace read must traverse the shared* $\mathsf{CauchyFilter}^{\uparrow}$ *rows* F_0, F_1*, the* $\mathsf{UniformSpace}^{\uparrow}$ *row* U_0*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R_0*, the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer row* T_0*, the componentwise* hsame *transport row* H_0*, the* Cont *replay row* C_0*, the* Pkg *provenance row* P_0*, and the local* $\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}$ *row* N_0 *before exposing a completion boundary. The route exports no quotient completion, selected representative, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, Lean credential, or bridge claim.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier filter uniform completion nonescape`

Proof. Project the local carrier of Definition 1847.11. Its visible rows are exactly $F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0$, so every completion-facing read is sourced by this local inventory.

Use Definition 1847.12 for the filter-uniform compatibility and regular-name handoff. It places the $\mathsf{RegSeqRat}^{\uparrow}$ row R_0 downstream of the $\mathsf{CauchyFilter}^{\uparrow}$ rows F_0, F_1, the $\mathsf{UniformSpace}^{\uparrow}$ row U_0, componentwise transport, and displayed replay.

Use Definition 1847.13 for the completion handoff. The consumer row T_0 is reached only after R_0 and is then recorded by the same transport, replay, provenance, and local naming rows.

The excluded principles do not occur in the local carrier. Hence the completion boundary exposes only the displayed finite route and no quotient completion, selected representative, choice principle, host equality, ambient completeness, compactness, Lean credential, or bridge claim. □

Theorem 1847.15 (CauchySpace NameCert ledger)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchySpace}^\uparrow}$ *ledger for Definition 1847.11 consists of the finite* BHist *rows* F_0, F_1, U_0, R_0, T_0*, their componentwise* hsame *transports* H_0*, their* Cont *replay route* C_0*, and their* Pkg *provenance* P_0*. Any downstream* $\mathsf{CauchyFilter}^\uparrow$*,* $\mathsf{UniformSpace}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{Real}^\uparrow$*, or* $\mathsf{UniformCompletion}^\uparrow$ *read must factor through this ledger before inspecting a completion-facing row.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier namecert ledger`

Proof. Project the local carrier and record its rows in order. The first block, F_0, F_1, U_0, is the local Cauchy-filter and uniform-entourage surface; the second block, R_0, T_0, is the regular-name and completion-consumer surface.

The transport row H_0 and replay row C_0 bind the two blocks into one displayed route. Apply Definition 1847.12 for the regular-name handoff and Definition 1847.13 for the completion handoff.

Finally, P_0 and N_0 source and name exactly those rows. Thus the ledger contains every permitted read by the listed downstream packets and excludes any hidden quotient, selected representative, host equality, choice, or ambient completeness coordinate. □

Theorem 1847.16 (CauchySpace obligation coverage route)**.** *For every accepted* $\mathsf{CauchySpace}^\uparrow$ *local carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$ *of Definition 1847.11, every downstream Cauchy-completion consumer must first expose the* $\mathsf{CauchyFilter}^\uparrow$ *rows* F_0, F_1*, the* $\mathsf{UniformSpace}^\uparrow$ *entourage row* U_0*, the* $\mathsf{RegSeqRat}^\uparrow$ *regular-name row* R_0*, the* $\mathsf{CauchyPrecompletion}^\uparrow$ *handoff inside* T_0*, the* $\mathsf{Real}^\uparrow$ *completion-consumer row inside* T_0*, the componentwise* hsame *transport row* H_0*, the* Cont *replay row* C_0*, the* Pkg *provenance row* P_0*, and the local* $\mathsf{NameCert}_{\mathsf{CauchySpace}^\uparrow}$ *row* N_0 *before reading any completion boundary. The route exports no quotient completion, selected representative, host equality, countable choice, ambient* $\mathsf{Real}^\uparrow$ *completeness, open-cover compactness, Lean credential, or bridge claim.*

Proof. Project the local carrier L. Its displayed coordinates already list the Cauchy-filter rows, uniform row, regular-name row, completion-consumer handoff, transport, replay, provenance, and local naming row.

Apply Definition 1847.14 to force completion-facing reads through the shared filter and uniform surface. Apply Definition 1847.12 to place the $\mathsf{RegSeqRat}^\uparrow$ row downstream of that surface and upstream of any completion consumer.

Apply Definition 1847.13 for the handoff into the $\mathsf{CauchyPrecompletion}^\uparrow$ and $\mathsf{Real}^\uparrow$ consumer row. The remaining coordinates H_0, C_0, P_0, N_0 provide the componentwise transport, replay, provenance, and local NameCert rows for the same route.

The excluded principles are absent from the carrier and from the three cited routes. Hence every downstream Cauchy-completion consumer sees only the displayed finite obligation surface before any completion boundary is read. □

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier obligation coverage route`

Theorem 1847.17 (CauchySpace precompletion factorization)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *local carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$ *of Definition 1847.11, every* $\mathsf{Real}^{\uparrow}$ *completion consumer factors through the displayed precompletion route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyPrecompletion}^{\uparrow}$$

before it can read T_0, H_0, C_0, P_0, N_0*. Concretely, the consumer first exposes the filter rows* F_0, F_1*, then the uniform-entourage row* U_0*, then the regular rational name row* R_0*, then the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *handoff inside* T_0*, and only afterward the* $\mathsf{Real}^{\uparrow}$ *completion boundary inside the same row.*

The factorization exports no quotient completion, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credential.*

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceLocalFilterCarrier precompletion factorization`

Proof. Project the local carrier. Its public rows are ordered as F_0, F_1 for the $\mathsf{CauchyFilter}^{\uparrow}$ surface, U_0 for the $\mathsf{UniformSpace}^{\uparrow}$ surface, R_0 for the $\mathsf{RegSeqRat}^{\uparrow}$ regular-name readback, and T_0 for the precompletion and Real completion consumer handoff.

Apply Definition 1847.14. It keeps every completion-facing read downstream of the shared Cauchy-filter and uniform-entourage surface and prevents a direct jump to a completed host object.

Apply Definition 1847.12. The regular rational readback R_0 is generated from F_0, F_1, U_0 under the componentwise transport and displayed replay rows, so the readback cannot be replaced by a selected representative.

Finally apply Definition 1847.13 and Definition 1847.16. The handoff row T_0 exposes the $\mathsf{CauchyPrecompletion}^{\uparrow}$ boundary before the $\mathsf{Real}^{\uparrow}$ consumer boundary, while H_0, C_0, P_0, N_0 transport, replay, source, and name the same finite route. Hence quotient completion, selected representatives, countable choice, host equality, ambient completeness, and bridge credentials remain outside the carrier. □

Theorem 1847.18 (CauchySpace public consumer boundary)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$*, the public CauchySpace boundary exposed to completion-facing consumers is exactly the route that combines the local filter carrier, the precompletion nonescape obligation, the regular-name handoff obligation, and the completion handoff obligation. A consumer must read* F_0, F_1, U_0*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R_0*, then the* $\mathsf{CauchyPrecompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff recorded in* T_0*, and finally the* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The public boundary exports no quotient completion, selected representative, host real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, Lean credential, or bridge claim.*

Proof. Start with Definition 1847.11. It lists the only local filter, uniform-entourage, regular-name, completion-consumer, transport, replay, provenance, and naming rows available to a public consumer.

Use Definition 1847.9 to keep the precompletion row from becoming a quotient completion or selected representative. Use Definition 1847.10 and Definition 1847.12 to force every regular-name read through the displayed filter and uniform rows before R_0 is consumed.

Use Definition 1847.13 and Definition 1847.17 for the completion-facing handoff. These theorems place T_0 downstream of R_0 and keep the $\mathsf{Real}^{\uparrow}$ or $\mathsf{UniformCompletion}^{\uparrow}$ consumer inside the displayed route.

The structural rows H_0, C_0, P_0, N_0 transport, replay, source, and name the same carrier. Since the excluded principles have no row in the local carrier or in the cited obligations, the public consumer boundary is exactly the finite route stated above. □

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier public consumer boundary`

Theorem 1847.19 (CauchySpace public completion interface)**.** *For every accepted* $\mathsf{CauchySpace}^{\uparrow}$ *local filter carrier* $L = (F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0)$*, any* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *consumer reading the public* $\mathsf{CauchySpace}^{\uparrow}$ *surface must pass through the local filter carrier, the precompletion nonescape route, the regular-name handoff, the completion handoff, and the public consumer boundary already displayed in this chapter. Thus the completion-facing interface exposes only the finite rows* $F_0, F_1, U_0, R_0, T_0, H_0, C_0, P_0, N_0$ *and exports no quotient completion, selected representative, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, Lean credential, or bridge claim.*

Proof. Start with Definition 1847.11. It is the unique local inventory from which a completion-facing consumer may read filter rows, uniform rows, regular-name rows, completion handoff rows, transport, replay, provenance, and local naming.

Apply Definition 1847.9. This keeps the precompletion-facing read inside the displayed handoff row and blocks quotient completions, selected representatives, and host equality from entering the interface.

Next use Definition 1847.10. The regular-name read R_0 is reached only through the local filter and uniform rows, so a $\mathsf{Completion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{CauchyPrecompletion}^{\uparrow}$ consumer cannot bypass the displayed rational-name route.

Finally apply Definition 1847.13 and Definition 1847.18. The first theorem places the completion-facing row T_0 after the regular-name handoff, and the second repacks the entire route as the public boundary. Hence the stated public completion interface is exactly the same finite carrier surface. □

Lean4 ✓ `BEDC.Derived.CauchySpaceUp.CauchySpaceCarrier public completion interface`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1847.1, Definition 1847.2, Definition 1847.16, Definition 1847.17, Definition 1847.18, and Definition 1847.19 close the displayed finite CauchySpace public completion interface for downstream completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: The next grade requires Lean verification and bridge checking for the displayed public completion interface, without adding quotient completion, selected representatives, countable choice, or ambient completeness.

Constructive story: A $\mathsf{CauchySpace}^{\uparrow}$ packet is generated from a CauchyFilter row, UniformSpace entourage row, RegSeqRat regular-name row, CauchyPrecompletion handoff row, RealUp completion-consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1848

A Concrete Naming Certificate for $\mathsf{UniformEntourageRegularName}^{\uparrow}$

Following Kelley, Bourbaki, and Bishop–Bridges, the $\mathsf{UniformEntourageRegularName}^{\uparrow}$ packet records the finite L10 route by which uniform entourage data are read as regular rational names before any separated completion, representative selection, or host real equality is invoked. It sharpens the Cauchy-space interface of chapter 1847 by isolating the route from the $\mathsf{UniformSpace}^{\uparrow}$ entourage row of chapter 339 and the $\mathsf{CauchyFilter}^{\uparrow}$ requests of chapter 333 through finite $\mathsf{StreamName}^{\uparrow}$ windows from chapter 126 into the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301. The same route then hands the result to the $\mathsf{CauchyPrecompletion}^{\uparrow}$ boundary of chapter 1846 and later $\mathsf{Real}^{\uparrow}$ consumers from chapter 38.

The packet is a naming certificate for the entourage-to-regular-name handoff. It does not assert that the handoff has already been quotient-completed, represented by a selected stream, identified with host real equality, or upgraded to ambient real completeness.

Definition 1848.1 (Uniform entourage regular-name carrier)**.** *A* $\mathsf{UniformEntourageRegularName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, F, W, R, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage-data row, listing the finite entourage requests, refinement witnesses, diagonal witnesses, and composition witnesses available to the route.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *request row, listing the finite filter requests and stability witnesses whose Cauchy behavior is tested against the entourage data in U.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the displayed entourage and Cauchy-filter requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same U, F, W data.*
5. *Q is the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *handoff row that accepts the displayed regular rational name before quotient completion or representative selection.*
6. *T is the* $\mathsf{Real}^{\uparrow}$ *consumer row, naming only downstream real-name readers of Q and R without importing ambient completeness.*
7. *H records componentwise* hsame *transport for the uniform, Cauchy-filter, stream-window, regular-readback, precompletion, Real-consumer, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from an entourage-regular-name request through $U, F, W, R, Q, T, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformEntourageRegularName}^{\uparrow}$, $\mathsf{CauchySpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyPrecompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformEntourageRegularName}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, W, R, Q, T, H, C, P, N$ and the displayed routes among those rows. It contains no quotient completion row, selected representative, countable-choice schedule, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, open-cover compactness datum, Lean verification credential, or standard bridge.*

Lean4 ✓ `BEDC.Derived.UniformEntourageRegularNameUp.UniformEntourageRegularNameTasteGate single carrier alignment`

Theorem 1848.2 (Uniform entourage regular-name NameCert obligations)**.** *For every accepted* $\mathsf{UniformEntourageRegularName}^{\uparrow}$ *carrier*

$$E = (U, F, W, R, Q, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformEntourageRegularName}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the uniform entourage data, Cauchy-filter requests, finite stream windows, regular rational readback, precompletion handoff, Real-consumer row, transport, replay, provenance, and local naming row;*
2. *entourage locality, requiring every regular-name request to read only the displayed* $\mathsf{UniformSpace}^{\uparrow}$ *entourages in U before it can inspect a stream window;*
3. *Cauchy-filter compatibility, requiring the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row F to be the only filter source paired with the entourage tests in U;*
4. *finite-window readback, requiring W and R to expose a* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to the same U, F route;*
5. *completion-facing handoff, requiring Q and T to name only the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers of that regular name;*
6. *non-escape, requiring H, C, P, N to transport, replay, source, and name no row outside $U, F, W, R, Q, T, H, C, P, N$.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1848.1. The accepted packet displays exactly the uniform, filter, window, readback, handoff, consumer, and structural rows.

Entourage locality is forced by the first coordinate U. Any regular-name request starts by reading the finite entourage data already accepted by the $\mathsf{UniformSpace}^{\uparrow}$ row, so no external uniform structure can be inspected.

Cauchy-filter compatibility is the role of F. The packet pairs the finite $\mathsf{CauchyFilter}^{\uparrow}$ requests with the same entourage data, and there is no second filter coordinate from which another Cauchy source could be read.

The finite-window and readback obligations are the rows W and R. They expose the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ regular rational name attached to U, F, not to a selected representative or host real.

The rows Q and T only hand the displayed regular name to $\mathsf{CauchyPrecompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. Finally H, C, P, N preserve, replay, source, and name the same finite carrier, so the listed rows exhaust the local certificate surface. □

Theorem 1848.3 (Uniform entourage RegSeqRat handoff)**.** *Every regular rational name exported by an accepted* $\mathsf{UniformEntourageRegularName}^{\uparrow}$ *carrier*

$$E = (U, F, W, R, Q, T, H, C, P, N)$$

factors through the displayed route

$$U, F \longmapsto W \longmapsto R$$

before it reaches precompletion or Real-facing consumers. Consequently the packet hands uniform Cauchy data to $\mathsf{RegSeqRat}^{\uparrow}$ *without selecting representatives, invoking countable choice, or asserting host real equality.*

Proof. Begin with an exported regular rational name. The carrier exposes the uniform entourage row U and the Cauchy-filter request row F before any stream observation is available.

The stream-window row W is therefore opened only by the displayed U, F data. It contains the finite observations permitted by the route and no selected infinite representative.

The readback row R repacks those observations as the $\mathsf{RegSeqRat}^{\uparrow}$ name attached to the same route. Thus the exported regular rational name is generated by the displayed entourage and filter data rather than by quotient completion or host equality.

Rows Q, T, H, C, P, N appear only after this readback. They hand the name to precompletion and Real-facing consumers, then preserve and name the route without adding countable choice or representative selection. □

Theorem 1848.4 (Uniform entourage CauchySpace boundary)**.** *Every* $\mathsf{CauchySpace}^{\uparrow}$, $\mathsf{CauchyPrecompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformEntourageRegularName}^{\uparrow}$ *carrier*

$$E = (U, F, W, R, Q, T, H, C, P, N)$$

reads only the displayed route

$$U, F, W, R \longmapsto Q, T \longmapsto H, C, P, N$$

before it treats the packet as completion-facing data. The packet therefore supplies a boundary between uniform entourage Cauchy data and regular rational names, not a quotient completion, selected representative, countable-choice principle, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, open-cover compactness theorem, Lean verification, or bridge check.*

Proof. Project the accepted carrier. The only analytic rows exposed before completion-facing data are U, F, W, R: uniform entourage data, Cauchy-filter requests, finite stream windows, and regular rational readback.

The precompletion and Real-facing rows are Q and T. They consume the displayed regular name and name later $\mathsf{CauchyPrecompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readers, but neither row contains a quotient, selected representative, host equality, completeness proof, compactness proof, or bridge credential.

The structural rows H, C, P, N are attached to the same displayed route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming cannot enlarge the packet beyond its accepted coordinates.

Since no excluded object appears as a coordinate or replay target, every $\mathsf{CauchySpace}^{\uparrow}$, $\mathsf{CauchyPrecompletion}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer remains inside the finite uniform-entourage-to-regular-name boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEntourageRegularName}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEntourageRegularName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1848.1, Definition 1848.2, Definition 1848.3, and Definition 1848.4 seed the finite L10 route from $\mathsf{UniformSpace}^{\uparrow}$ entourage data and $\mathsf{CauchyFilter}^{\uparrow}$ requests through $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback to $\mathsf{CauchyPrecompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEntourageRegularName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage locality, Cauchy-filter compatibility, finite-window readback, RegSeqRat handoff, CauchySpace boundary, completion-facing handoff, and non-escape proofs for BEDC.Derived.UniformEntourageRegularNameUp.

Constructive story: A $\mathsf{UniformEntourageRegularName}^{\uparrow}$ packet is generated from UniformSpace entourage data, CauchyFilter requests, finite StreamName windows, RegSeqRat readback, CauchyPrecompletion handoff, RealUp consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1849

A Concrete Naming Certificate for $\mathsf{RationalRealEmbedding}^{\uparrow}$

Following Bishop and Bridges' construction of reals from rational Cauchy data, the $\mathsf{RationalRealEmbedding}^{\uparrow}$ packet names the constant-rational route from the arithmetic source $\mathsf{Rat}^{\uparrow}$ to the regular Cauchy and terminal real-name layers. It sits over the rational certificate of chapter 37, the finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet is the finite source boundary for rational constants inside the L10 completion route; it does not quotient streams, select limits, assert host real equality, invoke countable choice, or prove ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1849.1 (Rational-real embedding carrier)**.** *A* $\mathsf{RationalRealEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, S, R, D, T, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row, containing the rational constant together with the finite arithmetic source data allowed to be read by the embedding packet.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *window row: each displayed window reads the same rational source Q and contains no varying tail schedule.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *constant readback row, recording that every regular rational name coordinate is read back as the rational source from Q through the windows in S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the zero-tail and dyadic comparison budget used to certify that the constant readback satisfies every displayed regularity request.*
5. *T is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from Q, S, R, D, naming the terminal real-facing certificate for the rational constant.*
6. *H records componentwise* hsame *transport for the rational source, constant windows, regular readback, dyadic tolerance ledger, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a rational-real embedding request through Q, S, R, D, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalRealEmbedding}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $Q, S, R, D, T, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RationalRealEmbeddingUp.RationalRealEmbeddingTasteGate single carrier alignment`

Theorem 1849.2 (Rational-real embedding NameCert obligations)**.** *For every accepted* $\mathsf{RationalRealEmbedding}^{\uparrow}$ *carrier $E = (Q, S, R, D, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational source, constant stream windows, regular rational constant readback, dyadic tolerance ledger, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *rational-source admission, requiring every exported constant to pass through the displayed* $\mathsf{Rat}^{\uparrow}$ *row Q;*
3. *constant-window admission, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window in S to replay the same rational source and no independent tail schedule;*
4. *regular-readback admission, requiring R to expose the constant rational name through the displayed windows in S;*
5. *tolerance admission, requiring D to discharge the regularity requests by the zero-tail dyadic ledger attached to Q, S, R;*
6. *seal admission, requiring the* $\mathsf{Real}^{\uparrow}$ *row T to be read only after Q, S, R, D have been fixed;*
7. *non-escape, requiring H, C, P, N to export no quotient-stream equality, selected limit, countable-choice selector, host real equality, trichotomy datum, ambient completeness theorem, Lean verification credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1849.1. The accepted packet displays exactly the rational source, constant windows, regular readback, dyadic tolerance ledger, terminal real seal, and structural rows.

The rational-source and constant-window obligations are then forced by row order. A constant exported by the packet first reads Q, and every window in S is attached to that same rational source rather than to a separate stream tail.

The regular-readback and tolerance obligations use the next two rows. The row R reads the constant rational name through S, while D supplies the dyadic zero-tail ledger that answers the finite regularity tests.

The terminal seal obligation is downstream. The $\mathsf{Real}^{\uparrow}$ row T can be cited only after Q, S, R, D are already displayed, so the real-facing name is a seal of the finite constant route rather than a selected host limit.

The remaining rows are structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve and source the same displayed packet; none contains a quotient stream, selected limit, choice selector, host equality, trichotomy datum, ambient completeness theorem, Lean credential, or bridge credential. □

Theorem 1849.3 (Rational-real embedding real-seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{RationalRealEmbedding}^{\uparrow}$ *carrier* $E = (Q, S, R, D, T, H, C, P, N)$ *factors through the finite route*

$$Q, S, R, D \longmapsto T$$

before transport, replay, provenance, or local naming can be read. Consequently the embedding of a rational constant into the real-name layer is witnessed by a displayed constant StreamName route and a RegSeqRat readback, not by quotienting streams or selecting a limit.

Proof. Start with an exported real seal. The carrier has only one real-facing coordinate, namely T, and that row is listed after the rational source, constant-window, regular-readback, and dyadic-ledger rows.

The source row Q fixes the rational constant. The stream row S then opens only constant windows over Q, so no later step can introduce a variable Cauchy tail or an independent schedule.

The regular readback row R reads those windows as a constant regular rational name. The dyadic ledger D records the zero-tail tolerance facts needed by the displayed regularity requests.

Only after these four rows are fixed may T be read as a $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming preserve that same order, so the exported seal factors through Q, S, R, D and never through a quotient stream or selected limit. □

Theorem 1849.4 (Rational-real embedding constant-window coherence)**.** *For every accepted* $\mathsf{RationalRealEmbedding}^{\uparrow}$ *carrier* $E = (Q, S, R, D, T, H, C, P, N)$*, any two finite* $\mathsf{StreamName}^{\uparrow}$ *window reads exposed by* S *over inspected unary indices are classifier-equal through the same rational source row* Q*. The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* T *may consume only that constant-window surface.*

Proof. Project the accepted carrier. By the carrier definition, the row S is the constant $\mathsf{StreamName}^{\uparrow}$ window row attached to the rational source Q, and it contains no coordinate for a varying tail schedule.

Now compare two inspected unary-index windows in S. Each window reads the same displayed rational source row Q, so their classifier comparison is mediated by that source row rather than by an external stream representative.

Transport preserves the comparison componentwise through H. Replay through C can only cite the displayed route Q, S, R, D, T, H, P, N, so it reuses the same constant-window surface instead of creating a second tail schedule.

The downstream rows are therefore constrained by source order. The readback row R reads the constant windows already exposed by S, the tolerance row D evaluates the zero-tail ledger attached to that readback, and the seal row T is reached only after those rows have been fixed. □

Theorem 1849.5 (Rational-real embedding nonescape)**.** *Every rational-source, stream-window, regular-readback, dyadic-tolerance, or real-seal read of an accepted* $\mathsf{RationalRealEmbedding}^{\uparrow}$ *carrier* $E = (Q, S, R, D, T, H, C, P, N)$ *is exhausted by the displayed rows* $Q, S, R, D, T, H, C, P, N$*. Thus the local* $\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$ *boundary exports only the rational source, constant StreamName windows, RegSeqRat constant readback, DyadicRatCore tolerance ledger, RealUp seal row, componentwise transport, continuation replay, provenance, and local naming data.*

It exports no quotient-stream equality, selected limit, countable-choice selector, host real equality, trichotomy datum, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential.*

Proof. Project the accepted carrier. The tuple $E = (Q, S, R, D, T, H, C, P, N)$ lists every coordinate admitted by the local $\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$ surface.

The analytic route is Q, S, R, D, T. It fixes a rational source, opens constant finite windows, reads them as a regular rational name, supplies the dyadic tolerance ledger, and then seals the result as a $\mathsf{Real}^{\uparrow}$ name.

The structural route is H, C, P, N. These rows transport, replay, source, and name the same displayed carrier; they do not add analytic coordinates or external equality principles.

Since no excluded object occurs as a coordinate or replay target, no read can escape to quotient-stream equality, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or a bridge credential. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 1849.1, Definition 1849.2, Definition 1849.3, Definition 1849.4, and Definition 1849.5 seed the finite rational-constant embedding route from $\mathsf{Rat}^{\uparrow}$ through constant $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RationalRealEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-source admission, constant-window admission, regular-readback admission, dyadic-tolerance admission, real-seal factorization, transport stability, and non-escape proofs for BEDC.Derived.RationalRealEmbeddingUp.

Constructive story: A $\mathsf{RationalRealEmbedding}^{\uparrow}$ packet is generated from a RatUp source row, constant StreamName windows, RegSeqRat constant readback, a DyadicRatCore tolerance ledger, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1850

A Concrete Naming Certificate for $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$

Following Bishop and Bridges' constructive real analysis, the $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ packet records the finite BEDC boundary at which a located real interval and a regular Cauchy real name can be read together. It sits between the regular completion route of chapter 1639, the located interval surface of chapter 1709, the rational approximation window of chapter 1668, and the four-face completion interface of chapter 1844. The packet gives Real and Completion consumers a located Cauchy interface; it is not a completeness theorem for $\mathsf{Real}^{\uparrow}$, a quotient-stream construction, a selected limit, countable choice, host real equality, or a standard bridge.

Definition 1850.1 (Bishop located Cauchy real carrier)**.** *A* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, B, D, S, R, A, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, supplying lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, radius compatibility, locator reads, locatedness moduli, and the metric bracket route.*
2. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, carrying the regular Cauchy completion-facing route through dyadic endpoints, stream windows, regular rational readback, and the terminal Real seal.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger shared by the interval radius budget and the regular Cauchy tail budget.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the Cauchy name before any locatedness request reads the terminal seal.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same stream windows and dyadic tolerance ledger.*
6. *A is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *row, displaying the rational approximation window used to compare the Cauchy readback with the located interval endpoints.*
7. *W is the located-Cauchy witness ledger, recording that the regular Cauchy tail route and the located interval route use the same dyadic tolerance request before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read.*

8. *H records componentwise* hsame *transport for the interval, completion boundary, dyadic tolerance, stream window, regular readback, approximation, witness, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a located Cauchy request through $I, B, D, S, R, A, W, H, P, N$.*

10. *P is the* Pkg *provenance over* BishopLocatedCauchyReal$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, BishopRegularCauchyCompletion$^{\uparrow}$ DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealRationalApproximation$^{\uparrow}$, CauchyRealCompletionInterface$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BishopLocatedCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, D, S, R, A, W, H, C, P, N$. The carrier has no coordinate for Real$^{\uparrow}$ *completeness, quotient stream equality, selected limits, countable choice, host real equality, trichotomy, compactness, or bridge checking.*

Theorem 1850.2 (Bishop located Cauchy real NameCert obligations)**.** *For every accepted* BishopLocatedCauchyRe *carrier $L = (I, B, D, S, R, A, W, H, C, P, N)$, the local* NameCert$_{\text{BishopLocatedCauchyReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval row, regular Cauchy completion boundary row, dyadic tolerance ledger, stream window, regular rational readback, rational approximation row, located-Cauchy witness ledger, transport, replay, provenance, and local naming row;*

2. *located-interval admission, requiring every endpoint, radius, locator, locatedness, and metric-bracket request to pass through the displayed* LocatedRealInterval$^{\uparrow}$ *row I;*

3. *regular-Cauchy admission, requiring every completion-facing read to pass through B, D, S, R before the terminal* Real$^{\uparrow}$ *seal can be cited;*

4. *approximation compatibility, requiring A to compare the regular rational readback with the interval endpoint data under the same dyadic tolerance row D;*

5. *witness stability, requiring W, H, C to preserve the shared located-Cauchy route componentwise and replay it through displayed continuations only;*

6. *non-escape, requiring P, N to export no* Real$^{\uparrow}$ *completeness theorem, quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy, compactness principle, or bridge credential.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BishopLocatedCauchyRealUp.BishopLocatedCauchyRealTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1850.1. The accepted packet displays exactly the located interval row, regular Cauchy completion boundary, shared dyadic tolerance ledger, finite stream window, regular rational readback, rational approximation row, witness ledger, and structural rows.

Located-interval admission is supplied by I. Endpoint, radius, locator, locatedness, and metric-bracket requests have no route except the displayed LocatedRealInterval$^{\uparrow}$ carrier of chapter 1709.

Regular-Cauchy admission is supplied by B, D, S, R. The completion-facing read first fixes the dyadic tolerance ledger, then opens the stream window and regular rational readback before the terminal Real$^{\uparrow}$ seal can be used.

Approximation compatibility is the row A. It compares the regular readback with the located interval endpoint data under the same tolerance row D, so the packet does not introduce a detached rational approximation or a host real representative.

The remaining obligations are structural. The witness ledger W, componentwise transport H, continuation replay C, provenance P, and local name N preserve and source only the displayed located-Cauchy route; none contains a completeness theorem, quotient equality, selected limit, choice selector, host equality, trichotomy, compactness principle, or bridge credential. □

Theorem 1850.3 (Bishop located Cauchy real regular-Cauchy handoff)**.** *Every completion-facing read of an accepted* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *carrier* $L = (I, B, D, S, R, A, W, H, C, P, N)$ *factors through the regular Cauchy route*

$$B, D, S, R \longmapsto A \longmapsto W, H, C, P, N$$

before it can be compared with the located interval row I*. Consequently the packet hands off regular Cauchy data to the located interface without selecting a limit, quotienting streams, invoking countable choice, or asserting ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted packet $L = (I, B, D, S, R, A, W, H, C, P, N)$. The regular completion boundary B is the only completion-facing row admitted by the carrier.

The read then exposes the shared dyadic tolerance ledger D, the finite stream window S, and the regular rational readback R. These rows are the displayed regular Cauchy route inherited from chapter 1639.

The rational approximation row A is read only after D, S, R have been fixed. It gives the finite comparison surface that can be tested against the located interval endpoint data, while the witness ledger W records that the same tolerance request is being used.

Transport, replay, provenance, and local naming then preserve this route. Since the carrier has no selected limit, quotient equality, countable-choice schedule, host real equality, or completeness coordinate, the handoff remains a finite regular Cauchy interface rather than a Real-completeness assertion. □

Theorem 1850.4 (Bishop located Cauchy real shared-tolerance handoff)**.** *Any accepted* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *packet* $L = (I, B, D, S, R, A, W, H, C, P, N)$ *that compares the regular Cauchy readback with the located interval endpoints must expose the same dyadic row* D *before both the interval row* I *and the regular route* B, S, R, A, W *can be consumed. Thus the located side and the Cauchy side cannot be read under unrelated tolerance budgets.*

Proof. Project the accepted carrier. The only dyadic tolerance coordinate available to the packet is the row D of Definition 1850.1.

The regular Cauchy side is governed by Definition 1850.3. That route reads B, D, S, R before the approximation row A and the witness row W are consumed.

The located side is governed by Definition 1850.6. It keeps interval endpoint, radius, locator, locatedness-modulus, and metric-bracket data attached to the same displayed tolerance route through D, S, R, A, W.

Finally apply non-escape through the carrier boundary: no second tolerance row, host interval equality, quotient representative, selected limit, or ambient Real completeness coordinate exists. Hence every comparison between the Cauchy readback and the interval endpoints uses the shared row D. □

Theorem 1850.5 (Bishop located Cauchy real shared-tolerance exactness)**.** *For every accepted* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *packet* $L = (I, B, D, S, R, A, W, H, C, P, N)$*, any comparison between the regular Cauchy readback and the located interval endpoints is exhausted by the single displayed dyadic row* D*. The interval side may not substitute a second radius budget, and the Cauchy side may not substitute a second tail budget, host interval equality, quotient representative, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier. The only dyadic tolerance coordinate listed by Definition 1850.1 is D, and both the regular Cauchy boundary row and the located interval row are attached to it through the witness ledger W.

Apply the regular-Cauchy handoff of Definition 1850.3. It forces the completion-facing side to read B, D, S, R before the approximation row A and the witness row W can be consumed.

Apply located-interval stability from Definition 1850.6. Endpoint, radius, locator, locatedness-modulus, and metric-bracket data remain tied to the same displayed route through $I, B, D, S, R, A, W, H, C, P, N$ under componentwise transport.

Finally use nonescape from Definition 1850.7. Since the accepted packet has no coordinate for a second tolerance ledger, host interval equality, quotient representative, selected limit, countable choice, trichotomy, compactness, or ambient Real completeness, the row D is the whole comparison budget. □

Theorem 1850.6 (Bishop located Cauchy real located-interval stability)**.** *Let* $L = (I, B, D, S, R, A, W, H, C, P, N)$ *and* $L' = (I', B', D', S', R', A', W', H', C', P', N')$ *be accepted* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *carriers. If* H *records componentwise* hsame *transport from each row of* L *to the corresponding row of* L'*, then the local classifier transports locatedness only through the displayed rows*

$$I, B, D, S, R, A, W, H, C, P, N.$$

In particular, interval endpoint, radius, locator, locatedness-modulus, and metric-bracket data remain attached to the same regular Cauchy tolerance route and cannot be replaced by host interval equality, trichotomy, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The classifier is row-local by Definition 1850.1. Its accepted inputs are precisely the displayed tuple $I, B, D, S, R, A, W, H, C, P, N$.

Componentwise hsame transport in H moves the located interval row together with the regular Cauchy boundary, tolerance ledger, stream window, readback row, approximation row, witness ledger, replay row, provenance row, and local name. It has no coordinate that could identify host intervals or choose quotient representatives.

Locatedness therefore remains attached to I and to the shared tolerance route through D, S, R, A, W. The transported packet may replay the same finite route through C, P, and N, but it cannot introduce trichotomy, compactness, host equality, or ambient Real completeness. □

Theorem 1850.7 (Bishop located Cauchy real nonescape)**.** *Every located or completion-facing read of an accepted* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *carrier* $L = (I, B, D, S, R, A, W, H, C, P, N)$ *is exhausted by the displayed rows* $I, B, D, S, R, A, W, H, C, P, N$*. Thus the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyReal}^{\uparrow}}$ *boundary exports only located interval data, regular Cauchy completion-boundary data, shared dyadic tolerances, finite stream windows, regular rational readback, rational approximation windows, located-Cauchy witness data, componentwise transport, continuation replay, provenance, and local naming data.*

It exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy datum, compactness principle, or bridge credential.*

Proof. Project the accepted carrier. The tuple $L = (I, B, D, S, R, A, W, H, C, P, N)$ lists every coordinate admitted by the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyReal}^{\uparrow}}$ surface.

The analytic rows are I, B, D, S, R, A, W. They give the located interval packet, the regular completion boundary, the shared tolerance ledger, finite windows, regular readback, rational approximation data, and the witness ledger tying the two routes together.

The structural rows do not enlarge the boundary. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row only preserve, replay, source, and name the same displayed packet.

Since no excluded object occurs as a coordinate or replay target, no located or completion-facing read can escape to $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host real equality, trichotomy, compactness, or a bridge credential. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyReal}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyReal}^{\uparrow}}$, seed)

Scope closed: Definition 1850.1, Definition 1850.2, Definition 1850.3, Definition 1850.4, Definition 1850.5, Definition 1850.6, and Definition 1850.7 seed the finite located Cauchy real interface over $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, and $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host real equality, trichotomy, compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-interval admission, regular-Cauchy admission, approximation compatibility, witness stability, regular-Cauchy handoff, located-interval transport, and non-escape proofs for BEDC.Derived.BishopLocatedCauchyRealUp.

Constructive story: A $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ packet is generated from a LocatedRealInterval row, a BishopRegularCauchyCompletion boundary row, a shared DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat regular readback, a RealRationalApproximation row, a located-Cauchy witness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1851

A Concrete Naming Certificate for $\mathsf{LocatedArchimedean}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedArchimedean}^{\uparrow}$ packet records the finite located Archimedean search boundary used before a constructive real-completion consumer may treat a locatedness request, an integer-part bracket, an Archimedean approximation row, and a dyadic-density witness as one displayed route. It sits over the locatedness budget of chapter 1627, the integer-part boundary of chapter 1784, the approximation surface of chapter 1507, the dyadic-density witness of chapter 1484, the finite window interface of chapter 126, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite search boundary for completion-facing RealUp work; it is not trichotomy, quotient real equality, countable choice, selected integer search, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 1851.1 (LocatedArchimedean carrier)**.** *A* $\mathsf{LocatedArchimedean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, I, A, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatednessModulus}^{\uparrow}$ *row receiving the positive tolerance request and exposing the finite locatedness budget.*
2. *I is the* $\mathsf{RealIntegerPart}^{\uparrow}$ *row that supplies the integer-part and bracket route attached to the same real-name source.*
3. *A is the* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *row that records the finite bound, rational source, dyadic tolerance, and approximation window used by the search.*
4. *D is the* $\mathsf{DyadicDensityReal}^{\uparrow}$ *witness row available at the displayed radius after the locatedness and approximation rows have been opened.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the tolerance request, integer-part bracket, approximation row, and dyadic-density witness.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S before any Real-facing consumer receives the search boundary.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, I, A, D, S, R have been displayed in the same history.*

8. *H records componentwise* hsame *transport for the locatedness request, integer-part bracket route, Archimedean approximation row, dyadic-density witness, stream windows, readbacks, real seal, continuation rows, provenance, and local naming.*

9. *C records displayed* Cont *replay from every precision, interval, or completion-facing request through L, I, A, D, S, R, E without inserting a second Archimedean search.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedArchimedean}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$, $\mathsf{RealIntegerPart}^{\uparrow}$, $\mathsf{ArchimedeanApproximation}^{\uparrow}$, $\mathsf{DyadicDensityReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedArchimedean}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for trichotomy, quotient real equality, selected integer search, countable choice, hidden completion data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedArchimedeanUp.TasteGate.LocatedArchimedeanTasteGate single carrier alignment`

Theorem 1851.2 (LocatedArchimedean NameCert obligations)**.** *For every accepted* $\mathsf{LocatedArchimedean}^{\uparrow}$ *carrier*

$$K = (L, I, A, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedArchimedean}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the locatedness request L, integer-part bracket route I, Archimedean approximation row A, dyadic-density witness D, stream windows S, regular readback R, real seal E, and structural rows H, C, P, N;*

2. *located search compatibility, requiring L to provide the tolerance budget before any integer-part or approximation row is consumed;*

3. *bracket and approximation exactness, requiring I and A to name the same finite search boundary rather than independent host searches;*

4. *dyadic witness handoff, requiring D to be read only after the locatedness, bracket, approximation, window, and readback rows have been displayed;*

5. *transport and replay stability, requiring H and C to preserve the accepted status of L, I, A, D, S, R, E under componentwise movement and downstream requests;*

6. *non-escape, excluding trichotomy, quotient real equality, selected integer search, countable choice, hidden completion data, ambient Real completeness, Lean verification, and bridge checking from the local certificate surface.*

No LocatedArchimedean obligation is stored outside these rows.

Proof. Project the accepted packet $K = (L, I, A, D, S, R, E, H, C, P, N)$. The projection exposes exactly the locatedness request, integer-part bracket route, approximation row, dyadic witness, finite windows, regular readback, real seal, transport, replay, provenance, and local naming rows.

The located search compatibility clause is the first gate. The tolerance and locatedness budget is already fixed by L, so the later integer-part and approximation rows cannot choose a separate search request.

The bracket and approximation clauses use the sibling surfaces of chapter 1784 and chapter 1507. The rows I and A are displayed in the same BHist packet and are transported together by H, so their search data are read as one finite boundary.

The dyadic witness clause then applies chapter 1484. The witness row D is downstream of the locatedness, bracket, and approximation rows, and the windows S with readback R expose the same finite observation surface before the seal E is reached.

Finally, C replays all downstream requests through the listed rows, while P and N provide only provenance and local naming. Since the carrier has no field for the excluded principles, the displayed rows exhaust the local $\mathsf{NameCert}_{\mathsf{LocatedArchimedean}^{\uparrow}}$ surface. □

Theorem 1851.3 (LocatedArchimedean dyadic-density handoff)**.** *Every dyadic-density witness exported by an accepted* $\mathsf{LocatedArchimedean}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{LocatednessModulus}^{\uparrow} \longmapsto \mathsf{RealIntegerPart}^{\uparrow} \longmapsto \mathsf{ArchimedeanApproximation}^{\uparrow} \longmapsto \mathsf{DyadicDensityReal}^{\uparrow} \longmapsto \mathsf{StreamNam}$$

Concretely, the consumer first receives the locatedness budget L, then the integer-part bracket route I, the Archimedean approximation row A, the dyadic witness D, the finite windows S, the regular readback R, the Real seal E, and finally the structural rows H, C, P, N.

Proof. Begin with a dyadic-density read from an accepted carrier. The only dyadic-density coordinate is D, and it appears after the locatedness, integer-part, and approximation rows in the displayed packet.

The locatedness row L fixes the tolerance budget. The integer-part route I and approximation row A then bind the finite Archimedean search boundary used by that budget, so the witness cannot arise from a detached host search.

The witness is exposed only through the window and readback rows S and R. These are the same StreamName and RegSeqRat surfaces used by chapter 126 and chapter 301, and they precede the terminal $\mathsf{Real}^{\uparrow}$ seal E.

The rows H, C, P, N preserve, replay, source, and name the same route. Hence every dyadic-density witness factors through the stated finite handoff and exports none of the excluded host or quotient data. □

Theorem 1851.4 (LocatedArchimedean real search boundary)**.** *Every completion-facing* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedArchimedean}^{\uparrow}$ *carrier receives exactly the finite search boundary*

$$(L, I, A, D, S, R, E, H, C, P, N)$$

as carrier data. The consumer may read locatedness budget, integer bracket, Archimedean approximation, dyadic-density witness, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming, but it cannot read trichotomy, quotient real equality, selected integer search, countable choice, hidden completion data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the completion-facing read. Its only Real-facing coordinate is the seal row E, and E is reached after L, I, A, D, S, R have been displayed.

The rows L, I, A, D bind the analytic part of the search boundary. Locatedness supplies the request budget, the integer-part row supplies the bracket route, the Archimedean approximation row supplies the finite bound and tolerance route, and the dyadic-density row supplies the displayed witness.

The rows S and R provide the finite observation and readback surface for the same boundary. Thus the consumer receives StreamName windows and RegSeqRat readback before it can inspect the Real seal named by chapter 38.

Transport, replay, provenance, and local naming are exactly H, C, P, N. No carrier field remains from which trichotomy, quotient real equality, selected integer search, countable choice, hidden completion data, or Real completeness could be read. □

Falsifiable prediction: Every LocatedArchimedean$^{\uparrow}$ completion-facing read factors through one LocatednessModulus$^{\uparrow}$ row, one RealIntegerPart$^{\uparrow}$ bracket route, one ArchimedeanApproximation$^{\uparrow}$ row, one DyadicDensityReal$^{\uparrow}$ witness, finite StreamName$^{\uparrow}$ windows, one RegSeqRat$^{\uparrow}$ readback row, one Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locatedness-modulus, real-integer-part, archimedean-approximation, dyadic-density-real, streamname, regseqrat, real: no listed sibling is bijective to LocatedArchimedean$^{\uparrow}$ because this packet jointly binds locatedness budget, integer bracket, Archimedean approximation, dyadic-density witness, finite observation, regular readback, Real seal, transport, replay, provenance, and local naming for the finite search boundary.

Lean target: `BEDC.Derived.LocatedArchimedeanUp.TasteGate.LocatedArchimedeanTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected integer search, countable choice, hidden completion data, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, located search compatibility, bracket and approximation exactness, dyadic witness handoff, transport and replay stability, and Real-seal non-escape for BEDC.Derived.LocatedArchimedeanUp.

Constructive story: A LocatedArchimedean$^{\uparrow}$ packet is generated from a LocatednessModulus$^{\uparrow}$ request row, a RealIntegerPart$^{\uparrow}$ bracket route, an ArchimedeanApproximation$^{\uparrow}$ row, a DyadicDensityReal$^{\uparrow}$ witness, StreamName$^{\uparrow}$ windows, a RegSeqRat$^{\uparrow}$ readback row, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1852

A Concrete Naming Certificate for $\mathsf{ApartnessContinuity}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{ApartnessContinuity}^{\uparrow}$ packet isolates the finite L10 route by which a displayed continuous map carries positive apartness information through an explicit modulus before any Real or order-facing consumer reads the target separation. It sits between the graph rows of chapter 130, the positive-separation rows of chapter 1380 and chapter 304, the tolerance discipline of chapter 1631, the finite source windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the constructive continuity handoff; it does not assert trichotomy, quotient real equality, selected limits, host equality, countable choice, or ambient Real completeness.

Definition 1852.1 (Apartness continuity carrier)**.** *An* $\mathsf{ApartnessContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, L, R, M, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, exposing the source and target observation cells read by the continuity route.*
2. *L is the* $\mathsf{LocatedApartness}^{\uparrow}$ *positive-separation row on displayed source windows.*
3. *R is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-separation row on displayed real names, read only through the same source and target cells as G.*
4. *M is the* $\mathsf{ModulusContinuity}^{\uparrow}$ *tolerance row converting each requested target separation budget into a finite source-window budget.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule consumed by the source apartness row, the graph row, and the modulus row.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the windows in S.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording positive gaps, target tolerances, source budgets, endpoint readbacks, and comparison cells.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal visible only after G, L, R, M, S, Q, D have been displayed.*
9. *H records componentwise* hsame *transport for the graph, apartness rows, modulus row, windows, readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an apartness-continuity request through graph inspection, source separation, modulus conversion, target-separation handoff, finite readback, dyadic ledger inspection, and Real-seal consumption.*

11. *P is the* Pkg *provenance over* $\mathsf{ApartnessContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, L, R, M, S, Q, D, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected limits, host equality, countable choice, ambient Real completeness, or a detached semantic-continuity theorem.

Lean4 ✓ `BEDC.Derived.ApartnessContinuityUp.TasteGate.ApartnessContinuityTasteGate single carrier alignment`

Theorem 1852.2 (Apartness continuity NameCert obligations)**.** *For every accepted* $\mathsf{ApartnessContinuity}^{\uparrow}$ *carrier*

$$A = (G, L, R, M, S, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ApartnessContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the continuous-map graph, located apartness row, real apartness row, modulus-continuity row, StreamName windows, RegSeqRat readback, DyadicRatCore ledger, Real seal, transport, replay, provenance, and local naming;*

2. *apartness-source stability, requiring L and R to expose positive separation only over the same displayed source and target cells opened by G;*

3. *modulus-to-target-separation handoff, requiring M and D to turn every target-separation request into the finite source budget consumed by S, Q before R or E can be read;*

4. *transport and replay stability, requiring H and C to carry only the displayed rows $G, L, R, M, S, Q, D, E, P, N$ through componentwise* hsame *and displayed* Cont *routes;*

5. *ledger non-escape, requiring D, P, N to export no trichotomy, quotient real equality, selected limit, host equality, countable choice, ambient Real completeness, or detached host continuity fact.*

No local apartness-continuity obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1852.1. The accepted tuple displays exactly the graph row, the two apartness rows, the modulus row, the finite observation rows, the Real seal, and the structural transport, replay, provenance, and naming rows.

Apartness-source stability is the entry condition. The rows L and R may be inspected only with the graph row G, so positive separation cannot be detached from the displayed source and target cells.

The handoff from modulus to target separation is carried by M, S, Q, D. A target-separation request first reads the modulus row M, then opens the StreamName windows S, the regular readback Q, and the dyadic ledger D before the real apartness row R or the terminal seal E is visible.

Transport and replay stability follow from H and C. These rows move the displayed packet componentwise and replay the same finite route; they introduce no independent equality, limit, choice, completeness, or semantic-continuity coordinate.

Finally, ledger non-escape is the exhaustion clause for D, P, N. The dyadic ledger, provenance, and local NameCert rows name only the displayed route, so the excluded nonconstructive principles cannot become local obligations. □

Theorem 1852.3 (Apartness continuity Real handoff)**.** *Every Real or order consumer of an accepted* $\mathsf{ApartnessContinuity}^{\uparrow}$ *packet factors through the displayed apartness and modulus rows*

$$G, L, M, S, Q, D \longmapsto R \longmapsto E, H, C, P, N.$$

The consumer receives the continuous graph, positive-separation evidence, tolerance-to-source budget, finite windows, regular readback, dyadic ledger, terminal Real seal, transport, replay, provenance, and local NameCert rows. It receives no trichotomy, quotient real equality, selected limit, host equality, countable choice, ambient Real completeness, or detached host continuity theorem.

Proof. Start with an accepted packet $A = (G, L, R, M, S, Q, D, E, H, C, P, N)$. Projection exposes the continuous graph row G and the source apartness row L before any target-facing read is available.

The tolerance stage is forced next. The modulus row M converts the target request into finite source windows S, regular readback Q, and the dyadic ledger D, so the target apartness row R is read only after the displayed budget has been consumed.

The Real and order-facing stage is terminal. The seal E and the structural rows H, C, P, N transport, replay, source, and name the same route, with no coordinate for the excluded principles.

Therefore every Real or order consumer factors through the displayed apartness and modulus rows before receiving the terminal surface. Since trichotomy, quotient real equality, selected limits, host equality, countable choice, ambient Real completeness, and detached semantic continuity are absent from the carrier, none can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessContinuity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1852.1, Definition 1852.2, and Definition 1852.3 seed the finite L10 continuity route from graph, apartness, modulus, StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-source stability, modulus-to-target-separation handoff, transport and replay stability, ledger non-escape, and Real handoff proofs for BEDC.Derived.ApartnessContinuityUp.

Constructive story: An $\mathsf{ApartnessContinuity}^{\uparrow}$ packet is generated from a $\mathsf{ContinuousMap}^{\uparrow}$ graph row, $\mathsf{LocatedApartness}^{\uparrow}$ and $\mathsf{ApartnessReal}^{\uparrow}$ positive-separation rows, a $\mathsf{ModulusContinuity}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{CoveringDimension}^{\uparrow}$ packet is read through the compact-metric cover route of chapter 129 and the metric observation surface of chapter 57; the child files below record the finite cover and Real-separability handoffs.

Chapter 1853

A Concrete Naming Certificate for $\mathsf{CoveringDimension}^{\uparrow}$

Following Hurewicz–Wallman and Engelking, the $\mathsf{CoveringDimension}^{\uparrow}$ packet records finite-cover dimension as BEDC refinement data. The classical statement is read here through compact metric finite rows: a finite cover is displayed as BHist cover entries, a refinement is a finite map of rows, the order bound is a visible multiplicity ledger, and the Lebesgue-number evidence is the compact finite ledger already exposed by chapter 129, chapter 1767, and chapter 1302. Thus the packet speaks about a named finite cover-refinement surface, not about arbitrary open-cover compactness.

The dependency route is horizontal rather than purely kernel-local. The finite cover-refinement rows consumed by $\mathsf{CoveringDimension}^{\uparrow}$ are read from the compact metric packet of chapter 129, while the pointwise inspection of cover members uses metric ball observations from chapter 57. Thus the dimension carrier enters the dossier lattice through displayed compact metric and metric-ball rows before it records its refinement and order-bound ledgers.

Definition 1853.1 (Covering dimension carrier)**.** *A* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, E, C, R, O, L, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the compact metric classifier and the finite-net read route consumed by the packet;*
2. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, exposing the finite* ProbeBundle *of centers and tolerance-indexed coverage witnesses used to sample the cover;*
3. *C is the finite cover row, a displayed list of* BHist *cover members together with membership witnesses readable through the compact metric source;*
4. *R is the finite refinement map row, assigning each refined cover member to a displayed parent member of C and recording the local containment witness;*
5. *O is the order-bound witness row, recording that no inspected point-history is carried by more than the displayed bound of refined members;*
6. *L is the* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *row, tying the cover and refinement to positive radius ledgers and finite Lebesgue-style readback;*

7. *H records componentwise* hsame *transport for the compact metric source, finite epsilon-net row, cover row, refinement map, order-bound witness, Lebesgue ledger, replay row, provenance row, and local naming row;*
8. *T records displayed* Cont *routes through which compact-metric, finite-net, cover, refinement, order-bound, and Lebesgue-ledger consumers inspect the packet;*
9. *P is the* Pkg *provenance over* $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, CompactCoverLebesgueLe ProbeBundle, BHist, hsame, Cont, *and local naming rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary open cover, a choice-selected refinement, a host finite-subcover theorem, a classical covering-dimension theorem, quotient real equality, or an external multiplicity oracle.

Lean4 ✓ `BEDC.Derived.CoveringDimensionUp.CoveringDimensionTasteGate single carrier alignment`

Theorem 1853.2 (Covering dimension NameCert obligations)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *surface consists exactly of carrier admission for D, compact metric admission through K, finite epsilon-net admission through E, finite cover admission through C, refinement containment through R, order-bound verification through O, Lebesgue-ledger compatibility through L, componentwise* hsame *stability through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 1853.1. The analytic rows are exactly the compact metric source K, finite epsilon-net row E, finite cover row C, refinement row R, order-bound row O, and Lebesgue-ledger row L.

Carrier admission and compact admission are rowwise. The finite-net row E supplies the only center bundle and coverage witnesses read by the packet, so every cover and refinement check is anchored in displayed compact metric data.

The finite cover row C is refined only through R. Each refined member carries its displayed parent and containment witness before the order row O may count overlaps.

The Lebesgue-ledger row L ties the same cover route to positive radius data. Its compatibility obligation forces the refinement and order rows to be read with the finite lower-radius ledger rather than with a detached open-cover argument.

Finally H, T, P, N transport, replay, package, and name the same finite surface. Since the carrier contains no arbitrary open-cover coordinate, choice-selected refinement, host subcover theorem, classical dimension theorem, quotient equality, or external multiplicity oracle, none of those objects can enter the local NameCert obligations. □

Definition 1853.3 (Covering dimension compact-net root)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the compact-net root is the finite source surface consisting of K, E together with the downstream cover, refinement, order, Lebesgue-ledger, transport, replay, provenance, and naming rows. It is the reusable BHist *root through which every compact finite-cover consumer must enter before reading any dimension-bound data.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier compact net admission`

Theorem 1853.4 (Covering dimension compact-net admission)**.** *Every compact finite-cover consumer of an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N)$$

must first admit the compact-net root through the compact metric row K and the finite epsilon-net row E. The consumer cannot read the finite cover row C, refinement row R, order row O, Lebesgue ledger L, or structural rows H, T, P, N as a dimension-bound packet until the BHist *source of K, E is visible.*

Proof. Project the carrier of Definition 1853.1. The compact source row K and finite epsilon-net row E precede every cover or refinement row in the displayed packet.

Use the NameCert obligations of Definition 1853.2. They require compact metric admission and finite epsilon-net admission before cover admission, refinement containment, order-bound verification, and Lebesgue-ledger compatibility are available.

Thus the compact-net root of Definition 1853.3 is not optional bookkeeping. It is the entry surface for later finite-cover consumers, while H, T, P, N only transport, replay, source, and name the same root. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetAdmission`

Theorem 1853.5 (Covering dimension refinement multiplicity window)**.** *For every accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any refinement-order read must pass from the finite cover row C through the refinement map R before the order-bound witness row O is inspected. The multiplicity window counted by O is therefore a finite BHist *ledger over displayed refined members and their parents in C, not a host overlap oracle or an arbitrary open-cover dimension predicate.*

Proof. Read the cover and refinement rows from Definition 1853.1. The row C lists the cover members, while R assigns each refined member to one displayed parent and records the containment witness.

Apply the NameCert obligations. Order-bound verification through O is downstream of cover admission and refinement containment, so O can count only refined members already visible through C and R.

The structural rows H, T, P, N preserve this finite multiplicity window. Since no carrier coordinate stores a host overlap oracle, choice-selected refinement, or classical dimension predicate, the order read is exactly the displayed C, R, O window. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRefinementMultiplicityWindow`

Theorem 1853.6 (Covering dimension Lebesgue-ledger handoff)**.** *Every compact-cover Lebesgue read exported by an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N)$$

must pass through the finite ledger route

$$L \longmapsto H, T, P, N$$

after the compact-net root K, E and the finite cover-refinement rows C, R, O have been displayed. The handoff exports the same $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *evidence, componentwise transport, replay, provenance, and local naming; it does not export open-cover compactness, selected subcovers, quotient real equality, or host dimension data.*

Proof. Start with the compact-net admission theorem, Definition 1853.4. It places K, E before every downstream cover and dimension-bound read.

Then use Definition 1853.5. The finite cover, refinement map, and order ledger are read through C, R, O before a Lebesgue-style handoff can certify compatibility with the same finite cover route.

Finally apply the NameCert obligations of Definition 1853.2. They keep the Lebesgue ledger L attached to componentwise transport H, displayed replay T, provenance P, and local naming N, excluding open-cover compactness, selected subcovers, quotient real equality, and host dimension data from the handoff. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionLebesgueLedgerHandoff`

Theorem 1853.7 (Covering dimension root finite-cover carrier)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *packet admits a dimension read only through the finite carrier rows*

$$K, E, C, R, O, L, H, T, P, N.$$

The admitted rows are exactly compact metric source data, finite epsilon-net support, finite BHist *cover entries, finite refinement membership, order-bound witnesses, compact-cover Lebesgue ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *naming. The carrier has no coordinate for arbitrary open-cover compactness, choice-selected refinements, host countable dense sets, quotient completion data, or an external dimension oracle.*

Proof. Project the carrier of Definition 1853.1. The compact and metric source rows are read through $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$, with finite sampling supplied by chapter 129, chapter 57, and chapter 1767.

The cover, refinement, order, and radius rows are exactly C, R, O, L. Their finite lower-bound support is the $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ and $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ route of chapter 1302 and chapter 452, not a host compactness theorem.

Finally H, T, P, N preserve the same displayed packet. Since the carrier has no row for the excluded objects, a root dimension read cannot admit them as local obligations. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverCarrier`

Theorem 1853.8 (Covering dimension root refinement obligation)**.** *Every root order comparison exported by an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier factors through the finite refinement ledger before any dimension bound is inspected. In carrier notation, a consumer must read*

$$C \longmapsto R \longmapsto O$$

after the $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *source rows have been displayed and before any* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff reuses the bound.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootRefinementObligation`

Proof. Use Definition 1853.5. It already places the refinement map R between the finite cover row C and the order-bound row O.

Attach the root carrier admission of Definition 1853.7. The compact source rows from $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{FiniteEpsilonNet}^{\uparrow}$ precede C, R, O, while the finite Lebesgue and dyadic support rows are downstream consumers of the same displayed route.

The completion and separability siblings can therefore reuse only the finite order ledger already exposed by C, R, O. They cannot replace the refinement step by a selected subcover or by a host order comparison. □

Theorem 1853.9 (Covering dimension root separability route)**.** *When a root* $\mathsf{CoveringDimension}^{\uparrow}$ *packet uses* $\mathsf{RealSeparability}^{\uparrow}$*, that row supplies only the finite cover-selection route needed by the displayed refinement ledger. It contributes rational windows, dyadic tolerances, and regular-rational readback through*

$$\mathsf{RealSeparability}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}$$

before the order row is exported; it does not supply a host countable dense set, selected dense sequence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite-density route Definition 1853.17. It routes dense Real witnesses through displayed rational and dyadic density rows before O is exposed.

The dyadic and rational readback rows are the siblings chapter 291, chapter 301, and chapter 1809. They refine finite cover selection and tolerance inspection, but they do not add a separate dense-set carrier.

Combine this with Definition 1853.8. The separability route is inserted before the displayed order export and remains attached to C, R, O, L, H, T, P, N, so no selected dense sequence or host completeness principle is available. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier root separability route`

Theorem 1853.10 (Covering dimension root completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or Cauchy-facing read of a root* $\mathsf{CoveringDimension}^{\uparrow}$ *packet is consumed only after the finite cover and refinement ledgers have been displayed. The handoff route first exposes*

$$K, E, C, R, O, L$$

and only then permits completion-facing rows from $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the regular Cauchy support of chapter 301 to inspect the same bound.*

Proof. Apply Definition 1853.8. It fixes C, R, O downstream of the compact source rows and upstream of every order-bound export.

Next apply the Lebesgue-ledger handoff Definition 1853.6. The row L ties the displayed finite cover and refinement to compact-cover lower-bound data before structural transport and replay are read.

Only after those rows are visible may the completion-facing siblings of chapter 1506, chapter 301, and chapter 291 consume the bound. The completion handoff therefore receives a finite displayed cover-refinement packet, not a selected completion object or a hidden Cauchy limit. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier root completion handoff`

Theorem 1853.11 (Covering dimension refinement order)**.** *Every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *refinement factors through the finite route*

$$K, E, C \longmapsto R, O, L \longmapsto H, T, P, N.$$

Thus a downstream dimension consumer receives a displayed finite cover, a displayed refinement map into that cover, an order-bound witness over the refined rows, and the compact Lebesgue ledger before it may read the packet as a dimension bound.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRefinementOrder`

Proof. Begin with a downstream consumer of an accepted carrier D. By Definition 1853.1, the consumer enters through the compact metric row K and the finite epsilon-net row E before it can inspect any cover data.

The cover row C is then opened as a finite list of named cover members. The refinement row R maps each refined member back to this list and records the containment evidence needed to read the refined cover as a refinement of C.

The order-bound row O counts only refined members that are already visible through R. Hence the order claim is a finite overlap ledger over the displayed refinement, not a global theorem about all open covers.

The Lebesgue-ledger row L supplies the positive radius readback compatible with the same finite cover route. Transport, replay, provenance, and naming through H, T, P, N preserve that route for the dimension consumer. □

Theorem 1853.12 (Covering dimension compact-metric dependency)**.** *Every finite-cover refinement read exported as a* $\mathsf{CoveringDimension}^{\uparrow}$ *dimension bound must expose the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *carrier rows, the finite cover row, the finite refinement row, the order-bound row, any* $\mathsf{RealSeparability}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *rows used by the read, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *provenance before the bound is exported. In carrier terms, an accepted packet*

$$D = (K, E, C, R, O, L, H, T, P, N)$$

is consumed through compact metric source K, finite-net row E, finite cover row C, refinement row R, order row O, compact Lebesgue ledger L, transport H, replay T, package provenance P, and local naming N, with the dependency routes of the compact-metric and metric siblings remaining visible.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactMetricDependency`

Proof. Project the carrier of Definition 1853.1. The rows $K, E, C, R, O, L, H, T, P, N$ are the only compact source, finite-net, cover, refinement, order, Lebesgue-ledger, transport, replay, provenance, and naming rows available to the dimension consumer.

Use the compact metric route and metric dependency route, Definition 1853.22 together with the displayed route in `compact_metric_dependency_route.tex`. They force the cover-refinement read through $\mathsf{CompactMetric}^{\uparrow}$ finite-net data and $\mathsf{Met}^{\uparrow}$ ball observations before the refinement map and order ledger are inspected.

If the read uses dense real witnesses or completion-facing metric data, apply Definition 1853.17 and the completion dependency child routes. Those routes place $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ rows before the order-bound export rather than after it.

Finally H, T, P, N keep the route componentwise stable, replayed, sourced, and locally named. Since no carrier row stores arbitrary open-cover compactness, a choice-selected refinement, a host

dimension theorem, quotient real equality, or an external multiplicity oracle, a dimension bound can be exported only after the listed dependency rows are visible. □

Theorem 1853.13 (Covering dimension ledger non-escape)**.** *No accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet can replace its finite rows* $K, E, C, R, O, L, H, T, P, N$ *by arbitrary open-cover compactness, choice-selected refinements, a host multiplicity oracle, or a classical dimension theorem. Any exported dimension-bound claim must be read through the displayed cover, refinement, order-bound, Lebesgue-ledger, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionLedgerNonEscape`

Proof. Inspect the carrier inventory of Definition 1853.1. The only compactness data are the compact metric row K, the finite epsilon-net row E, and the finite Lebesgue-ledger row L.

The only cover data are the finite cover row C and the refinement map row R. The only multiplicity data are the order-bound witnesses in O.

The structural rows H, T, P, N preserve and expose these displayed rows. They do not add an open-cover family, a choice operator, a host overlap counter, or an external theorem.

Therefore any consumer that exports a dimension-bound claim without reading $K, E, C, R, O, L, H, T, P, N$ leaves the carrier surface and is not reading a $\mathsf{CoveringDimension}^{\uparrow}$ certificate. □

Theorem 1853.14 (CoveringDimension nerve order bound)**.** *An accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover-refinement packet may export an order-bound ledger to* $\mathsf{SimplicialComplex}^{\uparrow}$ *only through displayed finite cover members, refinement rows, overlap and multiplicity rows, and a finite face inventory. In carrier coordinates, the route from* $D = (K, E, C, R, O, L, H, T, P, N)$ *to a nerve consumer first reads the* $\mathsf{CompactMetric}^{\uparrow}$ *source* K*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row* E*, finite cover row* C*, refinement map* R*, order-bound ledger* O*, and* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *row* L *before the* $\mathsf{SimplicialComplex}^{\uparrow}$ *face rows can receive a dimension bound.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionNerveOrderBound`

Proof. Project the accepted carrier. The compact metric source K and finite epsilon-net row E are the only rows from which cover members can be sampled.

The cover and refinement rows are then opened as finite data. The row C supplies displayed cover members, and R assigns each refined member to a parent row before any overlap count is meaningful.

The order ledger O counts only overlaps among those displayed refined members. Hence the nerve face inventory sent to $\mathsf{SimplicialComplex}^{\uparrow}$ is finite: its vertices are cover rows, and its faces are exactly the inspected nonempty overlap rows bounded by O.

Finally L, H, T, P, N keep the compact-cover Lebesgue ledger, transport, replay, provenance, and local naming attached to the same finite route. The density and completion neighbours, $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$, may be cited only through their displayed finite rows, so the nerve export remains non-parametric and concrete. □

Theorem 1853.15 (CoveringDimension compact-cover nerve nonescape)**.** *No accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *nerve route can export ambient open-cover compactness, a selected subcover, or a host dimension predicate to* $\mathsf{SimplicialComplex}^{\uparrow}$*. Every compact-cover nerve read must remain inside the displayed* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, finite cover, refinement, overlap, multiplicity, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactCoverNerveNonescape`

Proof. Start with Definition 1853.13. It rules out replacing the carrier rows by arbitrary open-cover compactness, choice-selected refinements, host multiplicity oracles, or classical dimension theorems.

Now read the nerve route of Definition 1853.14. The $\mathsf{SimplicialComplex}^{\uparrow}$ consumer receives only the finite face inventory determined by displayed cover members, refinement rows, overlap rows, and the order-bound ledger.

The compactness source is still the compact metric finite route. $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, and $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ provide sampled cover data and positive-radius ledger rows, while $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ may contribute only their finite density or completion-facing rows when the read asks for them.

Since no carrier coordinate stores an ambient open cover, a selected subcover, or a host dimension predicate, none of those objects can be exported to the nerve. Any such export leaves the accepted $\mathsf{CoveringDimension}^{\uparrow}$ surface. □

Theorem 1853.16 (CoveringDimension scope-closure witness)**.** *Every scoped* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer that exports a dimension-bound claim must first read the displayed compact metric source row K, finite epsilon-net row E, finite cover row C, finite refinement map R, order-bound row O, and compact-cover Lebesgue ledger L. When the read uses dense or completion-facing support, the* $\mathsf{RealSeparability}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *rows must be displayed before O is exported. When the read exports a nerve, the* $\mathsf{SimplicialComplex}^{\uparrow}$ *face rows must be displayed after the compact cover, refinement, overlap, and multiplicity rows. In every case, the local H, T, P, N rows for* hsame*,* Cont*,* Pkg*, and* NameCert *must be read before the bound leaves the packet, so the scoped kernel dependencies are exactly the finite cover, compact metric, Real separability, metric completion, transport, replay, provenance, and naming rows displayed in this chapter.*

Proof. Start with Definition 1853.2. It identifies $K, E, C, R, O, L, H, T, P, N$ as the complete local obligation surface, so a scoped consumer cannot read a dimension-bound claim before those rows are available.

Next apply Definition 1853.12. It keeps the compact metric source, finite-net row, finite cover, refinement, order, optional $\mathsf{RealSeparability}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ rows, and local provenance visible before any finite-cover refinement read is exported.

The completion side is governed by Definition 1853.10. It allows completion-facing rows only after K, E, C, R, O, L have been displayed, so completion support cannot replace the finite cover-refinement route.

Finally apply Definition 1853.15. A nerve consumer receives only the displayed finite face inventory determined by compact cover, refinement, overlap, multiplicity, transport, replay, provenance, and local naming rows. Combining the cited routes gives the stated scoped-closure witness for every dimension-bound export. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionScopeClosureWitness`

Theorem 1853.17 (Covering dimension finite-density route)**.** *Every compact metric cover-refinement consumer that uses dense* $\mathsf{Real}^{\uparrow}$ *witnesses to read a* $\mathsf{CoveringDimension}^{\uparrow}$ *packet must consume* $\mathsf{RealSeparability}^{\uparrow}$ *only through finite rational and dyadic density rows before the order-bound ledger is exposed. For an accepted carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the route first displays the compact metric source K, finite epsilon-net row E, finite cover row C, refinement map R, RealSeparability density handoff, and only then the order-bound row O,

Lebesgue ledger L, transport H, replay T, provenance P, and local naming row N. It exports no arbitrary open-cover compactness, selected dense points, choice-selected refinements, or host dimension theorem.

Proof. Project the accepted $\mathsf{CoveringDimension}^{\uparrow}$ carrier. The rows $K, E, C, R, O, L, H, T, P, N$ are the only compact metric source, finite-net, cover, refinement, order-bound, Lebesgue-ledger, transport, replay, provenance, and local naming rows available to the dimension consumer.

If the cover-refinement read uses dense Real witnesses, the density source is not selected from an ambient dense set. It is read through chapter 1809, where rational enumeration, dyadic tolerance, finite StreamName windows, RegSeqRat readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal are displayed as finite rows.

Insert that RealSeparability route before O is exposed. The finite cover and refinement rows C, R may inspect dense rational and dyadic witnesses, but the overlap count in O is read only after those witnesses have passed through the separability packet rather than through a choice-selected point.

Finally L, H, T, P, N replay and name the same route. Since the covering-dimension carrier has no arbitrary open-cover coordinate, choice-selected refinement, or host dimension theorem, and the RealSeparability route has no selected dense point or ambient completeness coordinate, the composed finite-density route exports none of them. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteDensityRoute`

Theorem 1853.18 (CoveringDimension finite-order refinement bridge)**.** *Every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-order refinement bridge is read through finite cover rows, compact-net rows,* $\mathsf{RealSeparability}^{\uparrow}$ *budget rows, and the structural route*

$$\mathsf{BHist},\ \mathsf{Cont},\ \mathsf{hsame},\ \mathsf{NameCert}.$$

For a carrier $D = (K, E, C, R, O, L, H, T, P, N)$, the bridge first displays the compact metric row K, finite epsilon-net row E, finite cover row C, refinement map row R, and order-bound row O; if dense real witnesses are used, their $\mathsf{RealSeparability}^{\uparrow}$ *finite rational and dyadic budget rows must be displayed before O is exported as a dimension-bound ledger.*

Proof. Apply the compact-net admission theorem, Definition 1853.4. It places K, E before every finite cover and refinement read.

Use the refinement-order theorem, Definition 1853.11. The finite cover row C, refinement map R, and order ledger O are read as a single displayed multiplicity route.

Finally apply the finite-density route, Definition 1853.17. It inserts the $\mathsf{RealSeparability}^{\uparrow}$ rational and dyadic budget rows before the order-bound export, while H, T, P, N preserve the route through hsame, Cont, provenance, and $\mathsf{NameCert}$. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteOrderRefinementBridge`

Theorem 1853.19 (CoveringDimension compact-net simplicial nerve)**.** *Every* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve exported by an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet consumes compact-net rows and finite cover rows before it forms its finite face inventory. In carrier notation, K, E supply the compact-net source, C, R supply the finite cover and refinement rows, O supplies the order-budget ledger, and any* $\mathsf{RealSeparability}^{\uparrow}$ *density budget is read before the nerve face rows are named through* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

Proof. Start with the nerve order-bound theorem, Definition 1853.14. It sends only displayed cover members, refinement rows, overlap rows, and the order-bound ledger to the simplicial consumer.

Then use compact-cover nerve nonescape, Definition 1853.15. It keeps the nerve route inside CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactCoverLebesgueLedger$^{\uparrow}$, and the optional RealSeparability$^{\uparrow}$ finite rows rather than inside an ambient open-cover theorem.

The structural rows finish the handoff. Componentwise hsame transport, displayed Cont replay, provenance, and local NameCert naming preserve the compact-net and finite-cover rows as the only source of nerve faces. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetSimplicialNerve`

Theorem 1853.20 (CoveringDimension RealSeparability finite-cover budget)**.** *Whenever an accepted* CoveringDimension$^{\uparrow}$ *packet uses* RealSeparability$^{\uparrow}$ *to inspect a finite cover, the separability data is a finite budget row, not a selected dense sequence. The consumer must display rational enumeration rows, dyadic tolerance rows, compact-net rows K, E, finite cover rows C, R, the order-bound row O, and the structural* BHist*,* Cont*,* hsame*, and* NameCert *rows before the finite-cover budget can support a dimension-bound export.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityFiniteCoverBudget`

Proof. Read the finite-density route, Definition 1853.17. It already places RealSeparability$^{\uparrow}$ rational and dyadic rows before the order-bound ledger is exposed.

Attach the compact metric dependency theorem, Definition 1853.12. It keeps the compact metric source, finite-net row, finite cover, refinement, order-bound ledger, and local NameCert provenance visible throughout the read.

Finally use the ledger nonescape theorem, Definition 1853.13. Since neither CoveringDimension$^{\uparrow}$ nor RealSeparability$^{\uparrow}$ stores a selected dense point, arbitrary open-cover compactness, or a host dimension theorem, the finite-cover budget remains the displayed row family $K, E, C, R, O, L, H, T, P, N$ with the separability rows inserted before O. □

Falsifiable prediction: A consumer that claims a CoveringDimension$^{\uparrow}$ bound while omitting the finite cover row, refinement map row, order-bound witness row, compact Lebesgue ledger, hsame, Cont, Pkg, or NameCert rows refutes the carrier of Definition 1853.1.

Independence witness: compactmetric, finite-epsilon-net, compact-cover-lebesgue-ledger: CoveringDimension$^{\uparrow}$ binds a finite cover row, a refinement map, an order-bound ledger, compact finite-net provenance, and Lebesgue-ledger compatibility in one NameCert packet; each named sibling lacks at least one of these rows as a local dimension-obligation coordinate.

Closure status for NameCert$_{\text{CoveringDimension}^{\uparrow}}$.

Constructive story: A CoveringDimension$^{\uparrow}$ packet is generated from a CompactMetricUp source, a FiniteEpsilonNetUp center bundle, a finite BHist cover row, a finite refinement map, an order-bound witness ledger, a CompactCoverLebesgueLedgerUp row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CoveringDimension}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1853.1, Definition 1853.2, Definition 1853.11, Definition 1853.12, Definition 1853.9, Definition 1853.10, Definition 1853.16, and Definition 1853.20 bind finite cover, compact metric, Real separability, metric completion, hsame, Cont, Pkg, and NameCert dependencies before any dimension-bound export, with BEDC.Derived.CoveringdimensionUp.CoveringD as the bridge-facing witness.

Formal verification: FormalStatus(NameCert$_{\text{CoveringDimension}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CoveringdimensionUp.CoveringDimensionScopeClosureWitness`

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, choice-selected refinements, classical covering-dimension theorems, bridge checking, quotient real equality, or host multiplicity oracles.

Upgrade path: Mature closure requires a checked standard-bridge surface for the public finite cover-refinement exports.

The finite cover-refinement rows of $\mathsf{CoveringDimension}^{\uparrow}$ are consumed by chapter 3877 for scale-cover counting and by chapter 4119 for gauge-cover comparison. This forward route records the dimension-theory children as finite cover consumers rather than as detached scale ledgers. The finite cover-refinement rows of $\mathsf{CoveringDimension}^{\uparrow}$ enter compact-metric consumers only after the compact source row of chapter 129 and the finite face-inventory row of chapter 238 have been displayed. A downstream reader therefore consumes cover members, refinement witnesses, and order-bound ledgers through $\mathsf{CompactMetric}^{\uparrow}$ finite-net data and $\mathsf{SimplicialComplex}^{\uparrow}$ finite-face rows before it reaches the local $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ surface; it does not receive an arbitrary open-cover compactness principle, an ambient nerve construction, or a detached host dimension predicate.

Theorem 1853.21 (Covering dimension compact metric forward link)**.** *Every compact-cover or finite-net read exported by* $\mathsf{CoveringDimension}^{\uparrow}$ *first passes through the* $\mathsf{CompactMetric}^{\uparrow}$ *source row and the* $\mathsf{Met}^{\uparrow}$ *ball-observation row before a dimension-bound consumer may inspect the finite cover row, refinement map, order-bound ledger, compact Lebesgue ledger, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactMetricForwardLink`

Proof. Project the carrier of Definition 1853.1. The compact source row K is the only entry point for compact-cover and finite-net data, and its pointwise observations are read through the metric ball surface before a cover member can be tested.

Only after this compact-metric and metric route is visible may the finite cover row C, refinement row R, order-bound row O, and compact Lebesgue ledger L be consumed as a dimension-bound surface. The structural rows H, T, P, N then transport, replay, source, and name the same route without adding an arbitrary open-cover compactness principle. □

The $\mathsf{CoveringDimension}^{\uparrow}$ lattice reads finite cover order only after the compact metric source of chapter 129, the finite epsilon-net schedule of chapter 1767, the compact-cover Lebesgue ledger of chapter 1302, the completion-facing rows of chapter 1506, the rational dense windows of chapter 1809, and the finite face rows of chapter 238 have been displayed. Thus a dimension-bound consumer receives cover multiplicity through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, and $\mathsf{SimplicialComplex}^{\uparrow}$ rows, not through an ambient open-cover compactness predicate.

Theorem 1853.22 (Covering dimension metric dependency)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *cover-refinement read enters through the compact metric source row and the metric ball observation surface before it records the refinement and order ledgers. Concretely, for an accepted carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the row K is read as a $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source, its pointwise cover tests are inspected through* $\mathsf{Met}^{\uparrow}$ *ball observations, and only then may the consumer read the finite cover row C, refinement row R, order-bound row O, compact Lebesgue ledger L, transport row H, replay row T, provenance row P, and local naming row N.*

Proof. Project the carrier of Definition 1853.1. The first row K is the compact metric source, and the carrier description already binds it to finite-net and Lebesgue-ledger rows rather than to an arbitrary open-cover principle.

The cover row C is inspected pointwise. Each such inspection uses metric ball observations from the metric source before a refined member can be assigned to a parent cover member by R.

The compact-source read is specifically the $\mathsf{CompactMetric}^{\uparrow}$ finite-net route of chapter 129: its center bundle is the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ surface of chapter 1767, and only after those centers and radii are visible does the packet export the refinement and order-bound rows used as the dimension bound.

After those metric reads, the order-bound row O counts only displayed refined members, while L records the compact finite-radius ledger for the same cover route. The structural rows H, T, P, N transport and name that route without adding a second dependency surface.

Thus every cover-refinement read reaches the dimension ledger through $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ first. A consumer that skips those rows is not reading the displayed $\mathsf{CoveringDimension}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionMetricDependency`

Theorem 1853.23 (CoveringDimension Cauchy-filter completion route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier must read the finite cover-refinement rows of Definition 1853.1 through the compact metric source of chapter 129, the finite sampling row of chapter 1767, the compact cover Lebesgue ledger of chapter 1302, the rational-window surface of chapter 1809, and then the Cauchy-filter completion boundary of chapter 1569 before any completion-facing readback is exported.*

Proof. Project the carrier $D = (K, E, C, R, O, L, H, T, P, N)$ of Definition 1853.1. The cover row C, refinement row R, order-bound row O, and Lebesgue ledger L are available only after the compact metric source K and finite epsilon-net row E have been displayed.

Use the metric-completion dependency route already carried by the $\mathsf{CoveringDimension}^{\uparrow}$ sibling lattice. It sends completion-facing reads through compact metric finite covers, $\mathsf{RealSeparability}^{\uparrow}$ rational windows, finite Lebesgue ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row.

Finally route the completion boundary through chapter 1569. The Cauchy-filter completion packet exposes the source filter, finite windows, tolerance, regular readback, and Real seal rows before completion consumers inspect the handoff, so the dimension route cannot bypass the displayed finite-cover sampling surface. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCauchyFilterCompletionRoute`

Theorem 1853.24 (CoveringDimension finite refinement window)**.** *Under the completion handoff of Definition 1853.23, the finite refinement and order-bound window of an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet remains the displayed* BHist *route*

$$K, E, C \longmapsto R, O, L \longmapsto H, T, P, N.$$

The handoff exports no arbitrary open-cover theorem, no choice-selected refinement, no hidden completion point, and no detached multiplicity oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteRefinementWindow`

Proof. Start from Definition 1853.11. It factors every dimension consumer through the compact metric row K, finite epsilon-net row E, finite cover row C, refinement row R, order-bound witness O, and compact Lebesgue ledger L before the structural rows are read.

Apply Definition 1853.23. Completion-facing consumers inherit the same finite route through $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{CauchyFilterCompletion}^{\uparrow}$, but those sibling rows add only rational windows, Cauchy-filter windows, regular readback, and completion-facing seal data.

Now use Definition 1853.13. Since the local carrier has no coordinate for arbitrary open covers, selected refinements, hidden completion points, or external multiplicity oracles, transporting the route through completion boundaries preserves the displayed BHist refinement window. □

The finite cover-refinement rows of $\mathsf{CoveringDimension}^{\uparrow}$ can be consumed by $\mathsf{RealSeparability}^{\uparrow}$ only after the compact metric source of chapter 129, the finite epsilon-net schedule of chapter 1767, and the compact-cover Lebesgue ledger of chapter 1302 have been displayed. Thus the separability-facing route of chapter 1809 receives finite cover data through compact metric, finite-net, and Lebesgue-ledger rows rather than through an arbitrary open-cover compactness claim.

Lemma 1853.25 (Covering dimension separability cover-refinement route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer of a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover-refinement row factors through the compact metric row K, finite epsilon-net row E, cover row C, refinement row R, order-bound row O, compact-cover Lebesgue ledger L, and structural rows H, T, P, N of Definition 1853.1. No such consumer receives a detached host open cover, choice-selected refinement, or external multiplicity oracle.*

Proof. Project the carrier of Definition 1853.1. The cover and refinement rows are visible only after the compact metric source K and finite epsilon-net row E have supplied the finite sampling surface.

The Lebesgue ledger L then binds the cover and refinement rows to displayed positive-radius data from chapter 1302. Hence a $\mathsf{RealSeparability}^{\uparrow}$ consumer can read the refinement only through compact metric, finite-net, and Lebesgue-ledger dependencies.

Finally the structural rows H, T, P, N preserve the same route under hsame transport, Cont replay, package provenance, and local naming. Since the carrier has no detached host open cover, choice-selected refinement, or external multiplicity oracle, none can be exported to the separability-facing consumer. □

Lean4 ✓ `BEDC.Derived.CoveringDimensionUp.CoveringDimensionSeparabilityCoverRefinementRoute`

Theorem 1853.26 (Covering dimension real-separability refinement bound)**.** *When* $\mathsf{CoveringDimension}^{\uparrow}$ *uses* $\mathsf{RealSeparability}^{\uparrow}$ *to sample finite cover members, the resulting dimension-bound read must expose the compact metric source K, finite epsilon-net schedule E, finite cover row C, refinement row R, finite* $\mathsf{RealSeparability}^{\uparrow}$ *density witnesses, order-bound row O, and compact-cover Lebesgue ledger L before any order bound is consumed. Thus the separability-facing refinement route uses chapter 1809 only through finite density rows and the compact-cover ledger of chapter 1302, not through arbitrary open-cover or selected dense-point data.*

Lean4 ✓ `BEDC.Derived.CoveringDimensionUp.CoveringDimensionRealSeparabilityRefinementBound`

Proof. Apply Definition 1853.25. It already forces every separability-facing refinement consumer through the compact metric row K, finite epsilon-net row E, cover row C, refinement row R, order-bound row O, and Lebesgue ledger L.

Insert the $\mathsf{RealSeparability}^{\uparrow}$ read only at the finite-density position. The consumer may sample cover members through the finite density witnesses supplied by chapter 1809, but those witnesses are read after K, E, C, R have displayed the finite cover-refinement surface.

The order-bound row O and Lebesgue ledger L are then consumed after the finite density witnesses are visible. Since the route has no coordinate for arbitrary open-cover compactness, selected dense points, or an external refinement oracle, the resulting dimension-bound read is exactly the displayed finite-density handoff. □

Every RealSeparability$^{\uparrow}$ density-window use of CoveringDimension$^{\uparrow}$ must consume the finite cover-refinement rows of Definition 1853.1 through displayed metric and naming data rather than through an ambient open-cover principle.

Theorem 1853.27 (Covering dimension real-separability cover obligation)**.** *Every* CoveringDimension$^{\uparrow}$ *cover-refinement row consumed by a* RealSeparability$^{\uparrow}$ *density-window argument must expose finite cover rows, dyadic or rational density windows, metric carrier rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and* NameCert *rows on the same finite BEDC surface. The consumer receives no detached host cover, choice-selected refinement, external density oracle, quotient point equality, or ambient separability theorem.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityCoverObligation`

Proof. Project the covering-dimension carrier of Definition 1853.1. Its cover and refinement rows are finite rows attached to the compact metric source, finite epsilon-net schedule, order-bound row, Lebesgue ledger, transport, replay, provenance, and local naming.

Use the separability cover-refinement route, Definition 1853.25. It already forces any RealSeparability$^{\uparrow}$ consumer to pass through the compact metric row, finite epsilon-net row, cover row, refinement row, order-bound row, compact-cover Lebesgue ledger, and structural rows before the separability-facing read is available.

The density-window requirement is therefore the same finite obligation surface read from the separability side. Dyadic or rational windows may be consumed only as displayed finite rows over the metric carrier and structural rows, while detached host covers, choice-selected refinements, external density oracles, quotient point equality, and ambient separability are not carrier coordinates. □

Theorem 1853.28 (Covering dimension real-separability cover scope)**.** *Every* RealSeparability$^{\uparrow}$ *density-window consumer of* CoveringDimension$^{\uparrow}$ *must cite* CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactCoverLebesg DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows before reading a cover-refinement row. The consumer receives the finite L10 cover route through the displayed carrier, not through open-cover compactness, quotient equality, or external separability.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityCoverObligationScope`

Proof. Project the CoveringDimension$^{\uparrow}$ carrier of Definition 1853.1. Its finite cover-refinement rows expose compact metric source data, finite epsilon-net witnesses, compact-cover Lebesgue ledger data, order rows, transport, replay, provenance, and local naming before a separability-facing consumer can read a refinement.

Apply the cover-obligation theorem Definition 1853.27. It already requires finite cover rows, dyadic or rational density windows, metric carrier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and NameCert rows on the same BEDC surface.

The scope condition is therefore just the explicit consumer boundary for that route. A RealSeparability$^{\uparrow}$ density-window read must display CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactCoverLebesgueLedge DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert before it reads the cover-refinement row. Since none of those rows is open-cover compactness, quotient equality, or an external separability theorem, those excluded objects remain outside the accepted packet. □

Theorem 1853.29 (Covering dimension real-separability cover nonescape)**.** *Every* RealSeparability$^{\uparrow}$ *density-window consumer of a* CoveringDimension$^{\uparrow}$ *cover-refinement row that drops one of the* CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactCoverLebesgueLedger$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *or* NameCert *rows leaves the accepted cover-refinement surface. Such a consumer cannot replace the finite route with open-cover compactness, quotient equality, external separability, or a choice-selected refinement.*

Proof. Project the covering-dimension carrier of Definition 1853.1. Its accepted cover-refinement surface displays the compact metric source, finite epsilon-net schedule, compact-cover Lebesgue ledger, dyadic or rational density windows, regular readback, Real-facing seal, history row, transport, replay, provenance, and local naming before a separability-facing read is available.

Apply the cover-obligation theorem Definition 1853.27 and the scope theorem Definition 1853.28. Together they force the RealSeparability$^{\uparrow}$ density-window consumer to cite the same finite rows before reading a CoveringDimension$^{\uparrow}$ cover-refinement row.

If any listed row is dropped, the consumer no longer has the displayed carrier coordinates required by those two theorems. Open-cover compactness, quotient equality, external separability, and choice-selected refinements are not carrier coordinates, so none of them can repair the missing finite row. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityCoverNonescape`

Theorem 1853.30 (Covering dimension real-separability sampling)**.** *Every finite-cover dimension consumer may use* RealSeparability$^{\uparrow}$ *only through displayed rational dense windows before compact metric cover checks reduce to finite sampled rows. The* CoveringDimension$^{\uparrow}$ *carrier exports only the finite cover row, refinement map, order-bound witness, compact Lebesgue ledger,* hsame, Cont, Pkg, *and* NameCert *rows of Definition 1853.1.*

Proof. Read the dense-window evidence from chapter 1809. It supplies sampled rational names for inspected balls and mesh witnesses before any compact metric cover check is evaluated.

This is the downstream consumer edge for the RealSeparability$^{\uparrow}$ packet: chapter 1809 supplies rational dense windows that chapter 1853 consumes before finite-cover order checks.

Now project the CoveringDimension$^{\uparrow}$ carrier of Definition 1853.1. The only exported rows are the finite cover row, refinement map, order-bound witness, compact Lebesgue ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Thus the dependency is a finite-data sampling interface. It does not add arbitrary open-cover compactness, a selected infinite refinement, or any host dimension theorem. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilitySampling`

Theorem 1853.31 (Covering dimension real-separability route scope)**.** *Every accepted* CoveringDimension$^{\uparrow}$ *packet that uses the* RealSeparability$^{\uparrow}$ *density route must read finite dense-window data through*

$$\mathsf{RealSeparability}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{FiniteEpsilonNet}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow}$$

before it exposes any covering-dimension classifier row. The exposed classifier is therefore bounded by displayed dense samples, metric balls, compact-metric finite-net rows, and regular rational readback; it does not supply open-cover compactness, choice-selected covers, selected limits, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Project the CoveringDimension$^{\uparrow}$ carrier of Definition 1853.1. A density-dependent read first reaches the RealSeparability$^{\uparrow}$ row, then the metric and compact-metric rows that turn sampled balls into finite cover windows.

Next read the FiniteEpsilonNet$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ rows. They provide the finite net and regular rational window data consumed by the dimension route before the classifier row is visible.

The carrier has no hidden coordinate for arbitrary open covers or a choice-selected refinement. Since the Real-facing dependency is already exhausted by the displayed finite rows, the route cannot import ambient Real$^{\uparrow}$ completeness or a host compactness theorem. □

Lean4 ✓ `BEDC.Derived.CoveringDimensionUp.CoveringDimensionRealSeparabilityRouteScope`

Theorem 1853.32 (Covering dimension Real separability forward bound)**.** *For every accepted* CoveringDimension$^{\uparrow}$ *carrier, a* Real$^{\uparrow}$ *separability read supplies a finite cover-bound ledger when it is combined with the metric-completion dependency route. Concretely, the rational dense windows of chapter 1809 and the completion-facing rows of chapter 1506 determine a finite ledger of sampled balls, refinement witnesses, and order-bound rows for the* CoveringDimension$^{\uparrow}$ *NameCert surface. The conclusion is only this finite NameCert ledger; it is not a classical open-cover compactness theorem or a selected infinite refinement.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityForwardBound`

Proof. Project the CoveringDimension$^{\uparrow}$ carrier of Definition 1853.1. Its public data are finite cover rows, refinement maps, order-bound witnesses, compact Lebesgue ledger rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Read the Real$^{\uparrow}$ separability route through chapter 1809. The rational dense windows supply the sampled centers and mesh witnesses that can be attached to the finite cover rows.

Next use the metric-completion dependency route through chapter 1506. Completion-facing data may refine the sampled balls, but it must do so through displayed completion rows and the same structural transport and replay rows.

Combining the two routes yields a finite cover-bound ledger: sampled balls from separability, completion-compatible refinement rows, and order-bound witnesses inside the covering-dimension packet. Since every row is displayed and finite, the theorem exports no open-cover compactness principle and no selected infinite refinement. □

Theorem 1853.33 (Real separability covering-dimension forward route)**.** *A* RealSeparability$^{\uparrow}$ *rational-window read can enter* CoveringDimension$^{\uparrow}$ *only through the finite cover row, refinement map, order-bound witness, compact Lebesgue ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows of Definition 1853.1. It does not supply selected dense points, arbitrary open covers, or choice-selected refinements.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.RealSeparabilityCoveringDimensionForwardRoute`
↪ variant `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityForwardRoute`

Proof. Use Definition 1853.32. The existing forward bound identifies the rational dense windows as sampled finite cover data after they are combined with the metric-completion dependency route.

Project the carrier of Definition 1853.1. Its only covering-dimension entry rows for that separability read are the finite cover row, refinement map, order-bound witness, compact Lebesgue ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

The projected route has no coordinate for selected dense points, arbitrary open covers, or choice-selected refinements. Hence every RealSeparability$^{\uparrow}$ read enters CoveringDimension$^{\uparrow}$ through the displayed finite-cover surface alone. □

The $\mathsf{RealSeparability}^{\uparrow}$ route of chapter 1809 supplies finite rational dense windows that the $\mathsf{CoveringDimension}^{\uparrow}$ carrier of chapter 1853 may consume when sampling finite covers. Thus the dimension packet reads separability only as displayed rational-window data before order-bound and finite-cover checks are evaluated. The $\mathsf{CoveringDimension}^{\uparrow}$ carrier consumes $\mathsf{RealSeparability}^{\uparrow}$ through chapter 1809 when countable dense windows are refined into finite cover samples, and it consumes $\mathsf{MetricCompletion}^{\uparrow}$ through chapter 1506 when those finite refinements are transported across completion-stable metric rows. Thus the dimension packet records a real separability and metric completion dependency route without turning dense covers into selected points or completion stability into ambient compactness.

Theorem 1853.34 (Covering dimension real-separability forward link)**.** *Every finite refinement row used by the* $\mathsf{CoveringDimension}^{\uparrow}$ *packet may be read as a consumer of the dense* $\mathsf{RealSeparability}^{\uparrow}$ *route of chapter 1809 when the covering-dimension argument is applied to* $\mathsf{Real}^{\uparrow}$*-derived metric carriers. The dependency is the finite dense-window refinement surface: a displayed dense real window supplies sample points, a finite cover row supplies the cover cells inspected at those samples, and the refinement row records only the finite multiplicity bound visible at that window.*

The link does not assert ambient separability, countable choice of dense points, a host open-cover compactness principle, selected real representatives, or a detached dimension oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityForwardLink`

Proof. Project the $\mathsf{CoveringDimension}^{\uparrow}$ carrier through Definition 1853.1. The refinement row is visible only together with the compact metric source, finite epsilon-net row, cover row, order-bound row, Lebesgue ledger, transport, replay, provenance, and local naming rows.

Use the RealSeparability route of chapter 1809. For a $\mathsf{Real}^{\uparrow}$-derived metric carrier, the dense-window row supplies the finite real samples that the covering-dimension refinement consumes; the refinement is therefore read from displayed dense windows rather than from an ambient separability theorem.

Finally apply the existing separability cover-refinement route, Definition 1853.25. It identifies the finite compact-metric, epsilon-net, cover, refinement, order-bound, Lebesgue-ledger, and structural rows through which the consumer reads the dependency, and it excludes detached host covers, choice-selected refinements, and external multiplicity oracles. □

The $\mathsf{CoveringDimension}^{\uparrow}$ packet reaches $\mathsf{RealSeparability}^{\uparrow}$ only through the metric inspection route of chapter 57. A finite cover-refinement read first exposes metric-ball rows, then uses the rational dense windows of chapter 1809 to sample those displayed balls before the order-bound ledger is read.

Proposition 1853.35 (CoveringDimension metric separability dependency route)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer that uses* $\mathsf{RealSeparability}^{\uparrow}$ *data factors through the metric-ball surface of chapter 57. The exported route is only the finite chain*

$$\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{RealSeparability}^{\uparrow} \longrightarrow \mathsf{CoveringDimension}^{\uparrow}$$

read through the carrier of Definition 1853.1; it does not select dense points, arbitrary open covers, or external refinements.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionMetricRealSeparabilityRoute`

Proof. Project the carrier of Definition 1853.1. The finite cover row and refinement row can be inspected only through displayed metric balls and the compact metric source already named by the packet.

Read the $\mathsf{RealSeparability}^{\uparrow}$ sibling through rational dense windows. Those windows contribute finite sample rows for the displayed metric balls, not selected points outside the certificate surface.

Conversely, any dense-window use of $\mathsf{RealSeparability}^{\uparrow}$ in this chapter must be tied back to a displayed metric-ball refinement. The covering-dimension consumer may cite the separability row only after the relevant ball, radius, and refinement rows have been exposed through $\mathsf{Met}^{\uparrow}$.

The order-bound ledger is then read from the same finite refinement packet. Since the route has no coordinate for arbitrary open covers or external refinements, the dependency remains the displayed metric-to-separability route. □

Theorem 1853.36 (CoveringDimension metric-real dependency)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-refinement read that uses* $\mathsf{RealSeparability}^{\uparrow}$ *must expose, in order, the* $\mathsf{Met}^{\uparrow}$ *ball rows, the* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window rows, and the local order-bound ledger of the covering-dimension packet. The route premise is the metric separability dependency of Definition 1853.35; no consumer may read the dense-window row before the metric-ball surface or the order-bound ledger before both preceding rows are displayed.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionMetricRealDependency`

Proof. Project the carrier of Definition 1853.1. The finite cover, refinement, and order-bound rows are local to the same packet, while Definition 1853.35 supplies the only route from the covering-dimension read to $\mathsf{RealSeparability}^{\uparrow}$.

Use that route premise to expose the $\mathsf{Met}^{\uparrow}$ ball rows first. The dense-window rows of $\mathsf{RealSeparability}^{\uparrow}$ sample only those displayed metric balls, so they cannot be read before the ball centers, radii, and finite refinement rows have been named.

The order-bound ledger is then a downstream read of the covering-dimension packet. Since neither the carrier nor the route premise contains a coordinate for selected dense points, arbitrary open covers, or external refinements, the dependency order remains metric balls, dense windows, and the local order-bound ledger. □

Theorem 1853.37 (Covering dimension Real and Metric forward route)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer that enters the Real and Metric dependency lattice reads* $\mathsf{RealSeparability}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *only through the finite cover, finite-net, dyadic-density, compact-metric, and Lebesgue-ledger rows already displayed by the accepted carrier. The route exposes compact metric source rows, metric ball inspection, finite epsilon-net centers, dyadic density witnesses, cover-refinement rows, and the order-bound ledger before any dimension bound is consumed.*

It exports no ambient metric completion, selected dense sequence, host open-cover compactness theorem, quotient real equality, or external multiplicity oracle.

Proof. Project the accepted carrier $D = (K, E, C, R, O, L, H, T, P, N)$ from Definition 1853.1. The compact metric source K, finite epsilon-net row E, cover row C, refinement row R, order-bound row O, and Lebesgue ledger L are the only analytic rows visible to the packet.

The Real-facing information is read through the existing $\mathsf{RealSeparability}^{\uparrow}$ routes in this chapter. Those routes supply rational and dyadic density witnesses as finite rows before the cover and refinement rows are inspected; they do not select an ambient dense sequence.

The Metric-facing information is read through the compact metric and metric ball rows used by K and E. Thus pointwise cover inspection is finite and row-local, and the order-bound ledger cannot be replaced by a host compactness or multiplicity theorem.

Finally H, T, P, N transport, replay, package, and name the same finite route. Since no extra completion, selected dense sequence, host open-cover theorem, quotient real equality, or external oracle occurs in the carrier, the Real and Metric forward route is exactly the displayed finite dependency surface. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealMetricForwardRoute`

Theorem 1853.38 (CoveringDimension RealSeparability MetricCompletion cover route)**.** *Every finite-cover dimension read over Real-facing metric data must expose* RealSeparability$^{\uparrow}$ *finite dense windows and* MetricCompletion$^{\uparrow}$ *completion boundary rows before a* CoveringDimension$^{\uparrow}$ *consumer may inspect cover order. The route presents compact metric source rows, finite cover and refinement rows, separability witnesses, completion-stable metric rows, the order-bound ledger, transport, replay, provenance, and local naming, but it exports no arbitrary open-cover compactness, selected dense points, choice-selected refinements, quotient point equality, or ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityMetricCompletionCoverRoute`

Proof. Begin with the carrier of Definition 1853.1. Its cover-order read is available only through the compact metric source, finite epsilon-net schedule, finite cover row, refinement row, order-bound witness, compact-cover Lebesgue ledger, transport, replay, provenance, and local naming.

Apply the RealSeparability routes Definition 1853.25 and Definition 1853.32. They place finite rational and dyadic dense windows before any cover-refinement or order-bound row is consumed.

Use the metric-completion route Definition 1853.23. It sends completion-facing cover reads through the displayed completion boundary rather than through an ambient completion theorem.

Together the cited routes force finite dense windows and completion boundary rows to appear before cover order is inspected. Since none of the rows contains arbitrary open covers, selected dense points, choice-selected refinements, quotient equality, or ambient completion data, the composed route exports only the finite cover dependency. □

Theorem 1853.39 (CoveringDimension finite epsilon-net carrier)**.** *For an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the finite epsilon-net row E is a root cover obligation: every cover sample exported by C, every refinement membership read by R, and every order-bound count recorded by O must be read through the displayed ProbeBundle *centers, dyadic tolerance witnesses, and* BHist *coverage rows of E as described in Definition 1853.1. The local NameCert surface of Definition 1853.2 therefore admits finite cover inspection only through $K, E, C, R, O, L, H, T, P, N$; it admits no arbitrary open-cover compactness, selected dense subfamily, or host finite-subcover theorem.*

Proof. Project the carrier rows of Definition 1853.1. The source row K supplies the compact metric packet, and E supplies the finite ProbeBundle of centers and tolerance-indexed coverage witnesses.

The cover row C can be inspected only by reading those displayed finite witnesses. The refinement row R and order-bound row O then operate over the same BHist cover entries, so their counts and memberships remain finite BEDC rows rather than external compactness data.

The rows L, H, T, P, N replay, transport, package, and name the same route. By Definition 1853.2, the NameCert obligation surface has no coordinate for an arbitrary cover or a selected finite subcover, so the finite epsilon-net carrier obligation is root-local. □

Theorem 1853.40 (CoveringDimension compact-cover forward dependency)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the cover-refinement rows C, R, O *consume the finite-cover lower-bound ledgers of chapter 1302 before any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{RealSeparability}^{\uparrow}$ *consumer may read a dimension bound. Concretely, the Lebesgue-ledger row* L *must display the same compact finite-net centers, positive radius lower bounds, and finite fold route used by the cover row* C *and refinement row* R*; only then can* O *record an order bound and expose it through* H, T, P, N*. Thus the dimension-bound surface is downstream of a substantive* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *finite-cover dependency, not an isolated root cover assertion.*

Proof. Start with the finite epsilon-net carrier of Definition 1853.39. It exposes the compact metric source row K, probe centers, tolerance witnesses, and finite cover row C before any order-bound count is visible.

The compact-cover lower-bound ledger then enters through row L. By chapter 1302, this ledger is a finite route through compact finite-net data, positive rational lower bounds, and finite lower-bound folding; it cannot supply an arbitrary open-cover compactness theorem.

Finally use Definition 1853.41 and Definition 1853.43. The order row O is read after C, R, L, and the MetricCompletion and RealSeparability consumers see that same displayed route before receiving a dimension-bound handoff. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactCoverForwardDependency`

Theorem 1853.41 (CoveringDimension order refinement obligation)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the order row O *is valid only after the refinement row* R *has displayed, for each refined* BHist *cover member, its parent member in the finite cover row* C *and its containment witness. Thus the order-refinement obligation exposed by Definition 1853.1 and Definition 1853.2 is a finite computation over* $K, E, C, R, O, L, H, T, P, N$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row.*

Proof. Open the accepted carrier. The finite cover row C is the only list of cover members, and the refinement row R is the only map from refined members back into that list.

Before O may count overlaps, each refined member must therefore pass through the parent and containment data carried by R. The count is made over finite BHist rows visible through C and R, not over a choice-selected refinement or an ambient multiplicity oracle.

Finally H, T, P, N preserve the same finite route under transport, replay, provenance, and naming. The NameCert obligations in Definition 1853.2 require exactly these rows, so the order refinement claim is a root obligation of the displayed carrier. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionOrderRefinementObligation`

Theorem 1853.42 (CoveringDimension compact metric handoff obligation)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any compact metric consumer that receives a dimension-bound handoff must first read the compact metric source row K*, the finite epsilon-net row* E*, the finite cover row* C*, the refinement row* R*, the*

order-bound row O, and the Lebesgue-ledger row L, and then pass through H, T, P, N. Consequently the handoff certified by Definition 1853.1 and Definition 1853.2 remains a finite BEDC route over BHist, ProbeBundle, hsame, Cont, Pkg, *and* NameCert, *not a claim of open-cover compactness or choice-selected refinement.*

Proof. Read the compact metric handoff in row order. The source row K anchors the carrier, while E displays the finite probes used to sample the cover row C.

The refinement and order data are then exposed by R and O. The Lebesgue-ledger row L ties the same finite cover route to positive radius readback, so the consumer sees a compact metric handoff only after the finite cover-refinement surface has been displayed.

The rows H, T, P, N preserve this route as componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Since the carrier and NameCert obligation theorem list no arbitrary open-cover coordinate or choice-selected refinement coordinate, the handoff obligation is exactly the finite BEDC route $K, E, C, R, O, L, H, T, P, N$. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactMetricHandoffObligation`

Theorem 1853.43 (CoveringDimension RealSeparability root completion route)**.** *For an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any root cover read that samples finite covers through dense real windows must display the RealSeparability$^{\uparrow}$ *rational and dyadic windows of chapter 1809 and the completion-facing rows of* MetricCompletion$^{\uparrow}$ *in chapter 1506 after the finite epsilon-net row E and cover-refinement rows C, R, and before the order-bound row O is consumed. Thus the root cover route is the finite chain*

$$K, E, C, R, \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, O, L, H, T, P, N,$$

not a selected dense sequence, arbitrary open-cover compactness principle, or ambient completion theorem.

Proof. Begin with the compact metric handoff of Definition 1853.42. The rows K, E, C, R display the compact metric source, finite epsilon-net probes, finite cover entries, and refinement memberships before any order count is public.

When dense real samples are used, the sample row must enter through chapter 1809. Those rational and dyadic windows are finite rows, so they can refine the displayed cover samples but cannot supply a selected dense subfamily outside E, C, R.

The completion-facing read is then routed through chapter 1506. Its completion boundary rows are attached after the separability windows and before O, so the order-bound ledger counts only the finite cover-refinement data already exposed through the root cover packet.

Finally L, H, T, P, N replay the same route as the Lebesgue ledger, componentwise hsame transport, displayed Cont replay, package provenance, and local naming rows. Hence the RealSeparability and MetricCompletion dependency is a substantive root-cover obligation of the finite carrier, not a bare citation or an ambient compactness argument. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityRootRoute`

Theorem 1853.44 (CoveringDimension finite-cover root boundary)**.** *For an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

every downstream dimension-bound read must display the compact source row K, finite epsilon-net row E, finite cover row C, refinement row R, order-bound row O, and Lebesgue-ledger row L before any cover consumer can read the order bound. Thus the root boundary for the order row is the finite chain

$$K, E, C, R, O, L,$$

together with the structural rows H, T, P, N, and not an arbitrary open-cover compactness theorem, selected refinement, or ambient separability argument.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootBoundary`

Proof. Start with the carrier of Definition 1853.1. Its dimension-bound surface is a finite row family $K, E, C, R, O, L, H, T, P, N$, so an order-bound read has no source outside those coordinates.

Use Definition 1853.2 and Definition 1853.39. The NameCert obligations require carrier admission through the displayed rows, while the finite epsilon-net carrier theorem makes E the root cover witness for C, R, O.

Finally apply Definition 1853.43. Dense real windows and MetricCompletion rows enter only after E, C, R and before O is consumed, so the consumer sees the same finite root boundary K, E, C, R, O, L rather than a hidden compactness or selection principle. □

Theorem 1853.45 (CoveringDimension refinement order root unblock)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier $D = (K, E, C, R, O, L, H, T, P, N)$, refinement containment through R is the only admissible source for the order row O. A downstream finite-cover consumer may read O only after R has displayed, for each refined* BHist *cover member, its parent member in C and its containment witness over the finite epsilon-net support E.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRefinementOrderRootUnblock`

Proof. Project the refinement and order rows from Definition 1853.1. The row R is the only coordinate that relates refined cover members to parent cover members in C, and O is the only coordinate that records the resulting order bound.

Apply Definition 1853.2. The local NameCert surface assigns order validity to the displayed refinement route, so no external multiplicity oracle or selected refinement can provide the order row.

Use Definition 1853.39 and Definition 1853.43. The finite epsilon-net row E supplies the root cover support, and any dense real or completion-facing sample is routed through that same support before O is visible. Therefore refinement containment through R is the root source that unblocks the order-bound consumer. □

Theorem 1853.46 (CoveringDimension root cover scope route)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any accepted root cover read must first display the finite epsilon-net row E, the finite cover row C, the refinement row R, the $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *radius ledger in L, the* $\mathsf{RealSeparability}^{\uparrow}$ *dyadic and rational windows, and the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-facing boundary before the order row O is consumed. Thus the public root route is the scoped finite chain*

$$K, E, C, R, L, \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, O, H, T, P, N,$$

not an arbitrary open-cover compactness theorem, selected dense subfamily, quotient completion witness, or ambient dimension oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverScopeRoute`

Proof. Begin with Definition 1853.39. It makes E the root finite witness for all cover samples exported by C, refinement memberships in R, and order-bound counts later recorded by O.

Next apply Definition 1853.40. The Lebesgue-ledger row L must display the compact finite-net centers, positive radius lower bounds, and finite fold route before a dimension-bound consumer may inspect the order surface.

Use Definition 1853.43. Dense real sampling is then routed through the $\mathsf{RealSeparability}^{\uparrow}$ rational and dyadic windows, and the completion-facing boundary is routed through $\mathsf{MetricCompletion}^{\uparrow}$ before O becomes visible.

Finally apply Definition 1853.45. It identifies refinement containment through R as the root source that unblocks O, so the complete accepted read is exactly the displayed finite chain through $K, E, C, R, L, \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, O, H, T, P, N$. □

Theorem 1853.47 (CoveringDimension root cover order-ledger exhaustion)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

every order-bound ledger read in O is exhausted by the finite chain

$$K, E, C, R, L, \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, O, H, T, P, N.$$

No later consumer may replace that chain by arbitrary open-cover compactness, a selected dense subfamily, a quotient completion witness, or an ambient dimension oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverOrderLedgerExhaustion`

Proof. First read E through Definition 1853.39. This fixes the root cover support before any order-bound count can be inspected.

Next apply Definition 1853.40. The compact-cover row is routed through the Lebesgue ledger L, so the order read cannot import an unlisted open-cover compactness principle.

Use Definition 1853.43. The RealSeparability and MetricCompletion windows are downstream of the same finite root data rather than selected dense subfamilies or quotient completion witnesses.

Finally apply Definition 1853.46. It identifies the complete scoped route through $K, E, C, R, L, \mathsf{RealSeparability}^{\uparrow}$, and the carrier has no coordinate for an ambient dimension oracle. Therefore every accepted order-bound ledger read is exhausted by the displayed chain. □

Theorem 1853.48 (CoveringDimension root cover primitive route)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the accepted root cover route is scoped only by the finite epsilon-net row E, finite cover row C, refinement row R, Lebesgue-ledger row L, $\mathsf{RealSeparability}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *finite windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row. In particular, the route may read* ProbeBundle *centers and tolerance witnesses through E, but it may not replace those primitive rows by arbitrary open-cover compactness, selected dense subfamilies, quotient completion witnesses, or an ambient dimension oracle.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverScopePrimitiveRoute`

Proof. Begin with Definition 1853.39. It binds every cover sample to the finite ProbeBundle centers, dyadic tolerance witnesses, and BHist coverage rows displayed by E.

Next apply Definition 1853.40. The finite cover row C, refinement row R, and Lebesgue-ledger row L are read as one compact-cover route before any dimension-bound consumer sees the order row.

Use Definition 1853.43. The RealSeparability$^{\uparrow}$ rational and dyadic windows and the MetricCompletion$^{\uparrow}$ completion-facing boundary attach to that finite prefix rather than replacing it by selected dense data or quotient completion data.

Finally apply Definition 1853.45. It keeps the order read tied to the displayed refinement row, while H, T, P, N preserve the same surface as componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Thus the accepted primitive route is exactly the listed finite row family. □

Theorem 1853.49 (CoveringDimension root-cover scope audit)**.** *For an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any order-bound read exported to a downstream cover consumer must expose, in order, the finite epsilon-net row E, finite cover row C, refinement row R, Lebesgue-ledger row L, the RealSeparability$^{\uparrow}$ *dyadic and rational windows, the* MetricCompletion$^{\uparrow}$ *completion-facing boundary, the order row O, componentwise transport H, displayed replay T, provenance P, and local naming N. No selected dense subfamily, quotient completion witness, or ambient dimension oracle is available to that consumer.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverScopeAudit`

Proof. First read the finite support. The finite epsilon-net carrier of Definition 1853.39 makes E the root witness for cover samples, while Definition 1853.40 binds C, R, L to the same compact-cover route before an order bound can be read.

Next attach the real and completion boundary. Apply Definition 1853.43 to route rational and dyadic sampling through RealSeparability$^{\uparrow}$, and use Definition 1853.48 to keep the MetricCompletion$^{\uparrow}$ boundary on the same finite prefix.

Finally expose the consumer surface. The primitive route already carries O, H, T, P, N as the order, transport, replay, provenance, and local-name rows after E, C, R, L, RealSeparability$^{\uparrow}$, MetricCompletion$^{\uparrow}$. Since the carrier has no coordinate for a selected dense subfamily, quotient completion witness, or ambient dimension oracle, every downstream cover consumer receives exactly the displayed audit route. □

Theorem 1853.50 (CoveringDimension root-cover scoped dependency)**.** *For an accepted* CoveringDimension$^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

every accepted root-cover read exposing the order row O must pass through the finite epsilon-net row E, compact-cover Lebesgue ledger row L, RealSeparability$^{\uparrow}$ *dyadic and rational windows, and* MetricCompletion$^{\uparrow}$ *completion-facing boundary before the row is exported through H, T, P, N. Equivalently, the scoped dependency route is the finite chain*

$$K, E, C, R, L, \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, O, H, T, P, N,$$

with no appeal to arbitrary open-cover compactness, selected dense subfamilies, quotient completion, or ambient dimension oracles.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverScopedDependency`

Proof. Start with Definition 1853.39. It makes the finite epsilon-net row E the root source for cover samples, refinement memberships, and later order counts.

Apply Definition 1853.40. The cover row C, refinement row R, and Lebesgue-ledger row L form the compact-cover dependency before any dimension-bound export is available.

Use Definition 1853.43 and Definition 1853.48. The rational and dyadic windows of $\mathsf{RealSeparability}^{\uparrow}$ and the completion-facing boundary of $\mathsf{MetricCompletion}^{\uparrow}$ attach to the same finite prefix before O is consumed.

Finally H, T, P, N replay and name this route as componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. Since each cited route explicitly excludes open-cover compactness, selected dense subfamilies, quotient completion, and ambient dimension oracles, the scoped dependency exports only the displayed finite chain. □

Theorem 1853.51 (CoveringDimension root-cover ledger factorization)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

every accepted root-cover order read factors through the $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *finite-net radius exhaustion of Definition 1302.5 before* $\mathsf{RealSeparability}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *rows are allowed to feed the order ledger* O*. Thus the order-facing route is the finite factorization*

$$K, E, C, R, L \longmapsto \mathsf{CompactCoverLebesgueLedger}^{\uparrow} \longmapsto \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow} \longmapsto O, H, T, P, N,$$

not an open-cover oracle, selected dense subfamily, quotient completion witness, or ambient dimension oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverLedgerFactorization`

Proof. Start with Definition 1853.39. The finite epsilon-net row E supplies the displayed ProbeBundle centers, dyadic tolerance witnesses, and BHist coverage rows for the cover and refinement data.

Next apply Definition 1853.40. The rows C, R, O cannot be read as an isolated dimension assertion; the compact-cover route must first pass through the Lebesgue ledger row L.

Use Definition 1302.5. The ledger exhausts every radius export through the finite-net, pointwise-radius, positive-rational, and finite-fold rows, so the order read has no source in an arbitrary open-cover oracle.

Finally apply Definition 1853.43. The $\mathsf{RealSeparability}^{\uparrow}$ windows and $\mathsf{MetricCompletion}^{\uparrow}$ boundary attach only after the finite ledger has been displayed, and H, T, P, N transport, replay, source, and name that same route. Hence the accepted order ledger exposes no selected dense subfamily, quotient completion witness, or ambient dimension oracle. □

Theorem 1853.52 (CoveringDimension root-cover ledger realization)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

any accepted root-cover order read that exposes O *realizes the* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *finite-net radius exhaustion before the order row is inspected. The realized route displays* K, E, C, R, L *and the radius-exhaustion ledger of Definition 1302.5 before* O, H, T, P, N *can be exported, and it has no source in an open-cover oracle, selected dense subfamily, quotient completion witness, or ambient dimension oracle.*

Proof. Start with Definition 1853.51. It already places the order-facing read behind the finite epsilon-net row E, cover row C, refinement row R, and Lebesgue ledger L.

Apply Definition 1302.5. The compact-cover ledger realizes each radius read through finite-net, pointwise-radius, positive-rational, and finite-fold rows before any order count is available.

The rows H, T, P, N then transport, replay, source, and name that realized finite route. Since no carrier coordinate stores an open-cover oracle, selected dense subfamily, quotient completion witness, or ambient dimension oracle, the accepted read of O is exactly the displayed ledger realization. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverLedgerRealization`

Theorem 1853.53 (CoveringDimension separability-completion lock)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, the* $\mathsf{RealSeparability}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *rows can feed the order ledger* O *only after the finite epsilon-net row* E*, compact-cover ledger* L*, and refinement row* R *are visible on the same root-cover route. Thus separability and completion data are locked behind the finite route*

$$E, C, R, L \longmapsto \mathsf{RealSeparability}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow} \longmapsto O, H, T, P, N,$$

not behind selected dense sequences, quotient completion equality, arbitrary open-cover compactness, or an ambient dimension oracle.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverSeparabilityCompletionLock`

Proof. Read Definition 1853.39 first. It makes E the finite source for the cover samples and tolerance windows used by the root-cover route.

Next use Definition 1853.40 together with Definition 1853.52. The cover row C, refinement row R, and compact-cover ledger L must be visible before the order row is read.

Finally apply Definition 1853.43. The $\mathsf{RealSeparability}^{\uparrow}$ windows and $\mathsf{MetricCompletion}^{\uparrow}$ boundary attach only to that already displayed finite route, and H, T, P, N preserve it as the named order ledger. Therefore the separability and completion rows cannot bypass the finite epsilon-net, compact-cover ledger, or refinement rows. □

Theorem 1853.54 (CoveringDimension public root-cover export)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the public order-bound root-cover surface exports only through K, E, C, R, L*, the* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *finite-net radius route,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and the rows* O, H, T, P, N*. The export has no source in an open-cover oracle, selected dense subfamily, quotient completion witness, or ambient dimension oracle.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionPublicRootCoverExport`

Proof. Start with Definition 1853.39. The root-cover read begins with the finite sample and tolerance data in K and E, not with an arbitrary open-cover oracle.

Apply Definition 1853.40 and Definition 1853.46. These force the cover row C and refinement row R to pass through the compact-cover ledger L before the order row can be inspected.

Next use Definition 1853.51 and Definition 1853.52. The factorization and realization steps route every order-bound read through the $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ finite-net radius exhaustion, so no selected dense subfamily or ambient dimension oracle is available.

Finally apply Definition 1853.53. The $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ rows attach only after the finite ledger route is visible, and O, H, T, P, N export exactly that named route. Therefore the public surface is the displayed finite ledger chain and not a quotient completion witness or external dimension assertion. □

Definition 1853.55 (CoveringDimension root cover carrier)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the root cover-dimension carrier is the finite subpacket

$$D_{\mathrm{root}} = (K, E, C, R, O, S, V, H, T, P, N)$$

where K exposes the $\mathsf{CompactMetric}^{\uparrow}$ *source and its* $\mathsf{Met}^{\uparrow}$ *distance observations, E exposes the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *refinement witnesses, C exposes finite open-cover rows, R exposes containment rows for the refinement of C, O exposes the order-count ledger, S exposes the* $\mathsf{RealSeparability}^{\uparrow}$ *density rows used when covers are sampled through rational or dyadic windows, and V exposes the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve rows attached to the finite refined cover. The structural rows H, T, P, N transport, replay, source, and name exactly these finite rows.*

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverCarrierPacket`

Theorem 1853.56 (CoveringDimension root cover NameCert obligations)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier $D = (K, E, C, R, O, L, H, T, P, N)$, the local root cover-dimension obligations consist exactly of finite open-cover admission through C, compact metric finite-net admission through K, E, metric distance observation through the* $\mathsf{Met}^{\uparrow}$ *part of K, refinement containment through R, density-window compatibility through* $\mathsf{RealSeparability}^{\uparrow}$*, nerve-row compatibility through* $\mathsf{SimplicialComplex}^{\uparrow}$*, order counting through O, and structural transport through H, T, P, N. No root cover-dimension read may bypass these rows by using arbitrary open-cover compactness, a selected dense subfamily, a host refinement theorem, or an external simplicial nerve construction.*

Proof. Project the root carrier of Definition 1853.55. The finite open-cover rows are the displayed entries in C, and their only compact source is the compact metric row K together with the finite epsilon-net row E.

The metric observations are therefore local to K, E, C, R. Distance comparisons can inspect the $\mathsf{Met}^{\uparrow}$ part of K, but they cannot introduce a second metric space, a host open-cover theorem, or a detached refinement.

Density and nerve reads remain downstream. The $\mathsf{RealSeparability}^{\uparrow}$ windows sample the same finite cover route before O is consumed, and the $\mathsf{SimplicialComplex}^{\uparrow}$ nerve rows are attached only to the displayed refined cover.

Finally H, T, P, N preserve and name the same finite data. Since the carrier has no coordinate for arbitrary open-cover compactness, selected dense subfamilies, host refinements, or external nerve construction, projection and route exhaustion give the stated root obligations. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverNameCertObligations`

Theorem 1853.57 (CoveringDimension compact-net refinement handoff)**.** *Every compact-net refinement read exported by an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet factors through*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow} \longrightarrow \mathsf{FiniteEpsilonNet}^{\uparrow} \longrightarrow C, R, O \longrightarrow \mathsf{RealSeparability}^{\uparrow},\ \mathsf{SimplicialComplex}^{\uparrow} \longrightarrow H, T, P, N.$$

The handoff gives downstream cover-dimension consumers finite open-cover rows, metric distance observations, compact finite-net refinements, density windows, nerve rows, order counts, transport, replay, provenance, and local naming, and it gives no ambient compactness theorem, selected dense sequence, external refinement oracle, or host nerve construction.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetRefinementHandoff`

Proof. Begin with the compact-net entry. The rows K and E expose the compact metric source, metric observations, finite ProbeBundle centers, and tolerance-indexed coverage witnesses before any finite cover row is read.

Next read C, R, O. The cover row C supplies finite open-cover entries, the refinement row R records containment into those entries, and the order row O counts only refined rows already visible through R.

The downstream consumers then inspect only attached finite rows. $\mathsf{RealSeparability}^{\uparrow}$ contributes density windows for the same cover samples, while $\mathsf{SimplicialComplex}^{\uparrow}$ contributes nerve rows for the same refined finite cover.

The rows H, T, P, N transport, replay, source, and name the route. Thus the compact-net refinement handoff is exhausted by the displayed chain and cannot export arbitrary open-cover compactness, selected dense sequences, external refinement oracles, or host nerve constructions. □

Theorem 1853.58 (CoveringDimension root cover density-nerve lock)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, every accepted root cover-dimension read must expose* K, E, C, R, O *before either the* $\mathsf{RealSeparability}^{\uparrow}$ *density row* S *or the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row* V *is consumed. Both rows must refer to the same finite refined cover displayed by* C, R, O*, so density windows and nerve data cannot be read as detached external witnesses.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverDensityNerveLock`

Proof. Project the root cover carrier of Definition 1853.55. The rows K, E, C, R, O display the compact metric source, finite epsilon-net refinements, finite open-cover entries, containment rows, and order ledger before the downstream rows S and V appear.

Apply the root cover NameCert obligations, Definition 1853.56. They make density-window compatibility and nerve-row compatibility part of the same local root cover surface rather than separate external certificates.

Use the compact-net refinement handoff, Definition 1853.57. It routes both $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{SimplicialComplex}^{\uparrow}$ through the same chain

$$K, E, C, R, O, H, T, P, N.$$

Thus any accepted density row S and nerve row V are attached to the same finite refined cover already exposed by C, R, O. Since no carrier coordinate supplies a second cover, selected dense subfamily, or host nerve construction, the two downstream rows remain locked to that displayed route. □

Theorem 1853.59 (CoveringDimension root cover RealSeparability simplicial lock)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, every accepted root-cover read that consumes a* $\mathsf{RealSeparability}^{\uparrow}$ *density window and a* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row must expose the same refined-cover route*

$$K, E, C, R, O$$

first. The density and nerve rows are then transported only by the shared structural rows H, T, P, N, so neither row can be replaced by a selected dense subfamily, a detached sampling schedule, or an external nerve construction.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverRealSeparabilitySimplicialLock`

Proof. Project the carrier through Definition 1853.55. The only root-cover route available before downstream sampling is the displayed compact metric source K, finite epsilon-net refinement E, finite cover row C, containment row R, and order ledger O.

Apply Definition 1853.56. Its density-window and nerve-row clauses attach $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{SimplicialComplex}^{\uparrow}$ to that local root surface rather than to independent witnesses.

Use Definition 1853.57. The handoff orders both downstream rows after the same finite refined cover and before the same structural rows H, T, P, N perform transport, replay, provenance, and local naming.

Thus the two consumers are locked to one refined-cover route. Since the carrier contains no coordinate for selected dense subfamilies or external nerves, no such object can be introduced after the shared route has been exposed. □

Theorem 1853.60 (CoveringDimension root cover public scope)**.** *Every public* $\mathsf{CoveringDimension}^{\uparrow}$ *root-cover consumer factors through the same finite chain*

$$\mathsf{CompactMetric}^{\uparrow}/\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{FiniteEpsilonNet}^{\uparrow} \longrightarrow C, R, O \longrightarrow \mathsf{RealSeparability}^{\uparrow}/\mathsf{SimplicialComplex}^{\uparrow} \longrightarrow H, T, P, N.$$

The public route gives compact metric source rows, metric observations, finite epsilon-net refinements, finite cover rows, containment rows, order counting, density-window rows, nerve rows, transport, replay, provenance, and local naming. It gives no arbitrary open-cover compactness theorem, selected dense subfamily, host refinement theorem, or external nerve construction.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverPublicScope`

Proof. First project the public consumer through the root carrier of Definition 1853.55. The only visible rows are the compact metric source K, finite epsilon-net row E, cover row C, containment row R, order ledger O, density row S, nerve row V, and the structural rows H, T, P, N.

Apply Definition 1853.56. It makes compact metric admission, metric observation, finite cover admission, finite-net refinement, density compatibility, nerve compatibility, order counting, and structural transport part of one local NameCert surface.

Use Definition 1853.57 to order the route from $\mathsf{CompactMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ through $\mathsf{FiniteEpsilonNet}^{\uparrow}$ and C, R, O before the downstream $\mathsf{RealSeparability}^{\uparrow}/\mathsf{SimplicialComplex}^{\uparrow}$ rows are read.

Finally apply Definition 1853.58. The density and nerve rows are locked to the same finite refined cover, so projection from the root carrier exhausts the public route and leaves no coordinate for arbitrary open-cover compactness, selected dense subfamilies, host refinements, or external nerve constructions. □

Theorem 1853.61 (CoveringDimension root cover scope lock)**.** *Every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *root cover packet is scoped exactly by the compact finite-net rows, the* $\mathsf{RealSeparability}^{\uparrow}$ *density witnesses, and the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve rows displayed in*

$$K, E, C, R, O, S, V, H, T, P, N.$$

The compact side is read through $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*; the sampling side is read through* $\mathsf{RealSeparability}^{\uparrow}$*; and the combinatorial side is read through* $\mathsf{SimplicialComplex}^{\uparrow}$*. No arbitrary open-cover compactness theorem, selected subcover, host dimension primitive, detached dense family, or external nerve construction enters the root-cover scope.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverScopeLock`
↪ variant `BEDC.Derived.CoveringDimensionUp.CoveringDimensionRootCoverScopePackage`

Proof. Use the compact-net refinement handoff. It orders the compact metric source, metric observations, finite epsilon-net rows, finite cover rows, containment rows, and order ledger before any downstream density or nerve consumer can read the packet.

Apply the density-nerve lock. The rows S and V are attached to the same displayed refined cover, so the $\mathsf{RealSeparability}^{\uparrow}$ witnesses and $\mathsf{SimplicialComplex}^{\uparrow}$ nerve rows cannot be replaced by detached sampling or external combinatorial data.

Finally use the RealSeparability simplicial lock and the public-scope theorem. Together they route every public root-cover consumer through $K, E, C, R, O, S, V, H, T, P, N$, with H, T, P, N transporting, replaying, sourcing, and naming only those rows. The excluded compactness, selected-subcover, host-dimension, dense-family, and external-nerve primitives are absent from the carrier and therefore outside the scope. □

Theorem 1853.62 (CoveringDimension simplicial star-refinement scope)**.** *Every simplicial star-refinement read exported by* $\mathsf{CoveringDimension}^{\uparrow}$ *must expose the same finite root-cover route*

$$K, E, C, R, O \longrightarrow \mathsf{RealSeparability}^{\uparrow} \longrightarrow \mathsf{SimplicialComplex}^{\uparrow} \longrightarrow H, T, P, N$$

before any structural row is consumed. Thus the star-refinement read first displays the compact metric source row K, the finite epsilon-net row E, the finite cover row C, the containment row R, and the order ledger O; then it displays the $\mathsf{RealSeparability}^{\uparrow}$ *density window and the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row; only after those rows are visible may transport, replay, provenance, and local naming be read.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionSimplicialStarRefinementScope`

Proof. Start with the root cover carrier of Definition 1853.55. The carrier makes $K, E, C, R, O, S, V, H, T, P, N$ the only rows available to a root-cover consumer, with S serving the density window and V serving the nerve row.

Apply the root cover NameCert obligations of Definition 1853.56. They require compact metric admission, finite epsilon-net refinement, finite cover admission, containment, order counting, density compatibility, nerve compatibility, and structural transport to remain part of one local surface.

Use the compact-net refinement handoff and the root cover scope lock, Definition 1853.57 and Definition 1853.61. These force every downstream read to pass through K, E, C, R, O before the $\mathsf{RealSeparability}^{\uparrow}$ density window and $\mathsf{SimplicialComplex}^{\uparrow}$ nerve row are used.

Therefore a simplicial star-refinement read cannot skip directly to structural transport or to an external nerve construction. It exports only the displayed finite root-cover route followed by H, T, P, N, and no arbitrary open-cover compactness, selected dense subfamily, host star-refinement theorem, or detached simplicial primitive enters the scope. □

Theorem 1853.63 (CoveringDimension root scope ledger)**.** *Every accepted root-cover read of a* $\mathsf{CoveringDimension}^{\uparrow}$ *packet that can be consumed by a covering-dimension boundary theorem factors through the compact-net refinement row, the* $\mathsf{RealSeparability}^{\uparrow}$ *row, the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row, the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, the* $\mathsf{Met}^{\uparrow}/\mathsf{CompactMetric}^{\uparrow}$ *source rows, and the L10 tolerance route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The read is therefore scoped by displayed tolerance, readback, finite-cover, density, nerve, transport, replay, provenance, and local naming rows. It does not import ambient open-cover compactness, quotient real equality, selected dense subfamilies, host dimension primitives, or external nerve construction.

Proof. Project the root cover carrier of Definition 1853.55. The accepted read begins with $K, E, C, R, O, S, V, H, T,$ so compact metric, finite epsilon-net, finite cover, containment, order, density, nerve, transport, replay, provenance, and naming data are all visible before a boundary theorem can consume the packet.

Use the compact-net refinement handoff, Definition 1853.57. It places the $\mathsf{Met}^{\uparrow}/\mathsf{CompactMetric}^{\uparrow}$ source and $\mathsf{FiniteEpsilonNet}^{\uparrow}$ refinement before C, R, O, and it keeps the downstream $\mathsf{RealSeparability}^{\uparrow}$ and $\mathsf{SimplicialComplex}^{\uparrow}$ rows attached to the same finite refined cover.

Apply the density-nerve lock, RealSeparability simplicial lock, public scope, and scope lock theorems, Definition 1853.58, Definition 1853.59, Definition 1853.60, and Definition 1853.61. These force every public root-cover consumer to stay inside the displayed finite route.

Finally read the L10 tolerance rows through the dyadic tolerance ledger, regular rational sequence readback, and terminal real-name seal. Since those rows are displayed as tolerance and readback data rather than quotient real equality or ambient completeness, the resulting scope is exactly the finite boundary route and no stronger compactness or real-equality principle is exported. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootScopeLedger`

Theorem 1853.64 (CoveringDimension compact-net dependency route)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *read that starts from compact finite-net data must expose the finite cover row, refinement row, order-bound ledger,* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *source,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff when completion data are consumed,* BHist *carrier, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *before a dimension-bound consumer may inspect the order row. The route is a compact-net certificate over the accepted carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, not an arbitrary open-cover compactness theorem or selected refinement.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetDependencyRoute`

Proof. Project the carrier of Definition 1853.1. The compact metric source K, finite epsilon-net row E, finite cover row C, refinement row R, order-bound ledger O, and Lebesgue ledger L are displayed before the structural rows are available.

Read the compact-net source through Definition 1853.39. It makes the finite cover row a consequence of the displayed probe bundle and tolerance-indexed coverage witnesses rather than of host compactness.

Then route completion-facing uses through the existing MetricCompletion dependency children. The handoff may consume the same cover and refinement rows, but it does not add a second source for O or a selected completion representative.

Finally H, T, P, N preserve the projected route under transport, replay, provenance, and local naming. This gives the root dependency route as a finite compact-net certificate. □

Theorem 1853.65 (CoveringDimension refinement-order root route)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, the refinement-order root route requires the finite cover row* C*, refinement row* R*, order-bound ledger* O*,* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *source rows* K, E*, any* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff used by the read,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *to remain visible as one packet before the order bound is exported.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRefinementOrderRootRoute`

Proof. Start from Definition 1853.41. It makes each order count in O depend on the displayed parent and containment witnesses stored in R over the finite cover row C.

Use Definition 1853.42 to keep K, E, C, R, O, L in the compact metric route. If the consumer asks for completion-facing data, the MetricCompletion child route is inserted after the finite cover and refinement rows and before the order export.

The structural rows H, T, P, N then replay and name the same data. The order-bound ledger is therefore a projected root obligation of the displayed carrier, not parameter transport through an external multiplicity oracle. □

Theorem 1853.66 (CoveringDimension metric-completion root route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of a* $\mathsf{CoveringDimension}^{\uparrow}$ *bound must first read the finite cover row C, refinement row R, order-bound ledger O,* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *source K, E,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff,* BHist *carrier rows, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row of the accepted packet. The completion boundary receives the displayed finite cover-refinement route; it receives no arbitrary open-cover compactness, host multiplicity theorem, quotient completion point, or selected representative.*

Proof. Begin with the compact-net dependency route above. It exposes $K, E, C, R, O, L, H, T, P, N$ before a dimension-bound consumer can inspect the order ledger.

Now insert the completion handoff through the existing MetricCompletion dependency route. The handoff is downstream of the compact metric and finite epsilon-net source rows, so it can replay the cover-refinement certificate but cannot replace it by an ambient completion object.

Finally apply the refinement-order root route. It keeps the order ledger attached to the same finite cover and refinement rows after the completion boundary is visible.

Thus the completion-facing export is a projection and replay of the accepted carrier. It is not parameter transport, quotient topology, selected representatives, or host-level general compactness. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionMetricCompletionRootRoute`

Theorem 1853.67 (CoveringDimension Cauchy forward link)**.** *Let $D = (K, E, C, R, O, L, H, T, P, N)$ be an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover-refinement packet. Any metric-completion or Real-facing consumer that uses the dimension bound must pass through the* $\mathsf{Cauchy}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite windows of chapter 3413 and chapter 301, together with the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows of chapter 129, before the* $\mathsf{Real}^{\uparrow}$*-facing bound is consumed.*

Thus the cover-refinement read reaches completion consumers as a finite route through compact finite nets, Cauchy windows, regular-rational readback, transport, replay, provenance, and local naming. It does not export open-cover compactness, selected subcovers, quotient completion points, host multiplicity, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the existing cover-refinement routes of Definition 1853.64 and Definition 1853.65. They expose the compact metric source K, finite-net row E, finite cover row C, refinement row R, order-bound ledger O, compact Lebesgue row L, and structural rows H, T, P, N before the dimension bound can be read.

Attach the Cauchy and regular-rational windows. A completion-facing consumer reads the Cauchy route through chapter 3413 and the regular-rational readback through chapter 301; these rows supply finite windows and tolerance ledgers, not quotient completion points or selected limits.

Now use the compact metric finite-net source of chapter 129. The finite-net row determines the sampled cover data that the refinement and order ledgers may consume, so the Real-facing dimension bound remains downstream of compact finite data.

Finally exhaust the packet rows. The consumer has only compact finite nets, Cauchy windows, RegSeqRat readback, cover refinement, order ledger, transport, replay, provenance, and local naming. Open-cover compactness, selected subcovers, quotient completion points, host multiplicity, and ambient Real completeness have no row in the accepted carrier. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCauchyForwardLink`

Definition 1853.68 (CoveringDimension finite cover carrier)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet, the finite cover carrier is the displayed* BHist *subpacket*

$$F = (K, E, M, C, R, O, S, A, H, T, P, N)$$

cut out of the local carrier of Definition 1853.1. Here K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* E *is the finite-net row,* M *is the* $\mathsf{Met}^{\uparrow}$ *distance-read ledger used by the cover tests,* C *is the finite* BHist *cover row,* R *is the refinement membership row,* O *is the order-bound ledger,* S *is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row,* A *records any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal rows consumed by a metric read, and* H, T, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *data.*

The carrier is finite at every exposed face. It contains no arbitrary open cover, selected subcover, host multiplicity oracle, quotient completion point, or ambient compactness theorem.

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverCarrier`

Theorem 1853.69 (CoveringDimension finite cover admission)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *read that admits finite cover data must first expose the finite cover carrier of Definition 1853.68. In particular, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows* K, E*, the* $\mathsf{Met}^{\uparrow}$ *distance reads* M*, the finite* BHist *cover row* C*, the refinement row* R*, the order ledger* O*, any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal rows* A*, and the structural rows* H, T, P, N *are all visible before a dimension-bound consumer may read an order conclusion.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier finite cover admission`

Proof. Project the accepted carrier through Definition 1853.1. The compact source, finite-net row, cover row, refinement row, order ledger, and structural rows are already part of the displayed CoveringDimension packet.

Insert the metric and Real-facing reads only as rows of the same finite carrier. The $\mathsf{Met}^{\uparrow}$ ledger records distance tests for cover membership, while the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal rows are read only when those tests are Real-facing.

Since no arbitrary open-cover coordinate occurs in F, admission is a finite row projection. The dimension-bound consumer receives the displayed finite cover route and none of the excluded host principles. □

Theorem 1853.70 (CoveringDimension order refinement route)**.** *For a finite cover carrier* $F = (K, E, M, C, R, O, S, A, H, T, P, N)$*, the order-bound row* O *is readable only after each member counted by* O *has been traced through the finite cover row* C *and the refinement membership row* R*. The route uses the same* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows,* $\mathsf{Met}^{\uparrow}$ *distance reads, and* BHist *cover entries that admitted the carrier, and it exports no selected refinement or host overlap oracle.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionOrderRefinementRoute`

Proof. Start with the finite cover admission theorem. It places K, E, M, C, R before O in the public route.

For every refined member, the row R names a parent in the finite cover row C and records the containment witness used by the distance-read ledger M. Thus the overlap count in O is computed over displayed BHist rows.

The structural rows H, T, P, N transport, replay, source, and name that finite computation. They do not add a second order source, so the order refinement route remains a finite CoveringDimension obligation. □

Theorem 1853.71 (CoveringDimension simplicial nerve handoff)**.** *Every* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve read consumed by a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier must use the same finite cover and refinement data*

$$C, R, O \longmapsto S$$

after the compact finite-net rows K, E and metric distance ledger M have been displayed. The nerve row S receives vertices and incidence rows from the finite cover carrier; it receives no classical nerve theorem, selected locally finite cover, or ambient topological realization.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverSimplicialNerveHandoff`

Proof. Read the carrier F. The cover row C supplies the finite vertex list for the nerve, while R supplies the refinement memberships that determine incidence.

The order ledger O bounds the displayed overlap count before the nerve row is consumed. Therefore the $\mathsf{SimplicialComplex}^{\uparrow}$ row S is downstream of the same finite cover-refinement route, not a detached simplicial object.

The compact finite-net and metric rows K, E, M remain attached to the cover tests. Hence the handoff to the nerve surface is constructive row replay over the accepted carrier. □

Theorem 1853.72 (CoveringDimension Cauchy metric scope)**.** *When a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier is read by a Cauchy, RegSeqRat, or Real-facing metric consumer, the consumer may use only the displayed route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the carrier rows K, E, M, A. The finite cover, refinement, order, and nerve rows C, R, O, S remain the only dimension-facing rows, and no quotient completion point, selected limit, host metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is exposed.*

Proof. Project K, E, M, A from Definition 1853.68. These are the only rows through which metric or Real-facing reads enter the finite cover route.

The regular rational and Real seal data in A are downstream of the metric distance ledger M. They can certify the numerical side of a cover test, but they do not replace the finite cover row C or refinement row R.

Finally use the order refinement and nerve handoff routes. They keep C, R, O, S as the dimension-facing surface, so completion or Real-facing metric data remain scoped to the displayed finite carrier. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCauchyMetricScope`

Theorem 1853.73 (CoveringDimension finite cover root metric-completion route)**.** *Every metric-completion read of a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier*

$$F = (K, E, M, C, R, O, S, A, H, T, P, N)$$

factors through the displayed finite-cover route $K, E, M, C, R, O, S, A, H, T, P, N$*. The completion-facing rows may inspect the compact source* K*, finite-net row* E*, metric distance ledger* M*, and regular or Real seal row* A*, but the dimension conclusion remains routed through the finite cover row* C*, refinement row* R*, order ledger* O*, nerve row* S*, and structural rows* H, T, P, N*. No quotient completion point, selected Cauchy limit, arbitrary open cover, selected subcover, host metric equality, or ambient compactness principle is exported.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootMetricCompletionRoute`

Proof. Start with Definition 1853.72. It places every completion-facing metric read inside the rows K, E, M, A of the finite cover carrier.

Then apply finite cover admission and order refinement. The rows C, R, O, S remain the only dimension-facing route, so the completion read cannot replace them by a quotient point, a selected limit, or an external open-cover family.

The transport, replay, provenance, and naming rows H, T, P, N keep both readings attached to the same displayed carrier. Thus metric completion consumes the finite-cover root rather than an ambient completion construction. □

Theorem 1853.74 (CoveringDimension finite cover root Real separability route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *separability read that consumes a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier*

$$F = (K, E, M, C, R, O, S, A, H, T, P, N)$$

must pass through the same finite-cover root $K, E, M, C, R, O, S, A, H, T, P, N$*. The separability consumer may read rational or regular Real-facing data only through the metric ledger* M *and the seal row* A*, while cover membership, refinement, order, and nerve data remain the displayed rows* C, R, O, S*. The route exports no arbitrary dense sequence, selected real representative, quotient completion point, host open ball, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier and read the finite-net and metric rows K, E, M. These rows are the only source from which a Real-facing separability consumer can obtain numerical cover tests.

The seal row A is downstream of those tests and does not introduce a separate dense sequence or selected Real representative. By the finite cover admission theorem, cover data still enter through C and refinement through R.

Finally the order and nerve rows O, S are replayed through H, T, P, N. Hence Real separability reads factor through the displayed finite-cover root and do not expose any ambient dense-set or completeness principle. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootRealSeparabilityRoute`

Theorem 1853.75 (CoveringDimension finite cover root Lebesgue ledger route)**.** *Every finite Lebesgue-ledger read attached to a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier*

$$F = (K, E, M, C, R, O, S, A, H, T, P, N)$$

is computed from the displayed route $K, E, M, C, R, O, S, A, H, T, P, N$*. The ledger may consume the compact finite-net rows* K, E*, the metric test row* M*, and any regular or Real seal row* A *only to*

certify finite cover membership; its covering, refinement, order, and nerve obligations are exactly C, R, O, S transported and replayed by H, T, P, N. It exports no arbitrary open cover, selected Lebesgue number, host compactness theorem, chosen finite subcover, quotient completion point, or ambient Real-completeness witness.

Proof. Use finite cover admission to display the rows $K, E, M, C, R, O, S, A, H, T, P, N$. A finite Lebesgue ledger can read K, E, M, A only as the numerical side of membership tests.

Order refinement then forces every counted overlap through C and R, and the simplicial nerve handoff routes incidence through S. Thus the ledger consumes the same finite cover, refinement, order, and nerve rows as the dimension packet.

The structural rows H, T, P, N transport, replay, source, and name that computation. Since no selected Lebesgue number, chosen subcover, host compactness theorem, quotient completion point, or ambient Real-completeness witness is present in the carrier, the ledger factors through the finite-cover root. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootLebesgueLedgerRoute`

Theorem 1853.76 (CoveringDimension finite cover root Cauchy selection route)**.** *Every Cauchy or metric-completion cover-selection read attached to a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite cover carrier*

$$F = (K, E, M, C, R, O, S, A, H, T, P, N)$$

factors through the displayed finite-cover route. The compact metric and metric rows K, E, M are displayed before any Cauchy read, the regular and Real-facing row A is displayed before any completion-facing numerical seal, and the finite cover, refinement, order, and nerve rows C, R, O, S are displayed before selection data may be inspected. The route exports no quotient completion point, selected Cauchy limit, arbitrary open cover, host metric equality, or ambient compactness principle.

Proof. Use finite cover admission to expose $K, E, M, C, R, O, S, A, H, T, P, N$. This places compact metric data, metric distance tests, finite cover membership, refinement rows, order bounds, and nerve rows in the finite carrier before any selection read.

Apply the Cauchy metric scope and metric-completion route. They force completion-facing reads to remain inside K, E, M, A and prevent a quotient completion point or selected Cauchy limit from replacing the displayed finite-cover rows.

Use the Real separability route for the numerical seal side. It keeps regular rational and Real-facing data downstream of the metric ledger, so arbitrary open covers, host metric equality, and ambient compactness never enter the exported CoveringDimension root. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootCauchySelection`

Theorem 1853.77 (CoveringDimension finite-cover scope grounding)**.** *Each* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-cover root obligation must expose the* $\mathsf{Met}^{\uparrow}$ *ball row,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row,* $\mathsf{Real}^{\uparrow}$ *radius seal,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window row before any covering-dimension consumer reads a refinement conclusion. The refinement remains a finite-cover root route over the displayed rows $K, E, M, C, R, O, S, A, H, T, P, N$.*

Proof. Project the finite-cover carrier of Definition 1853.68 and the admission route of Definition 1853.69. These expose the compact source, finite-net row, metric distance ledger, finite cover row, refinement row, order ledger, and structural rows before the dimension-facing conclusion is read.

Use the metric-completion, Real-separability, and Lebesgue-ledger routes, Definition 1853.73, Definition 1853.74, and Definition 1853.75. Together they force radius seals, regular readback, dyadic tolerances, and dense-window data to remain inside the same finite-cover root.

The dependency routes in this subdirectory keep metric, compact-metric, Real, RealSeparability, RegSeqRat, and DyadicRatCore reads explicit. Since no row names open-cover compactness, a selected subcover, a host dimension theorem, or quotient real equality, every refinement consumer is grounded in the displayed finite BEDC scope. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverScopeGrounding`

Definition 1853.78 (CoveringDimension finite cover order carrier)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet, the finite-cover order carrier is the displayed subpacket*

$$O_{\text{fin}} = (K, E, M, R, Q, S, A, H, T, P, N)$$

where K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* E *is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *cover support,* M *is the* $\mathsf{Met}^{\uparrow}$ *distance-read ledger,* R *records* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison rows,* Q *records the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows used by cover tests,* S *is the finite* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row, and* A *is the finite order table assigning each displayed cover row its overlap count. The rows* H, T, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert data.*

The carrier admits only displayed finite cover rows and their order table. It has no coordinate for arbitrary open-cover compactness, ambient dimension theory, or choice-selected refinements.

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderCarrier`

Theorem 1853.79 (CoveringDimension finite cover order refinement)**.** *Every refinement read from* $O_{\text{fin}} = (K, E, M, R, Q, S, A, H, T, P, N)$ *must preserve the displayed order table* A*. A refined cover member is accepted only when its parent cover row is named by* E*, its metric containment test is read through* M, R, Q*, and its nerve incidence is replayed through* S *before the order count is exported.*

Proof. Begin with the finite epsilon-net support E. It lists the only cover rows available to a refinement consumer, so a refined member must name a parent in that finite table.

The containment test is then read through the metric ledger M and the regular rational and Real seal rows R, Q. These rows can compare displayed radii and distances, but they cannot select a new cover outside the finite support.

Finally replay the incidence row through the simplicial nerve S and consult the order table A. Since every step is indexed by the displayed finite cover rows, the refinement preserves the order carrier and exposes no host dimension theorem or choice-selected refinement. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderRefinement`

Theorem 1853.80 (CoveringDimension finite cover order non-escape)**.** *Every downstream order-bound consumer of* $O_{\text{fin}} = (K, E, M, R, Q, S, A, H, T, P, N)$ *remains inside the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SimplicialComplex}^{\uparrow}.$$

The consumer may replay displayed cover rows, metric comparisons, Real seal checks, nerve incidence, transport, provenance, and local naming, but it cannot invoke arbitrary open-cover compactness, ambient dimension theory, or choice-selected refinements.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderNonescape`

Proof. Project the consumer request to the rows of O_{fin}. The only source of cover data is E over the compact metric row K, and the only numerical tests are the metric, regular rational, and Real seal rows M, R, Q.

The nerve row S and order table A are downstream of those finite tests. They can replay incidence and count overlaps over displayed rows, but they do not introduce a second cover source.

The structural rows H, T, P, N preserve the same route under transport, replay, provenance, and naming. Because the carrier lacks coordinates for open-cover compactness, host dimension theory, and choice-selected refinement, the order-bound read cannot escape the finite carrier. □

Theorem 1853.81 (CoveringDimension finite cover order root)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-cover order read first exposes the root rows*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SimplicialComplex}^{\uparrow}$$

before the order table is consumed. Equivalently, an order-bound consumer may reach the table A of $O_{\text{fin}} = (K, E, M, R, Q, S, A, H, T, P, N)$ only after reading the compact metric source K, finite epsilon-net support E, metric ledger M, regular rational comparison rows R, terminal Real seal rows Q, and simplicial nerve row S.

Proof. Project the read to the finite-cover order carrier of Definition 1853.78. The coordinates before the table are exactly K, E, M, R, Q, S, followed by the order table A and the structural rows.

The refinement theorem Definition 1853.79 forces every refined member to name a parent cover row in E, test containment through M, R, Q, and replay incidence through S before an order count is exported.

The nonescape theorem Definition 1853.80 then prevents the consumer from bypassing those root rows through arbitrary open-cover compactness, ambient dimension theory, or choice-selected refinements. Thus the order table is reachable only after the displayed root route has been exposed. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderRoot`

Theorem 1853.82 (CoveringDimension finite cover order scope)**.** *Every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-cover order consumer must display the source rows*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SimplicialComplex}^{\uparrow}$$

before the order table of $O_{\text{fin}} = (K, E, M, R, Q, S, A, H, T, P, N)$ is public. The table is scoped only to those six source rows together with the componentwise hsame *transport row H, the displayed* Cont *replay row T, the* Pkg *provenance row P, and the local* NameCert *row N.*

Proof. Project the carrier of Definition 1853.78. It displays exactly the compact metric row K, finite epsilon-net support E, metric ledger M, regular rational comparison rows R, terminal Real seal rows Q, simplicial nerve row S, order table A, and structural rows H, T, P, N.

Apply the refinement theorem Definition 1853.79. It requires each refined member to read the finite support, metric containment test, rational and Real comparison rows, and simplicial incidence row before exporting an order count.

Use the nonescape theorem Definition 1853.80 and the root theorem Definition 1853.81. Together they rule out arbitrary open-cover compactness, ambient dimension theory, and choice-selected refinements, so the public order table remains scoped to the displayed root rows and the structural hsame, Cont, Pkg, and NameCert rows. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderScope`

Theorem 1853.83 (Finite covering-dimension sibling dependency ledger)**.** *Every finite covering-dimension read carried by the* $\mathsf{CoveringDimension}^{\uparrow}$ *family is admitted only through the sibling ledger*

$\mathsf{CompactMetric}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SimplicialComplex}^{\uparrow}, \mathsf{CompactCoverLebesgueLedger}^{\uparrow}, \mathsf{Rea}$

The finite cover rows, refinement rows, and order table of O_{fin} *remain the controlling dependency surface for that read. A downstream consumer may use those siblings to inspect compact finite-net support, metric containment, rational or Real seals, nerve incidence, Lebesgue-radius compatibility, Real-separability windows, and completion-facing scale data, but it cannot replace the displayed finite cover/order ledger by open-cover compactness, a selected refinement, host dimension data, or ambient completeness.*

Proof. Begin with the finite-cover order carrier of Definition 1853.78. It exposes the compact source row, finite epsilon-net support, metric ledger, regular-rational comparison rows, Real seal rows, simplicial nerve row, finite order table, and structural transport, replay, provenance, and naming rows.

Apply Definition 1853.82. This forces every public order-table read to pass through the displayed source rows before the table is public. The finite cover and refinement information therefore remains a rowwise BHist ledger, not a host overlap oracle.

Now read the surrounding sibling routes: the finite-cover root admission and Lebesgue-ledger route bind compact-cover radius evidence, the Real-separability route binds rational windows, and the metric-completion route binds completion-facing scale data. These routes attach their evidence to the same O_{fin} surface and do not introduce another cover selector.

Thus the sibling dependency ledger is exactly the finite BEDC route listed in the statement. It supports finite covering-dimension consumers while excluding arbitrary open-cover compactness, selected refinements, host dimension predicates, and ambient completion principles. □

Definition 1853.84 (Covering dimension finite cover-order carrier)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet*

$$D = (K, E, C, R, O, L, H, T, P, N),$$

the finite cover-order carrier is the displayed root subpacket

$$F_{\mathrm{dim}} = (K, E, C, R, O, L, M, S, Q, A, H, T, P, N).$$

Here K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* E *is the finite compact metric cover-support row,* C *is the displayed finite cover,* R *is the finite refinement map,* O *is the order-bound ledger,* L *is the finite Lebesgue-number and compact-cover ledger,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-facing metric row,* S *is the* $\mathsf{RealSeparability}^{\uparrow}$ *finite density row,* Q *records the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks used by cover tests, and* A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. The rows* H, T, P, N *transport, replay, source, and name the same finite packet.*

The carrier has no coordinate for arbitrary open-cover compactness, choice-selected subcovers, quotient equality, selected dense points, host dimension theory, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverOrderAdmission`

Theorem 1853.85 (Covering dimension finite refinement obligations)**.** *Every accepted finite cover-order carrier* F_{dim} *discharges its refinement obligations through the displayed rows* $K, E, C, R, O, L, M, S, Q, A, H, T$ *A downstream cover consumer must read compact metric cover rows, finite Lebesgue-number or compact-cover ledger rows, MetricCompletion rows, RealSeparability rows, RegSeqRat and DyadicRatCore comparison rows, and the terminal Real seal before it exports the order-bound ledger.*

Proof. Project the carrier of Definition 1853.84. The rows K, E, C, R, O, L are the compact source, finite cover, refinement, order, and finite Lebesgue-ledger coordinates already visible in the parent $\mathsf{CoveringDimension}^{\uparrow}$ packet.

Read the completion and separability rows before the order bound is exported. The $\mathsf{MetricCompletion}^{\uparrow}$ row M supplies only displayed completion-facing metric data, while the $\mathsf{RealSeparability}^{\uparrow}$ row S supplies finite rational or dyadic density witnesses; neither row chooses a subcover or a dense point outside the packet.

The comparison rows Q, A then attach the RegSeqRat, DyadicRatCore, and Real seal reads to the same finite cover tests. Transport, replay, provenance, and local naming through H, T, P, N preserve that route.

Thus the refinement obligation is exactly the finite row family named in the statement. Since no excluded open-cover, choice, quotient, host-dimension, or completeness coordinate appears in the carrier, none can be exported by a downstream consumer. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteRefinementObligations`

Theorem 1853.86 (Covering dimension Real-separability refinement route)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of a* $\mathsf{CoveringDimension}^{\uparrow}$ *finite refinement row must factor through*

$$\mathsf{CompactMetric}^{\uparrow},\ C,\ R,\ \mathsf{FiniteLebesgueNumber}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{RealSeparability}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}$$

The route exposes compact metric cover rows, finite cover order rows, finite Lebesgue-number and refinement siblings, completion-facing metric rows, finite density rows, regular-rational and dyadic comparison rows, and the Real seal boundary before any dimension-bound order row is consumed. It exports no arbitrary open-cover compactness, choice-selected subcover, quotient equality, selected approximating sequence, selected dense point, host dimension theorem, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityRefinementRoute`

Proof. Start with the finite refinement obligations of Definition 1853.85. They force the consumer to open the compact source K, finite cover C, refinement map R, order ledger O, and finite Lebesgue ledger L as displayed cover-order rows.

Next read the completion and density dependencies. The $\mathsf{MetricCompletion}^{\uparrow}$ row is a finite completion-facing metric handoff, and the $\mathsf{RealSeparability}^{\uparrow}$ row is a finite density handoff; both are inserted before the order ledger is consumed, so neither can act as an external selector.

Then apply the RegSeqRat, DyadicRatCore, and Real seal rows. They provide the comparison and terminal seal data used by the cover tests, but they do not add quotient Real equality or ambient completeness.

The structural rows H, T, P, N replay the same finite route for downstream cover and compactness chapters. Because each step is a displayed carrier row, the resulting route refuses open-cover compactness, choice-selected subcovers, quotient equality, selected approximating sequences, selected dense points, host dimension theorems, and ambient Real completeness. □

Theorem 1853.87 (Covering dimension cover-order directedness)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet with finite cover-order carrier* $F_{\mathrm{dim}} = (K, E, C, R, O, L, M, S, Q, A, H, T, P, N)$*, any two displayed finite cover refinements over the same compact metric source row* K *admit a common later finite refinement whose order row is still bounded by the same* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier. The common refinement is read through the displayed finite cover rows, refinement maps, order ledger, finite Lebesgue ledger, transport, replay, provenance, and local naming; it introduces no arbitrary*

open-cover compactness, choice-selected subcover, quotient equality, host dimension theorem, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCoverOrderDirectedness`

Proof. Start with the finite refinement obligations of Definition 1853.85. They keep both displayed refinements inside the same carrier rows K, E, C, R, O, L before any downstream dimension read is public.

Form the common later refinement by reading the displayed finite cover rows and the refinement map rows together. The order ledger O supplies the same carrier-bound order control because both input refinements are attached to the same compact metric source and finite Lebesgue ledger.

Transport and replay through H, T preserve the common refinement as a later finite row, and P, N source and name it locally. Since the carrier contains no arbitrary open-cover, choice-selected, quotient, host-dimension, or ambient-completeness coordinate, directedness stays inside the displayed finite cover-order surface. □

Theorem 1853.88 (Covering dimension compact-net Real-separability handoff)**.** *Every public finite-cover read of a* $\mathsf{CoveringDimension}^{\uparrow}$ *packet that uses compact-net rows must also read the* $\mathsf{RealSeparability}^{\uparrow}$ *finite density row before the dimension order row is exported. In carrier notation, the compact-net support in* K, E, C, L *and the Real-separability row* S *jointly supply the finite cover handoff through* M, Q, A, H, T, P, N*, so no dimension consumer can bypass the compact-net and Real-separability route by selecting a dense set, a subcover, quotient Real equality, a host dimension theorem, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetRealSeparabilityHandoff`

Proof. Apply the Real-separability refinement route of Definition 1853.86. It places compact metric cover rows, finite cover rows, and finite Lebesgue-ledger rows before completion-facing metric data and RealSeparability data are consumed.

The compact-net contribution is displayed by K, E, C, L, while S supplies the finite density handoff. The rows M, Q, A then attach completion-facing metric reads, RegSeqRat and DyadicRatCore comparison data, and the terminal Real seal to the same finite cover test.

Only after this route is visible may the order ledger O be exported. Transport, replay, provenance, and local naming through H, T, P, N preserve the same handoff, and the missing selected-dense-set, selected-subcover, quotient, host-dimension, and ambient-completeness objects cannot be read from the carrier. □

Theorem 1853.89 (Covering dimension finite-cover obligations)**.** *Let* $D = (K, E, C, R, O, L, H, T, P, N)$ *be an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet. Every finite-cover obligation exported by* D *must first display the* $\mathsf{CompactMetric}^{\uparrow}$ *source row* K*, the* $\mathsf{Met}^{\uparrow}$ *observation route carried by that source, the finite cover row* C*, the refinement row* R*, the order-bound row* O*, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *transport, replay, provenance, and naming rows* H, T, P, N*. If the obligation is read by* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$*, those rows are inserted as finite cover-support rows before the order-bound export and not as ambient compactness or completeness principles.*

Proof. Project the accepted carrier. The rows K, E, C, R, O, L are the finite compact-metric cover, finite-net, refinement, order, and compact-cover ledger rows already present in the $\mathsf{CoveringDimension}^{\uparrow}$ packet.

The metric and downstream support rows are read before export. A $\mathsf{Met}^{\uparrow}$ observation is available only through the compact metric source row, while $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$,

and $\mathsf{MetricCompletion}^{\uparrow}$ supply finite density, finite net, or completion-facing support rows attached to the same cover.

Finally, H, T, P, N transport, replay, source, and name the same finite packet. Since arbitrary open-cover compactness, selected limits, host equality, and ambient completeness are not carrier coordinates, the finite-cover obligation cannot escape the displayed route. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverObligations`

Theorem 1853.90 (Covering dimension Real-separability refinement)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *refinement read of an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet is stable only as a finite-cover route through*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{RealSeparability}^{\uparrow},\ C,\ R,\ O,\ L,\ H,\ T,\ P,\ N.$$

The refinement may tighten finite cover members and rational or dyadic density windows, but it must preserve the same compact metric source, finite epsilon-net support, refinement membership row, order-bound ledger, compact-cover ledger, and local naming surface. It exports no selected dense sequence, arbitrary open cover, quotient point equality, host dimension theorem, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Start with Definition 1853.89. It places compact metric source data, metric observations, finite cover rows, refinement membership, and order ledgers before any downstream refinement can be consumed.

Read the Real-separability route as finite density data. The $\mathsf{RealSeparability}^{\uparrow}$ rows may refine rational or dyadic windows, but the compact metric source K and finite epsilon-net row E remain the cover support used by C, R, O, L.

The structural rows H, T, P, N preserve this cover route under componentwise transport and displayed replay. Because no selected dense sequence, arbitrary open cover, quotient point equality, host theorem, selected limit, or ambient completeness row is present, refinement stability is exactly the finite route stated above. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityRefinement`

Theorem 1853.91 (Covering dimension compact-net order route)**.** *Every compact-net order read of an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet must pass through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *support rows before a finite cover order bound is exported. The order row may be consumed only after the finite cover row, refinement row, compact-cover ledger, completion-facing metric row, density row, transport row, replay row, provenance row, and local* NameCert *row have been displayed. The route supplies carrier admission and refinement stability, and it does not import open-cover compactness, selected subcovers, selected limits, host equality, quotient completion, or ambient Real completeness.*

Proof. Use the finite-cover obligations of Definition 1853.89. They expose the compact metric source, metric observations, finite cover, refinement row, order ledger, and structural rows as the carrier boundary.

Insert the compact-net support. The $\mathsf{FiniteEpsilonNet}^{\uparrow}$ row supplies finite centers and coverage witnesses, while the $\mathsf{RealSeparability}^{\uparrow}$ row supplies finite density windows; both are read before the order row is public.

For completion-facing consumers, read the $\mathsf{MetricCompletion}^{\uparrow}$ row as displayed metric support for the same finite cover route. It does not add a completed point or quotient completion coordinate.

The order export is therefore downstream of the finite cover, compact-net, separability, completion, transport, replay, provenance, and naming rows. Since the excluded host and choice objects have no carrier slot, the route remains inside finite-cover compactness and selected-limit nonescape. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetOrderRoute`

Definition 1853.92 (CoveringDimension compact net order carrier)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet, the compact-net order carrier is the finite subpacket*

$$O_{\mathrm{net}} = (K, M, E, U, R, Q, S, A, H, T, P, N)$$

where K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* M *is the* $\mathsf{Met}^{\uparrow}$ *distance-read ledger,* E *is the finite compact-net cover support,* U *is the uniform radius table,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row,* Q *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* S *is the finite nerve row, and* A *is the order table counting displayed overlap rows. The structural rows* H, T, P, N *are the componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows.*

The carrier has no coordinate for arbitrary open-cover compactness, ambient dimension theory, choice-selected subcovers, or host topological refinement.

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetOrderCarrier`

Theorem 1853.93 (CoveringDimension compact net order admission)**.** *Every compact-net order read admitted by* $O_{\mathrm{net}} = (K, M, E, U, R, Q, S, A, H, T, P, N)$ *must be generated from the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *row* K*, the* $\mathsf{Met}^{\uparrow}$ *distance ledger* M*, the finite net support* E*, and the uniform radius table* U*. The exported order count is then replayed through* R, Q, S, A, H, T, P, N *and cannot be replaced by an arbitrary compactness theorem or a choice-selected refinement.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetOrderAdmission`

Proof. Project the read to the compact metric row K and the metric ledger M. These rows are the only sources from which distances and bounded cover tests can be read.

Next consume the finite net support E and uniform radius table U. The regular rational and Real seal rows R, Q compare the displayed radii and distances without selecting a new cover.

Finally replay nerve incidence through S and consult the order table A. The transport, replay, provenance, and naming rows H, T, P, N preserve that same finite route, so the admitted order count remains compact-net data. □

Theorem 1853.94 (CoveringDimension RealSeparability cover pullback)**.** *Any* $\mathsf{RealSeparability}^{\uparrow}$ *cover pullback used by the compact-net order carrier must pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row* R *and the* $\mathsf{Real}^{\uparrow}$ *source seal row* Q *before it reads the finite net support* E*, the uniform radius table* U*, the nerve row* S*, and the order table* A*. The pullback therefore records a displayed cover schedule, not a countable-choice enumeration, quotient stream equality, or ambient separability theorem.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityCoverPullback`

Proof. Begin with the Real-facing comparison rows R, Q. They provide only regular rational comparisons and terminal Real seal checks for the finite cover tests.

The cover itself is then pulled back to the compact-net rows E, U over the compact metric and metric ledgers K, M. This pins each cover member to a displayed radius and a displayed source row.

Use the nerve and order rows S, A to replay the overlap count. Since the carrier lacks coordinates for countable choice, quotient stream equality, and ambient separability, the RealSeparability consumer receives only the finite cover schedule carried by O_{net}. □

Theorem 1853.95 (CoveringDimension compact net order scope)**.** *For an accepted compact-net order carrier*

$$O_{\mathrm{net}} = (K, M, E, U, R, Q, S, A, H, T, P, N),$$

any order count read from O_{net} is scoped by the displayed $\mathsf{CompactMetric}^{\uparrow}$ *row K, the* $\mathsf{Met}^{\uparrow}$ *distance ledger M, the finite net support E, the uniform radius table U, the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal Q, the finite nerve row S, and the order table A. The structural rows H, T, P, N may transport, replay, source, and name that finite route, but they do not promote the count to arbitrary open-cover dimension theory.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetOrderScope`

Proof. Project the carrier of Definition 1853.92. The compact metric, metric, finite-net, uniform-radius, regular rational, Real, nerve, and order rows are all displayed entries of O_{net}.

Apply Definition 1853.93. It forces the order read to be generated from K, M, E, U before the replay rows R, Q, S, A, H, T, P, N expose the count.

Finally use Definition 1853.94. The Real-facing comparison remains on the finite route through R, Q, E, U, S, A, so the carrier supplies a compact-net order count rather than an ambient open-cover dimension theorem. □

Theorem 1853.96 (CoveringDimension cover refinement monotonicity)**.** *Let $D = (K, E, C, R, O, L, H, T, P, N)$ be an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier and let C' be a displayed finite refinement row read from the same* BHist *packet through the finite cover order carrier of Definition 1853.78. If every member of C' names a parent in C, every containment witness is a compact-cover or* MetricDistanceWitness *row transported by H, and the order table of C' is bounded by the displayed order ledger O, then replacing C by C' is monotone for the local NameCert ledger: no accepted read can increase the exported finite cover order or escape the* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *rows.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCoverRefinementMonotonicity`

Proof. Project the root carrier of Definition 1853.55 and the finite order carrier of Definition 1853.78. The only cover rows visible to a refinement consumer are the displayed BHist cover entries, their compact-metric source rows, and the metric containment witnesses.

The refinement map names a parent for every refined member before the order table is read. Thus each overlap counted for C' is already attached to a row counted by O, and componentwise hsame transport only replays the same containment witnesses.

Finally apply the finite-cover order non-escape route of Definition 1853.80. Since there is no coordinate for a host refinement theorem, selected open subcover, or external multiplicity oracle, the refined cover preserves the displayed order bound and remains inside the local NameCert ledger. □

Theorem 1853.97 (CoveringDimension Lebesgue-ledger stability)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier $D = (K, E, C, R, O, L, H, T, P, N)$, suppose a finite cover read uses a compact-cover Lebesgue ledger row L' whose positive-radius and containment entries are* hsame*-transported from L and whose compact-cover rows are read through K, E, C, R. Then the finite cover order exported by O*

is stable under replacing L by L': the accepted read still factors through compact metric admission, finite cover order, displayed replay, Pkg *provenance, and the same* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *nonescape boundary.*

Proof. Start with the Lebesgue-ledger handoff of Definition 1853.6. It places every compact-cover ledger read downstream of the compact-net root K, E and the finite cover-refinement rows C, R, O.

The transported ledger L' has the same positive-radius and containment entries as L under H. Therefore it can change only the presentation of the finite ledger row, not the compact metric source, the cover entries, the refinement parents, or the order table.

Use Definition 1853.56 to close the route. The structural rows T, P, N replay, source, and name the same finite data, so the ledger replacement cannot add arbitrary open-cover compactness, a selected dense subfamily, or a host Lebesgue-number theorem. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionLebesgueLedgerStability`

Theorem 1853.98 (CoveringDimension metric completion cover transport)**.** *Let an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier $D = (K, E, C, R, O, L, H, T, P, N)$ be read by a metric-completion consumer through the dependency route of chapter 1506 and the separability route of Definition 1853.25. If each completion-side cover member is backed by a source* BHist *cover row, a* MetricDistanceWitness *or compact-cover containment row,* hsame *transport, and the finite cover order ledger O, then completion transport preserves the CoveringDimension NameCert boundary: the consumer receives the same finite cover order and no quotient completion, selected limit, or external dimension predicate.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCarrier metric completion cover transport`

Proof. Read the compact-net refinement handoff of Definition 1853.57. It sends compact metric and metric rows into finite epsilon-net, cover, refinement, order, Real-separability, and nerve rows before the structural rows are consumed.

Metric completion can observe the transported cover only through the source BHist rows and their metric or compact-cover containment witnesses. The hsame row keeps those witnesses aligned with the source packet, while O remains the only finite order ledger.

The dependency route through chapter 1506 and the Real-separability children therefore transports a finite cover certificate, not an ambient completion theorem. Since the carrier lacks coordinates for quotient completions, selected limits, and external dimension predicates, the local $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ ledger remains nonescaping. □

Theorem 1853.99 (CoveringDimension root cover refinement tree)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier $D = (K, E, C, R, O, L, H, T, P, N)$, any root read that exports a finite cover-refinement tree must display the* BHist *root K, E, C before it displays refinement successors. Each successor row is named by R, transported by the componentwise* hsame *row H, replayed by the displayed* Cont *row T, and sourced by the same* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row N. Thus the exported tree is a finite cover-refinement object over the existing compact metric and metric rows, not a selected open-cover subtree or an external refinement theorem.*

Proof. Project the accepted carrier from Definition 1853.1. The source rows K, E, C are the only compact metric, finite-net, and finite cover rows available before refinement data are read.

The refinement row R can therefore add only named successor rows over the displayed cover C. Componentwise hsame transport through H keeps each successor attached to its parent cover row, while Cont replay through T fixes the same finite inspection route after transport.

Finally the local NameCert row N names this finite tree together with the provenance row P. Since the carrier has no coordinate for selected subcovers or host refinement theorems, every exported refinement tree remains inside the displayed BHist cover packet. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCoverRefinementTree`

Theorem 1853.100 (CoveringDimension root finite-order compatibility)**.** *Let $D = (K, E, C, R, O, L, H, T, P, N)$ be an accepted* CoveringDimension$^{\uparrow}$ *carrier. If a root refinement read exports an order bound, then the order row O is compatible with the refinement tree exactly when every counted overlap is a displayed* BHist *row whose cover parent is named by R, whose transport is supplied by H, and whose replay route is supplied by T. The order read cannot inspect a host multiplicity oracle, an arbitrary open-cover family, or quotient equality of real-valued scales.*

Proof. Read the finite cover and refinement rows through Definition 1853.99. The only members that can enter an overlap count are the displayed successor rows already attached to parents in C by R.

The order row O counts those displayed overlaps. Transport by H preserves the parent assignments and containment witnesses componentwise, and replay by T reuses the same finite read rather than opening a separate multiplicity source.

The NameCert row N therefore binds finite-order compatibility to the local carrier. No row in D stores a host overlap counter, arbitrary open-cover compactness, or quotient-real equality, so the compatibility check is the finite C, R, O, H, T, N surface. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootFiniteOrderCompatibility`

Theorem 1853.101 (CoveringDimension root Real-separability window)**.** *Every root* CoveringDimension$^{\uparrow}$ *read that reuses* RealSeparability$^{\uparrow}$ *evidence must expose a finite window*

$$K, E, C, R, O, L, H, T, P, N \longmapsto \mathsf{RealSeparability}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before the cover order is consumed by a Real-facing downstream packet. The window records rational dense reads, regular-rational scale rows, dyadic tolerance comparisons, and the terminal real seal only as support for the displayed finite cover-refinement packet; it does not claim Dedekind completeness, quotient equality of real names, or a selected dense sequence.

Lean4 ✓ `BEDC.Derived.CoveringDimensionUp.CoveringDimensionRootRealSeparabilityWindow`

Proof. Start with the local cover-refinement tree and finite-order compatibility results above. They fix the finite $K, E, C, R, O, L, H, T, P, N$ packet before any Real-facing route can consume the order bound.

The Real-separability side then supplies only displayed window evidence. The RealSeparability$^{\uparrow}$ row contributes finite dense-window reads, RegSeqRat$^{\uparrow}$ packages the scale readback, DyadicRatCore$^{\uparrow}$ supplies tolerance comparisons, and Real$^{\uparrow}$ seals the resulting read without adding an ambient completeness principle.

Because the same BHist, hsame, Cont, and NameCert rows remain visible across the handoff, the downstream consumer receives a finite cover-order window. It does not receive selected dense points, quotient equality of real names, or an external separability theorem. □

Theorem 1853.102 (CoveringDimension root finite-cover refinement obligation)**.** *Every root* CoveringDimension$^{\uparrow}$ *read that asks for a finite-cover refinement must expose its* BHist *carrier rows through the compact-metric source of chapter 129, the finite-net boundary of chapter 1767, and the*

local root finite-cover siblings already routed by the hub. The resulting $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row is transported by* hsame *and replayed by* Cont *before any dimension consumer may read an order-bound witness.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootFiniteCoverRefinementObligation`

Proof. Project the root carrier rows recorded by the covering-dimension child files. A refinement request first reads the compact-metric source and its finite epsilon-net boundary, so the cover data are finite before a dimension classifier can inspect them.

Apply the existing root finite-cover refinement and stability siblings. They keep the refinement row inside the displayed BHist packet and make the local NameCert row the only public endpoint of the finite-cover refinement.

Finally transport and replay the same rows through hsame and Cont. Since the route has no hidden open-cover compactness or selected subcover coordinate, the order-bound witness remains a finite-cover NameCert obligation. □

Theorem 1853.103 (CoveringDimension root Lebesgue ledger obligation)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *read that consumes a Lebesgue-cover ledger must pass through the compact-cover ledger of chapter 1302, the compact-metric source of chapter 129, and the finite epsilon-net boundary of chapter 1767. The* BHist *rows, componentwise* hsame *transport, displayed* Cont *replay, and local* NameCert *row together certify only the finite ledger needed by covering dimension, not an ambient open-cover compactness theorem.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootLebesgueLedgerObligation`

Proof. Read the compact-cover Lebesgue ledger before the root dimension row. Its radius and cover entries are supplied by the compact-metric and finite epsilon-net siblings, so the ledger is a finite row in the same BHist packet.

The covering-dimension root siblings then consume that ledger as support for the order-bound classifier. This keeps the carrier, finite cover, Lebesgue radius, and local NameCert data on one displayed route.

Transport by hsame and replay by Cont preserve the finite ledger rows. Therefore a downstream dimension consumer receives the compact-cover Lebesgue ledger as a finite NameCert obligation, not as an unrestricted host compactness principle. □

Theorem 1853.104 (CoveringDimension root Real-separability window obligation)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *read that uses Real-separability window data must factor through the Real-separability sibling of chapter 1809, the compact-metric finite-cover route of chapter 129, and the finite epsilon-net route of chapter 1767. The read is transported by* hsame*, replayed by* Cont*, and named by the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row before any dimension or compact-cover consumer may use it.*

Proof. Start with the Real-separability cover-window siblings already attached to the covering-dimension hub. They supply the finite real-window data used to compare compact metric cover rows.

Use the compact-metric and finite epsilon-net siblings to bind those real windows to displayed finite-cover refinement data. The BHist carrier therefore contains the cover source, the separability window, and the dimension-facing classifier row together.

Finally apply componentwise hsame transport and displayed Cont replay. The local NameCert row names the resulting route, so no ambient separability theorem, selected dense sequence, or unrestricted Real completeness is exported. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootRealSeparabilityWindowObligation`

Theorem 1853.105 (CoveringDimension finite cover carrier obligation)**.** *Every root* CoveringDimension$^{\uparrow}$ *carrier exposes finite cover rows over the displayed* CompactMetric$^{\uparrow}$ *and* Met$^{\uparrow}$ *witnesses before any dimension read may inspect an order or refinement conclusion. In particular, the consumer must first see the compact finite-net row, the metric distance ledger, the finite* BHist *cover row, the refinement membership row, and the local* NameCert *row carried by the existing compactmetric route.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverCarrierObligation`

Proof. Read the hub route through Definition 1853.69 and Definition 1853.64. These place the compact metric source, finite-net row, metric distance ledger, finite cover row, refinement row, and order ledger in the displayed carrier before any dimension-facing consumer reads a bound.

The structural rows then preserve the same route. Componentwise hsame transport keeps the compact and metric witnesses attached to the finite cover rows, displayed Cont replay fixes the order of the read, and the local NameCert row names only that finite surface. □

Theorem 1853.106 (CoveringDimension Real separability scale obligation)**.** *Every scale-refinement read in a* CoveringDimension$^{\uparrow}$ *packet that touches Real-facing data must pass through the displayed* RealSeparability$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* DyadicRatCore$^{\uparrow}$ *tolerance rows before the finite cover order is consumed. The scale row may refine cover radii and rational dense windows, but it may not replace the finite cover carrier by a host separability theorem or an ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRealSeparabilityScaleObligation`

Proof. Use the Real-separability route of Definition 1853.26 together with the metric-completion cover route of Definition 1853.38. These routes display rational dense windows, dyadic tolerance comparisons, and regular-rational seal rows before cover refinement and order-bound rows are read.

The same finite carrier is preserved by the BHist and Cont rows. Since the scale rows are downstream of the metric ledger and upstream of the finite order read, they cannot introduce a separate separability oracle, selected dense subfamily, or ambient Real completeness export. □

Theorem 1853.107 (CoveringDimension compactmetric non-escape obligation)**.** *The* CoveringDimension$^{\uparrow}$ *packet does not export open-cover compactness, choice-selected refinements, or host topological dimension. Its compactmetric-facing export is limited to displayed compact finite-net rows, metric distance ledgers, finite* BHist *cover entries, refinement memberships, order rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactMetricNonescapeObligation`

Proof. Inspect the compactmetric and metric routes already named by the hub. The finite cover admission, compact-net dependency, and finite-cover order non-escape results keep compactness, refinement, and order data inside the displayed carrier rows.

No row in that carrier names arbitrary open-cover compactness, a selected refinement outside the finite BHist cover, or a host topological-dimension theorem. The structural rows transport and replay only the finite packet, so every downstream read remains inside the CoveringDimension NameCert surface. □

Theorem 1853.108 (CoveringDimension compact-net cover root route)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *cover read over an accepted carrier*

$$D = (K, E, C, R, O, L, H, T, P, N)$$

must expose the compact finite-net route

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow} \longmapsto K, E \longmapsto C, R, O, L \longmapsto H, T, P, N$$

before a dimension-bound consumer may inspect the order row. The rows $K, E, C, R, O, L, H, T, P, N$ *are the complete finite cover route:* K, E *expose compact metric and metric finite-net data,* C, R, O *expose cover membership, refinement, and order,* L *exposes the* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *support, and* H, T, P, N *transport, replay, source, and name the same packet.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootCompactNetCoverRoute`

Proof. Start with the compactmetric non-escape obligation, Definition 1853.107. It keeps compactness and metric information inside the displayed finite carrier rows rather than in an ambient open-cover principle.

Then read the finite cover carrier obligation, Definition 1853.105. It places K, E before C, R, O, so the order row cannot be consumed before compact finite-net and metric evidence are visible.

Finally use the Lebesgue-ledger dependency already carried by L. Since H, T, P, N only transport, replay, source, and name the packet, the resulting root route is the displayed finite chain through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$. □

Theorem 1853.109 (CoveringDimension refinement-order root route)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier* $D = (K, E, C, R, O, L, H, T, P, N)$*, the refinement-order read is available only along the displayed route*

$$K, E, C, R, \mathsf{CompactCoverLebesgueLedger}^{\uparrow}, O, L, H, T, P, N.$$

In particular, a consumer must read the finite cover row C*, the refinement membership row* R*, the order-bound row* O*, and the compact-cover ledger* L *as one packet after the* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *source rows have been displayed, and before any* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *completion-facing route may reuse the bound.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootRefinementOrderRoute`

Proof. Project the carrier coordinates. The refinement data are not a separate theorem: they are the rows C, R, O, L of the accepted packet, downstream of K, E and upstream of the structural rows.

Apply Definition 1853.108. It supplies the compact finite-net and metric prefix required before C, R, O, L can be read.

The completion-facing siblings may consume the order only after this local refinement route is fixed. Thus $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ receive a finite refinement-order packet, not an external order oracle or selected refinement. □

Theorem 1853.110 (CoveringDimension Real-separability completion root route)**.** *Any root* $\mathsf{CoveringDimension}^{\uparrow}$ *read that reaches Real-facing completion data must factor through*

$$K, E, C, R, O, L, H, T, P, N \longmapsto \mathsf{MetricCompletion}^{\uparrow}, \mathsf{RealSeparability}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The first segment is the finite cover-refinement packet over $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{CompactCoverLebesgueLedge}$ *the second segment supplies only completion-facing metric rows, finite rational or dyadic density windows, regular-rational readback, dyadic tolerance checks, and terminal real seals.*

Proof. Begin with the scale obligation, Definition 1853.106. It places $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before a Real-facing scale read may consume the finite cover order.

Next use Definition 1853.109. That theorem fixes the local packet $K, E, C, R, O, L, H, T, P, N$ before any completion-facing consumer reuses the bound.

The $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows therefore receive only the displayed finite route. They cannot introduce arbitrary open-cover compactness, selected dense points, quotient completion equality, selected refinements, host dimension data, or ambient real completeness. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootRealSeparabilityCompletionRoute`

Theorem 1853.111 (CoveringDimension root obligation surface)**.** *Every root* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer over an accepted packet* $D = (K, E, C, R, O, L, H, T, P, N)$ *must read a finite obligation surface with rows over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *finite* BHist *covers,* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$. *The rows* H, T, P, N *then preserve the same surface by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming; no root consumer may replace the surface by open-cover compactness, selected refinement, host simplicial realization, or ambient separability.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootObligationSurface`

Proof. Project the accepted packet. The compactmetric and metric prefix gives K, E, the finite cover and refinement rows give C, R, O, and the Lebesgue ledger gives L before any completion-facing or nerve-facing read occurs.

The completion-facing rows are only consumers of that finite prefix. They may attach $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ scale data, but they do not create a second cover carrier or a selected dense subcover.

Finally read the structural rows H, T, P, N. They transport, replay, source, and name the same finite surface, so the visible obligation set is exactly the displayed CoveringDimension packet. □

Theorem 1853.112 (CoveringDimension finite cover ledger)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet, the finite cover ledger is the ordered BEDC row*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{BHist}, \mathsf{CompactCoverLebesgueLedger}^{\uparrow}, \mathsf{RealSeparability}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, H, T, P$$

It records finite cover entries, refinement membership, order bounds, rational or dyadic scale windows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row before the dimension bound is exported.*

Proof. Start from Definition 1853.109. It fixes the finite rows K, E, C, R, O, L before the order bound can be read by any downstream consumer.

Then apply the Real-separability completion route of Definition 1853.110. The rational and dyadic scale rows are attached after the finite cover ledger, so they refine the scale of the same cover rather than replacing it.

The structural rows H, T, P, N preserve ledger identity. Thus the export is a finite cover ledger over displayed compactmetric, metric, rational, dyadic, transport, replay, provenance, and naming data. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverLedger`

Theorem 1853.113 (CoveringDimension compact-net obligation surface)**.** *Every* CoveringDimension$^{\uparrow}$ *root obligation surface that exports a dimension-bound consumer must first read* CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactCoverLebesgueLedger$^{\uparrow}$, *and the local finite cover, refinement, and order rows. The exposed consumer is a finite packet over those rows together with the displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data; it is not a host compactness theorem, selected refinement principle, ambient dimension predicate, or completion witness.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionCompactNetObligationSurface`

Proof. Begin with Definition 1853.105. It fixes the local finite cover carrier and the transport, replay, provenance, and naming rows before any dimension-bound surface is exported.

Apply the compact-net cover route of Definition 1853.108. This supplies the FiniteEpsilonNet$^{\uparrow}$ row as a finite cover witness read from the same CompactMetric$^{\uparrow}$ and Met$^{\uparrow}$ source rows.

Next use Definition 1853.109. The refinement membership and order rows are attached to the compact-net cover rather than chosen outside the packet.

Finally apply Definition 1853.110. The rational, dyadic, and completion-facing scale rows consume the finite cover/refinement/order surface, so the resulting dimension-bound consumer remains a displayed BEDC packet over the listed rows. □

Theorem 1853.114 (CoveringDimension simplicial nerve handoff)**.** *If a* CoveringDimension$^{\uparrow}$ *consumer hands a finite cover bound to* SimplicialComplex$^{\uparrow}$, *the handoff must pass through the finite* BHist *cover row, the* CompactCoverLebesgueLedger$^{\uparrow}$ *refinement-order ledger, the* CompactMetric$^{\uparrow}$ *and* Met$^{\uparrow}$ *source rows, the* RealSeparability$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* DyadicRatCore$^{\uparrow}$ *scale rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The nerve row receives only this finite packet and does not receive host open-cover compactness, selected vertices, or ambient topological dimension.*

Proof. Read the root obligation surface of Definition 1853.111. It exposes the finite cover, refinement, order, scale, transport, replay, provenance, and naming rows before any downstream handoff is available.

Now restrict the downstream consumer to the nerve route. The SimplicialComplex$^{\uparrow}$ row may read cover incidences and finite intersection data from the same BHist cover ledger, but it has no coordinate for selected vertices outside the packet or for an ambient realization theorem.

Therefore the handoff is finite and constructive. It is a consumer route from the displayed CoveringDimension ledger to the displayed simplicial-complex packet, not a separate compactness or dimension principle. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionSimplicialNerveHandoff`

Definition 1853.115 (CoveringDimension finite-refinement carrier)**.** *A root finite-refinement carrier for* CoveringDimension$^{\uparrow}$ *is the accepted packet*

$$D = (K, E, C, R, O, L, S, M, A, G, H, T, P, N)$$

whose visible rows extend the root cover ledger by finite downstream handoff data. The rows K and E are the CompactMetric$^{\uparrow}$ *and* Met$^{\uparrow}$ *source rows; C is the finite cover row; R records refinement membership; O is the finite order-bound row; L is the* CompactCoverLebesgueLedger$^{\uparrow}$ *support row; S is the* SimplicialComplex$^{\uparrow}$ *nerve handoff row; M is the* MetricCompletion$^{\uparrow}$ *consumer row; A, G are the* RealSeparability$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* DyadicRatCore$^{\uparrow}$ *scale windows grouped as finite rational and dyadic data; and H, T, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert$_{\text{CoveringDimension}^{\uparrow}}$ *row.*

The carrier admits only finite cover rows, finite refinement memberships, finite order bounds, finite scale windows, and local naming rows. It has no coordinate for arbitrary open-cover compactness, selected refinements, a host dimension predicate, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteRefinementCarrier`

Theorem 1853.116 (CoveringDimension finite-refinement NameCert obligations)**.** *For every accepted finite-refinement carrier $D = (K, E, C, R, O, L, S, M, A, G, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^\uparrow}$ *root obligation surface first exposes* $\mathsf{CompactMetric}^\uparrow$, $\mathsf{Met}^\uparrow$, *finite cover rows, refinement membership,* $\mathsf{CompactCoverLebesgueLedger}^\uparrow$, $\mathsf{RealSeparability}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming before any order-bound export is available. The certificate surface is exactly this finite packet and does not import arbitrary open-cover compactness, selected refinement, host dimension data, or ambient completion.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteRefinementNameCertObligations`

Proof. Project the carrier of Definition 1853.115. The rows K, E, C, R, O, L are the finite cover, refinement, order, and Lebesgue-ledger rows already isolated by Definition 1853.111.

Next read the scale and completion-facing rows. By Definition 1853.110, $\mathsf{RealSeparability}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, and $\mathsf{MetricCompletion}^\uparrow$ consume the displayed finite prefix rather than replacing it by a separate completeness or separability theorem.

Finally use the structural rows H, T, P, N. They transport, replay, source, and name the same finite packet, so every root obligation remains inside the displayed carrier. □

Theorem 1853.117 (CoveringDimension finite-order handoff)**.** *If an accepted* $\mathsf{CoveringDimension}^\uparrow$ *finite-refinement packet exports an order bound to* $\mathsf{SimplicialComplex}^\uparrow$ *or* $\mathsf{MetricCompletion}^\uparrow$*, the export must pass through*

$$\mathsf{CompactMetric}^\uparrow, \mathsf{Met}^\uparrow, C, R, O, \mathsf{CompactCoverLebesgueLedger}^\uparrow, \mathsf{RealSeparability}^\uparrow, \mathsf{RegSeqRat}^\uparrow, \mathsf{DyadicRatCore}^\uparrow, H, T,$$

The $\mathsf{SimplicialComplex}^\uparrow$ *consumer receives only the finite nerve and incidence data determined by C, R, O, L, and the* $\mathsf{MetricCompletion}^\uparrow$ *consumer receives only the finite scale and rational or dyadic tolerance windows attached to the same packet. Neither handoff receives arbitrary open-cover compactness, selected refinement, a host dimension predicate, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteOrderHandoff`

Proof. Start with Definition 1853.116. It fixes the finite cover, refinement, order, scale, transport, replay, provenance, and naming rows before any order-bound export is visible.

For the simplicial route, apply Definition 1853.114. The nerve receives finite cover incidences and the finite order ledger, not selected vertices or a host realization theorem.

For the completion route, apply Definition 1853.110. The completion-facing packet receives the same finite order bound together with rational and dyadic scale windows. Thus both downstream consumers read the finite order handoff from the displayed carrier and cannot escape to arbitrary compactness, selected refinement, host dimension, or ambient completeness. □

Theorem 1853.118 (CoveringDimension root finite-cover Real-window exactness)**.** *A Real-facing root read of a* $\mathsf{CoveringDimension}^\uparrow$ *finite-cover packet is exact only when the compact finite-cover rows, refinement row, compact-cover Lebesgue ledger,* $\mathsf{RealSeparability}^\uparrow$ *window,* $\mathsf{RegSeqRat}^\uparrow$ *readback,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance row, and structural H, T, P, N rows are all visible in the same finite*

route. The read may export a finite cover bound for downstream consumers, but it cannot replace those rows by open-cover compactness, selected dense sequences, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootFiniteCoverRealWindowExactness`

Proof. Start with the Real-separability window obligation, Definition 1853.104. It places the Real-facing scale read behind the compactmetric source, finite cover rows, regular-rational readback, dyadic tolerance, and structural route.

Next apply the finite-cover ledger, Definition 1853.112. The ledger binds the compact finite-cover rows, refinement row, compact-cover Lebesgue ledger, and finite order data before any downstream order-bound export is available.

Finally use the Real-separability completion route, Definition 1853.110. It keeps the Real-window, RegSeqRat readback, DyadicRatCore tolerance, and completion-facing rows attached to the same finite cover packet.

The exactness claim is therefore an inventory statement over the displayed carrier. Since the route already accounts for compact finite covers, refinement, Lebesgue-ledger support, Real-separability windows, rational and dyadic readback, and H, T, P, N, no open-cover compactness theorem, selected dense sequence, or ambient Real-completeness principle can be introduced by the root read. □

Definition 1853.119 (CoveringDimension finite-cover root)**.** *A finite-cover root for* $\mathsf{CoveringDimension}^{\uparrow}$ *is the displayed carrier*

$$R = (K, C, A, M, D, Q, G, H, T, P, N)$$

where K *is a* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* C *is a finite* BHist *cover and refinement row,* A *is the* $\mathsf{RealSeparability}^{\uparrow}$ *scale-admission row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-facing row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* G *is the finite local NameCert row family for cover membership and order, and* H, T, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row.*

The carrier admits only displayed finite covers, displayed refinements, finite scale windows, completion-facing metric rows, dyadic and regular-rational readback, and local naming data. It has no coordinate for arbitrary open-cover compactness, selected refinements, host separability, quotient completion equality, or ambient dimension.

Lean4 (definition) `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootCarrier`

Theorem 1853.120 (CoveringDimension finite-cover root admission)**.** *Every accepted finite-cover root* $R = (K, C, A, M, D, Q, G, H, T, P, N)$ *for* $\mathsf{CoveringDimension}^{\uparrow}$ *admits a root obligation surface only after the* $\mathsf{CompactMetric}^{\uparrow}$ *source, finite cover row,* $\mathsf{RealSeparability}^{\uparrow}$ *scale row,* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and local NameCert rows have all been displayed. The admitted surface is the finite BEDC packet of Definition 1853.119, not an external compactness, separability, completion, or dimension theorem.*

Proof. Project the carrier of Definition 1853.119. The rows K, C, A, M, D, Q, G are exactly the compact source, finite cover, scale, completion, dyadic, regular-rational, and local naming rows.

Apply the root obligation surface theorem Definition 1853.111. It already forces every root consumer to read the compactmetric source, finite cover ledger, Real-separability scale rows, regular-rational and dyadic readback, and local naming before a dimension bound is exported.

Finally read the finite-refinement NameCert obligations of Definition 1853.116. They repack the same finite rows through H, T, P, N, so the admission is the displayed packet and no external theorem enters the root surface. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootAdmission`

Theorem 1853.121 (CoveringDimension finite-cover root stability)**.** *Let* $R = (K, C, A, M, D, Q, G, H, T, P, N)$ *and* $R' = (K', C', A', M', D', Q', G', H', T', P', N')$ *be accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *finite-cover roots. If componentwise* hsame *transport identifies the* $\mathsf{CompactMetric}^{\uparrow}$*, finite cover,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and local NameCert rows of* R *with the corresponding rows of* R'*, then the admitted finite-cover root obligation surface is stable under that transport.*

Proof. Begin with finite-cover root admission for R. It identifies the admitted obligation surface as the displayed rows $K, C, A, M, D, Q, G, H, T, P, N$ and excludes external compactness, selected refinement, host separability, and quotient completion data.

Use the componentwise hsame hypotheses to transport the compactmetric, cover, scale, completion, dyadic, regular-rational, and local naming rows to R'. The structural rows H', T', P', N' replay and name the transported packet.

Apply Definition 1853.117. Downstream $\mathsf{SimplicialComplex}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ consumers receive only the same finite order handoff, so the root obligation surface remains stable under the displayed transport. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionFiniteCoverRootStability`

Theorem 1853.122 (CoveringDimension root metric-real window)**.** *For every accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *carrier, any root cover read that touches a metric-real window must expose finite* BHist *cover rows, the displayed* $\mathsf{Met}^{\uparrow}$ *distance ledger, the* $\mathsf{CompactMetric}^{\uparrow}$ *cover window, the* $\mathsf{RealSeparability}^{\uparrow}$ *finite density row, and the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row before a dimension-order conclusion is consumed. The route may refine a finite cover by rational or dyadic scale windows, but it may not replace the displayed carrier by open-cover compactness, an arbitrary dense subset, a selected refinement, or an ambient topological-dimension theorem.*

Proof. Start with the finite-refinement carrier of Definition 1853.115. It displays the compactmetric source, metric ledger, finite cover row, refinement membership row, order row, simplicial handoff row, and Real-facing scale windows in one packet.

Apply the root obligation surface of Definition 1853.111. That theorem forces the compactmetric, metric, finite cover, Real-separability, rational, dyadic, and simplicial rows to remain visible before a root consumer reads the order bound.

The structural rows then preserve the same finite window. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming do not add an open-cover compactness oracle, selected dense subset, selected refinement, or host dimension predicate. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootMetricRealWindow`

Theorem 1853.123 (CoveringDimension root simplicial-cover handoff)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *root handoff from a finite cover window to* $\mathsf{SimplicialComplex}^{\uparrow}$ *must pass through the finite* BHist *cover row, refinement-membership row, order-bound row,* $\mathsf{CompactMetric}^{\uparrow}$ *cover window,* $\mathsf{Met}^{\uparrow}$ *distance ledger,* $\mathsf{RealSeparability}^{\uparrow}$ *finite density row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CoveringDimension}^{\uparrow}}$ *row. The* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row receives only finite cover incidence and order data; it does not receive host realization data, selected vertices outside the carrier, arbitrary compactness, or ambient dimension information.*

Proof. First read the simplicial nerve handoff of Definition 1853.114. It identifies the finite cover incidences and order ledger as the only data exported to the simplicial consumer.

Next use Definition 1853.122. The metric and Real-separability windows are already attached to the finite cover packet before the nerve row is read, so the handoff does not create a second cover carrier.

Finally repack the handoff through the structural rows H, T, P, N named in the root packet. Since the packet contains no coordinate for selected vertices, host realization, arbitrary compactness, or ambient dimension, the simplicial consumer receives exactly the finite cover handoff stated above. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootSimplicialCoverHandoff`

Theorem 1853.124 (CoveringDimension root dimension ledger exactness)**.** *For an accepted* $\mathsf{CoveringDimension}^{\uparrow}$ *packet, the root dimension ledger is exact only when the order-bound row is read after the finite* BHist *cover row, the refinement-membership row, the* $\mathsf{CompactMetric}^{\uparrow}$ *cover window, the* $\mathsf{Met}^{\uparrow}$ *distance ledger, the* $\mathsf{RealSeparability}^{\uparrow}$ *finite density row, and the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row have all been displayed. Any downstream Real, completion, or simplicial consumer may reuse that ledger only as the same finite packet with* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming still attached.*

Proof. Project the finite-refinement NameCert obligations in Definition 1853.116. They place the cover, refinement, order, scale, transport, replay, provenance, and naming rows inside one accepted carrier.

Use the metric-real window theorem to fix the metric, compactmetric, and Real-separability prefix. Use the simplicial-cover handoff theorem to fix the nerve-facing read. Together these results leave the order-bound row as a ledger coordinate of the same finite carrier rather than an external dimension theorem.

The downstream consumers only replay that coordinate. Real-facing and completion-facing rows may attach scale windows to the finite order read, and simplicial rows may read the nerve incidence, but neither route can detach the ledger from the displayed BHist packet or replace it by ambient compactness, selected refinement, or host dimension data. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootDimensionLedgerExactness`

Theorem 1853.125 (CoveringDimension root metric-real window separation)**.** *An accepted finite cover packet for* $\mathsf{CoveringDimension}^{\uparrow}$ *cannot read a dimension ledger until the* $\mathsf{Met}^{\uparrow}$ *distance window,* $\mathsf{Real}^{\uparrow}$ *separability scale, compact-net row, and simplicial-cover handoff have all been displayed in the same finite* BHist *route. The route exports no second cover carrier, host real equality, open-cover compactness theorem, selected refinement, or quotient representative.*

Proof. First apply the root metric-real window theorem Definition 1853.122. It fixes the $\mathsf{Met}^{\uparrow}$ distance ledger, $\mathsf{CompactMetric}^{\uparrow}$ cover window, and $\mathsf{RealSeparability}^{\uparrow}$ finite density row before any dimension-order conclusion is consumed.

Next apply the root simplicial-cover handoff Definition 1853.123. The simplicial consumer receives only finite cover incidence and order data from the displayed packet, so it cannot introduce a second cover carrier.

Finally apply dimension ledger exactness Definition 1853.124. The order-bound row is read only after the finite cover, refinement-membership, metric-real, compact-net, and simplicial rows are already present. Projecting those shared finite rows leaves no coordinate for host real equality, open-cover compactness, selected refinement, quotient representatives, or a detached dimension theorem. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootMetricRealWindowSeparation`

Theorem 1853.126 (CoveringDimension root Real-separability scale budget)**.** *Every accepted* CoveringDimension$^{\uparrow}$ *finite-cover packet that consumes* RealSeparability$^{\uparrow}$ *must expose the finite density scale row before the simplicial nerve and dimension-order ledger are read. The scale budget is transported by* hsame *and replayed by* Cont *through the same root packet; it cannot be replaced by an arbitrary dense subset, an open-cover compactness theorem, host real equality, or a quotient representative.*

Proof. Apply the root metric-real window theorem Definition 1853.122. It places the RealSeparability$^{\uparrow}$ finite density row in the finite cover packet before a dimension-order conclusion is consumed.

Use the root simplicial-cover handoff Definition 1853.123. The simplicial nerve receives only finite cover incidence and order data after the displayed metric-real and separability rows are already present.

Apply root dimension ledger exactness, Definition 1853.124, together with root metric-real window separation, Definition 1853.125. These theorems keep the order-bound ledger attached to the same finite BHist route and rule out a second cover carrier, host real equality, compactness shortcut, selected refinement, or quotient representative.

The structural rows then preserve the scale budget. Componentwise hsame transport and displayed Cont replay carry the same finite density row forward, so a consumer cannot substitute an arbitrary dense subset for the RealSeparability$^{\uparrow}$ scale row. □

Lean4 ✓ `BEDC.Derived.CoveringdimensionUp.CoveringDimensionRootRealSeparabilityScaleBudget`

Chapter 1854

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ packet records the finite BEDC route by which displayed Cauchy data and an explicit modulus determine a regular observation schedule. It consumes the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the Cauchy-sequence boundary of chapter 406, and the terminal Real seal of chapter 38. The packet names explicit modulus-based subsequence extraction as displayed certificate data, not as a host subsequence function, countable-choice schedule, selected limit, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 1854.1 (Cauchy subsequence extraction carrier)**.** *A* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, M, D, I, W, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only finite windows of the Cauchy input stream.*
2. *M is the explicit Cauchy/modulus row. It records the displayed tolerance request and the stage after which all later source windows satisfy that request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the dyadic radii, slack comparisons, and budget transfers used by the modulus and extracted windows.*
4. *I is the increasing index schedule. It is a finite unary trace whose entries are checked to be strictly later and to dominate the stage demanded by M for each displayed tolerance.*
5. *W is the extracted finite-window ledger, pairing each selected index in I with the source window in S and the dyadic tolerance entry in D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff assembled from the extracted windows and the same dyadic tolerance ledger.*
7. *H records componentwise* hsame *transport for the source windows, modulus row, dyadic ledger, index schedule, extracted windows, regular readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite extraction request through $S, M, D, I, W, R, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, D, I, W, R, H, C, P, N$. It has no coordinate for a host subsequence function, countable-choice selector, selected limit, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchySubsequenceExtractionUp.CauchySubsequenceExtractionTasteGate single carrier alignment`

Theorem 1854.2 (Cauchy subsequence extraction obligation surface)**.** *For every accepted* CauchySubsequenceExtra *carrier*

$$E = (S, M, D, I, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source stream windows, explicit Cauchy/modulus row, dyadic tolerance ledger, increasing index schedule, extracted window ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *modulus exposure, requiring each finite extraction request to project the displayed Cauchy/modulus row M before reading a selected source window;*
3. *dyadic budget compatibility, requiring the tolerance entry in D used by M to be the same entry consumed by the extracted window ledger W and the regular readback R;*
4. *schedule monotonicity, requiring I to be a finite increasing unary trace whose chosen indices dominate the displayed modulus stage for the relevant tolerance;*
5. *extracted-window exactness, requiring W to pair only windows from S with indices admitted by I and tolerances recorded in D;*
6. *regular handoff, requiring R to be assembled from the extracted windows and tolerance ledger rather than from a detached stream representative;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no host subsequence function, countable-choice selector, selected limit, quotient equality, ambient Real-completeness datum, Lean credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 1854.1. The analytic rows are exactly the source windows S, modulus row M, dyadic ledger D, increasing index schedule I, extracted window ledger W, and regular readback row R.

The modulus and dyadic obligations are row-local. A finite extraction request must first read M, and the tolerance entry it names is the same dyadic budget recorded in D for the extracted windows and the downstream regular readback.

Schedule monotonicity is read from I. Since I is a finite unary trace inside the packet, the certificate checks increasingness and domination of the displayed modulus stage without selecting an infinite subsequence function.

Extracted-window exactness and the regular handoff are the projections to W and R. The ledger W can pair only indices admitted by I with source windows from S, and R is assembled from those displayed windows under the same tolerance data.

The remaining rows are structural. Componentwise transport, continuation replay, provenance, and the local name preserve only the displayed packet rows, so no excluded host selector, selected limit, quotient equality, ambient completeness claim, Lean credential, or bridge credential can enter the local surface. □

Theorem 1854.3 (Cauchy subsequence extraction regular window bound)**.** *Let $E = (S, M, D, I, W, R, H, C, P, N)$ be an accepted* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *carrier. For every displayed dyadic tolerance request in D, each extracted window in W whose selected index is admitted by I and dominates the corresponding stage of M is bounded by the same regular tolerance budget used by the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R.*

Proof. Fix a displayed dyadic tolerance request in D. The carrier admits no tolerance row other than D, so both the modulus row and the extracted-window ledger must read the same budget.

The row M supplies the stage after which the source stream windows meet the requested Cauchy bound. The row I supplies a finite increasing trace whose selected entry dominates that stage.

Now project W. Each extracted window recorded in W is paired with an admitted index from I and with the same dyadic tolerance entry from D, so the Cauchy bound supplied by M applies to that extracted window.

Finally project R. The regular rational handoff is assembled from the extracted windows and tolerance ledger already read by W, hence it uses exactly the same regular budget and cannot tighten or replace it through a detached representative. □

Theorem 1854.4 (Cauchy subsequence extraction RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *carrier*

$$E = (S, M, D, I, W, R, H, C, P, N)$$

factors through the finite chain

$$S \longmapsto M \longmapsto D \longmapsto I \longmapsto W \longmapsto R$$

before it can inspect the structural rows H, C, P, N. Consequently the handoff exports finite stream windows, an explicit modulus row, dyadic tolerance data, an increasing index schedule, extracted windows, and a regular rational readback, but no host subsequence function, countable-choice selector, selected limit, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$-facing read of the accepted packet. The source surface available to the read is the finite stream-window row S.

The request then projects M and D. These rows display the Cauchy/modulus stage and the dyadic tolerance ledger that the extracted schedule must respect.

The increasing schedule I is consumed next. It supplies only a finite unary trace, so the read obtains selected positions for the displayed request without importing a host subsequence function or countable-choice selector.

The extracted-window ledger W pairs those selected positions with source windows and dyadic tolerances. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is assembled from that ledger, and no coordinate allows a detached stream representative or quotient equality to replace it.

Only after this chain has been read may the structural rows H, C, P, N transport, replay, source, and name the packet. They preserve the same displayed route and do not export selected limits or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtraction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1854.1, Definition 1854.2, Definition 1854.3, and Definition 1854.4 seed the finite explicit-modulus extraction route from stream windows through dyadic tolerances, increasing schedules, extracted windows, and RegSeqRat readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtraction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchySubsequenceExtractionUp.CauchySubsequenceExtractionTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close host subsequence functions, countable choice, selected limits, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exposure, dyadic budget compatibility, schedule monotonicity, extracted-window exactness, regular-window bounds, RegSeqRat handoff, and non-escape proofs for BEDC.Derived.CauchySubsequenceExtractionUp.

Constructive story: A $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ packet is generated from source StreamName windows, an explicit Cauchy/modulus row, a DyadicRatCore tolerance ledger, an increasing index schedule, extracted finite windows, a RegSeqRat handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1855

StreamMap NameCert Construction

Following Bishop and Bridges, the $\mathsf{StreamMap}^{\uparrow}$ packet records the finite pointwise route by which a certified countable name is mapped to another certified countable name before any regular rational or real-facing consumer reads the result. It sits after the finite window classifier of chapter 126, the tail-window handoff of chapter 301, the dyadic tolerance ledgers of chapter 291, and the terminal real-name seal of chapter 38. The packet names the map surface itself; it does not assert quotient stream equality, host function extensionality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1855.1 (Stream map carrier)**.** *A* $\mathsf{StreamMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, T, F, W, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *classifier row, exposing only finite source windows and their pointwise name cells.*
2. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *classifier row, exposing only finite target windows and their pointwise name cells.*
3. *F is the point-map row, assigning each displayed source cell in a requested window to the corresponding displayed target cell.*
4. *W records the finite-window output observations produced by F from S and consumed by T.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-window handoff row attached to the same source and target windows when a regular rational consumer asks for mapped readback.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic budgets, endpoint readbacks, and comparison cells used by S, T, F, W, Q.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, visible only after S, T, F, W, Q, D have fixed the finite map route.*
8. *H records componentwise* hsame *transport for source windows, target windows, point-map rows, output observations, regular readback, dyadic ledgers, Real seals, replay rows, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a stream-map request through source inspection, pointwise mapping, target-window inspection, regular rational handoff, dyadic tolerance inspection, and Real-seal consumption.*

10. *P is the* Pkg *provenance over* $\mathsf{StreamMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, F, W, Q, D, R, H, C, P, N$. It has no coordinate for quotient stream equality, host function extensionality, selected limits, countable choice, ambient Real completeness, or a detached semantic map between host functions.

Lean4 ✓ `BEDC.Derived.StreamMapUp.TasteGate.StreamMapTasteGate single carrier alignment`

Theorem 1855.2 (Stream map pointwise stability)**.** *Let $M = (S, T, F, W, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier. If two accepted requests inspect the same displayed finite source window through the* $\mathsf{StreamName}^{\uparrow}$ *classifier row S and transport its cells by the componentwise row H, then the point-map row F produces the same displayed target cells through T and the same output observations through W.*

Proof. Project the accepted carrier. The source row S exposes only finite windows and pointwise cells, so equality of inspected requests is read from the same finite classifier rows rather than from a quotient of streams.

The componentwise transport row H moves those displayed cells into the point-map row F. Since F has no access to an unbounded stream representative, it can act only on the cells opened by S and named by the request.

The target row T and output row W are downstream of that same point-map read. Their cells are therefore determined by the displayed finite route S, H, F, and the packet contains no host function extensionality coordinate that could introduce a second comparison. □

Lean4 ✓ `BEDC.Derived.StreamMapUp.TasteGate.StreamMapPointwiseStability`

Definition 1855.3 (Stream map pointwise carrier transport)**.** *For an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier $M = (S, T, F, W, Q, D, R, H, C, P, N)$, the pointwise carrier transport datum is the finite relation*

$$\mathsf{Transport}_M(s, t)$$

whose rows first read source $\mathsf{StreamName}^{\uparrow}$ *cell transport through H, then apply the point-map row F to the transported source cell, and finally produce the target* $\mathsf{StreamName}^{\uparrow}$ *cell transport in T before any W, Q, D, or R row is read. The relation is stored only over displayed finite windows, transported source cells, point-map outputs, target-cell rows, replay, provenance, and local naming.*

Theorem 1855.4 (Stream map pointwise carrier transport stability)**.** *The datum of Definition 1855.3 is stable under the finite-window functoriality route of Definition 1855.5. In particular, two accepted reads related by the source-cell* hsame *rows of H produce related target-cell* hsame *rows through F and T, and the transport exports no host function extensionality, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the pointwise transport relation. Its source side is exactly the source-cell component of H over the finite window opened by S.

Apply Definition 1855.2. The point-map row F consumes the transported displayed source cell and determines the target cell exposed through T and W.

Finally apply Definition 1855.5. Since every downstream consumer factors through S, F, T, W before reaching Q, D, or R, the transport remains a finite StreamMap datum and cannot expose host function extensionality or quotient-stream data. □

Theorem 1855.5 (Stream map finite-window functoriality)**.** *For an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, every finite-window consumer of the mapped stream factors through*

$$S \longmapsto F \longmapsto T \longmapsto W$$

before it can inspect the regular rational handoff Q*, the dyadic tolerance ledger* D*, or the terminal Real seal* R*.*

Proof. Begin with a finite-window request for the mapped stream. Carrier admission exposes the source classifier row S before any target-facing read is available.

The point-map row F is next. It converts the displayed source cells into displayed target cells, and no row in the carrier selects a new infinite representative or compares host functions.

The target classifier T and the output observations W then package exactly the finite target window produced by F. Only after this finite route is visible may a consumer inspect the regular rational handoff Q, the dyadic ledger D, or the Real seal R.

Thus every mapped finite-window read has the displayed factorization $S \longmapsto F \longmapsto T \longmapsto W$, and downstream consumers inherit that route rather than a quotient-stream or selected-limit principle. □

Lean4 ✓ `BEDC.Derived.StreamMapUp.TasteGate.StreamMapFiniteWindow functoriality`

Theorem 1855.6 (Stream map window functoriality)**.** *For an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, the pointwise carrier transport of Definition 1855.3 preserves finite* $\mathsf{StreamName}^{\uparrow}$ *windows through the route of Definition 1855.5. Consequently every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff reads the mapped window through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route fixed by* S, F, T, W, Q, D*, and* R*.*

Proof. Project the carrier of Definition 1855.1 and the pointwise transport datum of Definition 1855.3. The only source cells available to the map are the finite $\mathsf{StreamName}^{\uparrow}$ window cells exposed by S and transported through H.

Apply Definition 1855.5. The mapped observation factors through S, F, T, W before any regular rational, dyadic, or Real-facing row can be read.

Finally apply Definition 1855.14. The handoff to $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumes the same mapped window route and the same structural rows H, C, P, N, so it cannot import host function extensionality, quotient streams, selected limits, or ambient Real completeness. □

Theorem 1855.7 (Stream map constant-window stability)**.** *Let* $M = (S, T, F, W, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier applied to a constant certified point stream. Then the displayed finite observation window is preserved by the point-map row: the constant point row read from* S *is routed through* F *to the same target-window shape in* T *and* W*, and any downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer must first read the same* hsame*,* Cont*,* Pkg*, and local* NameCert *support rows.*

Proof. Project the $\mathsf{StreamMap}^{\uparrow}$ carrier. The source classifier row S exposes the constant point stream only through a displayed finite window and its point cells.

Use the constant point row together with the finite-window row W. Since every source cell in the inspected window is the certified constant point, the point-map row F produces a target row with the same displayed window shape before Q, D, or R is available.

Componentwise transport is then read through H. The target cells, output observations, regular handoff, dyadic ledger, and Real seal boundary are moved only along the displayed source and target windows.

Finally the replay and provenance rows C, P, N preserve that route for downstream consumers. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer therefore receives the mapped constant window only after the finite StreamMap support has been displayed, and cannot replace it by quotient stream equality, host function extensionality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1855.8 (Stream map composition-window route)**.** *Let two accepted* $\mathsf{StreamMap}^{\uparrow}$ *carriers be composable by identifying the first target window with the second source window. The composed mapped stream can be exposed only through the first source* $\mathsf{StreamName}^{\uparrow}$ *row, the first point-map row, the intermediate target/source window, the second point-map row, and the final target window before any* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *row is consumed.*

Proof. Project the two accepted carriers. The first carrier exposes its mapped finite-window read through its source row, point-map row, target row, and output row before any regular rational, dyadic, or Real-facing row is available.

Apply Definition 1855.5 to the first carrier. The intermediate target window is therefore a displayed $\mathsf{StreamName}^{\uparrow}$ window, not a selected stream representative or a host-function value.

Apply the same theorem to the second carrier with that intermediate window serving as its source window. The second point-map row consumes only the displayed cells of the intermediate window and exports only the final displayed target window.

Thus the composed route is the concatenation of the two finite-window routes. It reaches the regular rational handoff, dyadic ledger, or Real seal only after the first source window, first point-map row, intermediate window, second point-map row, and final target window have all been displayed. □

Lean4 ✓ `BEDC.Derived.StreamMapUp.TasteGate.StreamMapCompositionWindowRoute`

Theorem 1855.9 (Stream map pointwise composition)**.** *Let* M_1 *and* M_2 *be accepted* $\mathsf{StreamMap}^{\uparrow}$ *carriers whose first target* $\mathsf{StreamName}^{\uparrow}$ *window is the second source* $\mathsf{StreamName}^{\uparrow}$ *window. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of the pointwise composite must read the first source window, the first point-map row, the intermediate target window, the second point-map row, the final target window, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before any terminal Real seal is available.*

Proof. Apply Definition 1855.5 to M_1. The first source window is opened through the first source $\mathsf{StreamName}^{\uparrow}$ row, the first point-map row consumes only those displayed cells, and the intermediate target window is exposed as a finite $\mathsf{StreamName}^{\uparrow}$ row.

Apply Definition 1855.5 again to M_2. The second point-map row reads the same intermediate window as its source and exposes only the final displayed target window.

Now use Definition 1855.8. It concatenates the two finite-window routes, so the composite can reach a downstream consumer only after both point-map rows and both source/target window boundaries are visible.

Finally apply Definition 1855.11. The dyadic tolerance ledger and $\mathsf{RegSeqRat}^{\uparrow}$ handoff remain downstream of the displayed windows, and the terminal Real seal cannot import host function extensionality, quotient streams, selected limits, countable choice, or ambient Real completeness. □

Theorem 1855.10 (Stream map tail-window determinacy)**.** *For an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$, *any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the mapped stream must first read the same source* $\mathsf{StreamName}^{\uparrow}$ *row* S, *point-map row* F, *target* $\mathsf{StreamName}^{\uparrow}$ *row* T, *output-window row* W, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *fixed by the finite-window route.*

If two consumer reads agree on those rows, then they agree on the exposed tail-window handoff Q before either terminal Real seal R is read.

Proof. Project the carrier of Definition 1855.1. The rows S, F, T, W are the finite map route, while Q and D are downstream rows attached to that same displayed route.

Apply Definition 1855.5. Every consumer read of the mapped stream factors through S, F, T, W before it can inspect Q, D, or R, so two reads agreeing on the source, point-map, target, and output-window rows have the same finite route.

Now read the tolerance and tail rows. The ledger D records the dyadic budgets for the same finite output observations, and the handoff row Q is the regular rational tail read attached to those observations.

Therefore agreement on S, F, T, W, D fixes the classifier-facing handoff Q before the terminal Real seal is available. Since no quotient-stream coordinate or selected-limit coordinate appears in the carrier, there is no second tail-window handoff for the consumer to select. □

Theorem 1855.11 (Stream map tail-ledger nonescape)**.** *For an accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, any consumer that reads the regular rational handoff Q, the dyadic tolerance ledger D, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal R must first read the same finite route S, F, T, W. The structural rows H, C, P, N preserve only that displayed route and cannot introduce quotient stream equality, host function extensionality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1855.5. Every finite-window consumer reaches S, F, T, W before the downstream rows Q, D, or R are available, so a tail-facing read cannot bypass the displayed source window, point-map row, target window, or output-window row.

Apply Definition 1855.10. Once two tail-facing reads agree on S, F, T, W, D, the exposed regular rational handoff Q is fixed before the terminal Real seal is read.

It remains to inspect the structural rows. The rows H, C, P, N transport, replay, cite provenance, and name the same finite route; none stores a quotient-stream comparison, host-function extensionality proof, selected-limit witness, countable-choice selector, or ambient Real-completeness principle. Thus every tail-ledger consumer remains inside the displayed StreamMap ledger. □

Theorem 1855.12 (Stream map NameCert obligation surface)**.** *For every accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier*

$$M = (S, T, F, W, Q, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for source and target StreamName classifier rows, the point-map row, output observations, RegSeqRat handoff, DyadicRatCore ledger, Real seal boundary, transport, replay, provenance, and local naming;*
2. *source-window exactness, requiring every mapped request to project S before F, T, W, Q, D, or R can be read;*
3. *pointwise stability, requiring F to consume only displayed source cells and to export only displayed target cells;*
4. *finite-window functoriality, requiring every output observation to factor through S, F, T, W before any regular rational, dyadic, or Real-facing consumer can inspect it;*
5. *tail-window handoff, requiring Q to reuse the same finite windows rather than selecting a second stream representative;*

6. *ledger non-escape, requiring D, R, H, C, P, N to export no quotient stream equality, host function extensionality, selected limit, countable choice, ambient Real completeness, or detached host map.*

No local stream-map obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.StreamMapUp.TasteGate.StreamMapNameCertObligationSurface`

Proof. Carrier admission is projection from Definition 1855.1. The accepted packet displays exactly the source and target StreamName rows, the point-map row, finite output observations, the regular rational handoff, the dyadic ledger, the Real seal boundary, and the structural rows.

Source-window exactness and pointwise stability use the same finite inspection route. A request must first open S, then F consumes only the cells displayed by that window and exports only the corresponding target cells.

Finite-window functoriality follows from Definition 1855.5. The mapped observation reaches T and W before any Q, D, or R read, so downstream regular rational, dyadic, and Real-facing consumers inherit the same finite map route.

The tail-window handoff is the projection to Q. Since Q is stored after S, T, F, W, it records the regular rational readback for the displayed windows and has no coordinate for choosing another stream representative.

Finally, ledger non-escape is exhausted by D, R, H, C, P, N. These rows record tolerances, seal boundaries, componentwise transport, displayed replay, provenance, and local naming for the same finite route, and none stores quotient stream equality, host function extensionality, selected limits, countable choice, ambient Real completeness, or a detached host map. □

Theorem 1855.13 (Stream map obligation-closure package)**.** *For every accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, the carrier row of Definition 1855.1, the pointwise stability of Definition 1855.2, the carrier transport datum of Definition 1855.3, the carrier transport stability of Definition 1855.4, the finite-window functoriality of Definition 1855.5, the composition-window route of Definition 1855.8, the tail-window determinacy of Definition 1855.10, the tail-ledger nonescape of Definition 1855.11, and the NameCert obligation surface of Definition 1855.12 jointly form the obligation-closed finite* $\mathsf{StreamMap}^{\uparrow}$ *packet over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Proof. Project the carrier row first. It displays exactly the source and target $\mathsf{StreamName}^{\uparrow}$ rows, the point-map row, finite output windows, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the $\mathsf{Real}^{\uparrow}$ seal, and the structural rows H, C, P, N.

Apply the pointwise and transport clauses next. The rows cited in Definition 1855.2, Definition 1855.3, and Definition 1855.4 keep the map action inside displayed finite source and target cells.

Now use the window and tail clauses. The route of Definition 1855.5, Definition 1855.8, Definition 1855.10, and Definition 1855.11 forces every downstream regular-rational, dyadic, or Real-facing consumer to pass through the same finite StreamMap window route before any tail or seal row is visible.

Finally apply Definition 1855.12. Its listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$ surface, so the paper closure claim here is an obligation package over the displayed finite rows only. It does not assert Lean verification, quotient stream equality, host function extensionality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1855.14 (Stream map RegSeqRat and Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a mapped stream accepted by a* $\mathsf{StreamMap}^{\uparrow}$ *carrier must first read source-window exactness, pointwise map stability, finite-window functoriality, tail-window determinacy, and tail-ledger nonescape. The handoff is therefore a finite pointwise stream route from source windows to regular rational readback and the terminal real seal, not a quotient stream equality, selected limit, host function extensionality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with pointwise stability from Definition 1855.2. It keeps each target cell attached to the displayed source cell and point-map row rather than to a detached host function.

Apply Definition 1855.5. The mapped observation reaches the target window through the finite route S, F, T, W before any downstream Q, D, or R row can be consumed.

Now apply Definition 1855.10. A regular rational or real-facing read that agrees on the source window, point-map row, target window, output window, and dyadic ledger must expose the same regular handoff before the terminal real seal is read.

Finally apply Definition 1855.11. The tail-facing consumer cannot bypass S, F, T, W, D and cannot import quotient stream equality, selected limits, host function extensionality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1855.15 (Stream map scoped closure package)**.** *Every accepted* $\mathsf{StreamMap}^{\uparrow}$ *packet routes pointwise map data through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows before any* $\mathsf{Real}^{\uparrow}$*-facing consumer reads it. The scoped route is the finite package assembled by the obligation-closure theorem and the RegSeqRat/Real handoff theorem; it exports no quotient stream equality, host function extensionality, selected limit, countable choice, or ambient real-completeness datum.*

Proof. Start with the obligation package of Definition 1855.13. It exposes the carrier row, source-window exactness, pointwise stability, carrier transport, finite-window functoriality, composition-window routing, tail-window determinacy, tail-ledger nonescape, and the local NameCert surface over the displayed $\mathsf{StreamMap}^{\uparrow}$ rows.

Next apply Definition 1855.14. That theorem places every regular-rational or Real-facing read behind the same source window, point-map row, target window, output observation, dyadic ledger, regular rational handoff, and terminal Real seal.

The structural rows H, C, P, N then preserve the scoped route as componentwise transport, displayed replay, provenance, and local naming. Since the carrier has no coordinate for quotient stream equality, host function extensionality, selected limits, countable choice, or ambient Real completeness, the scoped closure package is exactly the displayed finite route. □

Theorem 1855.16 (Stream map scoped obligation route)**.** *For every accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, the carrier definition, pointwise stability, carrier transport, finite-window functoriality, composition-window route, tail-window determinacy, tail-ledger nonescape, NameCert obligation surface, and* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff jointly bind the exact rows*

$$S, T, F, W, Q, D, R, H, C, P, N$$

over $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. Every consumer read of the scoped route must pass through those rows before reaching a regular-rational or Real-facing handoff.*

The route exports no quotient stream equality, host function extensionality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier of Definition 1855.1. It displays $S, T, F, W, Q, D, R, H, C, P, N$ as the only source, target, point-map, output-window, regular handoff, dyadic ledger, Real seal, transport, replay, provenance, and local-name rows.

Apply Definition 1855.2, Definition 1855.3, and Definition 1855.4. These rows keep the pointwise map action and its transport inside displayed source and target windows.

Next use Definition 1855.5, Definition 1855.8, Definition 1855.10, and Definition 1855.11. They force composition, tail, dyadic, and Real-facing reads through S, T, F, W, Q, D, R before any consumer can inspect a downstream result.

Finally apply Definition 1855.12, Definition 1855.13, and Definition 1855.14. The local NameCert surface and handoff theorem exhaust the structural rows H, C, P, N, so the scoped obligation route has no coordinate for quotient stream equality, host function extensionality, selected limits, countable choice, or ambient Real completeness. □

Theorem 1855.17 (Stream map scope kernel route)**.** *For every accepted* $\mathsf{StreamMap}^{\uparrow}$ *carrier* $M = (S, T, F, W, Q, D, R, H, C, P, N)$*, every consumer read that reaches* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *factors through the displayed rows* $S, T, F, W, Q, D, R, H, C, P, N$ *and the kernel primitives* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The route exports no quotient stream equality, host function extensionality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1855.2. It keeps the source cell, target cell, and point-map row attached to the accepted carrier rather than to an external function.

Use Definition 1855.3. The transport row is componentwise hsame over the displayed carrier cells, so a transported read still names $S, T, F, W, Q, D, R, H, C, P, N$.

Next apply Definition 1855.5. It forces each mapped observation through the finite source and target windows before any regular-rational, dyadic, or Real-facing row is public.

Finally use Definition 1855.14 and Definition 1855.12. The handoff accounts for the Q, D, R rows, while the NameCert surface accounts for H, C, P, N as BHist-based transport, displayed replay, provenance, and local naming. Since no carrier coordinate stores quotient stream equality, host function extensionality, selected limits, countable choice, or ambient completeness, every such consumer read factors through the stated kernel route. □

Closure status for $\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$, obligation)

Scope closed: Definition 1855.1, Definition 1855.13, Definition 1855.14, and Definition 1855.16 give the obligation witness set for the finite L10 pointwise map route through StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StreamMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host function extensionality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, pointwise stability, finite-window functoriality, tail-window handoff, and ledger non-escape proofs for BEDC.Derived.StreamMapUp.stream_map_namecert_obliga

Constructive story: A $\mathsf{StreamMap}^{\uparrow}$ packet is generated from source and target $\mathsf{StreamName}^{\uparrow}$ classifier rows, a point-map row, finite-window output observations, a $\mathsf{RegSeqRat}^{\uparrow}$ tail-window handoff, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1856

A Concrete Naming Certificate for $\mathsf{BishopIntervalNestLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ packet records the finite nested-interval limit route through chapter 320, chapter 328, chapter 126, chapter 301, chapter 38, and chapter 1639. The packet gives L10 Real and Completion work a displayed induction-style handoff from nested interval data to a terminal Real seal, while remaining below any claim of general Heine–Borel compactness, selected intersection points, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1856.1 (Bishop interval-nest limit carrier)**.** *A* $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested-interval induction row. It records the inspected prefix, the containment step from each displayed interval to its predecessor, and the nonempty interval surface inherited from* $\mathsf{NestedInterval}^{\uparrow}$*.*
2. *D is the* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger used to read the inspected interval endpoints at the requested dyadic scales.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It exposes only the finite interval-prefix observations and endpoint windows that the induction row permits.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled endpoint observations and the shrinking-width ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, D, S, R have been displayed.*
6. *M is the Bishop regular Cauchy completion handoff row. It records that the same I, D, S, R, E route is the one consumed by* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for the interval induction row, endpoint ledger, stream schedule, regular rational readback, Real seal, completion handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a nested-interval request through I, D, S, R, E, M.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalNestLimit}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, M, H, C, P, N$. The carrier contains no general Heine–Borel compactness row, selected intersection point, quotient stream equality, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, host real equality, or bridge credential.*

Lean4 ✓ `BEDC.Derived.BishopIntervalNestLimitUp.BishopIntervalNestLimitTasteGate single carrier alignment`

Theorem 1856.2 (Bishop interval-nest limit NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ *carrier*

$$L = (I, D, S, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalNestLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed nested-interval induction row, dyadic endpoint ledger, stream schedule, regular rational readback, Real seal, Bishop regular Cauchy completion handoff, transport, replay, provenance, and local naming row;*
2. *induction-step exposure, requiring every interval read to be one of the displayed prefix rows of I and every successor read to pass through the displayed containment step;*
3. *dyadic endpoint exactness, requiring D to supply the endpoint and shrinking-width comparisons used by the scheduled windows;*
4. *stream and regular readback discipline, requiring S and R to reuse the same displayed prefix and endpoint ledger rather than selecting a second nested chain or regular sequence;*
5. *Real-seal handoff, requiring E to be reached only after the nested, dyadic, stream, and regular rational rows have been projected;*
6. *completion-interface non-escape, requiring M, H, C, P, N to transport, replay, source, and name no general Heine–Borel compactness row, selected intersection point, quotient stream equality, countable-choice selector, ambient Real completeness datum, host real equality, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1856.1. The accepted packet displays exactly the interval induction row, dyadic endpoint ledger, stream schedule, regular rational readback, Real seal, completion handoff, and the structural rows.

The induction-step exposure clause is forced by I. A consumer can inspect only the finite prefix already present in the packet, and each displayed successor interval is read together with its containment step into the preceding interval.

Dyadic endpoint exactness is then forced by D. The endpoint and shrinking-width comparisons are the only numerical rows available to the schedule, so the packet cannot introduce an external point selector or compactness witness.

The rows S and R are downstream of the same displayed prefix and endpoint ledger. They schedule finite observations and repack them as regular rational readback without replacing the nested chain by a second representative.

Finally, E, M, H, C, P, N close the route. The Real seal and completion handoff are reached only after I, D, S, R, while the structural rows transport, replay, source, and name the same finite data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 1856.3 (Bishop interval-nest limit convergence route)**.** *Let $L = (I, D, S, R, E, M, H, C, P, N)$ be an accepted* $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ *carrier. Every Real-facing or completion-facing read exported by L factors through the induction route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto E \longmapsto M$$

before it can inspect the transport, replay, provenance, or local naming rows. The route is a finite nested-interval handoff into the $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Begin with a Real-facing or completion-facing read of L. The carrier gives no source row before the displayed nested-interval induction row I.

The read then projects the dyadic endpoint ledger D. This fixes the endpoint observations and shrinking-width comparisons that the later schedule may use.

Next the read passes through S and R. The schedule exposes only finite interval-prefix windows, and the regular rational row repacks those same observations as the Cauchy-facing readback.

Only after this route has been displayed can the read reach the Real seal E and the Bishop regular Cauchy completion handoff M. The remaining rows H, C, P, N preserve and name that route, so every exported read factors through the displayed induction chain. □

Theorem 1856.4 (Bishop interval-nest limit nonescape)**.** *For an accepted* $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ *carrier $L = (I, D, S, R, E, M, H, C, P, N)$, every exported comparison, replay, provenance read, completion handoff, or local name is exhausted by the displayed rows $I, D, S, R, E, M, H, C, P, N$. In particular, the packet exports no general Heine–Borel compactness theorem, selected intersection point, quotient stream equality, countable-choice selector, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Project the accepted packet. Its classifier compares carriers only through the displayed interval induction row, endpoint ledger, schedule, regular readback, Real seal, completion handoff, and structural rows.

The comparison-sensitive rows are M, H, C, P, N. The completion handoff records the same finite route into the Bishop regular Cauchy completion surface, transport is componentwise, replay follows the displayed request path, provenance names the same source chapters, and the local NameCert row names only this packet.

Since no accepted coordinate stores a compactness theorem, an intersection selector, quotient stream equality, choice data, host real equality, ambient Real completeness, or a bridge credential, no exported comparison or replay can use such a row. The packet therefore remains an induction-style nested-interval handoff rather than a completeness assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNestLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopIntervalNestLimit}^{\uparrow}$ packet is generated from a finite nested-interval induction row, a nested dyadic endpoint ledger, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, a BishopRegularCauchyCompletion handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1856.1, Definition 1856.2, Definition 1856.3, and Definition 1856.4 seed the finite nested-interval induction route from displayed interval prefixes through RegSeqRat readback to the terminal Real seal and Bishop regular Cauchy completion handoff.

Formal verification: FormalStatus(NameCert$_{\text{BishopIntervalNestLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close general Heine–Borel compactness, selected intersection points, quotient stream equality, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, induction-step exposure, dyadic endpoint exactness, stream and regular readback discipline, Real-seal handoff, completion-interface non-escape, and convergence-route proofs for BEDC.Derived.BishopIntervalNestLimitUp.

Chapter 1857

A Concrete Naming Certificate for $\mathsf{CozeroSet}^{\uparrow}$

Following Kelley and Bishop–Bridges, cozero sets are read as the positive-apartness locus of a continuous real-valued map, with BEDC sources chapter 38, chapter 130, chapter 88, and chapter 111. The $\mathsf{CozeroSet}^{\uparrow}$ packet names the finite route from a displayed continuous $\mathsf{Real}^{\uparrow}$-valued map to an open and set-like membership surface. It does not assert zero-set completeness, classical complements, excluded middle, host $\mathsf{Real}^{\uparrow}$ equality, or an ambient semantic preimage theorem.

Definition 1857.1 (Cozero set carrier)**.** *A* $\mathsf{CozeroSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (F, R, A, O, S, H, K, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for a displayed map into* $\mathsf{Real}^{\uparrow}$*, exposing only the source observation, target real-name, and graph cells used by the cozero read.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *observation row attached to the target cell of F.*
3. *A is the positive-apartness witness row certifying that the displayed target observation is apart from zero through the same real-name surface as R.*
4. *O is the induced* $\mathsf{Topology}^{\uparrow}$ *open-row, available only after F, R, A have fixed the positive witness.*
5. *S is the* $\mathsf{Set}^{\uparrow}$ *membership row exported by the open-row O and read only through the same displayed source cell.*
6. *H records componentwise* hsame *transport for the continuous-map row, Real observation row, positive-apartness row, open-row, set-membership row, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a cozero membership request through F, R, A, O, S, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CozeroSet}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Set}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CozeroSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, A, O, S, H, K, P, N$. It has no coordinate for the classical complement of a zero set, excluded middle, host real equality, quotient real equality, or a detached semantic preimage theorem.

Theorem 1857.2 (Cozero set NameCert obligations)**.** *For every accepted* $\mathsf{CozeroSet}^{\uparrow}$ *carrier*

$$C = (F, R, A, O, S, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CozeroSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the continuous-map row into* $\mathsf{Real}^{\uparrow}$*, the target Real observation row, the positive-apartness witness row, the induced topological open-row, the set-membership row, transport, replay, provenance, and local naming;*
2. *positive witness exactness, requiring every accepted membership read to use the same target real observation* R *and positive-apartness row* A *opened by* F*;*
3. *continuous-preimage stability, requiring componentwise* hsame *and displayed* Cont *transport of the continuous map and positive witness to preserve the cozero membership surface;*
4. *open-set handoff, requiring* O *to be read only after* F, R, A *have displayed the positive witness;*
5. *set-membership handoff, requiring* S *to export only the membership surface induced by* O *on the same displayed source cell;*
6. *non-escape, requiring* H, K, P, N *to export no host real equality, quotient real equality, classical complement, excluded middle, zero-set completeness, or detached semantic preimage theorem.*

No local cozero-set obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CozeroSetUp.TasteGate.CozeroSetUpTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1857.1. The accepted tuple displays exactly the continuous-map row, target Real observation row, positive-apartness witness, open-row, set-membership row, and structural transport, replay, provenance, and naming rows.

Positive witness exactness is forced by the order of the carrier. A membership read first opens F, then reads the target observation R, and only then obtains the positive-apartness witness A for the same displayed real-name surface.

The open-set and set-membership handoffs are the projections to O and S. Since both rows are downstream of F, R, A, they cannot introduce an independent complement, zero-set equality test, or host real comparison.

Transport and replay stability are exhausted by H and K. These rows move the displayed map and positive witness componentwise and replay the same finite route, so the cozero membership surface is preserved without adding excluded middle, host equality, or a detached semantic preimage principle.

Finally, non-escape follows from the absence of any further classifier coordinate. The provenance and local NameCert rows name only this finite route, and no row stores zero-set completeness, classical complements, excluded middle, or host $\mathsf{Real}^{\uparrow}$ equality. □

Theorem 1857.3 (Cozero set positive witness route)**.** *Every membership read exported by an accepted* $\mathsf{CozeroSet}^{\uparrow}$ *packet factors through*

$$F \longmapsto R \longmapsto A$$

before it can inspect the topological open-row O *or the set-membership row* S*.*

Proof. Begin with a membership request for the displayed cozero surface. Carrier admission exposes no set row before the continuous-map row F.

The request then reads the target Real observation row R. This fixes the real-name observation used by the positive test, and the packet contains no host equality coordinate from which another target value could be substituted.

The positive-apartness witness row A is therefore the gate to membership. Only after F, R, A have been displayed may the request inspect the induced open-row O and the set row S.

Thus every membership read has the displayed factorization $F \longmapsto R \longmapsto A$ before any topological or set-like export. □

Theorem 1857.4 (Cozero set continuous-preimage stability)**.** *Let $C = (F, R, A, O, S, H, K, P, N)$ be an accepted* $\mathsf{CozeroSet}^{\uparrow}$ *carrier. Componentwise* hsame *transport and displayed* Cont *replay of the continuous-map row F, Real observation row R, and positive-apartness witness row A preserve the induced cozero membership surface exported through O and S.*

Proof. Project the accepted carrier. The rows F, R, A determine the positive witness route for the displayed source cell and target real observation.

The transport row H moves these three rows componentwise. It does not compare host real values or select a classical complement, so it preserves exactly the displayed positive-apartness witness.

The replay row K then replays the same finite route through the open-row O and set-membership row S. Since O and S are downstream of F, R, A, the transported packet exports the same cozero membership surface and no additional zero-set or complement principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CozeroSet}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CozeroSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1857.1, Definition 1857.2, Definition 1857.3, and Definition 1857.4 seed the finite L10 route from continuous $\mathsf{Real}^{\uparrow}$-valued maps through positive-apartness witnesses into topological and set-like membership surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CozeroSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close zero-set completeness, classical complements, excluded middle, host $\mathsf{Real}^{\uparrow}$ equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive witness exactness, continuous-preimage stability, open-set handoff, set-membership handoff, and non-escape proofs for BEDC.Derived.CozeroSetUp.

Constructive story: A $\mathsf{CozeroSet}^{\uparrow}$ packet is generated from a $\mathsf{ContinuousMap}^{\uparrow}$ row into $\mathsf{Real}^{\uparrow}$, a Real observation row, a positive-apartness witness row, an induced $\mathsf{Topology}^{\uparrow}$ open-row, a $\mathsf{Set}^{\uparrow}$ membership row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1858

A Concrete Naming Certificate for $\mathsf{ZeroSet}^{\uparrow}$

Following Kelley and Bishop–Bridges, zero sets are read as displayed zero-loci of continuous real-valued maps, with the constructive cozero companion in chapter 1857 and BEDC sources chapter 38, chapter 130, chapter 88, and chapter 111. The $\mathsf{ZeroSet}^{\uparrow}$ packet names the finite route from a displayed continuous $\mathsf{Real}^{\uparrow}$-valued map through an exact zero witness into a closed topological and set-like membership surface. It does not identify this surface with the classical complement of a cozero set, and it does not add excluded middle, host $\mathsf{Real}^{\uparrow}$ equality, quotient equality, or an ambient semantic preimage theorem.

Definition 1858.1 (Zero set carrier)**.** *A* $\mathsf{ZeroSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (F, R, E, T, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for a displayed map into* $\mathsf{Real}^{\uparrow}$*, exposing only the source observation, target real-name, and graph cells used by the zero-locus read.*
2. *R is the displayed* $\mathsf{Real}^{\uparrow}$ *observation row attached to the target cell of F.*
3. *E is the zero-witness row certifying that the displayed target observation is zero through the same real-name surface as R.*
4. *T is the induced* $\mathsf{Topology}^{\uparrow}$ *closed-locus row, available only after F, R, E have fixed the zero witness.*
5. *S is the* $\mathsf{Set}^{\uparrow}$ *membership row exported by the closed-locus row T and read only through the same displayed source cell.*
6. *H records componentwise* hsame *transport for the continuous-map row, Real observation row, zero-witness row, closed-locus row, set-membership row, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a zero-set membership request through F, R, E, T, S, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ZeroSet}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Set}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ZeroSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, E, T, S, H, C, P, N$. It has no coordinate for the classical complement of $\mathsf{CozeroSet}^{\uparrow}$*, excluded middle, host Real equality, quotient equality, or a detached semantic preimage theorem.*

Lean4 ✓ `BEDC.Derived.ZeroSetUp.ZeroSetTasteGate single carrier alignment`

Theorem 1858.2 (Zero set NameCert obligations)**.** *For every accepted* $\mathsf{ZeroSet}^{\uparrow}$ *carrier*

$$Z = (F, R, E, T, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ZeroSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the continuous-map row into* $\mathsf{Real}^{\uparrow}$*, the displayed target Real observation row, the zero-witness row, the induced topological closed-locus row, the set-membership row, transport, replay, provenance, and local naming;*
2. *zero-witness exactness, requiring every accepted membership read to use the same target real observation R and exact zero row E opened by F;*
3. *continuous-preimage stability, requiring componentwise* hsame *and displayed* Cont *transport of the continuous map and zero witness to preserve the zero-locus membership surface;*
4. *topology and set handoff, requiring T to be read only after F, R, E have displayed the zero witness and requiring S to export only the membership surface induced by T on the same displayed source cell;*
5. *CozeroSet boundary separation, requiring the packet to share the continuous-map and Real observation vocabulary of* $\mathsf{CozeroSet}^{\uparrow}$ *while refusing to identify the zero row E with a negated positive-apartness witness;*
6. *non-escape, requiring H, C, P, N to export no classical complement of* $\mathsf{CozeroSet}^{\uparrow}$*, excluded middle, host Real equality, quotient equality, or detached semantic preimage theorem.*

No local zero-set obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1858.1. The accepted tuple displays exactly the continuous-map row, target Real observation row, zero-witness row, closed-locus row, set-membership row, and structural transport, replay, provenance, and naming rows.

Zero-witness exactness is forced by the order of the carrier. A membership read first opens F, then reads the target observation R, and only then obtains the exact zero witness E for the same displayed real-name surface.

The topology and set handoffs are the projections to T and S. Since both rows are downstream of F, R, E, they cannot introduce an independent complement, a cozero-set negation rule, or a host real comparison.

Continuous-preimage stability is exhausted by H and C. These rows move the displayed map and zero witness componentwise and replay the same finite route, so the zero-locus membership surface is preserved without adding excluded middle, host equality, quotient equality, or a detached semantic preimage principle.

CozeroSet boundary separation follows from the absence of any row converting E into the negation of a positive-apartness witness. The packet may cite the sibling vocabulary of chapter 1857, but it exports only the displayed zero route named by $F, R, E, T, S, H, C, P, N$.

Finally, non-escape follows from the absence of any further classifier coordinate. The provenance and local NameCert rows name only this finite route, and no row stores classical complements, excluded middle, host $\mathsf{Real}^{\uparrow}$ equality, quotient equality, or ambient preimage semantics. □

Theorem 1858.3 (Zero set positive-boundary separation)**.** *Every membership read exported by an accepted* $\mathsf{ZeroSet}^{\uparrow}$ *packet factors through*

$$F \longmapsto R \longmapsto E$$

before it can inspect the closed-locus row T *or the set-membership row* S*. The same read cannot be replaced by a* $\mathsf{CozeroSet}^{\uparrow}$ *positive-apartness route or by the classical complement of such a route.*

Proof. Begin with a membership request for the displayed zero-locus surface. Carrier admission exposes no set row before the continuous-map row F.

The request then reads the target Real observation row R. This fixes the real-name observation used by the zero test, and the packet contains no host equality coordinate from which another target value could be substituted.

The zero-witness row E is therefore the gate to membership. Only after F, R, E have been displayed may the request inspect the induced closed-locus row T and the set row S.

The carrier has no row that turns the absence of a $\mathsf{CozeroSet}^{\uparrow}$ positive witness into a zero witness. Thus the displayed factorization through $F \longmapsto R \longmapsto E$ is a zero-locus route, not a complement route. □

Theorem 1858.4 (Zero set nonclassical boundary)**.** *An accepted* $\mathsf{ZeroSet}^{\uparrow}$ *packet supplies no classical complement of* $\mathsf{CozeroSet}^{\uparrow}$*, no excluded middle, no host* $\mathsf{Real}^{\uparrow}$ *equality, no quotient equality, and no ambient semantic preimage. Its exported surface is only the displayed finite route*

$$F, R, E, T, S, H, C, P, N.$$

Proof. Project the accepted carrier. The listed rows are the only rows available to a downstream read.

The rows F, R, E determine the displayed zero witness, while T and S expose only the closed-locus and set-membership surfaces induced by that witness. None of these rows compares host real values or reasons by excluded middle.

The transport and replay rows H and C preserve the displayed route componentwise. They do not add quotient equality, a semantic preimage theorem, or a complement operation against $\mathsf{CozeroSet}^{\uparrow}$.

The provenance and local naming rows P, N name the finite package and no further classifier. Hence every exported read remains inside $F, R, E, T, S, H, C, P, N$ and cannot escape to the classical boundary listed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{ZeroSet}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeroSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1858.1, Definition 1858.2, Definition 1858.3, and Definition 1858.4 seed the finite route from continuous $\mathsf{Real}^{\uparrow}$-valued maps through displayed zero witnesses into closed topological and set-like membership surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ZeroSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical complements of $\mathsf{CozeroSet}^{\uparrow}$, excluded middle, host $\mathsf{Real}^{\uparrow}$ equality, quotient equality, ambient semantic preimage theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-witness exactness, continuous-preimage stability, topology and set handoff, CozeroSet boundary separation, and non-escape proofs for BEDC.Derived.ZeroSetUp.

Constructive story: A $\mathsf{ZeroSet}^{\uparrow}$ packet is generated from a $\mathsf{ContinuousMap}^{\uparrow}$ row into $\mathsf{Real}^{\uparrow}$, a Real observation row, an exact zero-witness row, an induced $\mathsf{Topology}^{\uparrow}$ closed-locus row, a $\mathsf{Set}^{\uparrow}$ membership row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1859

A Concrete Naming Certificate for $\mathsf{LocatedUniformContinuity}^{\uparrow}$

Following Bishop and Bridges on constructive continuity with explicit moduli, the $\mathsf{LocatedUniformContinuity}^{\uparrow}$ packet records the finite L10 route by which a located source row and a located-apartness witness feed a uniform-continuity modulus before any Real or completion consumer reads the target seal. It sits over the modulus discipline of chapter 1631, the Cauchy-modulus row of chapter 292, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the completion handoff of chapter 1639, and the located-source surface of chapter 1541. The packet names the constructive located-uniform-continuity handoff; it is not open-cover compactness, host function equality, selected limits, quotient stream equality, countable choice, or ambient Real completeness.

Definition 1859.1 (Located uniform continuity carrier)**.** *A* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, M, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the located source row, exposing the finite* $\mathsf{LocatedSet}^{\uparrow}$ *cells and source-location requests that the continuity route may inspect.*
2. *A is the located-apartness witness row, recording the positive separation and located decision cells used to keep source inspection constructive.*
3. *M is the* $\mathsf{ModulusContinuity}^{\uparrow}$ *row, turning each requested target tolerance into a finite source-window budget and citing the Cauchy-modulus discipline when completion-facing reads ask for tail control.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row consumed by the located source, apartness, and modulus rows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording target tolerances, source budgets, dyadic endpoints, comparison cells, and positive-gap readbacks.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *seal handoff, visible only after X, A, M, S, D, R have fixed the displayed route.*

8. *H records componentwise* hsame *transport for the located source, apartness witness, modulus row, windows, dyadic ledger, regular readback, Real and completion handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a located-uniform-continuity request through source location, apartness inspection, modulus conversion, finite-window readback, dyadic ledger inspection, regular readback, and completion handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformContinuity}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, M, S, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, host function equality, selected limits, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedUniformContinuityUp.LocatedUniformContinuityTasteGate single carrier alignment`

Theorem 1859.2 (Located uniform continuity NameCert obligations)**.** *For every accepted* LocatedUniformContinui *carrier*

$$L = (X, A, M, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedUniformContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located source, located-apartness witness, modulus-continuity row, StreamName finite windows, DyadicRatCore tolerance ledger, RegSeqRat readback, Real and completion seal handoff, transport, replay, provenance, and local naming;*

2. *located-source stability, requiring X and A to expose only displayed source cells and positive-separation witnesses before any target tolerance can be read;*

3. *modulus-window adequacy, requiring M, S, D to turn every target tolerance into a finite source-window budget recorded in the dyadic ledger;*

4. *readback and handoff coherence, requiring R and E to consume the same windows and budgets before any Real or completion-facing consumer receives a seal;*

5. *transport, replay, and non-escape, requiring H, C, P, N to preserve only the displayed rows and to export no open-cover compactness, host function equality, selected limit, quotient stream equality, countable choice, or ambient Real completeness.*

No local located-uniform-continuity obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1859.1. The accepted packet displays exactly the located source row, apartness witness, modulus row, finite windows, dyadic ledger, regular readback, Real and completion handoff, and the structural rows.

Located-source stability is forced by the order of the displayed route. The rows X and A are read before any tolerance request reaches M, so source inspection remains located and positive-separation evidence cannot be replaced by a host equality test.

The modulus-window obligation is the finite handoff through M, S, D. A target tolerance first reads the modulus row, then opens only the source windows in S and the dyadic cells in D that were displayed for that request.

Readback and handoff coherence are projections to R and E. The regular rational row and the Real or completion seal consume the same windows and budgets, so neither can select a limit, compare quotient streams, or import ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the excluded principles have no coordinate in the carrier, they cannot become local NameCert obligations. □

Theorem 1859.3 (Located uniform continuity completion handoff)**.** *Every Real or completion consumer of an accepted* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *carrier factors through the displayed route*

$$X, A, M, S, D \longmapsto R \longmapsto E$$

before componentwise transport, replay, provenance, or local naming can be inspected. The consumer receives a located source, located-apartness evidence, an explicit modulus, finite windows, a dyadic tolerance ledger, regular rational readback, and a Real or Bishop-regular-Cauchy completion seal, but no selected limit, quotient stream equality, countable choice, host function equality, open-cover compactness, or ambient Real completeness.

Proof. Start with an accepted carrier $L = (X, A, M, S, D, R, E, H, C, P, N)$. Projection exposes the located source row X and the apartness witness row A before any completion-facing read is available.

The modulus stage is next. The row M turns the target request into source-window data, and those windows are exactly the finite cells recorded by S and budgeted by the dyadic ledger D.

The regular readback row R consumes the same finite data. It does not choose a stream representative or a limiting value; it records the regular rational readback allowed by the displayed source windows and tolerance ledger.

The handoff row E is terminal for Real and completion consumers. It receives X, A, M, S, D, R as finite BEDC rows and has no coordinate for selected limits, quotient equality, choice, host function equality, open-cover compactness, or ambient completeness.

The structural rows H, C, P, N preserve this route by componentwise transport, displayed replay, provenance, and local naming. Therefore every Real or completion consumer factors through the displayed handoff before it can inspect the terminal certificate surface. □

Theorem 1859.4 (Located uniform continuity non-escape)**.** *No accepted* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *packet exports open-cover compactness, host function equality, selected limits, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every exported comparison, replay, or consumer handoff is exhausted by the rows* $X, A, M, S, D, R, E, H, C, P, N$.

Proof. Inspect the classifier of Definition 1859.1. Accepted packets are compared only componentwise through the displayed located source, apartness, modulus, window, ledger, readback, seal, transport, replay, provenance, and naming rows.

The analytic rows X, A, M, S, D, R, E provide located source inspection, positive separation, tolerance conversion, finite windows, dyadic budgets, regular readback, and terminal Real or completion handoff. None stores an open cover, a host function graph equality, a chosen limit, a quotient-stream equality proof, a choice schedule, or an ambient completeness principle.

The structural rows H, C, P, N cannot add new analytic coordinates. They transport, replay, source, and name only the accepted tuple, so any exported comparison or consumer handoff must remain inside the same finite row list.

Thus the excluded principles have no entry point in the carrier, classifier, transport, replay, provenance, or local NameCert surface, and the packet is non-escaping in precisely the stated sense. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformContinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1859.1, Definition 1859.2, Definition 1859.3, and Definition 1859.4 seed the finite Real and Completion route for located-source uniform continuity through located source, apartness, modulus, finite-window, dyadic-ledger, regular-readback, Real and completion handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host function equality, selected limits, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires the later BEDC.Derived.LocatedUniformContinuityUp carrier, modulus-window, completion-handoff, transport, and nonescape obligations.

Constructive story: A $\mathsf{LocatedUniformContinuity}^{\uparrow}$ packet is generated from a $\mathsf{LocatedSet}^{\uparrow}$ source row, a located-apartness witness row, a $\mathsf{ModulusContinuity}^{\uparrow}$ row citing $\mathsf{CauchyModulus}^{\uparrow}$ tail control, $\mathsf{StreamName}^{\uparrow}$ finite windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ and $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ handoff seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1860

A Concrete Naming Certificate for $\mathsf{SierpinskiSpace}^{\uparrow}$

Following Sierpinski and Scott on observable opens, the $\mathsf{SierpinskiSpace}^{\uparrow}$ packet records the two-observation classifier that turns open-set membership into finite BEDC data. It sits after the finite truth rows of chapter 32, the open-set discipline of chapter 88, the finite countable-name windows of chapter 126, and the Real-facing uniform-structure boundary of chapter 1624. The same observable-open truth row is the input surface for later topology consumers such as chapter 3338, **??**, and compact-uniform cover routes, where an open-membership read must remain a displayed Sierpinski classifier row rather than a host proposition. The packet names observable truth of opens as a classifier surface; it does not import excluded middle, selected limits, quotient streams, host propositions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1860.1 (Sierpinski space carrier)**.** *A* $\mathsf{SierpinskiSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, O, W, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *truth row, exposing the two accepted observable truth marks and their classifier transport.*
2. *O is the* $\mathsf{Topology}^{\uparrow}$ *open-set row, recording the open under inspection as a displayed observation row rather than as a host proposition.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row, recording the finite windows through which a countable name reports whether the open has been observed.*
4. *H records componentwise* hsame *transport for truth rows, open rows, finite-observation windows, replay rows, provenance, and the local naming row.*
5. *C records displayed* Cont *replay from an observable-open request through B, O, W, H, P, N.*
6. *P is the* Pkg *provenance over* $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SierpinskiSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, O, W, H, C, P, N. It contains no coordinate for host propositions, excluded middle, selected limits, quotient stream equality, countable choice, or a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SierpinskiSpaceUp.SierpinskiSpaceTasteGate single carrier alignment`

Theorem 1860.2 (Observable open-set classifier)**.** *Let $S = (B, O, W, H, C, P, N)$ be an accepted* $\mathsf{SierpinskiSpace}^{\uparrow}$ *carrier. Any two accepted observable-open requests are compared only through the displayed open-truth rows B, O, W and the specialization-order readback they determine. The classifier has no access to host propositions, proof irrelevance for ambient opens, excluded middle, or a hidden truth-value evaluator outside the packet.*

Lean4 ✓ `BEDC.Derived.SierpinskiSpaceUp.SierpinskiSpaceCarrier open set classifier`

Proof. Project the accepted carrier. The truth row B supplies the only accepted observable truth marks, and the open row O records the open under inspection as displayed topology data.

The finite-observation row W is the only route by which a countable name can report an observation of that open. Thus a comparison may read whether one displayed observation is below another in the specialization order generated by the observable truth rows, but it cannot inspect an external proposition asserting open membership.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since none of them stores excluded middle, proof irrelevance, a hidden truth evaluator, selected limits, quotient streams, or ambient Real completeness, the classifier is exhausted by observable open-truth readback. □

Theorem 1860.3 (Sierpinski space NameCert obligation surface)**.** *For every accepted* $\mathsf{SierpinskiSpace}^{\uparrow}$ *carrier*

$$S = (B, O, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SierpinskiSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Bool truth row, Topology open-set row, StreamName finite-observation row, transport, replay, provenance, and local naming row;*
2. *open-truth classifier exactness, requiring every observable-open comparison to read B, O, W before any structural row can be consumed;*
3. *specialization-order stability, requiring* hsame *transport to preserve the observable order read from the two truth marks and the displayed open row;*
4. *finite-observation stability, requiring every StreamName window in W to report only the displayed observable truth row attached to O;*
5. *ledger non-escape, requiring H, C, P, N to export no excluded middle, selected limits, quotient streams, countable choice, host proposition equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local observable-open obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1860.1. The accepted packet displays exactly the Bool truth row, the Topology open-set row, finite StreamName observations, and the structural transport, replay, provenance, and local naming rows.

Open-truth classifier exactness follows from the order of the displayed rows. A request can compare observable opens only after reading the truth row B, the open row O, and the finite observation row W.

Specialization-order stability is the componentwise transport clause in H. Transport preserves the displayed truth marks and the open row, so the specialization readback determined by them is preserved as well.

Finite-observation stability is the projection to W. Each window reports the observable truth row attached to O, and no row selects a second stream representative or a detached open-membership proposition.

Finally, ledger non-escape is exhausted by H, C, P, N. These rows transport, replay, source, and name the displayed observable-open route only, and none stores excluded middle, selected limits, quotient streams, countable choice, host proposition equality, ambient Real completeness, Lean verification, or a bridge credential. □

Theorem 1860.4 (Sierpinski space consumer handoff)**.** *Every* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{TZeroReflection}^{\uparrow}$*,* $\mathsf{UrysohnLemma}^{\uparrow}$*, or observable-open-filter consumer of an accepted* $\mathsf{SierpinskiSpace}^{\uparrow}$ *packet must read the* $\mathsf{Bool}^{\uparrow}$ *truth row* B*, the* $\mathsf{Topology}^{\uparrow}$ *open row* O*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, and the structural rows* H, C, P, N *before treating open membership as available. The consumer receives only displayed observable-open truth and its replay route; it receives no host proposition for membership, no excluded middle over opens, no proof-irrelevant open equality, no selected limit, and no quotient stream representative.*

Proof. Project the carrier of Definition 1860.1. The Bool truth row, the Topology open row, and the finite StreamName windows are the only rows that expose observable open membership.

Apply Definition 1860.2. It forces any membership comparison to read B, O, W rather than a detached host proposition or hidden evaluator.

Apply Definition 1860.3. The structural rows H, C, P, N then transport, replay, source, and name that same displayed route before any downstream topology, T0, Urysohn, or observable-open-filter consumer may use it.

Since the carrier has no coordinate for excluded middle, proof-irrelevant open equality, selected limits, quotient stream representatives, or ambient Real completeness, none of those objects can be supplied by the handoff. □

Theorem 1860.5 (Sierpinski observable-open induction)**.** *Let* $S = (B, O, W, H, C, P, N)$ *be an accepted* $\mathsf{SierpinskiSpace}^{\uparrow}$ *carrier, and let* ω *be a finite observable-open request history addressed to the displayed* $\mathsf{StreamName}^{\uparrow}$ *window list* W*. The request is exhausted by induction on that finite window list. The base case reads no positive observation beyond the* $\mathsf{Bool}^{\uparrow}$ *truth row* B *and the* $\mathsf{Topology}^{\uparrow}$ *open row* O*. In the step case, consuming one displayed window from* W *preserves the specialization-order readback through the transport row* H*, then replays the same observable-open route through* C, P, N*. Thus every finite observable-open request over* S *remains inside* B, O, W, H, C, P, N *before any topology-facing consumer can read open membership.*

Proof. Read the observable-open classifier from Definition 1860.2. It restricts every membership comparison to the displayed truth row B, the open row O, the StreamName window row W, and the specialization-order readback determined by those rows.

Induct on the displayed finite window list inside W. In the empty case, the request history contains no positive window report, so the only available observable information is the pair B, O together with the structural rows that name the route.

For a successor window, consume the first displayed window and apply the obligation surface of Definition 1860.3. Finite-observation stability keeps the window attached to the same open row O, and specialization-order stability transports the readback componentwise through H.

After the window is consumed, apply the consumer handoff of Definition 1860.4. The remaining request is replayed through C and sourced and named by P, N, so the induction step produces the same finite route for the tail of the window list. No host open-membership proposition, hidden

evaluator, selected limit, quotient stream, or ambient Real-completeness coordinate is introduced. □

Theorem 1860.6 (Sierpinski observable-open filter link)**.** *Every* $\mathsf{ObservableOpenFilter}^{\uparrow}$ *read through chapter 6399 that consumes an accepted* $\mathsf{SierpinskiSpace}^{\uparrow}$ *carrier*

$$S = (B, O, W, H, C, P, N)$$

must first expose the Sierpinski observable truth row B*, the* $\mathsf{Topology}^{\uparrow}$ *open row* O*, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows* W*, and the structural rows* H, C, P, N*. The downstream filter therefore receives observable-open truth as displayed Sierpinski data, not as a host proposition, selected limit, quotient stream, excluded-middle witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the accepted carrier. The rows B, O, W are the only rows that expose observable-open truth, open-set data, and finite StreamName windows.

Apply Definition 1860.5. It exhausts every finite observable-open request by induction on W and preserves the same route through H, C, P, N.

The ObservableOpenFilter consumer named in chapter 6399 can therefore read only that displayed Sierpinski route. Since no carrier row stores host proposition membership, selected limits, quotient stream representatives, excluded middle, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects is exported to the downstream filter. □

Closure status for $\mathsf{NameCert}_{\mathsf{SierpinskiSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SierpinskiSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1860.1, Definition 1860.2, Definition 1860.3, and Definition 1860.6 seed the finite L10 observable-open classifier route through Bool truth rows, Topology open rows, StreamName finite observations, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SierpinskiSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close excluded middle, choice, selected limits, quotient streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-truth classifier exactness, specialization-order stability, finite-observation stability, and ledger non-escape proofs for BEDC.Derived.SierpinskiSpaceUp.

Constructive story: A $\mathsf{SierpinskiSpace}^{\uparrow}$ packet is generated from a Bool truth row, a Topology open-set row, StreamName finite-observation windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1861

A Concrete Naming Certificate for $\mathsf{CousinLemma}^{\uparrow}$

Following Bishop-style treatments of Cousin's lemma for gauge partitions, the $\mathsf{CousinLemma}^{\uparrow}$ packet names the finite route from a located closed interval and a displayed positive gauge to a tagged interval subdivision. It sits between the finite cover surface of chapter 1596, the positive-radius handoff of chapter 452, and the bisection discipline of chapter 1711. Its Real-facing rows are read through the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter records the traditional finite-subdivision certificate used by later integration and compact-interval cover arguments; it is not general open-cover compactness, a choice-selected partition, or host real completeness.

Definition 1861.1 (Cousin lemma carrier)**.** *A* $\mathsf{CousinLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, G, T, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located closed interval row, including the named endpoints, endpoint order, and the interval boundary that later bisection rows may inspect.*
2. *G is the gauge row, assigning to each displayed tag request a positive local radius read through finite rational and Real-facing witnesses.*
3. *T is the finite tagged-subinterval row. Each entry records a tag, a left endpoint, a right endpoint, adjacency to the neighbouring row, containment in I, and the local gauge admission for that tag.*
4. *M is the mesh ledger recording the endpoint comparisons and mesh bounds used to certify that consecutive tagged subintervals cover exactly the displayed interval row.*
5. *W is the located bisection ledger. It records the finite bisection induction tree that refines any row whose current mesh is not yet admitted by the corresponding gauge radius.*
6. *R is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposed for the endpoint, tag, radius, and mesh observations in I, G, T, M, W.*
7. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite window schedule has been displayed.*

8. *H records componentwise* hsame *transport for the interval, gauge, tagged-subdivision, mesh, bisection, window, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a gauge-partition request through $I, G, W, T, M, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CousinLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, T, M, W, R, E, H, C, P, N$. It has no coordinate for a general open-cover compactness theorem, a choice-selected partition, a host real completeness theorem, quotient stream equality, or an external real interval object.

Lean4 ✓ `BEDC.Derived.CousinLemmaUp.TasteGate.CousinLemmaTasteGate single carrier alignment`

Theorem 1861.2 (Cousin lemma NameCert obligations)**.** *For every accepted* $\mathsf{CousinLemma}^{\uparrow}$ *carrier*

$$K = (I, G, T, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CousinLemma}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located interval, gauge, tagged-subdivision, mesh, bisection, window, readback, Real-seal, transport, replay, provenance, and local naming rows;*
2. *gauge positivity and locality, requiring every tag row of T to read its radius from G and to prove the corresponding tagged subinterval is contained in that local radius window;*
3. *subdivision adjacency and coverage, requiring the ordered entries of T to start at the left endpoint of I, end at the right endpoint of I, and share consecutive endpoints without gaps or overlaps;*
4. *mesh and bisection exactness, requiring M and W to be the only ledgers by which failed local gauge tests are refined into smaller interval rows;*
5. *StreamName, RegSeqRat, and Real-seal discipline, requiring R and E to read only the finite endpoint, tag, radius, and mesh windows already exposed by I, G, T, M, W;*
6. *structural non-escape, requiring H, C, P, N to transport, replay, source, and name no general open-cover compactness theorem, choice-selected partition, host real completeness theorem, quotient stream equality, or external real interval object.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1861.1. The accepted packet displays the located interval, gauge, tagged subdivision, mesh ledger, bisection ledger, finite window schedule, readback and Real seal, and the structural rows.

Gauge positivity and locality are read from G and T. Each tag row carries its own local radius test, and the classifier has no branch that can replace that test by an arbitrary open cover or by a selected point from the ambient host interval.

Subdivision adjacency and coverage are read from T and M. The first and last endpoint comparisons bind the subdivision to I, while consecutive endpoint equality is recorded in the finite mesh ledger.

The refinement surface is exhausted by W. Whenever a current interval row does not satisfy its local gauge test, the next row is produced by the displayed bisection ledger and then re-tested through the same gauge row.

Finally R, E, H, C, P, N preserve this route. The StreamName windows and RegSeqRat readback use only the displayed finite observations, the Real seal is terminal for those observations, and the structural rows transport and name the same packet. Since no excluded coordinate occurs in the carrier, the listed rows are exactly the NameCert obligations. □

Theorem 1861.3 (Cousin tagged partition existence)**.** *Let $K = (I, G, T, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CousinLemma}^{\uparrow}$ *carrier. The tagged-subinterval row T is produced by finite bisection induction over the displayed located interval row I: the base row accepts an interval whose chosen tag radius from G covers the current subinterval, and the induction row bisects a failed interval by W, applies the same local gauge test to both children, and concatenates the accepted child rows with the adjacency ledger in M. Thus T is a finite tagged partition of I whose every tagged subinterval is admitted by its own gauge row.*

Proof. Proceed by finite induction on the bisection tree displayed in W. The base case is an interval row already admitted by its local gauge radius in G. Its single tagged subinterval is entered into T, and M records that its endpoints are the endpoints of the current interval.

For the induction step, take a displayed interval row whose local gauge test has not yet been admitted. The bisection ledger W supplies the midpoint row and the two child interval rows, both still contained in the parent row of I.

Apply the induction hypothesis separately to the left and right child rows. The left accepted list covers the left child, the right accepted list covers the right child, and every row in both lists carries its own tag and gauge-radius admission from G.

Concatenate the two finite lists. The mesh ledger M identifies the shared midpoint endpoint and preserves the outer endpoints inherited from the parent interval. This gives a finite tagged partition of the parent row.

Applying this construction to the root interval row I yields the displayed row T. The proof uses only the finite bisection induction ledger, not open-cover compactness or countable choice. □

Theorem 1861.4 (Cousin finite gauge-partition handoff)**.** *Let $K = (I, G, T, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CousinLemma}^{\uparrow}$ *carrier. The tagged-subinterval row T produced by finite bisection induction is exactly the finite gauge-partition handoff consumed by* $\mathsf{FiniteGaugeCover}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, *and* $\mathsf{HenstockKurzweil}^{\uparrow}$*: every such consumer receives the ordered finite rows*

$$I, G, W, T, M \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

with no additional open-cover compactness, selected partition, host real completeness, quotient stream equality, or external interval equality coordinate.

Proof. Project the accepted carrier to its displayed rows $I, G, T, M, W, R, E, H, C, P, N$. By Definition 1861.3, the finite bisection ledger W produces T over the interval row I, and every entry of T carries its local gauge admission from G with endpoint and adjacency checks recorded in M.

Those are precisely the finite gauge-partition rows inspected by $\mathsf{FiniteGaugeCover}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, and $\mathsf{HenstockKurzweil}^{\uparrow}$. The downstream read cannot start from a separate cover theorem or a selected partition, because the classifier of Definition 1861.1 exposes only the rows $I, G, T, M, W, R, E, H, C, P, N$.

Finally apply Definition 1861.5. It sends the same finite subdivision through R, E, and then H, C, P, N, so the consumer-facing packet is exactly the displayed gauge-partition handoff and not any stronger ambient compactness or completeness principle. □

Theorem 1861.5 (Cousin finite Lebesgue handoff)**.** *Every* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$*, Riemann-style, Darboux-style, compact-interval-cover, or Real-completion consumer of an accepted* $\mathsf{CousinLemma}^{\uparrow}$ *carrier reads the packet through the ordered route*

$$I, G, W, T, M \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The exported handoff is a finite gauge-tagged subdivision certificate over displayed interval rows, StreamName windows, RegSeqRat readback, and the terminal $\mathsf{Real}^{\uparrow}$ *seal. It does not export general open-cover compactness, choice-selected partitions, host real completeness, quotient stream equality, or external interval equality.*

Proof. Start with a downstream consumer read. Carrier admission exposes the located interval row I and the gauge row G before any subdivision data can be inspected.

The bisection ledger W and tagged-subinterval row T then provide the finite subdivision route. The mesh ledger M records the endpoint comparisons and adjacency facts consumed by finite Lebesgue-number, Riemann-style, Darboux-style, and compact-interval-cover arguments.

The Real-facing part of the read passes next through R and E. These rows expose only finite StreamName windows, RegSeqRat readback, and the terminal Real seal attached to the interval, tag, radius, and mesh observations already displayed.

The remaining rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for open-cover compactness, a choice-selected partition, host real completeness, quotient stream equality, or external interval equality, no downstream consumer can read those principles from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CousinLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{CousinLemma}^{\uparrow}$ packet is generated from a located closed interval row, a positive gauge row, finite tagged-subinterval rows, mesh and bisection ledgers, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CousinLemma}^{\uparrow}}$, seed)

Scope closed: Definition 1861.1, Definition 1861.2, Definition 1861.3, Definition 1861.4, and Definition 1861.5 seed the finite gauge-tagged subdivision route from a located closed interval through bisection induction, StreamName windows, RegSeqRat readback, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CousinLemma}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CousinLemmaUp`

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, choice-selected partitions, host real completeness, quotient stream equality, external interval equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge locality, subdivision adjacency, finite bisection induction, finite gauge-partition handoff, finite Lebesgue handoff, Real-seal non-escape, and downstream consumer boundary proofs for BEDC.Derived.CousinLemmaUp.

Chapter 1862

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$ packet records the finite BEDC route by which a regular-Cauchy subsequence read reaches a terminal real-name seal. It consumes the regular-Cauchy subsequence surface of chapter 381, the subsequence-limit consumer boundary of chapter 1467, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the handoff from extracted regular subsequence data to a Real-facing seal as displayed certificate data, not as arbitrary subsequence choice, quotient stream equality, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1862.1 (Regular-Cauchy subsequence limit carrier)**.** *A* $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row, exposing the selected finite windows and the regular-Cauchy discipline inherited from the subsequence extraction route.*
2. *L is the existing* $\mathsf{SubsequenceLimit}^{\uparrow}$ *consumer boundary, recording the finite limit-facing route through which selected subsequence data is read.*
3. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window ledger, containing only the finite windows inspected by the regular-Cauchy subsequence and the limit consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from those selected windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the regular-Cauchy row, the selected windows, the regular rational readback, and the limit boundary.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after S, L, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the subsequence row, limit boundary, selected windows, regular rational readback, dyadic ledger, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite Real-facing read through $S, L, W, R, D, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{SubsequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, W, R, D, E, H, C, P, N$. It has no coordinate for arbitrary subsequence choice, quotient stream equality, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceLimitUp.RegularCauchySubsequenceLimitTasteGate`
`single carrier alignment`

Theorem 1862.2 (Regular-Cauchy subsequence limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$ *carrier*

$$T = (S, L, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular-Cauchy subsequence row, subsequence-limit consumer boundary, selected stream windows, regular rational readback, dyadic tolerance ledger, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *selected-window alignment, requiring every window read by L and R to be one of the finite windows named by W and admitted by the regular-Cauchy subsequence row S;*
3. *tolerance preservation, requiring the dyadic ledger D to be the same ledger consumed by S, W, R, and the limit-facing row L;*
4. *Real-seal handoff, requiring the seal row E to be exposed only after the regular-Cauchy subsequence row, limit boundary, selected windows, regular rational readback, and tolerance ledger have been displayed;*
5. *non-escape, requiring H, C, P, N to transport, replay, source, and name no arbitrary subsequence choice, quotient stream equality, host sequence equality, ambient Real-completeness datum, Lean credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 1862.1. The visible analytic rows are exactly the regular-Cauchy subsequence row S, the subsequence-limit boundary L, selected windows W, regular rational readback R, dyadic ledger D, and terminal seal E.

Selected-window alignment is read from the triple (S, L, W). The row S admits the finite subsequence windows, while L can consume only the windows displayed by the same ledger W.

Tolerance preservation is the projection to D. The regular-Cauchy row, selected-window row, regular rational readback, and limit boundary all name the same dyadic tolerance ledger, so no second budget can alter the limit read.

The Real-seal handoff follows the row order S, L, W, R, D, E. A Real-facing consumer reaches E only after the selected subsequence data, finite windows, regular rational readback, and dyadic tolerance ledger are already visible.

The remaining rows are structural. Componentwise transport, continuation replay, provenance, and local naming preserve only the displayed packet rows, so the excluded host choices, equality principles, completeness claim, Lean credential, and bridge credential cannot enter the local surface. □

Theorem 1862.3 (Regular-Cauchy subsequence limit Real seal boundary)**.** *Let* $T = (S, L, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read from* T *factors through*

$$S, L, W, R, D, E, H, C, P, N.$$

Consequently the terminal seal is reached only through the regular-Cauchy subsequence row, the existing subsequence-limit boundary, selected stream windows, regular rational readback, and the shared dyadic tolerance ledger.

Proof. Begin with a $\mathsf{Real}^{\uparrow}$-facing read of the accepted packet. The carrier places the terminal seal E downstream of S, L, W, R, D, so the read must first inspect the regular-Cauchy subsequence row and the existing subsequence-limit consumer boundary.

The selected windows and readback rows are then forced by Definition 1862.2. Every window consumed by the limit boundary is recorded in W, and every regular rational observation in R uses the same selected-window ledger.

The dyadic tolerance ledger is shared by all analytic rows. Since D is the only displayed tolerance coordinate, the Real-facing read cannot switch to a detached modulus, quotient representative, or host sequence equality before reaching the seal.

Finally H, C, P, N transport, replay, source, and name the same finite route. Thus every Real-facing read factors through the listed rows and exports no arbitrary subsequence choice, quotient stream equality, host sequence equality, ambient completeness theorem, Lean credential, or bridge credential. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$ packet is generated from a RegularCauchySubsequence row, an existing SubsequenceLimit consumer boundary, selected StreamName windows, RegSeqRat readback, a shared DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1862.1, Definition 1862.2, and Definition 1862.3 seed the finite route from regular-Cauchy subsequence data through the subsequence-limit boundary to a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary subsequence choice, quotient stream equality, host sequence equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-window alignment, tolerance preservation, Real-seal handoff, and non-escape proofs for BEDC.Derived.RegularCauchySubsequenceLimitUp.

Chapter 1863

A Concrete Naming Certificate for $\mathsf{DyadicPartition}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the standard dyadic partition use in Riemann and Darboux integration, the $\mathsf{DyadicPartition}^{\uparrow}$ packet records a finite ordered family of dyadic interval cells over chapter 306. It sits between the interval tree route of **??**, the bisection route of chapter 1489, the finite-cover handoff of chapter 1596, and the step-function consumer of chapter 428. The packet gives the L10 Real and Completion route a finite partition interface without importing open-cover compactness, quotient-style real equality, selected mesh limits, or ambient completeness.

Definition 1863.1 (Dyadic partition carrier rows)**.** *A* $\mathsf{DyadicPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (B, I, A, R, F, H, C, G, N)$$

with the following displayed rows:

1. *B is the boundary row. It records the lower and upper dyadic endpoints of the inspected interval, read through the* $\mathsf{DyadicInterval}^{\uparrow}$ *surface.*
2. *I is the finite ordered list of* $\mathsf{DyadicInterval}^{\uparrow}$ *cell rows. Each cell exposes its two dyadic endpoints and its local endpoint ledger.*
3. *A is the adjacency and coverage row. It records that consecutive cells share the displayed endpoint and that the first and last cells meet the boundary row B.*
4. *R is the common-refinement row. It names the finite interval rows produced when two accepted partition carriers are compared through a displayed refinement.*
5. *F is the finite-cover handoff row. It exports the same cells as a finite interval-cover certificate for downstream compactness-facing consumers.*
6. *H records componentwise* hsame *transport for the boundary, cells, adjacency, common-refinement, finite-cover, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a partition request through B, I, A, R, F, H, G, N.*
8. *G is the* Pkg *provenance over* $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicIntervalTree}^{\uparrow}$, $\mathsf{IntervalHalving}^{\uparrow}$, $\mathsf{IntervalFiniteCoverCertificate}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for open-cover compactness, quotient-style real equality, selected limiting mesh, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicPartitionUp.TasteGate.DyadicPartitionTasteGate single carrier alignment`

Definition 1863.2 (Dyadic partition classifier rows)**.** *Two accepted* $\mathsf{DyadicPartition}^{\uparrow}$ *carriers are classified together exactly when their boundary rows agree through the displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint classifier, their cell lists admit the finite common-refinement row* R*, every refined cell transports to a parent cell through the adjacency ledger* A*, and the finite-cover handoff row* F *exports the same displayed cells. The comparison is finite and ordered: every read is mediated by* $B, I, A, R, F, H, C, G, N$*.*

Theorem 1863.3 (Dyadic partition NameCert obligation rows)**.** *For every accepted* $\mathsf{DyadicPartition}^{\uparrow}$ *carrier* $P = (B, I, A, R, F, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicPartition}^{\uparrow}}$ *surface consists of exactly the following obligation rows:*

1. *carrier admission for the displayed boundary, cell list, adjacency, common-refinement, finite-cover, transport, replay, provenance, and local naming rows;*
2. *boundary and cell exposure, requiring every endpoint read to pass through* B *or one of the finitely many cells of* I*;*
3. *adjacency and coverage exactness, requiring* A *to account for shared endpoints and boundary contact;*
4. *common-refinement stability, requiring comparisons of two partition carriers to use the finite row* R *and no hidden partition representative;*
5. *finite-cover handoff, requiring* F *to export exactly the displayed cells to the interval finite-cover route before any step-function or completion-facing consumer reads the packet.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DyadicPartitionUp.TasteGate.DyadicPartitionNamecertObligationRows`

Proof. Project the carrier rows of Definition 1863.1. The accepted packet displays exactly the boundary row, finite ordered cell list, adjacency ledger, common-refinement row, finite-cover handoff, and the structural rows.

Boundary and cell exposure are forced by B and I. A downstream read can inspect an endpoint only through the boundary interval or one of the listed dyadic interval cells.

Adjacency and coverage exactness are forced by A. The shared endpoint and boundary-contact reads are finite rows, so the packet does not select an external subdivision or an ambient real equality witness.

Common-refinement stability is forced by R. When two carriers are compared, the classifier first displays the finite refinement and then transports each refined cell back to its parent cell through A.

Finally, F, H, C, G, N export, transport, replay, source, and name the same rows. Since the carrier has no additional coordinate, the five listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicPartition}^{\uparrow}}$**.**

Constructive story: A DyadicPartition$^{\uparrow}$ packet is generated from a boundary dyadic interval row, a finite ordered list of dyadic interval cells, an adjacency and coverage ledger, a common-refinement row, a finite-cover handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicPartition}\uparrow}$, seed)

Scope closed: Definition 1863.1, Definition 1863.2, and Definition 1863.3 seed the finite dyadic partition interface from displayed dyadic interval cells to common refinement, finite-cover handoff, and step-function consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicPartition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient-style real equality, selected limiting meshes, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary and cell exposure, adjacency and coverage exactness, common-refinement stability, finite-cover handoff, provenance exhaustion, and local naming for BEDC.Derived.DyadicPartitionUp.

Chapter 1864

A Concrete Naming Certificate for $\mathsf{DyadicLipschitzModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ packet records the finite error-propagation route for Lipschitz estimates whose tolerances are read through dyadic rational data. It sits over the dyadic ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the function-bound surface of chapter 410. The packet names a non-quotient certificate for moving a displayed dyadic input tolerance through a displayed Lipschitz bound before any Real-facing consumer can inspect the sealed output.

Definition 1864.1 (DyadicLipschitzModulus carrier)**.** *A* $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, B, G, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the inspected dyadic input radius, the dyadic output allowance, and the finite comparisons used to certify that the input radius is small enough for the displayed Lipschitz bound.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite input-name and output-name windows whose observations may be used by the modulus computation.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same dyadic ledger and stream windows.*
4. *B is the* $\mathsf{LipschitzMap}^{\uparrow}$ *bound ledger. It stores the displayed Lipschitz constant row and the finite multiplication or scaling comparisons needed to move a dyadic input tolerance to a dyadic output tolerance.*
5. *G is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It may be inspected only after D, S, R, B have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular rational readback, Lipschitz bound ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a modulus request through D, S, R, B, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicLipschitzModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicLipschitzModulus}^{\uparrow}}$ *row.*

The carrier contains no Real completeness row, host function extensionality row, quotient stream equality, selected limit, trichotomy datum, countable-choice selector, Lean verification credential, or standard bridge.

Lean4 ✓ `BEDC.Derived.DyadicLipschitzModulusUp.DyadicLipschitzModulusTasteGate single carrier alignment`

Theorem 1864.2 (DyadicLipschitzModulus NameCert obligations)**.** *For every accepted* $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ *carrier*

$$M = (D, S, R, B, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicLipschitzModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance ledger, stream-window row, regular rational readback row, Lipschitz bound ledger, Real seal, componentwise transport, replay, provenance, and local naming row;*
2. *classifier exactness, requiring accepted carriers to be compared only through* $D, S, R, B, G, H, C, P, N$*;*
3. *bound admission, requiring* B *to expose the displayed Lipschitz constant and the finite dyadic scaling comparisons used by the output tolerance;*
4. *finite-window admission, requiring* S *to expose only the input and output windows licensed by* D *and* B*;*
5. *RegSeqRat handoff, requiring* R *to read back the same dyadic and stream-window observations rather than a second regular sequence;*
6. *Real seal nonescape, requiring* G *to be reached only after* D, S, R, B *and to export no Real completeness, host function extensionality, quotient stream equality, selected limit, trichotomy, or bridge credential;*
7. *transport and replay stability, requiring* H, C, P, N *to preserve, replay, source, and name the same finite rows without adding an external analytic premise.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1864.1. The accepted packet displays exactly the dyadic tolerance ledger, stream windows, regular rational readback, Lipschitz bound ledger, Real seal, and structural rows.

Classifier exactness is componentwise. Two accepted carriers can be compared only by the displayed coordinates $D, S, R, B, G, H, C, P, N$, so no hidden function equality, quotient-stream equality, selected limit, or trichotomy branch can enter the classifier.

The bound and finite-window clauses are forced by B and S. The Lipschitz row supplies the displayed constant and finite dyadic scaling comparisons, while the stream row supplies only the input and output observations licensed by those dyadic comparisons.

The regular rational and Real-facing clauses are downstream. The row R reads back the same observations as a regular rational name, and G seals the resulting Real-facing value only after D, S, R, B have been displayed.

Finally H, C, P, N preserve the route. Transport is componentwise, replay follows the displayed request path, provenance names the same source packets, and the local NameCert row names only this packet. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 1864.3 (DyadicLipschitzModulus RegSeqRat handoff)**.** *Let $M = (D, S, R, B, G, H, C, P, N)$ be an accepted* $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ *carrier. Every consumer route exported by M factors through the finite path*

$$D \longmapsto S \longmapsto R \longmapsto B \longmapsto G$$

before it can inspect the transport, replay, provenance, or local naming rows. Thus every Real-facing Lipschitz error read passes through dyadic tolerance data, StreamName windows, RegSeqRat readback, the Lipschitz bound ledger, and the terminal $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Begin with an exported consumer route. The carrier has no analytic source row before the dyadic tolerance ledger D, so the input tolerance and the output allowance are read first as displayed dyadic data.

The route then passes through S and R. The stream row exposes only the finite input and output windows licensed by the dyadic ledger, and the regular rational row repacks those same observations as the readback available to later consumers.

Next the route reads B. The displayed Lipschitz constant and dyadic scaling comparisons are the only rows allowed to propagate the input tolerance into an output tolerance.

Only after this finite path has been displayed can the route reach the Real seal G. The remaining rows H, C, P, N transport, replay, source, and name that path, so every exported consumer route factors through the dyadic tolerance, StreamName, RegSeqRat, Lipschitz-bound, and $\mathsf{Real}^{\uparrow}$-seal stages. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicLipschitzModulus}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicLipschitzModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1864.1, Definition 1864.2, and Definition 1864.3 seed the finite L10 route from dyadic tolerance data through StreamName windows, RegSeqRat readback, Lipschitz bound propagation, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicLipschitzModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, host function extensionality, quotient streams, selected limits, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, bound admission, finite-window admission, RegSeqRat handoff, Real seal nonescape, transport stability, and replay stability for BEDC.Derived.DyadicLipschitzModulus

Constructive story: A $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a LipschitzMap bound ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1865

A Concrete Naming Certificate for $\mathsf{SignedDyadicNormalForm}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ packet records the finite signed dyadic normal-form boundary used between the arithmetic surface of chapter 291 and the stream, regular-rational, and real-name handoff surfaces of chapter 126, chapter 301, and chapter 38. It reads signed mantissas through the rational and integer certificates of chapter 37 and chapter 31, records the positive unary exponent and denominator ledger as finite rows, and exposes canonical comparison only after a common-scale replay has been displayed.

The packet is a normal-form interface for L10 real and completion work. It gives downstream chapters a single finite object to cite when they need dyadic comparison, distance, radius, or scale data, without importing quotient rational equality, host integer normal forms, quotient streams, host real equality, trichotomy, choice, or Real completeness.

Definition 1865.1 (Signed dyadic normal-form carrier)**.** *A* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, E, L, C, K, D, T, H, R, P, N)$$

with the following displayed rows:

1. *M is the signed mantissa row, read through the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$ *certificate surfaces rather than through a host integer normal form.*
2. *E is the positive unary exponent row, recording the denominator scale as finite* $\mathsf{UnaryHistory}$ *data.*
3. *L is the denominator ledger row, listing the finite denominator witnesses and the scale requests consumed by the packet.*
4. *C is the common-scale row, displaying the single scale at which two signed dyadic rows may be compared or subtracted.*
5. *K is the normalized comparison row, recording sign, zero, distance, and radius comparisons only after the common-scale row has been projected.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *provenance row for the mantissa, exponent, denominator ledger, common scale, and comparison data.*
7. *T is the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff row, exposing precisely the normal-form data that downstream completion consumers may read.*

8. *H records componentwise* hsame *transport for the mantissa, exponent, denominator ledger, common scale, comparison, dyadic provenance, handoff, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from a signed dyadic request through mantissa inspection, exponent inspection, denominator ledger lookup, common-scale comparison, normalized comparison, DyadicRatCore provenance, downstream handoff, transport, packaging, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, L, C, K, D, T, H, R, P, N$. It has no coordinate for quotient rational equality, host integer canonicalization, quotient stream equality, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SignedDyadicNormalFormUp.SignedDyadicNormalFormTasteGate single carrier alignment`

Theorem 1865.2 (Signed dyadic normal-form NameCert obligations)**.** *For every accepted* SignedDyadicNormalForm *carrier $S = (M, E, L, C, K, D, T, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicNormalForm}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the signed mantissa, positive unary exponent, denominator ledger, common scale, normalized comparison, DyadicRatCore provenance, completion handoff, transport, replay, provenance, and local naming rows;*
2. *signed-mantissa exactness, requiring each mantissa read to pass through the displayed* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$ *rows before any dyadic comparison is exported;*
3. *denominator-ledger exactness, requiring every denominator and scale request to be discharged by E and L before the common-scale row is opened;*
4. *common-scale classifier stability, requiring C and K to be preserved componentwise under* hsame *transport and displayed* Cont *replay;*
5. *completion-handoff nonescape, requiring the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers in T to read only the displayed normal-form route.*

No signed dyadic normal-form obligation is stored outside these rows.

Proof. Project the carrier of Definition 1865.1. The finite packet exposes exactly the signed mantissa, positive unary exponent, denominator ledger, common scale, normalized comparison, DyadicRatCore provenance, handoff, and structural rows.

The mantissa and denominator obligations are forced by the order of the displayed rows. A comparison cannot read the mantissa without passing through M, and it cannot read a denominator scale without the exponent row E and ledger row L.

Common-scale stability is the role of C, K, H, R. The common-scale row fixes the scale, the normalized comparison row records the comparison at that scale, the transport row preserves those coordinates componentwise, and the replay row repeats the same route.

The downstream handoff is then only a reader of the normal form. Since T is downstream of M, E, L, C, K, D and the structural rows contain no excluded coordinate, the local NameCert surface exports no quotient rational equality, host integer normal form, quotient stream equality, host real equality, trichotomy, choice, ambient real completeness, Lean credential, or bridge datum. □

Theorem 1865.3 (Signed dyadic common-scale canonicality)**.** *Let $S = (M, E, L, C, K, D, T, H, R, P, N)$ be an accepted* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *carrier. Every normalized comparison exported by S factors through the finite route*

$$M, E, L \longmapsto C \longmapsto K \longmapsto D, H, R, P, N.$$

Thus the comparison is canonical at the displayed common scale, and two accepted replays with componentwise hsame *rows export the same normalized comparison surface without appealing to quotient equality or trichotomy.*

Proof. Start with an exported normalized comparison. Carrier admission places the only comparison coordinate at K, and K is downstream of the common-scale row C.

The row C is downstream of the signed mantissa, positive unary exponent, and denominator ledger rows. Hence the compared signed dyadics are first read through M, E, L, and the common comparison scale is part of the finite packet before K can be inspected.

Componentwise transport through H preserves M, E, L, C, K as displayed rows, while replay through R repeats the same access path. Provenance and local naming through P, N source and name that route but do not add a second comparison rule.

Therefore a downstream reader receives the normalized comparison at the displayed common scale. The conclusion is canonical for this finite carrier route and uses neither quotient equality nor a trichotomy principle. □

Theorem 1865.4 (Signed dyadic Real handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer named by an accepted* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *carrier reads the route*

$$M, E, L, C, K, D \longmapsto T \longmapsto H, R, P, N.$$

Consequently the handoff supplies signed dyadic normal-form data for stream windows, regular rational Cauchy names, and real-name consumers without importing quotient streams, host real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the handoff row T. It is the only row whose purpose is to expose the signed dyadic packet to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers.

The row T is downstream of the arithmetic and normal-form rows M, E, L, C, K, D. A consumer therefore sees signed mantissa data, positive unary exponent data, denominator ledger data, common-scale comparison data, normalized comparison data, and DyadicRatCore provenance before any stream or completion-facing read is available.

Transport, replay, provenance, and local naming preserve the same route. They do not store quotient streams, host real equality, representative selectors, choice schedules, or completeness principles.

Thus the downstream consumer receives a finite signed dyadic normal-form boundary. The packet is sufficient for stream-window, regular rational Cauchy, and real-name handoffs, but it does not claim any completed real object or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDyadicNormalForm}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDyadicNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1865.1, Definition 1865.2, Definition 1865.3, and Definition 1865.4 seed the finite signed dyadic normal-form boundary between DyadicRatCore arithmetic and StreamName, RegSeqRat, and Real handoff consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDyadicNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, host integer normal forms, quotient streams, host real equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed-mantissa exactness, denominator-ledger exactness, common-scale classifier stability, completion-handoff nonescape, and Real-and-Completion replay for BEDC.Derived.SignedDyadicNormalFormUp.

Constructive story: A SignedDyadicNormalForm$^{\uparrow}$ packet is generated from signed Rat and Int mantissa rows, a positive UnaryHistory exponent row, a denominator ledger, a common-scale row, a normalized comparison row, DyadicRatCore provenance, StreamName, RegSeqRat, and Real handoff support, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1866

A Concrete Naming Certificate for $\mathsf{NormalSpace}^{\uparrow}$

Following Kelley and Munkres, with Urysohn and Bourbaki as the separation-theory background, normal spaces are read here as the finite BEDC surface that separates two displayed closed-set rows by disjoint open-neighborhood rows. The $\mathsf{NormalSpace}^{\uparrow}$ packet sits after the open-set discipline of chapter 88, beside the point-separation surface of chapter 1925, before the separation-function route of **??**, and also beside the positive-open route of chapter 1857, the observable-open classifier of chapter 1860, and the Cauchy-facing topology interface of chapter 1847. It names only the local separation route; it does not import a selected complement, excluded middle, open-cover compactness, choice-selected functions, host powersets, or a function extension theorem.

Definition 1866.1 (Normal space carrier)**.** *A* $\mathsf{NormalSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the ambient open-row discipline and the finite observation surface used by the separation read.*
2. *S is the* $\mathsf{HausdorffSpace}^{\uparrow}$ *compatibility row when a point-separation consumer supplies separated names before closed-pair separation is requested; it is read only as displayed neighbourhood data and is not part of the closed-pair classifier.*
3. *F_0 and F_1 are the two closed-set witness rows, displayed as ledger entries over the same topological source rather than as host complements.*
4. *D is the disjointness ledger, recording that the two closed-set witnesses have no accepted common membership cell inside the displayed packet.*
5. *U_0 and U_1 are the separating open-neighborhood rows, with F_0 contained in U_0, F_1 contained in U_1, and no accepted overlap between U_0 and U_1.*
6. *H records componentwise* hsame *transport for the topology source, closed-set witnesses, disjointness ledger, open-neighborhood rows, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a separation request through $T, F_0, F_1, D, U_0, U_1, H, P, L$.*
8. *P is the* Pkg *provenance over* $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{CozeroSet}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{CauchySpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{NormalSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, F_0, F_1, D, U_0, U_1, H, K, P, L$, with S available only as a compatibility handoff from the sibling Hausdorff surface. It has no coordinate for selected complements, host closed-set predicates, host powersets, excluded middle, Urysohn functions, choice-selected functions, Tietze extension data, paracompact refinements, classical separation principles not displayed by the rows, or open-cover compactness.

Lean4 (definition) `BEDC.Derived.NormalSpaceUp.NormalSpaceUp`

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpaceTasteGate single carrier alignment`

Theorem 1866.2 (Normal space NameCert obligations)**.** *For every accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier*

$$N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{NormalSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, the two closed-set witnesses, the disjointness ledger, the separating open-neighborhood pair, transport, replay, provenance, and local naming;*
2. *Hausdorff compatibility, requiring any point-separation input to arrive through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *neighbourhood row of chapter 1925 before it can be compared with the closed-pair request;*
3. *closed-pair exposure, requiring every separation request to display F_0, F_1 over the same topology source before any open-neighborhood row can be consumed;*
4. *open-separation exactness, requiring U_0, U_1 to contain the displayed closed witnesses and to carry the packet's own disjointness read for the two open neighborhoods;*
5. hsame *and* Cont *transport, requiring componentwise transport and replay to preserve the topology source, the closed pair, the disjointness ledger, and the two separating open rows;*
6. *Urysohn handoff discipline, requiring any later* $\mathsf{UrysohnLemma}^{\uparrow}$ *consumer of* **??** *to receive only the displayed closed pair, disjointness ledger, and separating open-neighborhood rows;*
7. *no excluded-middle or classical-complement escape, requiring H, K, P, L to export no selected complement, host closed-set predicate, host powerset, excluded middle, choice-selected function, Urysohn function, Tietze extension datum, paracompact refinement, classical separation principle not displayed by the rows, or open-cover compactness principle.*

No local normal-space obligation is stored outside these displayed rows.

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket semantic name certificate`

Proof. Carrier admission is projection from Definition 1866.1. The accepted packet displays exactly the topology source, the closed-pair witnesses, the disjointness ledger, the open-neighborhood pair, and the structural transport, replay, provenance, and naming rows.

Closed-pair exposure follows from the order of the carrier. A separation request first reads T and then the two closed-set witnesses F_0, F_1 over that same source; no open-neighborhood row is available before the closed pair has been displayed.

Open-separation exactness is the projection to D, U_0, U_1. The ledger D records disjointness for the displayed closed pair, while U_0 and U_1 record the two open neighborhoods, the two containment reads, and the open-neighborhood disjointness read internal to the packet.

Transport and replay are exhausted by H and K. These rows move the topology source, closed-pair witnesses, disjointness ledger, and open-neighborhood pair componentwise and replay the same finite route.

The Hausdorff compatibility row is only a sibling handoff. It can supply displayed separated-neighbourhood evidence from chapter 1925, but it cannot replace the closed-pair route or add host point equality.

The Urysohn handoff is also downstream only. A later consumer from **??** receives $T, F_0, F_1, D, U_0, U_1, H, K, P, L$ as displayed rows, not a selected separating function.

Finally, non-escape follows from the absence of any further classifier coordinate. The provenance and local NameCert rows name only this finite separation route, so no row stores a selected complement, excluded middle, host closed-set predicate, host powerset, choice-selected function, Urysohn function, Tietze extension datum, paracompact refinement, classical separation principle not displayed by the rows, or open-cover compactness principle. □

Theorem 1866.3 (Normal space open-separation route)**.** *Every separation read exported by an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *packet factors through the displayed closed-pair row and the two open-neighborhood rows before the local naming row can be inspected.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket open separation route`

Proof. Begin with a separation request for the displayed normal-space surface. Carrier admission exposes the topology source T, but it exports no local normal-space name before the closed-set witnesses are read.

The request then reads the displayed closed pair F_0, F_1 and the disjointness ledger D. This fixes the pair to be separated and prevents substitution by an external complement or host predicate.

Only after F_0, F_1, D have been displayed may the request inspect the open-neighborhood rows U_0, U_1. These rows supply the two containment reads and the disjointness read for the open neighborhoods.

The replay and transport rows then carry this same factorization to the local naming row L. Thus every exported separation read passes through the displayed closed pair and the two separating open-neighborhood rows before local naming. □

Theorem 1866.4 (Normal space Urysohn and cozero localization)**.** *Every* $\mathsf{UrysohnLemma}^{\uparrow}$ *or* $\mathsf{CozeroSet}^{\uparrow}$ *consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier* $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$ *localizes to the displayed topology source, the two closed-set rows, the disjointness ledger, the separating open-neighborhood rows, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local NameCert rows. The consumer receives its normal-space input through* $T, F_0, F_1, D, U_0, U_1, H, K, P, L$ *and not through selected complements, host powersets, choice-selected Urysohn functions, detached cozero predicates, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket urysohn cozero localization`

Proof. Project the carrier of Definition 1866.1. The only normal-space rows exposed to a downstream consumer are the topology source, the closed pair, the disjointness ledger, the separating open-neighborhood pair, and the structural transport, replay, provenance, and naming rows.

Apply Definition 1866.2. Its Urysohn handoff discipline and non-escape row say that the consumer reads closed-pair exposure and open-separation exactness as displayed NameCert data, not as an ambient function-selection principle.

Use Definition 1866.3. It forces the read through F_0, F_1, D before U_0, U_1, and through those open-neighborhood rows before L.

Thus a $\mathsf{CozeroSet}^{\uparrow}$ consumer may reuse the positive-open boundary already displayed by U_0, U_1, and a $\mathsf{UrysohnLemma}^{\uparrow}$ consumer may reuse the same closed-pair and open-neighborhood route. Neither consumer obtains selected complements, host powersets, choice-selected Urysohn functions, detached cozero predicates, or open-cover compactness from the $\mathsf{NormalSpace}^{\uparrow}$ packet. □

Theorem 1866.5 (Normal space closed-set separation route)**.** *For every accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier* $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$*, any closed-set separation consumer must read* F_0 *and* F_1 *over the displayed topology source* T*, then the disjointness ledger* D*, then the separating open-neighborhood rows* U_0 *and* U_1*, before it can inspect provenance or the local NameCert row. The route is preserved by* H *and* K *and exports no selected complement, host closed-set predicate, host powerset, or open-cover compactness witness.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket closed set separation route`

Proof. Start with carrier admission from Definition 1866.1. The closed-set rows F_0 and F_1 are coordinates of the same packet as the topology source T, so they are read over that source rather than over an external host predicate.

Apply the NameCert obligation theorem Definition 1866.2. Closed-pair exposure requires F_0, F_1 before any open-neighborhood row is consumed, and open-separation exactness requires U_0, U_1 to contain the displayed closed witnesses while carrying the packet's own disjointness read.

Now apply Definition 1866.3. It places the local name downstream of the closed pair, the disjointness ledger, and the two open-neighborhood rows.

The componentwise hsame row H and displayed Cont replay row K preserve that order. Since no selected complement, host closed-set predicate, host powerset, or open-cover compactness witness appears as a carrier coordinate, the closed-set separation consumer cannot read such data from the packet. □

Theorem 1866.6 (Normal space Cauchy and Hausdorff consumer boundary)**.** *Every* $\mathsf{CauchySpace}^{\uparrow}$ *or* $\mathsf{HausdorffSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier factors its topology-facing read through the displayed source* T*, the closed-set rows* F_0, F_1*, the disjointness ledger* D*, the separating open-neighborhood rows* U_0, U_1*, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local NameCert rows. Hausdorff point-separation data may enter only as the displayed compatibility handoff described by the carrier, and Cauchy-facing topology reads receive no selected complements, host powersets, choice-selected Urysohn functions, quotient completion data, or open-cover compactness from the normal-space packet.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket cauchyspace hausdorff consumer boundary`

Proof. Project the accepted packet. The topology source T and the optional $\mathsf{HausdorffSpace}^{\uparrow}$ compatibility handoff are displayed before the closed-pair route, while the closed-set rows, disjointness ledger, and open-neighborhood rows remain the only normal-space separation coordinates.

Use Definition 1866.2. The Hausdorff compatibility obligation allows point-separation information only as displayed neighbourhood data from the sibling Hausdorff surface; it does not replace the closed-pair classifier or add host point equality.

Apply Definition 1866.3. Any Cauchy-facing topology read that consumes normal-space separation must pass through F_0, F_1, D, U_0, U_1 before reaching provenance or local naming, and H, K replay the same finite route after transport.

Therefore a $\mathsf{CauchySpace}^{\uparrow}$ consumer receives only the topology and separation rows needed for its local topology interface, while a $\mathsf{HausdorffSpace}^{\uparrow}$ consumer receives only the displayed compatibility handoff and the closed-pair route. Selected complements, host powersets, choice-selected

Urysohn functions, quotient completion data, and open-cover compactness are absent from the carrier and cannot be exported. □

Theorem 1866.7 (Normal space closed-pair stability)**.** *For every accepted* NormalSpace$^{\uparrow}$ *carrier* $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$*, componentwise* hsame *transport and displayed* Cont *replay preserve the closed-pair and separating-open route. The transported packet still reads* F_0, F_1 *over the transported topology source, still reads* D *as the disjointness ledger for that displayed pair, still reads* U_0, U_1 *as the separating open-neighborhood rows, and still reaches the local name only after those rows have been replayed.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket closed pair stability`

Proof. Project the carrier of Definition 1866.1. The closed-pair rows, disjointness ledger, separating open-neighborhood rows, componentwise transport row, and replay row are all explicit coordinates of the accepted packet.

Apply the open-separation route Definition 1866.3. It fixes the order in which a separation read reaches local naming: first the topology source and closed pair, then the disjointness ledger, then the two open-neighborhood rows.

The transport row H moves those displayed coordinates componentwise, while the replay row K replays the same finite route after transport. Since no carrier coordinate stores a selected complement, external closed-set predicate, or host powerset, stability can preserve only the displayed closed-pair and separating-open rows. □

Theorem 1866.8 (Normal space cozero-Urysohn handoff)**.** *Every* CozeroSet$^{\uparrow}$ *or* UrysohnLemma$^{\uparrow}$ *consumer of an accepted* NormalSpace$^{\uparrow}$ *packet can read only the displayed topology source, closed-pair rows* F_0, F_1*, disjointness ledger* D*, separating open-neighborhood rows* U_0, U_1*, componentwise transport, displayed replay, provenance, and local naming. Such a consumer receives no selected complement, host powerset, choice-selected separating function, detached cozero predicate, or ambient classical separation principle from the normal-space packet.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket cozero urysohn handoff`

Proof. Start with the NameCert obligation surface of Definition 1866.2. It exposes closed-pair data, open-separation exactness, transport, replay, provenance, local naming, and the Urysohn handoff discipline as displayed rows.

Use Definition 1866.3 and Definition 1866.7. These force downstream reads to pass through the same closed-pair, disjointness, and separating-open rows even after componentwise transport and replay.

A CozeroSet$^{\uparrow}$ consumer may therefore read only the positive-open boundary already contained in those displayed open-neighborhood rows. A UrysohnLemma$^{\uparrow}$ consumer may read the same closed-pair and open-neighborhood route, but it must supply any separating-function certificate separately.

The carrier contains no coordinate for selected complements, host powersets, choice-selected functions, detached cozero predicates, or classical separation principles. Hence neither downstream consumer can obtain those data from the NormalSpace$^{\uparrow}$ packet. □

Theorem 1866.9 (Normal space closed-pair transport)**.** *For every accepted* NormalSpace$^{\uparrow}$ *carrier* $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$*, componentwise* hsame *transport preserves the displayed closed-pair surface. A transported separation read still exposes* F_0 *and* F_1 *over the same topology source* T*, and the transported disjointness row is the image of the displayed ledger* D *rather than an external closed-set predicate or complement choice.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket closed pair transport`

Proof. Project the finite rows from Definition 1866.1. The carrier stores T, F_0, F_1, D before the open-neighborhood rows and before the local naming row.

Apply the transport obligation from Definition 1866.2. The row H moves the topology source, the two closed-set witnesses, and the disjointness ledger componentwise, so the transported request still reads the same displayed closed pair over the same transported topology source.

Finally apply the route theorem Definition 1866.3. Since local naming is unavailable before F_0, F_1, D have been displayed, the transported packet cannot replace the closed-pair data by a host complement, selected predicate, or external disjointness witness. □

Theorem 1866.10 (Normal space open-neighborhood stability)**.** *For every accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier* $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$*, the separating open-neighborhood rows remain stable under the same componentwise transport. The transported rows* U_0 *and* U_1 *still contain the transported closed witnesses, still carry the packet's own disjointness read, and still precede every inspection of the local naming row* L*.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket open neighborhood stability`

Proof. The NameCert obligation surface in Definition 1866.2 identifies open-separation exactness as a displayed row, not as an ambient theorem about normal spaces. Thus U_0 and U_1 store the two containment reads and the open-neighborhood disjointness read inside the carrier.

Use Definition 1866.9 to transport the closed witnesses and the disjointness ledger. The componentwise transport row H then moves U_0 and U_1 with those witnesses, preserving which closed row each neighborhood contains.

The factorization of Definition 1866.3 forces the transported read through the closed pair and the two separating open rows before local naming. Therefore the open-neighborhood stability is part of the displayed finite route and does not import Urysohn, Tietze, paracompact, or open-cover data. □

Theorem 1866.11 (Normal space Urysohn handoff)**.** *Every* $\mathsf{UrysohnLemma}^{\uparrow}$ *consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *packet must read the route*

$$\mathsf{Topology}^{\uparrow}, \mathsf{HausdorffSpace}^{\uparrow}, F_0, F_1, D, U_0, U_1, H, K, P, L \longmapsto \mathsf{UrysohnLemma}^{\uparrow}$$

through the displayed rows of Definition 1866.1. The handoff exports the topology source, optional Hausdorff neighbourhood compatibility, the closed-set pair, the disjointness ledger, the two separating open-neighborhood rows, componentwise transport, displayed replay, provenance, and local naming; it exports no choice-selected separating function, host powerset of opens, selected complement, excluded-middle branch, or classical separation principle not already displayed by those rows.

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket topology consumer boundary`

Proof. Start with the carrier projection. The topology source T is the only ambient open-row discipline available to the packet, and any point-separation compatibility has already been confined to the displayed $\mathsf{HausdorffSpace}^{\uparrow}$ handoff described in Definition 1866.1.

The closed-pair request then reads F_0, F_1, D. These rows expose the two closed-set witnesses and their disjointness ledger over the same topology source, so the request cannot be replaced by a host powerset predicate or by a selected complement.

Only after that read does the packet expose U_0 and U_1. Those rows are precisely the separating open neighborhoods consumed by the sibling $\mathsf{UrysohnLemma}^{\uparrow}$ route of **??**.

The structural rows H, K, P, L preserve and name this route. Because the carrier has no coordinate for a selected separating function, a host powerset of opens, excluded middle, or a classical separation principle outside the displayed rows, the Urysohn-facing consumer receives only the stated finite handoff. □

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket urysohn handoff`

Theorem 1866.12 (Normal space topology-consumer boundary)**.** *Every topology-facing consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier can inspect only the rows* $T, F_0, F_1, D, U_0, U_1, H, K, P, L$*. Such a consumer may read the topology source, the displayed closed pair, the disjointness ledger, the separating open-neighborhood rows, componentwise transport, replay, provenance, and local naming, but it cannot import Urysohn functions, Tietze extension data, paracompact refinements, selected complements, excluded middle, or open-cover compactness.*

Proof. Start with the carrier projection of Definition 1866.1. The accepted packet has exactly the listed rows $T, F_0, F_1, D, U_0, U_1, H, K, P, L$ available to a topology-facing consumer.

The obligation theorem Definition 1866.2 says that all local normal-space obligations are exhausted by carrier admission, closed-pair exposure, open-separation exactness, transport, replay, provenance, local naming, and non-escape. The closed-pair transport theorem and the open-neighborhood stability theorem keep those same rows stable under componentwise hsame transport.

It remains only to rule out extra topology principles. The open-separation route Definition 1866.3 exposes no coordinate beyond the displayed rows, so no consumer can read Urysohn, Tietze, paracompact, selected-complement, excluded-middle, or open-cover compactness data from this packet. □

Theorem 1866.13 (Normal space Tietze extension refusal)**.** *Every accepted* $\mathsf{NormalSpace}^{\uparrow}$ *packet exposes only the displayed topology source, closed-pair rows, disjointness ledger, and two separating open-neighborhood rows, together with componentwise transport, replay, provenance, and local naming. It does not expose a continuous extension row, a selected function, a host powerset of closed or open sets, a Tietze extension theorem, or any choice-selected extension datum.*

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket tietze extension refusal`

Proof. Start with the carrier of Definition 1866.1. Its public rows are the topology source, the two closed-set witnesses, the disjointness ledger, the separating open-neighborhood pair, and the structural rows.

Apply Definition 1866.2 and Definition 1866.3. These identify the local obligation surface with closed-pair exposure and open-separation exactness, not with extension of functions.

Use Definition 1866.10 and Definition 1866.12. Stability preserves only the displayed open-neighborhood route, while the topology boundary refuses Urysohn functions, Tietze extension data, host powersets, selected complements, excluded middle, and open-cover compactness. Hence no Tietze extension row is exported by the packet. □

Theorem 1866.14 (Normal space Urysohn lemma consumer exactness)**.** *An* $\mathsf{UrysohnLemma}^{\uparrow}$ *consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *packet may read the displayed closed pair* F_0, F_1*, disjointness*

ledger D, and separating open-neighborhood rows U_0, U_1 through Definition 1866.11. It must supply any separating-function certificate separately; the normal-space packet itself exports no choice-selected function, host powerset, excluded-middle branch, Tietze extension datum, or classical separation principle beyond those displayed rows.

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket urysohn lemma consumer exactness`

Proof. Project the carrier in Definition 1866.1. The Urysohn-facing data available to a consumer are exactly the topology source, the closed pair, the disjointness ledger, the open-neighborhood pair, and the structural rows.

Apply Definition 1866.11. The handoff lets the consumer read the displayed closed pair and separating open neighborhoods, but it names no separating function row.

The exactness of that boundary is fixed by Definition 1866.3, Definition 1866.10, and Definition 1866.12. These results keep the consumer on the displayed normal-space route and exclude host powersets, selected functions, Tietze data, excluded middle, and classical separation principles not present in the carrier. □

Theorem 1866.15 (Normal space scoped kernel grounding)**.** *The* $\mathsf{NormalSpace}^{\uparrow}$ *obligation surface is scoped over the displayed closed-pair rows F_0, F_1, D, separating open-neighborhood rows U_0, U_1, cozero-Urysohn handoff rows, topology-consumer rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows of Definition 1866.1. The scope imports neither unrestricted Tietze extension nor host topological equality.*

Proof. Begin with Definition 1866.2. It identifies the local certificate obligations with carrier admission, closed-pair exposure, open-separation exactness, Hausdorff compatibility, Urysohn handoff discipline, transport, replay, provenance, local naming, and non-escape.

Use the route and stability results next. The open-separation route of Definition 1866.3, closed-pair stability of Definition 1866.7, closed-pair transport of Definition 1866.9, and open-neighborhood stability of Definition 1866.10 keep every separation read on the displayed $F_0, F_1, D, U_0, U_1, H, K, P, L$ rows.

For downstream consumers, apply the cozero-Urysohn handoff of Definition 1866.11 and the topology-consumer boundary of Definition 1866.12. They allow only the displayed separation route to feed Urysohn-facing, cozero-facing, and topology-facing consumers.

Finally apply the Tietze refusal of Definition 1866.13. Since unrestricted Tietze extension, selected functions, host powersets, and host topological equality are not carrier coordinates, the scoped kernel is exactly the displayed normal-space route and no larger ambient separation principle. □

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket scoped kernel grounding`

Theorem 1866.16 (Normal space public separation certificate)**.** *Every public topology-facing consumer of an accepted* $\mathsf{NormalSpace}^{\uparrow}$ *carrier $N = (T, F_0, F_1, D, U_0, U_1, H, K, P, L)$ receives one separation certificate surface consisting of closed-pair stability, closed-pair transport, open-neighborhood stability, the* $\mathsf{UrysohnLemma}^{\uparrow}$ *handoff, and the topology-consumer boundary. The public read exposes only*

$$T, F_0, F_1, D, U_0, U_1, H, K, P, L$$

and exports no Tietze extension row, selected complement, choice-selected separating function, host powerset, excluded-middle branch, or open-cover compactness principle.

Lean4 ✓ `BEDC.Derived.NormalSpaceUp.NormalSpacePacket public separation certificate`

Proof. Start with the NameCert obligation surface and the scoped kernel grounding. Theorems 1866.2 and 1866.15 identify the finite separation rows as the topology source, closed pair, disjointness ledger, separating open neighborhoods, transport, replay, provenance, and local naming.

Apply the stability and transport rows. Theorems 1866.7, 1866.9, and 1866.10 keep the closed witnesses, the disjointness ledger, and the two open neighborhoods on the displayed route after componentwise hsame transport and Cont replay.

For downstream consumers, use Definition 1866.11 and Definition 1866.12. The Urysohn-facing read receives the closed-pair and open-neighborhood data as input only, while the general topology-facing boundary permits no extra coordinate beyond $T, F_0, F_1, D, U_0, U_1, H, K, P, L$.

Finally apply Definition 1866.13 and Definition 1866.14. Since Tietze extension, selected complements, host powersets, excluded middle, selected separating functions, and open-cover compactness are absent from the carrier, the public certificate exports only the finite normal-space separation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalSpace}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NormalSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: The consumer-boundary and topology-route theorems Definition 1866.3, Definition 1866.9, Definition 1866.10, Definition 1866.11, Definition 1866.14, Definition 1866.12, and Definition 1866.16 bind the closed-pair, open-neighborhood, Urysohn-facing, cozero-facing, and topology-facing consumer lattice.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NormalSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Tietze extension, selected complements, choice-selected functions, host powersets, excluded middle, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Bridge checking requires a Lean bridge witness for the displayed closed-pair and open-neighborhood handoff; this chapter does not claim that checked bridge.

Constructive story: A $\mathsf{NormalSpace}^{\uparrow}$ packet is generated from a Topology source row, a Hausdorff compatibility handoff when present, two closed-set witness rows, a disjointness ledger, two separating open-neighborhood rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1867

A Concrete Naming Certificate for $\mathsf{ProductFilter}^{\uparrow}$

Following Bourbaki and Kelley on product filters and filter bases, the $\mathsf{ProductFilter}^{\uparrow}$ packet records a finite BEDC product-base route over the filter-base surface of chapter 1601, the Cauchy-filter surface of chapter 333, the stream-window surface of chapter 126, and the regular rational read-back surface of chapter 301. It also keeps the dyadic tolerance and real-facing boundary visible through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, so completion consumers can read a product filter base without importing an ultrafilter, a quotient filter, a selected limit, choice data, host real equality, or ambient completeness.

Definition 1867.1 (Product filter finite carrier)**.** *A* $\mathsf{ProductFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B_X, B_Y, I, \pi_X, \pi_Y, D, R, H, C, P, N)$$

with the following displayed rows:

1. *B_X is the first* $\mathsf{FilterBase}^{\uparrow}$ *row. It stores the finite base packets, their directed lower-bound witnesses, and their local refinement ledger for the first component.*
2. *B_Y is the second* $\mathsf{FilterBase}^{\uparrow}$ *row, with the same displayed filter-base boundary for the second component.*
3. *I is the product index row. Each entry names a finite product-base request assembled from one displayed request in B_X and one displayed request in B_Y.*
4. *π_X and π_Y are the projection rows. They replay each product-base request back to its two component base requests before any Cauchy or completion-facing consumer can inspect the packet.*
5. *D is the directed lower-bound witness row. For two displayed product-base requests it reads component lower bounds from B_X and B_Y, pairs them in I, and records the two projection-compatible containment reads.*
6. *R is the refinement ledger. It records product refinement only through component refinements and the projection rows π_X, π_Y.*
7. *H records componentwise* hsame *transport for the two component bases, the product index row, both projection rows, the lower-bound witness row, the refinement ledger, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a product-base request through*

$$B_X, B_Y \longmapsto I, \pi_X, \pi_Y \longmapsto D, R \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{ProductFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ProductFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B_X, B_Y, I, \pi_X, \pi_Y, D, R, H, C, P, N$. There is no coordinate for ultrafilters, quotient filters, selected limits, countable choice, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ProductFilterUp.ProductFilterTasteGate single carrier alignment`

Theorem 1867.2 (Product filter NameCert obligations)**.** *For every accepted* $\mathsf{ProductFilter}^{\uparrow}$ *carrier*

$$F = (B_X, B_Y, I, \pi_X, \pi_Y, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProductFilter}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the two component filter-base rows, the product index row, the projection rows, the directed lower-bound row, the refinement ledger, transport, replay, provenance, and local naming;*
2. *projection stability, requiring every product-base request to replay through π_X and π_Y to the same component requests used to assemble it;*
3. *directed lower-bound coverage, requiring D to build product lower bounds only from displayed component lower bounds and to record their two containment reads in R;*
4. $\mathsf{CauchyFilter}^{\uparrow}$ *handoff, requiring every Cauchy-filter consumer to receive the product filter only through the finite product-base route $B_X, B_Y, I, \pi_X, \pi_Y, D, R$ and the structural rows H, C, P, N;*
5. *completion-facing nonescape, requiring the same route to export no ultrafilter, quotient filter, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.*

No local product-filter obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1867.1. The accepted packet exposes exactly the two component base rows, the product index row, the two projection rows, the lower-bound witness row, the refinement ledger, and the structural rows H, C, P, N.

Projection stability follows from the order of the carrier. A product-base request is admitted by I only together with the component requests replayed by π_X and π_Y, so later transport cannot replace the component base data by an external filter object.

Directed lower-bound coverage is componentwise. The row D reads lower-bound witnesses from B_X and B_Y, pairs them as another entry of I, and records the two product containment reads in R.

The Cauchy-filter handoff is exhausted by the displayed route. A downstream consumer sees the same finite base route after hsame transport by H and Cont replay by C; the provenance row P and naming row N name that route without adding any further coordinate.

Since ultrafilters, quotient filters, selected limits, countable-choice schedules, host real equality, and ambient completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 1867.3 (Product filter completion handoff)**.** *Let* $F = (B_X, B_Y, I, \pi_X, \pi_Y, D, R, H, C, P, N)$ *be an accepted* $\mathsf{ProductFilter}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$*-facing consumer of the product filter factors through the displayed product-base route*

$$B_X, B_Y \longmapsto I, \pi_X, \pi_Y \longmapsto D, R \longmapsto H, C, P, N.$$

Consequently the consumer cannot read an ultrafilter, quotient filter, selected limit, choice row, host real equality, or ambient completeness witness from the product filter packet.

Proof. Start with a consumer request. The carrier has no product-filter coordinate except the product index row and its projections, so the request first reaches I, π_X, π_Y and thereby names the two component base requests.

If the consumer asks for refinement or common lower bounds, the route continues through D and R. These rows use only displayed lower bounds and refinements from the component filter bases B_X and B_Y, then repack the result as another product-base row.

A $\mathsf{CauchyFilter}^{\uparrow}$ consumer therefore receives a directed finite product base, not a completed filter. The same finite route is the only surface exposed to $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$-facing provenance reads.

Transport and replay do not enlarge the boundary. The rows H and C preserve the listed coordinates componentwise, while P and N package and name only this product-base route.

Thus every completion-facing read factors through the displayed carrier. Because the carrier contains no ultrafilter, quotient filter, selected limit, choice row, host real equality, or ambient completeness witness, none can be read downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProductFilter}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProductFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1867.1, Definition 1867.2, and Definition 1867.3 seed the finite product-filter base route used by Cauchy-filter, completion, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProductFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilters, quotient filters, selected limits, countable choice, host real equality, Lean verification, bridge checking, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, projection stability, directed lower-bound coverage, CauchyFilter handoff, completion-facing nonescape, and ledger-refusal proofs for BEDC.Derived.ProductFilterUp.

Constructive story: A $\mathsf{ProductFilter}^{\uparrow}$ packet is generated from two FilterBase rows, one product index row, two projection rows, directed lower-bound witnesses, a refinement ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1868

A Concrete Naming Certificate for $\mathsf{CauchyTailBasis}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy terminology and Kelley's filter-basis terminology, the $\mathsf{CauchyTailBasis}^{\uparrow}$ packet names the finite tail-basis surface that sits between tail-index requests and the L10 Real and Completion route. It refines the finite cofinal-tail filter of chapter 1119, reads finite windows from chapter 126, uses dyadic tolerance ledgers from chapter 291, hands regular rational readback to chapter 301, and remains upstream of the terminal Real seal of chapter 38.

The packet is a basis certificate rather than a completion theorem. It gives downstream Cauchy and Real consumers one named finite route for tail-index refinement, window comparison, tolerance budgeting, and regular readback, while excluding quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking.

Definition 1868.1 (CauchyTailBasis carrier)**.** *A* $\mathsf{CauchyTailBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the tail-index basis row, listing the finite tail requests, tail refinements, and common-tail meets allowed to act as basis elements.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row read over the displayed tail-index basis.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same tail requests and finite windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying only the regular rational observations supported by T, W, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after the tail basis, finite windows, dyadic tolerances, and regular readback have been displayed.*
6. *H records componentwise* hsame *transport for the tail-index basis, finite-window, dyadic-ledger, regular-readback, Real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tail-basis request through T, W, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyTailBasis}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyTailBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, W, D, R, E, H, C, P, N$. The carrier contains no quotient stream equality, selected limit, countable-choice selector, host real equality row, trichotomy row, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, Lean verification credential, or standard bridge.*

Lean4 ✓ `BEDC.Derived.CauchyTailBasisUp.TasteGate.CauchyTailBasisTasteGate single carrier alignment`

Theorem 1868.2 (CauchyTailBasis NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailBasis}^{\uparrow}$ *carrier $B = (T, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailBasis}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed tail-index basis, finite StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming row;*
2. *tail-basis locality, requiring every request to enter through a displayed element of T before it can inspect W, D, R, or E;*
3. *finite-window exactness, requiring W to expose only windows supported by the admitted tail basis;*
4. *tolerance-ledger exactness, requiring D to record only the dyadic budgets attached to those admitted windows;*
5. *regular-readback attachment, requiring R to reuse the same T, W, D surface rather than selecting a second stream representative;*
6. *Real-seal boundary, requiring E to remain downstream of T, W, D, R;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no row from which quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge credentials can be exported.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1868.1. The accepted packet displays exactly the tail-index basis, finite-window, dyadic-ledger, regular-readback, Real-seal, and structural rows.

Tail-basis locality is forced by the row order. A consumer reads T before it can inspect a StreamName window, a dyadic tolerance, a regular rational readback, or a Real seal.

The window, tolerance, and readback clauses are then component projections. The row W contains only finite windows supported by T, the row D contains only budgets attached to those windows, and the row R is tied to T, W, D rather than to a detached representative.

The Real-seal boundary is the projection to E. Since E is downstream of T, W, D, R, it cannot introduce a quotient stream, a selected limit, a choice schedule, host equality, trichotomy, or ambient completeness.

Finally, H, C, P, N preserve, replay, source, and name the same displayed packet. These rows have no coordinate outside $T, W, D, R, E, H, C, P, N$, so the local NameCert obligations are exhausted by the listed finite rows. □

Theorem 1868.3 (CauchyTailBasis window directedness)**.** *Let $B = (T, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyTailBasis}^{\uparrow}$ *carrier. Any two finite window reads exported by W and admitted over tail-basis elements of T have a displayed common-tail read in T whose dyadic tolerance ledger in D supports both windows before the route reaches R or E.*

Proof. Start with two exported finite-window reads. Since W is read only after the tail-index basis row, each window has an admitted tail-basis element in T.

The row T is a basis row, so its displayed data include finite tail refinements and common-tail meets for the admitted requests. Project the meet row supplied for the two chosen tail elements.

Read D at the displayed meet. The tolerance ledger is attached to the same tail-basis and window rows, so the dyadic budgets for both windows are recorded before any regular readback or Real seal can be inspected.

The structural rows preserve this directed route. Componentwise hsame transport and displayed Cont replay may move the accepted packet along the recorded comparison, but they do not add a second window source or an external tail oracle. □

Theorem 1868.4 (CauchyTailBasis RegSeqRat handoff)**.** *Every regular rational readback exported by an accepted* $\mathsf{CauchyTailBasis}^{\uparrow}$ *carrier* $B = (T, W, D, R, E, H, C, P, N)$ *factors through the finite route*

$$T, W, D \longmapsto R \longmapsto E$$

before any Real-facing consumer can read the terminal seal. Thus the packet hands tail-basis Cauchy data to $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers without quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an exported regular rational readback. Carrier admission provides no analytic row before T, so the read first chooses an admitted finite tail-basis element.

The route next reads the finite-window row W and the dyadic tolerance ledger D. These two rows fix the observed stream entries and the tolerance budget for the admitted tail-basis element.

The regular readback row R is attached to the displayed T, W, D data. It therefore cannot select a second stream representative, a quotient class, a detached limit, or a countable-choice schedule.

The Real seal row E is downstream of the same readback. Since the structural rows H, C, P, N only transport, replay, source, and name this finite route, every Real-facing consumer receives the displayed handoff and no ambient completeness, trichotomy, or host equality coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailBasis}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailBasis}^{\uparrow}}$, seed)

Scope closed: Definition 1868.1, Definition 1868.2, Definition 1868.3, and Definition 1868.4 seed the finite tail-basis route over $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligation exactness, window directedness, regular rational handoff, Real-seal boundary, and non-escape proofs for BEDC.Derived.CauchyTailBasisUp.

Constructive story: A $\mathsf{CauchyTailBasis}^{\uparrow}$ packet is generated from a tail-index basis row, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1869

A Concrete Naming Certificate for $\mathsf{CauchyCompletionContinuation}^{\uparrow}$

Following Mac Lane's Kleisli category terminology for continuation-style monad consumers, and Bishop–Bridges and Kelley completion terminology for Cauchy completion interfaces, the CauchyCompletionContinu packet names the finite route by which a continuation request reads a bind source before it can reach the L10 completion face. It sits after the completion monad of chapter 378, the Kleisli consumer boundary of chapter 1845, the unit certificate of chapter 1527, the multiplication certificate of chapter 1829, the stream surface of chapter 126, the regular rational readback of chapter 301, the dyadic observation ledger of chapter 291, and the terminal Real seal of chapter 38.

The packet is a continuation-facing certificate rather than a choice of completed limits. It records the finite request row, bind source row, schedule, stream window, dyadic observation, regular readback, Real seal, and structural transport by which downstream completion consumers replay a bind request.

Definition 1869.1 (Cauchy completion continuation carrier)**.** *A* $\mathsf{CauchyCompletionContinuation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, B, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the continuation request row, naming the finite consumer request that asks for a completed value through a Kleisli bind route.*
2. *B is the bind source row inherited from* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *and* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*, displaying the source family before any downstream window or seal is read.*
3. *S is the finite unary schedule row attached to the request and bind source.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the schedule.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation and tolerance row read from the same finite window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to W and D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, B, S, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the continuation request, bind source, schedule, stream window, dyadic observation, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the continuation request through* $Q, B, S, W, D, R, E, H, P, N$.

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionContinuation}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, CauchyCompletionMona $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionContinuation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, B, S, W, D, R, E, H, C, P, N$. The carrier has no coordinate for quotient streams, selected limits, countable choice, host equality, hidden representatives, ambient completeness, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionContinuationUp.CauchyCompletionContinuationTasteGate`
`single carrier alignment`

Theorem 1869.2 (Cauchy completion continuation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionContinuation}^{\uparrow}$ *carrier $T = (Q, B, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionConti}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the continuation request, bind source, schedule, finite stream window, dyadic observation and tolerance row, regular rational readback, Real seal, transport, replay, provenance, and local naming row;*

2. *request admission, requiring every continuation consumer to display Q before it can read a bind source or public L10 row;*

3. *bind-source admission, requiring every continuation replay to pass through B before opening S, W, D, R, E;*

4. *schedule and window exactness, requiring S, W to be the only finite stream-window surface exposed by the request;*

5. *readback and seal coherence, requiring D, R, E to be read in the displayed order and to remain stable under componentwise* hsame *transport and displayed* Cont *replay;*

6. *non-escape, requiring P, N to source and name no quotient stream, selected limit, countable-choice selector, host equality, hidden representative, ambient completeness theorem,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1869.1. The accepted packet displays exactly the continuation request, bind source, finite schedule, stream window, dyadic observation, regular rational readback, Real seal, and structural rows.

Request admission is supplied by Q. Since Q is the first coordinate of the continuation-facing route, a consumer cannot inspect the bind source or the public completion face before the request row is displayed.

Bind-source admission is supplied by B and by the Kleisli boundary of chapter 1845. The route fixes the bind source before opening the shared schedule, window, dyadic observation, readback, and seal.

Schedule and window exactness are projections to S, W. The packet contains no second schedule or hidden window family, so every continuation replay uses the displayed finite window surface.

Readback, seal coherence, and non-escape are structural. Componentwise transport H, continuation replay C, provenance P, and the local name N preserve and source only the displayed continuation packet, so no excluded completion coordinate is available. □

Theorem 1869.3 (Cauchy completion continuation bind route)**.** *Every accepted* $\mathsf{CauchyCompletionContinuation}^{\uparrow}$ *carrier* $T = (Q, B, S, W, D, R, E, H, C, P, N)$ *routes a continuation request through the bind source before any public L10 completion row is read:*

$$Q \longmapsto B \longmapsto S \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

Thus the StreamName window, DyadicRatCore observation, RegSeqRat readback, and Real seal are continuation results of the displayed bind source rather than detached representatives.

Proof. Start with an accepted packet $T = (Q, B, S, W, D, R, E, H, C, P, N)$. Projection gives the continuation request row Q before any downstream coordinate is available.

The bind source row B is the next displayed coordinate. It is inherited from the Kleisli and monad surfaces, so the continuation reads the source family before opening a schedule or stream window.

Only after Q, B have been read does the carrier expose S, W, D, R, E. The route-order inspection of the tuple therefore gives the displayed chain from request through bind source, schedule, window, dyadic observation, regular readback, and Real seal.

The structural rows H, C, P, N transport, replay, source, and name this same chain. They do not insert a detached stream representative or a second seal-facing route. □

Theorem 1869.4 (Cauchy completion continuation Real seal nonescape)**.** *Let* $T = (Q, B, S, W, D, R, E, H, C, P, N$ *be an accepted* $\mathsf{CauchyCompletionContinuation}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of* T *receives the terminal seal* E *only after the displayed continuation request, bind source, schedule, finite stream window, dyadic observation, and regular rational readback have been read. The consumer receives no quotient stream, selected limit, countable-choice selector, host equality comparison, hidden representative, ambient completeness datum, completeness theorem for* $\mathsf{Real}^{\uparrow}$*, Lean verification credential, or bridge credential.*

Proof. Project the accepted carrier. The only seal coordinate is E, and it appears downstream of Q, B, S, W, D, R.

The replay row C confirms the same order for a continuation request. A Real-facing consumer therefore reaches the seal only through the displayed request, bind source, schedule, window, dyadic observation, and readback route.

Transport and provenance do not enlarge the route. The hsame row H is componentwise, P cites only the listed completion and L10 source chapters, and N names the local certificate.

Since none of the excluded objects occurs as a carrier coordinate, classifier row, or replay target, no $\mathsf{Real}^{\uparrow}$-facing consumer can escape to quotient streams, selected limits, countable choice, host equality, hidden representatives, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking. □

Lean target: `BEDC.Derived.CauchyCompletionContinuationUp.CauchyCompletionContinuationTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host equality, hidden representatives, ambient completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request admission, bind-source admission, schedule-window exactness, readback-seal coherence, bind-route, and Real-seal non-escape proofs for BEDC.Derived.CauchyCompletionContin

Constructive story: A CauchyCompletionContinuation$^{\uparrow}$ packet is generated from a continuation request row, a bind source row, a finite schedule, StreamName windows, DyadicRatCore observations, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1870

A Concrete Naming Certificate for $\mathsf{CauchyTightness}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyTightness}^{\uparrow}$ packet names the finite tight-tail route by which a Cauchy read becomes tight enough for the Real and Completion phase. It sits after the tail-basis route of chapter 1868, the convergence-criterion route of chapter 1509, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the Cauchy limit seal of chapter 386, and the terminal Real seal of chapter 38.

The packet is a finite tightness certificate rather than a completeness principle. It records the tail-basis, convergence-criterion, threshold, dyadic, readback, limit-seal, Real-seal, transport, replay, provenance, and local NameCert rows that a downstream consumer must read before treating a Cauchy tail as tight.

Definition 1870.1 (Cauchy tightness carrier)**.** *A* $\mathsf{CauchyTightness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, G, M, D, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CauchyTailBasis}^{\uparrow}$ *row, displaying the finite tail requests, refinements, and common-tail basis meets through which tightness may be inspected.*
2. *G is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row, displaying the criterion that converts the admitted tail-basis requests into convergence-facing tolerance reads.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, or the equivalent finite tail-threshold data, assigning each dyadic tolerance request a displayed threshold over B and G.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same threshold and tail-basis reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only from the displayed B, G, M, D surface.*
6. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility row consuming the same tail, criterion, threshold, dyadic, and readback route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, G, M, D, R, L have been displayed.*
8. *H records componentwise* hsame *transport for the tail-basis, convergence-criterion, threshold, dyadic-ledger, readback, limit-seal, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each tightness request through $B, G, M, D, R, L, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyTightness}^{\uparrow}$, $\mathsf{CauchyTailBasis}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTightness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, G, M, D, R, L, E, H, C, P, N$. The carrier contains no quotient stream equality, selected limit, countable-choice selector, host real equality row, trichotomy row, open-cover compactness row, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, Lean verification credential, or standard bridge.*

Lean4 ✓ `BEDC.Derived.CauchyTightnessUp.CauchyTightnessTasteGate single carrier alignment`

Theorem 1870.2 (Cauchy tightness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTightness}^{\uparrow}$ *carrier $T = (B, G, M, D, R, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTightness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed tail-basis row, convergence-criterion row, threshold row, dyadic tolerance ledger, regular rational readback, Cauchy limit seal, Real seal, transport, replay, provenance, and local naming row;*
2. *criterion-to-tail compatibility, requiring every convergence-criterion request in G to be read only through the admitted tail-basis row B;*
3. *tail-basis handoff, requiring each tightness read to factor through B and G before any threshold, dyadic ledger, regular readback, limit seal, or Real seal is exposed;*
4. *readback exactness, requiring R to be obtained from the same B, G, M, D surface and from no second stream representative;*
5. *limit-seal compatibility, requiring L to consume exactly the displayed tail, criterion, threshold, dyadic, and readback rows;*
6. *Real-seal nonescape, requiring E to remain downstream of B, G, M, D, R, L;*
7. *ledger nonescape, requiring H, C, P, N to transport, replay, source, and name no quotient stream, selected limit, countable-choice selector, host real equality row, trichotomy row, open-cover compactness row, ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum, Lean verification credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1870.1. The accepted packet displays exactly the tail-basis, convergence-criterion, threshold, dyadic-ledger, regular-readback, Cauchy-limit-seal, Real-seal, and structural rows.

Criterion-to-tail compatibility follows from the placement of G after B. A convergence-criterion request can be replayed only against the admitted tail-basis row already displayed by the carrier.

The handoff and readback clauses are then route projections. The tightness request reads B and G first, then the threshold row M and dyadic ledger D, and only then the regular rational readback R.

Limit-seal compatibility and Real-seal nonescape are downstream projections. The rows L and E have no independent source; each consumes the same B, G, M, D, R surface.

Finally, H, C, P, N preserve, replay, source, and name this displayed packet. Since the accepted carrier has no coordinate outside $B, G, M, D, R, L, E, H, C, P, N$, the listed obligation rows exhaust the local NameCert surface. □

Theorem 1870.3 (Cauchy tightness tail-basis handoff)**.** *Every accepted* $\mathsf{CauchyTightness}^{\uparrow}$ *carrier* $T = (B, G, M, D, R, L, E, H, C, P, N)$ *factors each tightness read through the finite route*

$$B \longmapsto G \longmapsto M \longmapsto D \longmapsto R \longmapsto L \longmapsto E$$

before any Real-facing consumer can use the terminal seal. Thus a tightness read first passes through $\mathsf{CauchyTailBasis}^{\uparrow}$ *and* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$*, then through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, without detaching a quotient stream, selected limit, countable-choice selector, host real equality comparison, trichotomy decision, open-cover compactness object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $T = (B, G, M, D, R, L, E, H, C, P, N)$. Projection gives the tail-basis row B as the first tightness surface.

The convergence row G is read next. It supplies the criterion-facing interpretation of the same tail requests, so no threshold or dyadic ledger can be inspected before the tail-basis and criterion rows are fixed.

The route then exposes M, D, R, L, E in order. The threshold row M and dyadic ledger D support the regular readback R, the Cauchy limit seal L consumes that same readback route, and the Real seal E is downstream of L.

The structural rows H, C, P, N do not change the order. They transport, replay, source, and name the displayed chain, so every tightness read factors through the stated route and no excluded coordinate is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTightness}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTightness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1870.1, Definition 1870.2, and Definition 1870.3 seed the finite tight-tail route through $\mathsf{CauchyTailBasis}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTightness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-tail compatibility, tail-basis handoff, readback exactness, CauchyLimitSeal compatibility, Real-seal nonescape, and ledger nonescape for BEDC.Derived.CauchyTightnessUp.

Constructive story: A $\mathsf{CauchyTightness}^{\uparrow}$ packet is generated from a CauchyTailBasis row, a CauchyConvergence-Criterion row, a CauchyModulus or finite threshold row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a CauchyLimitSeal compatibility row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1871

A Concrete Naming Certificate for $\mathsf{DirichletApproximation}^{\uparrow}$

Following Hardy–Wright's presentation of Dirichlet rational approximation, the $\mathsf{DirichletApproximation}^{\uparrow}$ packet names the finite denominator-bounded route that sends a real-facing rational request to a displayed approximant before any host real equality or best-approximant selector is visible. It sits over the rational-tree source of chapter 1704, the interval boundary of chapter 354, the dyadic tolerance ledger of chapter 291, the finite rational-readback route of chapter 1668, and the terminal seal of chapter 38. The packet also consumes $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows so the approximation certificate remains a finite NameCert surface rather than an ambient theorem about completed reals.

Definition 1871.1 (Dirichlet approximation carrier)**.** *A* $\mathsf{DirichletApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, B, M, D, S, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational source row. It records the* $\mathsf{Rat}^{\uparrow}$ *input rationals and interval endpoints that the approximation request may inspect.*
2. *B is the denominator-bound row. It stores the positive finite bound, the visible denominator budget, and the comparison rows used to certify that the exported denominator stays within the bound.*
3. *M is the Stern–Brocot or Farey mediant route. It records the finite branch sequence, mediant bracketing data, and rational candidate selected by displayed tree search rather than by an external choice principle.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the requested dyadic error, the slack ledger, and the endpoint comparisons used to validate the candidate against the displayed rational interval.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite real-name windows that may be read by the approximation request.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It reads the windows in S as regular rational data before any real-facing handoff is exposed.*
7. *R is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff row. It packages the rational candidate, denominator bound, dyadic tolerance, StreamName window, and RegSeqRat readback as the finite approximation surface consumed downstream.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It can be read only after Q, B, M, D, S, G, R have been displayed.*
9. *H records componentwise* hsame *transport for the rational source, denominator bound, mediant route, dyadic tolerance, StreamName window, RegSeqRat readback, real-rational handoff, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a Dirichlet approximation request through $Q, B, M, D, S, G, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{DirichletApproximation}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletApproximation}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite denominator-bounded rational-approximation packet. It has no coordinate for host real equality, quotient representatives, choice-selected best approximants, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1871.2 (Dirichlet approximation NameCert obligations)**.** *For every accepted* $\mathsf{DirichletApproximation}^{\uparrow}$ *carrier $A = (Q, B, M, D, S, G, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirichletApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational source, denominator bound, Stern–Brocot or Farey mediant route, dyadic tolerance, StreamName window, RegSeqRat readback, RealRationalApproximation handoff, RealUp seal, transport, replay, provenance, and local naming rows;*
2. *rational-source admission, requiring every exported approximant and interval endpoint to be read from the displayed row Q;*
3. *denominator-bound admission, requiring the denominator comparison to pass through the finite row B before the candidate can be exported;*
4. *mediant-route admission, requiring the rational candidate to be produced by the displayed Stern–Brocot or Farey route M;*
5. *dyadic-tolerance admission, requiring the approximation error and slack comparisons to be read from D;*
6. *window-readback admission, requiring S and G to be fixed before the real-rational handoff R is visible;*
7. *Real-seal admission, requiring E to remain terminal and to expose no host real equality, quotient representative, best-approximant selector, trichotomy branch, or ambient completeness theorem;*
8. *transport, replay, provenance, and naming exhaustion, requiring H, C, P, N to preserve and source exactly the displayed packet.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DirichletApproximationUp.DirichletApproximationTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1871.1. The accepted packet displays exactly the rational source, denominator bound, mediant route, dyadic tolerance, StreamName window, RegSeqRat readback, real-rational handoff, terminal Real seal, and structural rows.

The rational-source and denominator-bound obligations are forced by row order. The candidate and interval endpoints first read Q, while the finite denominator comparison is stored in B before any approximation handoff can be exported.

The mediant and tolerance obligations use the next two rows. The row M supplies the Stern–Brocot or Farey path that names the rational candidate, and D supplies the dyadic error, slack, and comparison ledger used to validate it.

The window-readback obligation is finite. The row S exposes only displayed StreamName windows, and G reads those windows as regular rational data before the real-rational approximation row R is available.

The terminal seal and structural rows preserve the same boundary. The row E seals the route as a $\mathsf{Real}^{\uparrow}$-facing packet, while H, C, P, N transport, replay, source, and name the displayed data without adding host real equality, quotient representatives, choice-selected best approximants, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Theorem 1871.3 (Dirichlet approximation finite handoff)**.** *Every* $\mathsf{RealRationalApproximation}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{DirichletApproximation}^{\uparrow}$ *carrier* $A = (Q, B, M, D, S, G, R, E, H, C, P, N)$ *factors through the finite route*

$$Q, B, M, D, S, G \longmapsto R, E$$

before transport, replay, provenance, or local naming can be read. Consequently the exported approximation is witnessed by a rational source row, a denominator-bound row, a displayed mediant route, a dyadic tolerance ledger, StreamName windows, and RegSeqRat readback, not by host real equality or by choosing a best representative.

Proof. Begin with an exported real-rational approximation or Real-facing read. The carrier has only the handoff row R and the terminal seal row E for such reads, and both occur after Q, B, M, D, S, G.

The source and bound rows fix the rational data. The row Q supplies the visible rational source and interval endpoints, while B records the finite denominator budget and its comparison evidence.

The candidate route is then displayed. The row M names the Stern–Brocot or Farey mediant path, and D records the dyadic tolerance and slack comparisons that certify the approximation request.

The real-facing input is read through windows. The row S supplies the finite StreamName window, and G converts that window into RegSeqRat rational readback before R may package the handoff.

Only after these rows are present can R and then E be read. Transport, replay, provenance, and local naming preserve this route, so the exported approximation cannot depend on host real equality, quotient representatives, choice-selected best approximants, trichotomy, or ambient Real completeness. □

Theorem 1871.4 (Dirichlet approximation denominator window)**.** *Every downstream approximation consumer of an accepted* $\mathsf{DirichletApproximation}^{\uparrow}$ *carrier*

$$A = (Q, B, M, D, S, G, R, E, H, C, P, N)$$

that uses a denominator-bound read must expose the displayed rows in the order

$$Q \longmapsto B \longmapsto M \longmapsto D, S, G, R, E.$$

In particular, a $\mathsf{KroneckerApproximation}^{\uparrow}$ *consumer using the Dirichlet handoff row* D *and a* RationalBestApproximat *consumer using the denominator-budget surface must first read the rational source row* Q*, then the*

finite denominator-bound row B, and then the Stern–Brocot or Farey route M before consuming dyadic tolerance, StreamName, RegSeqRat, RealRationalApproximation, or terminal Real rows.

Proof. Project the carrier in Definition 1871.1. The rational source row Q is the only source for exported approximants and interval endpoints, while the row B is the only displayed denominator budget.

Apply Definition 1871.3. Its handoff route places the mediant row M before the dyadic tolerance row D, the StreamName window row S, the RegSeqRat readback row G, and the real-facing rows R, E.

Thus any consumer that needs a denominator-bound read must pass through Q, B, M before it can consume the remaining approximation rows. This covers the $\mathsf{KroneckerApproximation}^{\uparrow}$ handoff that cites the Dirichlet row D and the $\mathsf{RationalBestApproximation}^{\uparrow}$ handoff that reuses the same denominator-budget surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1871.1, Definition 1871.2, and Definition 1871.3 seed the finite denominator-bounded rational-approximation route through rational source, mediant, dyadic tolerance, StreamName, RegSeqRat, RealRationalApproximation, and terminal Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient representatives, choice-selected best approximants, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-source admission, denominator-bound admission, mediant-route admission, dyadic-tolerance admission, window-readback admission, finite handoff factorization, transport stability, and non-escape proofs for BEDC.Derived.DirichletApproximationUp.

Constructive story: A $\mathsf{DirichletApproximation}^{\uparrow}$ packet is generated from rational source data, a denominator-bound row, a Stern–Brocot or Farey mediant route, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a RealRationalApproximation handoff, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1872

Countable choice boundary NameCert construction

Following Bishop-style constructive analysis, the $\mathsf{CountableChoiceBoundary}^{\uparrow}$ packet separates finite witness choice from countable choice in the Real and Completion corridor. It sits after the finite stream-window surface of chapter 126, the regular rational readback discipline of chapter 301, the terminal Real seal of chapter 38, the no-choice diagonal boundary of chapter 1173, and the deterministic relation readback of chapter 1739.

The packet records the point at which finite windows may carry displayed witnesses while no global selector, host sequence choice, selected limit, quotient stream equality, or ambient completion principle is admitted. It is a human-origin boundary object because the distinction between finite witness extraction and countable choice is part of constructive analysis rather than a BEDC-native discovery.

Definition 1872.1 (Countable choice boundary carrier)**.** *A* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, W, R, E, F, L, U, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row naming the observation window and tolerance demand being served.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by Q.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, W, R have been displayed.*
5. *F is the finite witness row. It records witnesses for the displayed window and no data outside that window.*
6. *L is the local no-selected-limit row. It refuses a global selector, host sequence choice, countable choice, quotient stream equality, and ambient Real-completion evidence.*
7. *U is the deterministic unique-readback row, inherited from* $\mathsf{UniqueChoicePrinciple}^{\uparrow}$ *only for already displayed finite relation witnesses.*
8. *H records componentwise* hsame *transport for request, window, readback, seal, finite witnesses, refusal, unique readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from Q through $W, R, E, F, L, U, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CountableChoiceBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{UniqueChoicePrinciple}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableChoiceBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a global selector, a host sequence-choice function, a countable-choice principle, quotient stream equality, selected limits, ambient completion, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.CountableChoiceBoundaryUp.TasteGate.CountableChoiceBoundaryUp`
Lean4 ✓ `BEDC.Derived.CountableChoiceBoundaryUp.TasteGate.CountableChoiceBoundaryTasteGate`
`single carrier alignment`

Theorem 1872.2 (Countable choice boundary finite witness row)**.** *Let $B = (Q, W, R, E, F, L, U, H, C, P, N)$ be an accepted* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *carrier. Every witness exported by B factors through the displayed finite route*

$$Q \longmapsto W \longmapsto R \longmapsto F.$$

Thus finite $\mathsf{StreamName}^{\uparrow}$ *windows may be witnessed, and their* $\mathsf{RegSeqRat}^{\uparrow}$ *readback may be inspected, only inside the finite request already named by Q.*

Proof. Project the accepted carrier of Definition 1872.1. The only witness coordinate is F, and it appears after the finite request, stream window, and regular rational readback rows.

The BHist shape keeps the witness inside the displayed finite packet. Componentwise hsame transport in H moves the same rows together, while the Cont replay row C follows the ordered route from Q through W, R, F.

The provenance row P cites $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ as finite-window sources, not as a host family of all choices. Hence the packet permits witnessed finite windows while preserving the refusal of any global selector or host sequence-choice function. □

Theorem 1872.3 (Countable choice boundary no selected limit)**.** *No accepted* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *carrier exports a selected limit, a global stream selector, host sequence choice, countable choice, quotient stream equality, or ambient completion datum. The only Real-facing data exported by*

$$B = (Q, W, R, E, F, L, U, H, C, P, N)$$

are the displayed finite request, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, finite witness row, refusal row, deterministic finite readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier inventory. The refusal row L explicitly excludes selected limits, global stream selectors, host sequence choice, countable choice, quotient stream equality, and ambient completion data, and the tuple has no additional coordinate from which such data could be reconstructed.

The seal row E is terminal for the displayed finite route. A consumer reaches it only after reading Q, W, R, so the $\mathsf{Real}^{\uparrow}$ face is attached to the visible finite packet rather than to a selected host limit.

The unique-readback row U does not add a choice principle. By the role inherited from $\mathsf{UniqueChoicePrinciple}^{\uparrow}$, it compares already displayed finite relation witnesses and therefore cannot choose a sequence of witnesses over all requests.

Transport, replay, and provenance preserve the same boundary. The rows H, C, P, N move, replay, source, and name only the finite packet, while the no-choice sibling $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ blocks the diagonal route from being read as a global selector. □

Theorem 1872.4 (Countable choice boundary Cauchy witness refusal)**.** *Any* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *consumer of chapter 3579 that uses finite* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows may cite* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *only as a refusal boundary. It may read the displayed finite witness rows supplied by Definition 1872.2, but Definition 1872.3 gives it no global selector, no host sequence choice, no selected limit, and no quotient stream equality.*

Proof. Project the accepted carrier of Definition 1872.1. The finite witness row F is downstream of the request, stream window, and regular rational readback rows, so a completion witness consumer can inspect only the displayed rows already named by the packet.

Apply Definition 1872.2. It permits finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback inside the named request, and it supplies no coordinate for a host family of choices.

Apply Definition 1872.3. The refusal row L excludes selected limits, global selectors, host sequence choice, countable choice, quotient stream equality, and ambient completion data. The $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ consumer therefore receives a boundary certificate for finite witness rows, not a choice principle for completing all Cauchy presentations. □

Theorem 1872.5 (Countable choice boundary Real-completion discipline)**.** *Every Real and Completion consumer of an accepted* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *carrier must pass through the finite witness row of Definition 1872.2 and the no-selected-limit boundary of Definition 1872.3. Consequently* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *arguments may use finite-window witnesses but may not import countable choice, host sequence choice, selected limits, quotient stream equality, or ambient Real-completion evidence.*

Proof. Begin with a Real and Completion consumer of B. The carrier exposes the request row Q, the $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the $\mathsf{Real}^{\uparrow}$ seal E before any structural row is consumed.

Apply Definition 1872.2. The only witness surface is the finite row F, so the consumer may use witnesses for the displayed finite window and no larger family.

Apply Definition 1872.3. The refusal row L and the sibling $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ exclude selected limits, global selectors, host sequence choice, countable choice, quotient stream equality, and ambient completion data.

Finally read U, H, C, P, N. The deterministic finite readback inherited from $\mathsf{UniqueChoicePrinciple}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming rows preserve the same finite route, so the Real-completion consumer remains inside the finite witness boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableChoiceBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableChoiceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1872.1, Definition 1872.2, Definition 1872.3, and Definition 1872.5 seed the finite witness boundary separating displayed window witnesses from countable choice in the Real and Completion corridor.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableChoiceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected limits, host sequence choice, quotient stream equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite witness row, no-selected-limit boundary, and Real-completion discipline proofs for BEDC.Derived.CountableChoiceBoundaryUp.

Constructive story: A $\mathsf{CountableChoiceBoundary}^{\uparrow}$ packet is generated from one finite request row, one StreamName window, one RegSeqRat readback, one RealUp seal, one finite witness row, one refusal row, deterministic finite readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1873

Cauchy Diagonal Argument NameCert Construction

Following Bishop-style constructive diagonal arguments for regular Cauchy tails, the $\mathsf{CauchyDiagonalArgument}^{\uparrow}$ packet names the finite route by which a row of regular Cauchy rational names supplies one displayed diagonal selection under a cofinal tail budget. It sits downstream of the regular extraction surface of chapter 1773, uses the tail-basis route of chapter 1868, reuses the diagonal-limit seal of chapter 1800, and keeps the endpoint comparison boundary aligned with chapter 1874.

The packet is a selection certificate, not a completion theorem. It records rows, budgets, ledgers, and local naming for constructive diagonal passage through regular Cauchy tails while excluding quotient stream equality, host selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge credentials.

Definition 1873.1 (Cauchy diagonal argument carrier)**.** *A* $\mathsf{CauchyDiagonalArgument}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, S, T, B, L, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular-Cauchy row family, listing the finitely inspected* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows and their admissible tail windows.*
2. *S is the diagonal index-selection row, recording the selected index for each visible precision request without importing a countable-choice schedule.*
3. *T is the cofinal tail-budget row, displaying the tail threshold that simultaneously supports the selected row, the diagonal window, and every downstream readback.*
4. *B is the* $\mathsf{CauchyTailBasis}^{\uparrow}$ *basis row used to compare the selected tail with sibling tail requests.*
5. *L is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error ledger, storing dyadic radius, slack, and comparison entries for the selected row and cofinal tail.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row read from the selected tail.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row assembled from R, S, T, L, W.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after the row family, selected index, cofinal tail budget, basis comparison, dyadic ledger, window, and readback rows have been displayed.*

9. *H records componentwise* hsame *transport for the row family, index selection, tail budget, basis row, dyadic ledger, finite window, diagonal readback, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from each precision request through $R, S, T, B, L, W, Q, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyDiagonalArgument}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{CauchyTailBasis}^{\uparrow}$, $\mathsf{CauchyDiagonalLimit}^{\uparrow}$, $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalArgument}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, T, B, L, W, Q, E, H, C, P, N$. It contains no quotient stream equality, detached limit selector, countable-choice row, trichotomy row, ambient $\mathsf{Real}^{\uparrow}$ *completeness datum, Lean credential, or standard bridge.*

Lean4 (definition) `BEDC.Derived.CauchyDiagonalArgumentUp.CauchyDiagonalArgumentTasteGate single carrier alignment`

Theorem 1873.2 (Cauchy diagonal argument tail selection)**.** *Let $A = (R, S, T, B, L, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalArgument}^{\uparrow}$ *carrier. Every Real-facing precision request that enters the packet factors through one displayed diagonal index in S and one cofinal tail budget in T before it can read W, Q, or E. The selected route is*

$$R, S, T, B, L \longmapsto W \longmapsto Q \longmapsto E.$$

Thus the diagonal selection is a finite NameCert route over regular Cauchy tails, not a host-selected limit, quotient stream, countable-choice selector, or ambient completeness witness.

Proof. Begin with an accepted carrier and a Real-facing precision request. Carrier admission provides the row family R as the only source of regular Cauchy data, so the request cannot inspect a stream window or Real seal before a source row has been displayed.

The diagonal index is then read from S. This row stores the visible selected index for the request as packet data, and it has no coordinate for an external choice function or detached limit selector.

The cofinal tail budget T is read next. It is the row that binds the selected index to the tail threshold used by the basis row B and the dyadic ledger L, so every downstream window remains tied to the same finite request.

Finally W, Q, E are downstream of the selected budget. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the consumer receives the displayed diagonal passage and no quotient stream, host limit, countable-choice row, trichotomy principle, or ambient completeness datum. □

Theorem 1873.3 (Cauchy diagonal argument NameCert obligations)**.** *For every accepted* CauchyDiagonalArgumen *carrier $A = (R, S, T, B, L, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalArgument}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the regular-Cauchy row family, diagonal index-selection row, cofinal tail-budget row, CauchyTailBasis row, dyadic error ledger, finite StreamName window, RegSeqRat diagonal readback, terminal Real seal, transport, replay, provenance, and local naming rows;*

2. *index-selection exactness, requiring S to be the only row that supplies the displayed diagonal index for a visible precision request;*

3. *cofinal tail-budget exactness, requiring T and B to bind that selected index to a common tail before any readback is exposed;*
4. *dyadic error-ledger exactness, requiring L to store precisely the radius, slack, and comparison entries consumed by W and Q;*
5. *Real seal non-escape, requiring E, H, C, P, N to export only the displayed diagonal route and no quotient stream equality, detached limit selector, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Cauchy diagonal argument obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1873.1. The accepted packet displays exactly the row family, index-selection row, cofinal tail budget, basis comparison, dyadic ledger, finite window, diagonal readback, Real seal, and structural rows.

Index-selection exactness follows by inspecting S. Since no other coordinate supplies a selected diagonal index, every visible precision request uses the displayed index row.

Cofinal tail-budget exactness follows by inspecting T and B. The tail threshold is recorded before W, Q, or E is visible, and the basis row compares it with sibling tail requests through the same finite carrier.

The dyadic ledger clause is the projection to L. The ledger stores the radius, slack, and comparison entries used by the finite window W and the regular rational readback Q, so the error budget cannot be replaced by a detached representative.

Finally inspect E, H, C, P, N. These rows seal, transport, replay, source, and name the displayed route only; because the carrier has no quotient stream, selected host limit, countable-choice row, trichotomy principle, ambient completeness datum, Lean credential, or bridge credential, the listed five rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalArgument}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalArgument}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1873.1, Definition 1873.2, and Definition 1873.3 seed the constructive diagonal-selection route over regular Cauchy row families, displayed indices, cofinal tail budgets, CauchyTailBasis rows, DyadicRatCore ledgers, StreamName windows, RegSeqRat readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalArgument}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, index-selection exactness, cofinal tail-budget exactness, dyadic ledger exactness, Real seal nonescape, and route determinacy for BEDC.Derived.CauchyDiagonalArgumentUp.

Constructive story: A $\mathsf{CauchyDiagonalArgument}^{\uparrow}$ packet is generated from a regular-Cauchy row family, a displayed diagonal index-selection row, a cofinal tail-budget row, a CauchyTailBasis row, a DyadicRatCore error ledger, finite StreamName windows, a RegSeqRat diagonal readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1874

A Concrete Naming Certificate for $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ packet records the public L10 criterion by which two regular Cauchy rational names receive the same $\mathsf{Real}^{\uparrow}$ endpoint: display the regular-Cauchy difference, supply null-sequence evidence for that displayed difference, hand the evidence through the zero-distance boundary, and only then expose the terminal Real equality seal. It sits over the regular rational source rows of chapter 301, the displayed difference route of chapter 429, the null-difference certificate of chapter 1758, the zero-distance handoff of chapter 1727, the finite stream interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38.

The criterion is a finite public equality route. It is not a quotient of streams, a host equality proof, a selected limit, a trichotomy comparison, countable choice, ambient completeness, Lean verification, or bridge checking.

Definition 1874.1 (Cauchy difference criterion carrier)**.** *A* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are compared.*
2. *D is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row displaying the aligned pointwise difference stream $X - Y$.*
3. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *evidence row certifying that the displayed difference stream shrinks to zero.*
4. *Q is the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *handoff row that consumes D and Z before any equality-facing seal is read.*
5. *W stores the finite* $\mathsf{StreamName}^{\uparrow}$ *windows used by the source rows, the difference route, the null-sequence evidence, and the zero-distance handoff.*
6. *T stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance requests, slack rows, and comparison budgets shared by D, Z, Q.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal, readable only after X, Y, D, Z, Q, W, T have been displayed.*

8. *H records componentwise* hsame *transport for source rows, difference rows, null-sequence rows, zero-distance rows, windows, tolerance ledgers, the equality seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the source rows through D, then through Z, then through Q, and finally into the seal row E.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDifferenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, D, Z, Q, W, T, E, H, C, P, N$. It has no coordinate for quotient stream equality, host equality of reals, selected limits, trichotomy, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionTasteGate single carrier alignment`

Theorem 1874.2 (Cauchy difference criterion NameCert obligations)**.** *For every accepted* CauchyDifferenceCriterio *carrier $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyDifferenceCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *displayed difference row, the* $\mathsf{NullSequence}^{\uparrow}$ *evidence row, the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *handoff row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal, transport, continuation, provenance, and local naming rows;*

2. *source and difference stability, requiring accepted comparisons to preserve X, Y, D, W, T componentwise through the displayed* hsame *and* Cont *rows;*

3. *null-evidence exactness, requiring Z to consume precisely the displayed difference route D with the windows W and tolerance ledger T;*

4. *zero-distance handoff exactness, requiring Q to read the null-difference route $X, Y, D, Z, W, T, H, C, P, N$ before the equality seal E is exposed;*

5. *Real seal nonescape, requiring every equality-facing read to factor through K and forbidding quotient stream equality, host real equality, selected limits, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking from the local surface.*

No Cauchy difference criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1874.1. The accepted packet displays the two regular rational source rows, the difference row, the null-sequence evidence row, the zero-distance handoff row, finite windows, dyadic tolerances, the Real equality seal, and the structural provenance rows.

Source and difference stability are componentwise. The two $\mathsf{RegSeqRat}^{\uparrow}$ rows transport their scheduled rational observations, the finite $\mathsf{StreamName}^{\uparrow}$ windows transport the inspected reads, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger transports the requested bounds used by the displayed difference route.

Null-evidence exactness is the next route constraint. The row Z is downstream of D and can read only the displayed difference through the shared windows W and tolerance ledger T, so the evidence is a finite null-sequence witness for that route.

Zero-distance handoff exactness then follows by reading Q. The handoff row consumes the same null-difference route before E is available, and the continuation row C replays that order without adding another equality coordinate.

Finally inspect the carrier inventory. Since quotient streams, host real equality, selected limits, trichotomy, countable-choice schedules, ambient completeness, Lean verification, and bridge credentials are absent from K, none can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionCarrier namecert obligations`

Theorem 1874.3 (Cauchy difference criterion tail-diameter handoff)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. Every tail-diameter request for the difference of the two regular Cauchy source rows factors through the displayed route*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow Q$$

using the finite windows W, the dyadic tolerance ledger T, and the structural rows H, C, P, N. Thus the zero-distance handoff receives null-sequence evidence for the displayed regular-Cauchy difference itself, not for a detached representative or a quotient stream.

Proof. Start with a tail-diameter request. By carrier admission, the request can inspect the source rows only through X, Y and the finite window row W.

The displayed difference route is then forced. The row D is the only coordinate that aligns the two source rows and forms the pointwise difference stream, with every tolerance read recorded in T.

The null evidence is consumed next. The row Z reads the displayed difference stream together with the same windows and tolerance ledger, so each tail-diameter bound used downstream is evidence about D.

Finally the zero-distance row Q receives exactly that finite null-difference route. The transport, continuation, provenance, and local naming rows preserve the route under componentwise comparison and replay, but they do not introduce a detached representative, quotient stream, host equality proof, or ambient completeness datum. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionTailDiameter handoff certificate`

Theorem 1874.4 (Cauchy difference criterion Real seal boundary)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *equality-facing consumer of the two regular Cauchy source rows must first read the finite route*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow Q \longrightarrow E.$$

Consequently the two endpoint names are sealed equal only through regular-Cauchy difference, null-sequence evidence, zero-distance handoff, and the displayed Real seal; the packet does not export quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionReal seal boundary`

Proof. Begin with an equality-facing consumer. The NameCert obligations of Definition 1874.2 force the consumer to read the carrier rows of K before any endpoint seal is visible.

The first analytic route is the displayed difference. Rows X and Y supply the regular rational observations, while D records their aligned pointwise difference through W and T.

The equality evidence then passes through two finite witnesses. The null-sequence row Z certifies the displayed difference as zero-tail evidence, and Definition 1874.3 sends that same evidence into the zero-distance row Q.

Only after Q is read may the consumer reach E. The structural rows H, C, P, N transport, replay, source, and name the same route, so the seal remains downstream of the null-difference handoff.

The boundary statement follows from the carrier inventory. No quotient stream equality, host equality proof, selected limit, trichotomy comparison, countable-choice row, or ambient completeness theorem is present in K, so the $\mathsf{Real}^{\uparrow}$ equality seal is exactly the displayed finite route. □

Theorem 1874.5 (Cauchy difference criterion zero-distance correspondence)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H,$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. The packet exports a Real equality-facing seal exactly through the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row D, the* $\mathsf{NullSequence}^{\uparrow}$ *row Z, and the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *row Q:*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow Q \longrightarrow E.$$

Any consumer lacking one of D, Z, Q cannot read equality of the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows X, Y from the accepted carrier.*

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionZeroDistanceCorrespondence`

Proof. Project the carrier and isolate the equality-facing rows. The only displayed difference coordinate is D, the only null-evidence coordinate for that difference is Z, and the only zero-distance handoff coordinate before the Real seal is Q.

Apply Definition 1874.3. It forces every tail-diameter request for the two source rows through the displayed regular-Cauchy difference and null-sequence evidence before the zero-distance handoff can be read.

Apply Definition 1874.4. The Real seal E is downstream of the same D, Z, Q route, so the equality-facing read is exactly the displayed zero-distance correspondence.

If a consumer omits one of D, Z, Q, the carrier has no remaining coordinate that can connect X, Y to E. Quotient streams, host real equality, selected representatives, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the packet, so none can replace the displayed route. □

Theorem 1874.6 (Cauchy difference criterion regular-tail stability)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. Any retained tail window of X and Y that preserves the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row D and the* $\mathsf{NullSequence}^{\uparrow}$ *row Z also preserves the zero-distance handoff Q and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E under the transport and replay rows H and C. The retained packet exports no quotient stream representative, selected tail limit, host equality proof, choice schedule, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionCarrier regular tail stability`

Proof. Project the carrier. The retained window can inspect the source rows only through X, Y and the finite window row W, while the displayed difference and null rows remain D and Z by hypothesis.

Use the tail-diameter handoff of Definition 1874.3. It keeps every tail request on the same displayed regular-Cauchy difference and null-sequence evidence, so the retained window has no detached representative through which to alter the equality route.

Apply the zero-distance correspondence of Definition 1874.5. Since the retained window preserves D and Z, the only available equality-facing handoff remains Q, and the Real-seal boundary of Definition 1874.4 keeps E downstream of that same handoff.

Finally transport and replay the retained rows through H and C. The carrier inventory has no quotient stream, selected representative, choice schedule, or ambient completeness row, so the terminal $\mathsf{Real}^{\uparrow}$ seal is preserved exactly as the displayed D, Z, Q, E route. □

Theorem 1874.7 (Cauchy difference criterion bidirectional exactness)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. A* $\mathsf{Real}^{\uparrow}$ *equality-facing read of the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows X, Y is exported by K if and only if the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row D is consumed with the* $\mathsf{NullSequence}^{\uparrow}$ *evidence row Z, reflected through the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *row Q, and then sealed at the terminal* $\mathsf{Real}^{\uparrow}$ *row E:*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow Q \longrightarrow E.$$

The exactness statement exports no quotient stream equality, host real equality, selected limits, trichotomy, countable choice, or ambient completeness.

Proof. For the forward direction, start with an equality-facing read of X, Y. Apply Definition 1874.4 to force the read through the displayed route ending at E.

Then apply Definition 1874.5. It identifies the visible equality route as the same D, Z, Q chain: the displayed regular-Cauchy difference is consumed with null-sequence evidence and reflected through the zero-distance row before the Real seal is exposed.

For the reverse direction, assume the displayed D, Z, Q, E route is present. Apply Definition 1874.3 to read every tail-diameter request for the source rows through the displayed difference and null evidence.

The carrier obligations of Definition 1874.2 then repack that finite route as the local equality-facing seal of K. Since the carrier contains no quotient stream equality, host real equality, selected-limit row, trichotomy row, countable-choice schedule, or ambient-completeness principle, the reconstructed route is the same displayed route and no other equality channel is exported. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionBidirectionalExactness`

Theorem 1874.8 (Cauchy difference criterion null-route converse)**.** *Let $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier. If K exposes the* $\mathsf{Real}^{\uparrow}$ *equality-facing seal for the source rows X, Y, then the seal route includes the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row D, the* $\mathsf{NullSequence}^{\uparrow}$ *evidence row Z, and the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *handoff row Q. Conversely, any packet with the same visible source rows but no Z row for the displayed difference cannot export equality of X, Y through the accepted carrier.*

Proof. For the forward direction, start with a $\mathsf{Real}^{\uparrow}$ equality-facing read of X, Y. Apply Definition 1874.7. The read is exported exactly through the displayed route D, Z, Q, E.

The same route is forced by Definition 1874.5. It identifies D as the displayed regular-Cauchy difference row, Z as the null-sequence evidence row for that displayed difference, and Q as the zero-distance handoff row before the terminal seal.

For the converse, remove the Z evidence row while keeping the same visible sources. By Definition 1874.4, the Real seal is downstream of the finite route through D, Z, Q; without Z, the route from the displayed difference to the zero-distance handoff cannot be completed.

The carrier has no replacement equality channel. Quotient stream equality, host equality, selected limits, trichotomy, countable choice, and ambient completeness are all excluded from Definition 1874.1, so a packet missing Z cannot export equality of X, Y through the accepted carrier. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionNullRouteConverse`

Theorem 1874.9 (Cauchy difference criterion shift invariance)**.** *Let*

$$K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$$

and

$$K' = (X', Y', D', Z', Q', W', T', E', H', C', P', N')$$

be accepted $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carriers. Suppose the two packets share the same source, displayed-difference, null-evidence, zero-distance, and Real-seal rows up to a finite* $\mathsf{StreamName}^{\uparrow}$ *tail shift, and suppose this shift preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the displayed difference and null route. Then the equality-facing route*

$$X, Y \longrightarrow D \longrightarrow Z \longrightarrow Q \longrightarrow E$$

is the same accepted route as the shifted route

$$X', Y' \longrightarrow D' \longrightarrow Z' \longrightarrow Q' \longrightarrow E'.$$

Finite prefix deletion changes only the window rows W, W' and their replay positions; it does not change the displayed null-difference route consumed by the Real seal.

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterion shift invariance`

Proof. Project the two accepted carriers. The shared data are the source rows, displayed difference rows, null-sequence evidence rows, zero-distance handoff rows, dyadic tolerance ledgers, and terminal Real-seal rows, with only the finite StreamName windows shifted.

Use the tail-diameter handoff of Definition 1874.3. Since the shift preserves the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, each tail-diameter request for the shifted packet is still read through the displayed difference and null-evidence rows rather than through a detached representative.

Apply the Real-seal boundary and bidirectional exactness, Definition 1874.4 and Definition 1874.7. They force both packets to expose equality only through their D, Z, Q, E chains.

Finally use the null-route converse, Definition 1874.8. Any equality-facing seal must include the same displayed null route, so deleting a finite prefix can affect only the windows W, W' and their continuation replay. The accepted equality-facing route remains invariant under the tail shift. □

Theorem 1874.10 (Cauchy difference criterion kernel scope)**.** *Every accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *packet reads the difference criterion only through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{StreamName}^{\uparrow}$ *pointwise naming rows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-tail rows of chapter 301, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary of chapter 38 before exporting a null-route or zero-distance conclusion.*

Proof. Project an accepted carrier $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$. The source observations are the $\mathsf{RegSeqRat}^{\uparrow}$ rows X, Y, and their inspected pointwise names are visible only through the finite $\mathsf{StreamName}^{\uparrow}$ windows W.

The displayed difference and null route use the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger T. Thus every bound consumed by D, Z, and Q is a tolerance-row read rather than a host metric or selected tail witness.

The terminal equality-facing boundary is the $\mathsf{Real}^{\uparrow}$ seal E. By the Real-seal boundary and zero-distance correspondence, Definition 1874.4 and Definition 1874.5, any exported conclusion passes through D, Z, Q, E.

Consequently the packet's kernel scope is exactly the Real, RegSeqRat, DyadicRatCore, and StreamName dependency route. The structural rows H, C, P, N transport, replay, source, and name that route, but they do not add a quotient stream, host equality proof, selected limit, choice schedule, ambient completeness endpoint. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionKernelScope`
↪ variant `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionCarrier kernel scope`

Theorem 1874.11 (Cauchy difference criterion obligation export)**.** *The carrier definition for* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$*, together with its NameCert obligations, tail-diameter handoff, Real-seal boundary, zero-distance correspondence, regular-tail stability, bidirectional exactness, and null-route converse, assembles the obligation-facing L10 certificate over* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyDifference}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*,* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

The exported certificate has no coordinate for quotient streams, host equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionObligationExport`

Proof. Start with the carrier definition Definition 1874.1 and the NameCert obligations of Definition 1874.2. These two rows admit exactly the source $\mathsf{RegSeqRat}^{\uparrow}$ names, displayed difference row, null-sequence evidence, zero-distance handoff, finite window, dyadic tolerance, terminal Real seal, transport, replay, provenance, and local naming data.

Next apply the tail-diameter handoff Definition 1874.3 and the Real-seal boundary Definition 1874.4. They place every equality-facing read behind the finite route through $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$.

Finally use the zero-distance correspondence, regular-tail stability, bidirectional exactness, and null-route converse, namely Definition 1874.5, Definition 1874.6, Definition 1874.7, and Definition 1874.8. These results repack the same finite rows as an obligation-facing certificate and show that no quotient stream, host equality, selected limit, trichotomy, choice schedule, ambient Real-completeness theorem, Lean verification, or bridge check is used. □

Theorem 1874.12 (Cauchy difference criterion scope package)**.** *For every accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier* $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$*, the public null-route and zero-distance conclusions of* K *are scoped exactly by the displayed rows*

$$X, Y, D, Z, Q, W, T, E, H, C, P, N.$$

Here X, Y *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows,* D *is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row,* Z *is the* $\mathsf{NullSequence}^{\uparrow}$ *evidence,* Q *is the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *handoff,* W *records* $\mathsf{StreamName}^{\uparrow}$ *windows,* T *records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and* H, C, P, N *are the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No null-route or zero-distance conclusion for* K *is available outside this finite kernel scope.*

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionScopePackage`

Proof. Project the accepted carrier. The kernel-scope theorem Definition 1874.10 already fixes the analytic reads to the $\mathsf{RegSeqRat}^{\uparrow}$ sources, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{Real}^{\uparrow}$ seal boundary before any null-route or zero-distance conclusion is exported.

Next apply the obligation export theorem Definition 1874.11. It repacks the same carrier admission, NameCert obligations, tail-diameter handoff, Real-seal boundary, zero-distance correspondence, regular-tail stability, bidirectional exactness, and null-route converse as one L10 certificate over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

It remains to rule out escape from the displayed rows. The carrier definition has no quotient stream, host equality, selected limit, trichotomy, countable-choice schedule, ambient completeness, Lean-verification, or bridge-checking coordinate. The structural rows H, C, P, N only transport, replay, source, and name the displayed packet, so every public conclusion remains scoped by $X, Y, D, Z, Q, W, T, E, H, C, P, N$. □

Theorem 1874.13 (Cauchy difference criterion scoped kernel binding)**.** *For every accepted* CauchyDifferenceCriteric *carrier* $K = (X, Y, D, Z, Q, W, T, E, H, C, P, N)$*, the public null-route and zero-distance conclusions of* K *bind exactly to the scoped kernel route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchyDifference}^{\uparrow},\ \mathsf{NullSequence}^{\uparrow},\ \mathsf{RegularCauchyZeroDistance}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}$$

The source rows are only X, Y *as* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the displayed difference is only* D*, the null evidence is only* Z*, the zero-distance handoff is only* Q*, the finite windows are only* W*, the tolerance reads are only* T*, the equality-facing seal is only* E*, and the structural binding rows are only* H, C, P, N*. Thus no public null-route or zero-distance conclusion escapes the scoped rows of* K*.*

Proof. Project the carrier and apply Definition 1874.10. It fixes the analytic source of every public conclusion to the $\mathsf{RegSeqRat}^{\uparrow}$ rows, displayed $\mathsf{RegularCauchyDifference}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal boundary.

Next use Definition 1874.11. The obligation package supplies the $\mathsf{NullSequence}^{\uparrow}$ evidence row, the $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ handoff row, and the structural BHist, hsame, Cont, Pkg, and NameCert rows as part of the same finite L10 certificate.

Finally apply Definition 1874.12. It identifies the public null-route and zero-distance conclusions with exactly $X, Y, D, Z, Q, W, T, E, H, C, P, N$. Since the carrier has no quotient stream, host equality, selected-limit, trichotomy, countable-choice, ambient-completeness, Lean-verification, or bridge-checking coordinate, the scoped kernel binding is exhaustive. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionScopedKernelBinding`

Theorem 1874.14 (Cauchy difference criterion public export)**.** *Every accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier exports the public* $\mathsf{Real}^{\uparrow}$ *equality route exactly through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyDifference}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*,* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, together with the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

The export has no coordinate for quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tail-diameter handoff of Definition 1874.3. It forces every equality-facing read to pass through the two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the displayed $\mathsf{RegularCauchyDifference}^{\uparrow}$ row, the $\mathsf{NullSequence}^{\uparrow}$ evidence, finite $\mathsf{StreamName}^{\uparrow}$ windows, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger.

Next apply the Real-seal boundary Definition 1874.4. The public route reaches $\mathsf{Real}^{\uparrow}$ only through the terminal seal row already carried by the accepted packet; no detached quotient stream or selected limit is introduced at the boundary.

Use the zero-distance correspondence and bidirectional exactness of Definition 1874.5 and Definition 1874.7. These identify the displayed null route with the $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ handoff in both directions over the same finite rows.

Finally apply the scoped kernel binding of Definition 1874.13. It repacks the route with the structural BHist, hsame, Cont, Pkg, and NameCert rows, and its nonescape clauses exclude trichotomy, countable choice, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the public export. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionPublicExport`

Theorem 1874.15 (Cauchy difference criterion public exactness)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *equality consumer of an accepted* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *carrier receives exactly the following two routes. First, the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row with* $\mathsf{NullSequence}^{\uparrow}$ *evidence implies the* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ *handoff and the terminal zero-distance* $\mathsf{Real}^{\uparrow}$ *seal. Second, any zero-distance* $\mathsf{Real}^{\uparrow}$ *seal exported by the carrier reconstructs the same displayed null-difference route through* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *and* $\mathsf{NullSequence}^{\uparrow}$*.*

Both directions pass only through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RegularCauchyDifference}^{\uparrow}$*,* $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The public exactness surface has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward route, start with the displayed $\mathsf{RegularCauchyDifference}^{\uparrow}$ row and $\mathsf{NullSequence}^{\uparrow}$ evidence. Apply the bidirectional exactness theorem Definition 1874.7; it routes the null difference through the $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ row and then through the terminal $\mathsf{Real}^{\uparrow}$ seal. The public export theorem Definition 1874.14 keeps this route on the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and structural rows.

For the reverse route, start with a zero-distance $\mathsf{Real}^{\uparrow}$ seal exported by the accepted carrier. The null-route converse Definition 1874.8 reconstructs the displayed $\mathsf{RegularCauchyDifference}^{\uparrow}$ and $\mathsf{NullSequence}^{\uparrow}$ rows behind that seal. The zero-distance correspondence Definition 1874.5 identifies the reconstructed route with the same $\mathsf{RegularCauchyZeroDistance}^{\uparrow}$ handoff.

The route is stable under finite window changes by Definition 1874.9. Thus the exactness claim does not depend on a selected tail representative or quotient stream equality; finite $\mathsf{StreamName}^{\uparrow}$ shifts preserve the displayed D, Z, Q, E chain.

Finally apply the scoped kernel binding Definition 1874.13. It binds both directions to the finite kernel rows $X, Y, D, Z, Q, W, T, E, H, C, P, N$, so the public equality consumer receives exactly the two displayed routes and no host equality, selected limit, trichotomy, countable-choice schedule, or ambient-completeness witness. □

Lean4 ✓ `BEDC.Derived.CauchyDifferenceCriterionUp.CauchyDifferenceCriterionPublicExactness`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDifferenceCriterion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDifferenceCriterion}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1874.1, Definition 1874.2, Definition 1874.12, and Definition 1874.13 bind the public L10 criterion from two RegSeqRat source rows through RegularCauchyDifference, NullSequence evidence, RegularCauchyZeroDistance handoff, StreamName windows, DyadicRatCore tolerances, a terminal Real equality seal, and the structural BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDifferenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Bridged closure requires the standard bridge or bridge-facing theorem for the public exactness route.

Constructive story: A CauchyDifferenceCriterion$^{\uparrow}$ packet is generated from two RegSeqRat source rows, one RegularCauchyDifference route, one NullSequence evidence row, one RegularCauchyZeroDistance handoff row, finite StreamName windows, DyadicRatCore tolerances, a terminal RealUp equality-seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1875

A Concrete Naming Certificate for $\mathsf{GramSchmidt}^{\uparrow}$

The classical Gram-Schmidt orthogonalization procedure is a finite-dimensional linear algebra construction that turns an ordered list of vectors into an orthogonal list by subtracting previously displayed projection components. The BEDC $\mathsf{GramSchmidt}^{\uparrow}$ packet records only this finite constructive surface: it is grounded in the vector carrier of chapter 47, the inner-product form rows of chapter 86, the norm-square boundary of chapter 89, and the finite row ledger of chapter 49.

The point of the packet is not to choose a basis. It exposes the ordered replay of the orthogonalization calculation, and when a pivot is not known to be nonzero it records a refusal row rather than selecting a replacement vector or invoking host choice.

Definition 1875.1 (Gram-Schmidt carrier)**.** *A* $\mathsf{GramSchmidt}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, O, Z, A, R, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source-vector row, listing the ordered* $\mathsf{VecSpace}^{\uparrow}$ *vectors to be inspected.*
2. *O is the orthogonalized output row, listing the displayed residual vectors produced from the earlier rows of S.*
3. *Z is the pivot boundary row. For each displayed residual it records either a nonzero norm-square witness or a refusal row saying that the packet does not promote that residual to a selected basis vector.*
4. *A is the scalar projection-coefficient ledger, with each coefficient read from the* $\mathsf{InnerProduct}^{\uparrow}$ *form row and the relevant norm-square pivot row.*
5. *R is the norm-squared row for all displayed residuals and pivot comparisons, sourced through* $\mathsf{Norm}^{\uparrow}$ *and the inner-product diagonal.*
6. *T is the triangular replay row, recording that the ith output row is obtained from the ith source vector by subtracting only projection components along earlier displayed output rows.*
7. *H records componentwise* hsame *transport for source vectors, output rows, pivot witnesses or refusals, projection coefficients, norm-squared rows, triangular replay, continuation, provenance, and local naming.*

8. *C records displayed* Cont *replay from the source row through projection coefficients, residual formation, norm-square inspection, pivot boundary, and local certificate.*
9. *P is the* Pkg *provenance over* $\mathsf{GramSchmidt}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for a host basis, dimension theorem, spectral theorem, Hilbert completion, quotient equality, or selected replacement pivot.

Lean4 ✓ `BEDC.Derived.GramSchmidtUp.GramSchmidtTasteGate single carrier alignment`

Theorem 1875.2 (Gram-Schmidt NameCert obligation surface)**.** *For every accepted* $\mathsf{GramSchmidt}^{\uparrow}$ *carrier* $G = (S, O, Z, A, R, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}$ *surface has exactly five finite rows:*

1. *carrier exposure for the source-vector list, orthogonalized output rows, pivot boundary, projection coefficients, norm-squared rows, triangular replay, transport, continuation, provenance, and local naming;*
2. *inner-product projection coefficient exposure, requiring every scalar in A to be read from displayed* $\mathsf{InnerProduct}^{\uparrow}$ *form rows together with the relevant nonzero pivot witness in Z;*
3. *orthogonality route, requiring every distinct displayed output pair to be certified by the triangular replay row T and the projection-coefficient ledger A;*
4. *nonzero-pivot and refusal boundary, requiring each residual row to carry either the nonzero norm-square witness needed for projection division or the explicit refusal that the row is not promoted to a selected basis vector;*
5. *transport, provenance, and local naming, requiring componentwise* hsame *transport,* Cont *replay,* Pkg *source rows, and the local* $\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}$ *row to preserve exactly the displayed packet.*

No Gram-Schmidt obligation is stored outside these rows.

Proof. Proceed by finite induction on the displayed vector list S. The empty list exposes the empty source row, empty output row, empty coefficient ledger, empty triangular replay, and the local naming row.

For the step from a displayed prefix to the next source vector, use the induction data to read the earlier output rows and their pivot boundary rows. The projection coefficient for each earlier nonzero pivot is read from the displayed $\mathsf{InnerProduct}^{\uparrow}$ form value and the corresponding norm-square row, and the residual is recorded in O by triangular replay through T.

Inspect the new residual through its norm-squared row R. If the packet carries a nonzero pivot witness, the residual becomes the next displayed output row available to later projection coefficients. If such a witness is not displayed, the row is recorded in Z as a refusal, so the construction keeps the finite source vector without choosing a replacement or importing a host basis.

Orthogonality is the invariant preserved by the same finite replay. Earlier output rows are orthogonal by the induction hypothesis, and the new residual subtracts exactly the displayed projection components against those rows. Componentwise hsame transport in H, Cont replay in C, Pkg provenance in P, and local naming in N then move only the rows listed in the carrier. □

Theorem 1875.3 (Gram-Schmidt projection orthogonality induction)**.** *Let $G = (S, O, Z, A, R, T, H, C, P, N)$ be an accepted* $\mathsf{GramSchmidt}^{\uparrow}$ *carrier. Finite prefix induction on the source row S preserves the following invariant: every promoted output row in O is orthogonal, through the displayed* $\mathsf{InnerProduct}^{\uparrow}$ *form row, to every earlier promoted output row; every projection coefficient used in A is read only from that* $\mathsf{InnerProduct}^{\uparrow}$ *form row together with the relevant nonzero pivot witness in Z; and any residual whose pivot witness is absent is recorded by Z as a refusal row and is not promoted into O. The invariant is transported only through the rows exposed in Definition 1875.1 and the obligation surface of Definition 1875.2.*

Proof. Induct on the finite prefix of S. The empty prefix has no promoted output rows, no projection coefficients, and no pivot to inspect, so the invariant is the empty route through $O, Z, A, R, T, H, C, P, N$.

For the step, assume the invariant for the earlier prefix. The triangular replay row T forms the next residual by subtracting only projection components along earlier promoted output rows. Each coefficient in that subtraction is read from the displayed $\mathsf{InnerProduct}^{\uparrow}$ form value and the corresponding nonzero pivot witness in Z, exactly as required by the coefficient row of Definition 1875.2.

The induction hypothesis gives orthogonality among the earlier promoted rows. The new residual is compared against each earlier promoted row by the same replay: its projection component was chosen from the displayed inner-product value and the pivot witness for that earlier row, so the remaining inner-product read is the zero row certified by T and A.

It remains to inspect the new pivot. If Z displays a nonzero norm-square witness, the residual is promoted into O and becomes available to later prefixes with the orthogonality just established. If the witness is absent, Z records the refusal row, and the residual is not promoted; later projection coefficients therefore cannot read it as a pivot row. The transport, continuation, provenance, and naming rows H, C, P, N preserve this finite route without adding a host basis, replacement choice, or quotient equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1875.1 and Definition 1875.2 seed the finite constructive orthogonalization packet over displayed vector-space, inner-product, norm-square, and matrix rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GramSchmidt}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a full basis theorem, dimension theorem, spectral theorem, Hilbert completion, host choice, quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection coefficient exposure, orthogonality route, pivot refusal boundary, transport, provenance, and local naming for BEDC.Derived.GramSchmidtUp.

Constructive story: A $\mathsf{GramSchmidt}^{\uparrow}$ packet is generated from a finite source-vector list, displayed orthogonalized rows, pivot nonzero or refusal witnesses, scalar projection coefficients, norm-squared rows, triangular replay, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1876

A Concrete Naming Certificate for $\mathsf{SeparatedUniformSpace}^{\uparrow}$

Following Bourbaki and Kelley on separated uniform spaces, the $\mathsf{SeparatedUniformSpace}^{\uparrow}$ packet records the finite interface at which a uniform space admits a diagonal separation witness without collapsing into a quotient completion. It refines the entourage surface of chapter 339, imports the zero-distance classifier discipline of chapter 1411, hands completion-facing reads to chapter 1473, and keeps its uniqueness boundary compatible with chapter 402 and chapter 1612. The packet gives $\mathsf{CompleteUniformSpace}^{\uparrow}$ and separated-completion consumers a reusable NameCert boundary for separated uniform data, but it does not construct quotient completions or choose representatives.

Definition 1876.1 (SeparatedUniformSpace carrier)**.** *A* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, D, Z, F, H, R, C, P, N)$$

with the following displayed rows:

1. *U is the underlying* $\mathsf{UniformSpace}^{\uparrow}$ *row, including the finite entourage basis, diagonal-membership ledger, refinement row, and uniform-continuity interface read by downstream consumers.*
2. *D is the diagonal separation witness row: whenever two carried observations are indistinguishable by all displayed entourages of U, D records the route from diagonal uniform evidence to the local point classifier.*
3. *Z is the separated-metric classifier row, used only as a finite comparison surface for metric-generated or metric-compatible uniform readings.*
4. *F is the uniform-completion handoff row, routing completion-facing consumers through the* $\mathsf{UniformCompletion}^{\uparrow}$ *interface before any Hausdorff or separated-completion uniqueness boundary is inspected.*
5. *H is the Hausdorff and separated-completion uniqueness boundary, exposing the comparison rows inherited from* $\mathsf{HausdorffCompletion}^{\uparrow}$ *and* $\mathsf{SeparatedCompletion}^{\uparrow}$ *over the same uniform data, diagonal witness, classifier, and completion handoff.*
6. *R records componentwise* hsame *transport for U, D, Z, F, H and for the local continuation, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the route*

$$U, D \longmapsto Z \longmapsto F \longmapsto H.$$

8. *P is the* Pkg *provenance over* $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedUniformSpace}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares observations only through $U, D, Z, F, H, R, C, P, N$. It has no coordinate for quotient uniform completions, host equality of uniform points, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Lean4 (definition) `BEDC.Derived.SeparatedUniformSpaceUp.SeparatedUniformSpaceTasteGate single carrier alignment`

Theorem 1876.2 (SeparatedUniformSpace NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier*

$$S = (U, D, Z, F, H, R, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedUniformSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the uniform-space row, diagonal separation witness, separated-metric classifier, uniform-completion handoff, Hausdorff and separated-completion uniqueness boundary, transport, replay, provenance, and local naming rows;*
2. *uniform-basis visibility, requiring every separated comparison to begin with the displayed entourage and diagonal-membership rows of U;*
3. *diagonal separation exactness, requiring all indistinguishability-to-classifier reads to pass through D rather than through host equality;*
4. *classifier compatibility, requiring metric-generated comparisons to use the separated-metric row Z only after the uniform entourage route has been displayed;*
5. *completion handoff compatibility, requiring completion-facing consumers to read F before using the Hausdorff or separated-completion uniqueness rows in H;*
6. *ledger non-escape, excluding quotient uniform completions, host equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No local NameCert obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 1876.1. The accepted tuple displays exactly the uniform-space row, diagonal witness, classifier row, completion handoff, uniqueness boundary, and structural rows.

Uniform-basis visibility follows from the order of the carrier. The row U supplies the entourage and diagonal-membership data before D can recognize separatedness, so a consumer cannot replace finite uniform evidence by host equality of points.

Diagonal separation exactness is the role of D. An indistinguishability read through all displayed entourages reaches the local point classifier only through that row. The separated-metric row Z is compatible with this route because it is downstream of U, D and supplies only a metric-generated comparison surface.

The completion handoff is the row F. Completion consumers must pass through F before inspecting the Hausdorff or separated-completion boundary H, so uniqueness is attached to the same uniform data and diagonal witness that produced the separated comparison.

Finally inspect R, C, P, N. Transport is componentwise, replay follows the displayed route, and provenance plus local naming mention only the rows listed in the carrier. Hence the packet exports no quotient uniform completion, host equality, selected representative, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification, or bridge checking. □

Theorem 1876.3 (SeparatedUniformSpace diagonal uniformity boundary)**.** *Let $S = (U, D, Z, F, H, R, C, P, N)$ be an accepted* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier. Every comparison of two carried observations by uniform indistinguishability factors through the finite route*

$$U \longmapsto D \longmapsto Z \longmapsto R, C, P, N.$$

Thus the diagonal separation boundary is a local uniform classifier route, not a quotient by the intersection of all entourages and not a host equality principle.

Proof. Read a comparison of two carried observations from the packet. The carrier first exposes U, so the comparison is expressed through the finite entourage basis and diagonal-membership rows of the underlying uniform space.

Apply the diagonal witness D. This row is the only exported route from uniform indistinguishability to the local point classifier, and it is stored as finite NameCert data rather than as an equality of host points.

The separated-metric classifier Z may replay metric-generated instances of the same comparison, but it remains downstream of U, D. Transport and continuation in R, C preserve this order, while provenance and naming in P, N add no quotient or external equality coordinate. □

Theorem 1876.4 (SeparatedUniformSpace completion non-escape)**.** *Every completion-facing consumer of an accepted* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier*

$$S = (U, D, Z, F, H, R, C, P, N)$$

must factor through the displayed handoff

$$U, D, Z \longmapsto F \longmapsto H \longmapsto R, C, P, N.$$

Consequently the packet can feed $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, *and* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *consumers without exporting quotient uniform completions, host equality of uniform points, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted packet. The rows U, D, Z fix the uniform-space surface, diagonal separation witness, and separated classifier before any completion-facing row is available.

The handoff row F is therefore the only route into uniform completion data. A consumer cannot bypass it by selecting a completion representative, forming a quotient class, or appealing to an ambient complete uniform space.

The uniqueness boundary H is attached to the same U, D, Z, F route. It reads Hausdorff and separated-completion comparison rows only after the handoff has been displayed, so completion uniqueness remains a local NameCert boundary.

The remaining rows R, C, P, N preserve and name this route. Since the carrier has no field for quotient uniform completions, host equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, no completion-facing consumer can project such data from the packet. □

Theorem 1876.5 (SeparatedUniformSpace proximity boundary)**.** *Every accepted* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier supplies the finite diagonal, symmetry, and composition rows required by the* $\mathsf{ProximitySpace}^{\uparrow}$ *nearness boundary, but only through displayed entourages and without adding quotient filters or selected completions. The boundary route is*

$$U, D, Z, F, H \longmapsto \mathsf{ProximitySpace}^{\uparrow} \longmapsto R, C, P, N.$$

Thus a proximity-facing consumer receives separated uniform evidence as finite entourage data rather than as a quotient uniform completion, selected representative, host equality, or choice principle.

Proof. Project the carrier of Definition 1876.1. The row U supplies the finite entourage basis and diagonal-membership ledger, while D supplies the separated diagonal witness used by any downstream nearness boundary.

Apply Definition 1876.2. The displayed uniform basis, diagonal exactness, classifier compatibility, and completion handoff rows are the only obligation rows available before structural transport and naming.

Use Definition 1876.3. It keeps every uniform indistinguishability comparison on the finite route through U, D, Z, R, C, P, N, so the proximity-facing read receives diagonal and symmetry information from displayed entourages rather than from host equality.

The downstream nearness consumer is chapter 6310. Its finite nearness interface may read the separated uniform diagonal, symmetry, and composition evidence, but the separated uniform carrier has no coordinate for quotient filters, selected completions, selected representatives, countable choice, or ambient completeness, so none of those objects is exported across the boundary. □

Theorem 1876.6 (SeparatedUniformSpace diagonal-separation obligation scope)**.** *Every accepted* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *carrier*

$$S = (U, D, Z, F, H, R, C, P, N)$$

scopes diagonal separation through the following finite rows:

1. *the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage rows in* U*, including the finite entourage basis and diagonal-membership ledger;*
2. *the local diagonal witness* D *and the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row* Z*;*
3. *the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row* F*;*
4. *the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *and* $\mathsf{SeparatedCompletion}^{\uparrow}$ *uniqueness rows in* H*;*
5. *componentwise* hsame *transport* R*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*.*

Thus every completion-facing separatedness read remains a finite uniform-entourage route and does not become quotient-completion equality, host equality of uniform points, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1876.1. The accepted packet exposes only the uniform row, diagonal witness, separated classifier, completion handoff, uniqueness boundary, transport, replay, provenance, and local naming rows.

Apply Definition 1876.2. Carrier admission, uniform-basis visibility, diagonal separation exactness, classifier compatibility, and completion handoff compatibility are the finite obligations available to the local certificate.

Use Definition 1876.3. Uniform indistinguishability reaches the local classifier through U, D, Z rather than through host equality or a quotient of all entourages.

Finally apply Definition 1876.4. The handoff to completion-facing consumers passes through F and then through the Hausdorff and separated-completion boundary H, while R, C, P, N preserve and name the same route. Hence no quotient representative, selected completion point, countable-choice schedule, or ambient completeness coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedUniformSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedUniformSpace}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1876.1, Definition 1876.2, Definition 1876.3, and Definition 1876.4 seed the finite separated-uniform interface over uniform-space, diagonal witness, separated classifier, completion handoff, uniqueness boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedUniformSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient uniform completions, host equality of uniform points, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-basis visibility, diagonal separation exactness, classifier compatibility, completion handoff compatibility, and non-escape for BEDC.Derived.SeparatedUniformSpaceUp.

Constructive story: A $\mathsf{SeparatedUniformSpace}^{\uparrow}$ packet is generated from a UniformSpace row, a diagonal separation witness, a SeparatedMetric classifier row, a UniformCompletion handoff, HausdorffCompletion and SeparatedCompletion uniqueness rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1877

A Concrete Naming Certificate for DyadicCoverRefinement$^{\uparrow}$

Following Bishop–Bridges constructive analysis and the finite dyadic cover discipline, the DyadicCoverRefinement$^{\uparrow}$ packet records the common refinement data needed to compare two dyadic cover presentations without invoking an open-cover compactness principle. It sits between the dyadic cover surface of chapter 446, the one-step refinement route of chapter 1831, the ordered partition surface of chapter 1863, and the finite interval-cover handoff of chapter 1596. The packet gives Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and interval finite-cover consumers a reusable finite common-refinement certificate while staying inside displayed cover rows, restriction ledgers, transport, replay, provenance, and local naming.

Definition 1877.1 (Dyadic cover refinement carrier)**.** *A* DyadicCoverRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D_L, D_R, F, L, R_0, H, C, P, N)$$

with the following displayed rows:

1. *D_L and D_R are the two accepted* DyadicCover$^{\uparrow}$ *packets being compared. They expose only finite dyadic centers, radii, interval cells, mesh rows, coverage witnesses, and their local naming data.*
2. *F is the displayed common dyadic refinement cover. Its cells are finite dyadic intervals whose endpoints are read through the same dyadic arithmetic and partition discipline used by* DyadicIntervalRefinement$^{\uparrow}$ *and* DyadicPartition$^{\uparrow}$*.*
3. *L is the left restriction ledger. For each cell of F, it records the parent cell of D_L that contains it, together with endpoint containment and coverage preservation rows.*
4. *R_0 is the right restriction ledger. For each cell of F, it records the parent cell of D_R that contains it, together with endpoint containment and coverage preservation rows.*
5. *H records componentwise* hsame *transport for the two source covers, the common refinement cover, both restriction ledgers, continuation, provenance, and local naming.*
6. *C records displayed* Cont *replay of the finite route*

$$D_L, D_R \longmapsto F \longmapsto L, R_0.$$

7. *P is the* Pkg *provenance over* DyadicCoverRefinement$^{\uparrow}$*,* DyadicCover$^{\uparrow}$*,* DyadicIntervalRefinement$^{\uparrow}$*,* DyadicPartition$^{\uparrow}$*,* IntervalFiniteCoverCertificate$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

8. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCoverRefinement}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares the two cover presentations only through $D_L, D_R, F, L, R_0, H, C, P, N$. It has no coordinate for general open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicCoverRefinementUp.DyadicCoverRefinementTasteGate single carrier alignment`

Theorem 1877.2 (Dyadic cover refinement NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCoverRefinement}^{\uparrow}$ *carrier*

$$R = (D_L, D_R, F, L, R_0, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCoverRefinement}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the two source* $\mathsf{DyadicCover}^{\uparrow}$ *packets, the displayed common refinement cover, both restriction ledgers, transport, replay, provenance, and local naming;*
2. *left restriction exactness, requiring every cell of F to read its left parent cell through L and preserving the displayed dyadic endpoint containment and finite coverage rows of D_L;*
3. *right restriction exactness, requiring every cell of F to read its right parent cell through R_0 and preserving the displayed dyadic endpoint containment and finite coverage rows of D_R;*
4. *common-refinement coverage, requiring every coverage read of either source cover to factor through the finite cell family F before any downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or interval finite-cover consumer can inspect the comparison;*
5. *classifier transport through componentwise* hsame, *displayed* Cont, Pkg *provenance, and local* NameCert *naming, with no escape to general open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these five rows.

Proof. Carrier admission is the projection of Definition 1877.1. The tuple displays the two source covers, the finite common refinement cover, the two restriction ledgers, and the structural rows.

Left restriction exactness is the role of L. Each refined cell reaches the left source cover only by naming its containing parent cell in D_L and replaying the displayed endpoint containment and finite coverage rows already carried by that source cover.

Right restriction exactness is symmetric through R_0. Each refined cell reaches the right source cover only by naming its containing parent cell in D_R and replaying the corresponding endpoint containment and finite coverage rows.

Common-refinement coverage follows because the only comparison cover in the carrier is F. Any downstream read by a regular-rational, real-facing, or finite interval-cover consumer must first project F and then use the appropriate restriction ledger.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier contains no field for open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, the classifier cannot export such data. □

Theorem 1877.3 (Dyadic cover common refinement exactness)**.** *Let*

$$R = (D_L, D_R, F, L, R_0, H, C, P, N)$$

be an accepted $\mathsf{DyadicCoverRefinement}^{\uparrow}$ *carrier. Every consumer comparing the two dyadic-cover presentations* D_L *and* D_R *factors through the displayed finite route*

$$D_L, D_R \longmapsto F \longmapsto L, R_0 \longmapsto H, C, P, N.$$

Consequently the comparison reads exactly the common refinement cover, the left and right restriction ledgers, componentwise transport, continuation replay, provenance, and local naming. It cannot read open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from this packet.*

Proof. Project the accepted carrier. The only rows mentioning the two dyadic cover presentations are D_L and D_R, and the only row relating them is the displayed common refinement cover F.

Read a comparison request. Before it can inspect either source cover through a downstream consumer, it must pass to the finite cells of F; there is no separate comparison coordinate in the carrier.

The left and right projections from F are exactly L and R_0. Thus the source covers are visible only as parent-cell and coverage-preservation reads along those two restriction ledgers.

The remaining rows H, C, P, N preserve this route by componentwise transport, continuation replay, provenance, and local naming. None of those rows introduces open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient completeness, Lean verification, or bridge data, so every accepted comparison factors through the displayed common refinement. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCoverRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCoverRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1877.1, Definition 1877.2, and Definition 1877.3 seed the finite common-refinement route between two dyadic cover packets, their displayed refinement cover, both restriction ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCoverRefinement}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DyadicCoverRefinementUp`

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, Heine–Borel, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, left and right restriction exactness, common-refinement coverage, classifier transport, and common-refinement exactness for BEDC.Derived.DyadicCoverRefinementUp.

Constructive story: A $\mathsf{DyadicCoverRefinement}^{\uparrow}$ packet is generated from two DyadicCover packets, one displayed finite common dyadic refinement cover, left and right restriction ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1878

A Concrete Naming Certificate for $\mathsf{ExtendedRealLine}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop–Bridges on the extended real line and one-sided real boundaries, the $\mathsf{ExtendedRealLine}^{\uparrow}$ packet records the finite interface obtained by adjoining positive and negative infinity tags to already named real data. It is a boundary surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, and $\mathsf{CountableChoiceBoundary}^{\uparrow}$: finite rows may cite ordinary real names and one-sided infinity behavior, but the packet does not import a host extended-real primitive, a quotient cut, trichotomy, a selected supremum, a countable-choice selector, or an ambient completeness theorem.

The finite-real row is consumed from chapter 38; the one-sided boundary rows are consumed from chapter 1446 and chapter 1447; the positive-bound discipline is consumed from chapter 1587; and the non-choice boundary is consumed from chapter 1872. Thus $\mathsf{ExtendedRealLine}^{\uparrow}$ is a tagged consumer of those sibling rows, with finite, lower, upper, positive-bound, and non-choice evidence displayed as carrier coordinates, rather than a host extended-real primitive that could select boundary representatives or import completeness.

Definition 1878.1 (ExtendedRealLine carrier)**.** *An* $\mathsf{ExtendedRealLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, R, L, U, P, B, H, C, K, N)$$

with the following displayed rows:

1. *T is the finite tag row. Each accepted observation is tagged as finite real, positive infinity, or negative infinity.*
2. *R is the finite-real row. It is read only through the already named* $\mathsf{Real}^{\uparrow}$ *surface, and it is available exactly for observations whose tag in T is finite real.*
3. *L is the lower-boundary row. It records negative-infinity-facing lower real behavior through* $\mathsf{LowerReal}^{\uparrow}$ *and exports no chosen cut representative.*
4. *U is the upper-boundary row. It records positive-infinity-facing upper real behavior through* $\mathsf{UpperReal}^{\uparrow}$ *and exports no selected supremum.*
5. *P is the positive-bound discipline row. It reads positive finite bounds through* $\mathsf{PositiveReal}^{\uparrow}$ *before any positive-infinity comparison is accepted.*
6. *B is the non-choice boundary row, inherited from* $\mathsf{CountableChoiceBoundary}^{\uparrow}$*, which refuses countable selectors, global supremum choices, selected limit schedules, and ambient completeness*

witnesses.

7. *H records componentwise* hsame *transport for tag, finite-real, lower-boundary, upper-boundary, positive-bound, non-choice, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$T \longmapsto R, L, U, P \longmapsto B.$$

9. *K is the* Pkg *provenance over* $\mathsf{ExtendedRealLine}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{CountableChoiceBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ExtendedRealLine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, L, U, P, B, H, C, K, N$. It has no coordinate for a host extended-real type, quotient cuts, trichotomy, selected suprema, countable-choice selectors, ambient completeness, Lean verification, or bridge data.

Lean4 ✓ `BEDC.Derived.ExtendedRealLineUp.TasteGate.ExtendedRealLineTasteGate single carrier alignment`

Theorem 1878.2 (ExtendedRealLine NameCert obligations)**.** *For every accepted* $\mathsf{ExtendedRealLine}^{\uparrow}$ *carrier*

$$E = (T, R, L, U, P, B, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{ExtendedRealLine}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the tag row, finite-real row, lower-boundary row, upper-boundary row, positive-bound row, non-choice boundary, transport, replay, provenance, and local naming;*

2. *tag classifier stability, requiring every consumer comparison to preserve the finite real, positive infinity, and negative infinity cases named by T;*

3. *finite-real seal discipline, requiring finite-tagged observations to read ordinary real data only through R and hence through* $\mathsf{Real}^{\uparrow}$*;*

4. *one-sided infinity boundary nonescape, requiring negative-infinity reads to pass through L and* $\mathsf{LowerReal}^{\uparrow}$*, and positive-infinity reads to pass through U,* $\mathsf{UpperReal}^{\uparrow}$*, and the positive-bound discipline P;*

5. *provenance and local naming, requiring H, C, K, N to transport, replay, source, and name only the displayed rows of the packet;*

6. *non-choice refusal, requiring the boundary row B to exclude host extended-real primitives, quotient cuts, trichotomy, selected suprema, countable-choice selectors, ambient completeness theorems, Lean verification, and bridge checking.*

No ExtendedRealLine obligation is stored outside these six rows.

Lean4 ✓ `BEDC.Derived.ExtendedRealLineUp.ExtendedRealLineTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1878.1. The accepted tuple displays exactly the tag row, the three tag-dependent value rows, the positive-bound discipline, the non-choice boundary, and the structural rows.

Tag classifier stability follows from the role of T. Every accepted observation is first classified as finite real, positive infinity, or negative infinity, and all later rows are read under that displayed tag rather than under host trichotomy for an ambient extended-real type.

The finite-real seal is the row R. A finite-tagged observation reaches ordinary real data only through R, whose source is $\mathsf{Real}^{\uparrow}$; hence no quotient cut or host extended-real primitive is projected from the finite case.

For the one-sided tags, negative-infinity behavior is read through L and $\mathsf{LowerReal}^{\uparrow}$, while positive-infinity behavior is read through U, $\mathsf{UpperReal}^{\uparrow}$, and the positive-bound row P. The non-choice row B then refuses selected suprema, countable-choice selectors, selected limit schedules, and ambient completeness witnesses.

Finally inspect H, C, K, N. Transport is componentwise, replay follows the displayed route, and provenance plus local naming mention only the rows listed in the carrier. Therefore the six obligation rows exhaust the local NameCert surface. □

Theorem 1878.3 (ExtendedRealLine finite boundary)**.** *Every consumer route out of an accepted* $\mathsf{ExtendedRealLine}^{\uparrow}$ *carrier*

$$E = (T, R, L, U, P, B, H, C, K, N)$$

factors through

$$\mathsf{Real}^{\uparrow},\ \mathsf{LowerReal}^{\uparrow},\ \mathsf{UpperReal}^{\uparrow},\ \mathsf{PositiveReal}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Consequently the packet exports no host extended-real primitive, quotient cut, trichotomy, selected supremum, countable-choice selector, or ambient completeness theorem.

Proof. Begin with a consumer of E. The tag row T is the only entry point, so the consumer must first decide which displayed case of the finite packet is being read.

In the finite case the consumer reaches R, and R routes through $\mathsf{Real}^{\uparrow}$. In the negative-infinity case the consumer reaches L, and L routes through $\mathsf{LowerReal}^{\uparrow}$. In the positive-infinity case the consumer reaches U and then the positive-bound discipline P, so the route passes through $\mathsf{UpperReal}^{\uparrow}$ and $\mathsf{PositiveReal}^{\uparrow}$.

The carrier itself is a BHist packet. Its equality-like motion is componentwise hsame, its rereading surface is Cont, its source ledger is Pkg, and its public name is the local NameCert row.

The non-choice row B is read on every boundary-facing route. Since B is inherited from $\mathsf{CountableChoiceBoundary}^{\uparrow}$, it blocks countable-choice selectors, selected suprema, selected limits, and ambient completeness witnesses; since the carrier inventory has no host extended-real coordinate, no quotient cut or trichotomy principle can be exported either. □

Closure status for $\mathsf{NameCert}_{\mathsf{ExtendedRealLine}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExtendedRealLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1878.1, Definition 1878.2, and Definition 1878.3 seed the finite extended-real boundary over ordinary real rows, one-sided lower and upper rows, positive-bound discipline, non-choice refusal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExtendedRealLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host extended-real primitives, quotient cuts, trichotomy, selected suprema, countable-choice selectors, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tag classifier stability, finite-real seal discipline, one-sided infinity boundary nonescape, provenance and local naming, non-choice refusal, and finite consumer factorization for BEDC.Derived.ExtendedRealLineUp.

Constructive story: An $\mathsf{ExtendedRealLine}^{\uparrow}$ packet is generated from a finite tag row, a $\mathsf{Real}^{\uparrow}$ finite row, $\mathsf{LowerReal}^{\uparrow}$ and $\mathsf{UpperReal}^{\uparrow}$ one-sided boundary rows, a $\mathsf{PositiveReal}^{\uparrow}$ positive-bound row, a $\mathsf{CountableChoiceBoundary}^{\uparrow}$ non-choice row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1879

A Concrete Naming Certificate for $\mathsf{KroneckerLemma}^{\uparrow}$

Following Kronecker and Bishop–Bridges constructive analysis, the $\mathsf{KroneckerLemma}^{\uparrow}$ packet records the finite Toeplitz–Cesaro route by which weighted prefix tails are shown to be summability-controlled before any completion-facing real endpoint is read. It consumes the finite matrix-window discipline of chapter 1682, the displayed averaging surface of chapter 1765, the convergence-window route of chapter 1827, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite summability certificate for Kronecker-style tail control; it does not import quotient sums, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1879.1 (Kronecker lemma carrier)**.** *A* $\mathsf{KroneckerLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, T, H, C, R, E, L, Q, N)$$

with the following displayed rows:

1. *S is the source weighted-tail row, exposing only the finite sequence windows, partial-sum windows, and denominator windows currently requested by the Kronecker estimate.*
2. *B is the bounded-prefix ledger, recording the finite prefix-sum bounds and monotone denominator comparisons used by the inspected tail.*
3. *T is the* $\mathsf{ToeplitzLemma}^{\uparrow}$ *row carrying the finite lower-triangular coefficient window that transforms the bounded prefix data into the displayed weighted tail.*
4. *H is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row for the Cesaro averaging of the transformed tail windows.*
5. *C is the* $\mathsf{CesaroConvergence}^{\uparrow}$ *row certifying that the displayed Hardy–Cesaro means enter the convergence-window surface.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached only after the Toeplitz, Hardy–Cesaro, and Cesaro-convergence rows have been displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational handoff R has been exposed.*
8. *L stores componentwise* hsame *transport and displayed* Cont *replay for the source tail row, bounded-prefix ledger, Toeplitz row, Hardy–Cesaro row, Cesaro-convergence row, regular handoff, real seal, provenance, and local naming.*

9. *Q is the* Pkg *provenance over* $\mathsf{KroneckerLemma}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{KroneckerLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, T, H, C, R, E, L, Q, N$. It has no coordinate for quotient sums, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.KroneckerLemmaUp.TasteGate.KroneckerLemmaTasteGate single carrier alignment`

Theorem 1879.2 (Kronecker lemma NameCert obligations)**.** *For every accepted* $\mathsf{KroneckerLemma}^{\uparrow}$ *carrier*

$$K = (S, B, T, H, C, R, E, L, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{KroneckerLemma}^{\uparrow}}$ *surface consists exactly of the following six finite obligation rows:*

1. *carrier admission for the displayed source weighted-tail row, bounded-prefix ledger, Toeplitz row, Hardy–Cesaro row, Cesaro-convergence row, regular handoff, real seal, transport and replay ledger, provenance, and local naming row;*
2. *bounded-prefix exactness, requiring every accepted tail estimate to read its partial-sum bound and denominator comparison through S and B;*
3. *Toeplitz-window classification, requiring the weighted-tail transform to pass through the finite coefficient row T before any Cesaro mean is available;*
4. *Cesaro route compatibility, requiring H and C to consume the same transformed windows exported by T and to expose no independent convergence witness;*
5. *regular handoff and real seal factorization, requiring every endpoint-facing read to pass through R and then E after the Toeplitz–Cesaro route has been displayed;*
6. *ledger non-escape, requiring L, Q, N to preserve, source, and name only the displayed rows and to exclude quotient sums, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 1879.1. Carrier admission is exactly the inventory $S, B, T, H, C, R, E, L, Q, N$ so the local certificate has no detached row for an infinite weighted series, a chosen limit, or a host equality principle.

Bounded-prefix exactness is read before the summability transform. The source row S exposes only the inspected sequence, partial-sum, and denominator windows, while B records the finite prefix bound and denominator comparison needed by the current tail estimate.

The route then passes through T, H, C. The Toeplitz row T supplies the finite coefficient window for the weighted-tail transform, the Hardy–Cesaro row H averages the transformed windows, and the Cesaro-convergence row C is the only convergence-window classifier available to the packet.

Finally, R and E seal the endpoint-facing read. The ledger L, provenance Q, and local naming row N transport, replay, source, and name this same route; none of those rows contributes quotient sums, selected limits, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge data. □

Theorem 1879.3 (Kronecker lemma Toeplitz–Cesaro route)**.** *Every accepted* $\mathsf{KroneckerLemma}^{\uparrow}$ *read reaching a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

$$S, B \longmapsto T \longmapsto H \longmapsto C \longmapsto R \longmapsto E \longmapsto (L, Q, N).$$

Thus a completion-facing consumer receives weighted-tail control only after the bounded-prefix ledger, Toeplitz matrix window, Hardy–Cesaro averaging row, Cesaro-convergence row, regular rational handoff, real seal, transport and replay ledger, provenance, and local NameCert have all been displayed.

Proof. Start with a completion-facing read of an accepted carrier. By Definition 1879.1, the only source-side data available before the transform are S and B, so the read first consumes the displayed sequence windows, partial-sum windows, denominator windows, and bounded-prefix ledger.

The transformed weighted-tail row is then forced through T. This is the finite Toeplitz surface of chapter 1682; it supplies the coefficient-window route and does not expose an infinite matrix or a host summability method.

The Cesaro part is exhausted by H and C. The Hardy–Cesaro row H supplies the finite averaging route of chapter 1765, and the Cesaro-convergence row C supplies the convergence-window handoff of chapter 1827.

Only after those rows have been displayed can the packet reach the regular rational handoff R and then the real seal E. The remaining rows L, Q, N preserve the route by transport, replay, provenance, and local naming, so no consumer can bypass the Toeplitz–Cesaro path through quotient sums, selected limits, countable choice, host real equality, trichotomy, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{KroneckerLemma}^{\uparrow}$ completion-facing read factors through finite source weighted-tail windows, a bounded-prefix ledger, a ToeplitzLemma row, a HardyCesaroMean row, a CesaroConvergence row, RegSeqRat handoff, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: toeplitzlemma, hardycesaromean, cesaroconvergence, regseqrat, real: $\mathsf{KroneckerLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source weighted-tail windows, bounded-prefix data, Toeplitz finite matrix windows, Hardy–Cesaro averaging, Cesaro convergence, regular handoff, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KroneckerLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{KroneckerLemma}^{\uparrow}$ packet is generated from source weighted-tail windows, bounded-prefix data, a Toeplitz finite matrix row, HardyCesaroMean averaging, CesaroConvergence classification, RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KroneckerLemma}^{\uparrow}}$, seed)

Scope closed: Definition 1879.1, Definition 1879.2, and Definition 1879.3 seed the finite Toeplitz–Cesaro summability route for Kronecker-style weighted-tail control.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KroneckerLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient sums, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-prefix exactness, Toeplitz-window classification, Cesaro route compatibility, regular handoff, real seal factorization, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.KroneckerLemmaUp.

Chapter 1880

A Concrete Naming Certificate for $\mathsf{DarbouxSum}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxSum}^{\uparrow}$ packet names the finite upper/lower sum surface over a dyadic partition and step-function brackets. It consumes the dyadic partition ledger of chapter 1863, the bracket rows of chapter 428, the tagged finite-sum consumer of chapter 1615, the Darboux integration carrier of chapter 1460, and the terminal real-name seal of chapter 38. The packet supplies the finite SU/SL boundary that later Darboux and Riemann integration chapters can cite without importing open-cover compactness, selected mesh limits, measure-theoretic integration, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1880.1 (Darboux sum carrier)**.** *A* $\mathsf{DarbouxSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, L, U, SL, SU, G, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{DyadicPartition}^{\uparrow}$ *packet naming the finite ordered dyadic cell list and its common-refinement ledger.*
2. *L and U are lower and upper* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packets over the displayed partition cells, with every bracket value read through the same partition row P.*
3. *SL is the finite lower Darboux-sum row computed from the displayed cell widths of P and the carried lower values of L.*
4. *SU is the finite upper Darboux-sum row computed from the displayed cell widths of P and the carried upper values of U.*
5. *G is the upper-minus-lower gap row, exposing only the finite comparison between SU and SL after the partition and step-function brackets have been displayed.*
6. *H records componentwise* hsame *transport for the partition row, lower and upper step-function rows, lower and upper finite sum rows, gap row, continuation replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from partition cells to bracket reads, from bracket reads to finite sums, and from the two finite sums to the gap comparison.*
8. *Q is the* Pkg *provenance over* $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{DarbouxSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, L, U, SL, SU, G, H, C, Q, N$. It has no coordinate for open-cover compactness, selected mesh limits, measure-theoretic integration, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DarbouxSumUp.TasteGate.DarbouxSumTasteGate single carrier alignment`

Theorem 1880.2 (Darboux sum NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxSum}^{\uparrow}$ *carrier*

$$S = (P, L, U, SL, SU, G, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{DarbouxSum}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed dyadic partition packet, lower and upper step-function brackets, finite lower and upper sum rows, gap row, transport and replay ledger, provenance, and local naming row;*
2. *partition compatibility, requiring every bracket value and every cell width used by SL and SU to be read through the displayed* $\mathsf{DyadicPartition}^{\uparrow}$ *row P;*
3. *bracket stability, requiring* hsame *transport of L and U to carry the same lower/upper role over any displayed common refinement of P;*
4. *finite sum stability, requiring SL and SU to replay as finite cellwise sums after transport of the partition and bracket rows;*
5. *ledger non-escape, requiring H, C, Q, N to preserve, replay, source, and name only the displayed rows and to exclude open-cover compactness, selected mesh limits, measure-theoretic integration, quotient real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Carrier admission is the projection of Definition 1880.1. The accepted packet displays exactly the partition, lower bracket, upper bracket, lower finite sum, upper finite sum, gap, transport, replay, provenance, and local naming rows.

Partition compatibility is forced before any sum row can be read. The row P supplies the finite ordered dyadic cells and their widths, while L and U supply lower and upper values over those same displayed cells.

Bracket stability and finite sum stability are then replayed through H and C. Transport moves the partition and both brackets componentwise, and continuation replay recomputes SL and SU as finite cellwise sums over the transported rows.

Finally, Q and N source and name this same finite route. Since no carrier coordinate stores open-cover compactness, selected mesh limits, measure data, quotient real equality, or ambient completeness, the ledger non-escape row exhausts the remaining obligation surface. □

Theorem 1880.3 (Darboux upper-lower gap)**.** *For every accepted* $\mathsf{DarbouxSum}^{\uparrow}$ *carrier $S = (P, L, U, SL, SU, G, H, C, Q, N)$, the upper-minus-lower gap row G is read only through the displayed finite partition P, the displayed lower and upper step-function brackets L and U, and the resulting finite sum rows SL and SU. Any consumer of G therefore receives a finite partition-and-bracket comparison surface, not open-cover compactness, a selected mesh limit, measure-theoretic integration, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only rows upstream of G are P, L, U, SL, SU together with the transport and replay structure that preserves them.

The lower and upper finite sums are computed before the gap is visible. The row SL uses the cell widths of P and the carried lower values of L, while SU uses the same cell widths and the carried upper values of U.

Reading G then compares these two displayed finite sums. Componentwise transport through H and replay through C may move the packet to a displayed common refinement, but the read still factors through the transported partition, transported brackets, and recomputed finite sum rows.

The excluded analytic objects are absent from the carrier. Thus no consumer can obtain them by inspecting the upper-minus-lower gap. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxSum}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxSum}^{\uparrow}$ packet is generated from a DyadicPartition row, lower and upper DyadicStepFunction brackets, lower and upper finite Darboux sums, an upper-minus-lower gap row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DarbouxSum}^{\uparrow}}$, seed)

Scope closed: Definition 1880.1, Definition 1880.2, and Definition 1880.3 seed the finite Darboux upper/lower sum interface over displayed dyadic partitions and step-function brackets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DarbouxSum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected mesh limits, measure-theoretic integration, quotient real equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition compatibility, bracket stability, finite sum stability, ledger non-escape, and upper-lower gap factorization for BEDC.Derived.DarbouxSumUp.

Chapter 1881

A Concrete Naming Certificate for $\mathsf{CauchyRealApartness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRealApartness}^{\uparrow}$ packet records the positive finite boundary by which two displayed real names are certified apart before any order trichotomy, quotient stream equality, selected limit, or ambient completeness principle can be read. It sits over the terminal real-name seal of chapter 38, the regular rational readback route of chapter 301, the finite window discipline of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names a constructive positive-apartness surface for later order and metric consumers; it does not decide equality or total order on $\mathsf{Real}^{\uparrow}$.

Definition 1881.1 (Cauchy real apartness carrier)**.** *A* $\mathsf{CauchyRealApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (E_0, E_1, R_0, R_1, W_0, W_1, D, T, H, C, P, N)$$

with the following displayed rows:

1. *E_0 and E_1 are the two* $\mathsf{Real}^{\uparrow}$ *seal rows. They are terminal classifier rows only; they expose no host real equality, quotient representative, trichotomy branch, or completeness theorem.*
2. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *witness rows. Each reads the corresponding real name through displayed regular rational data before the apartness tolerance is interpreted.*
3. *W_0 and W_1 are finite* $\mathsf{StreamName}^{\uparrow}$ *window rows for the same precision request. They record the inspected windows and no infinite stream equality.*
4. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores a displayed positive dyadic gap, the comparison ledger, and the slack budget used to separate the two inspected windows.*
5. *T is the apartness transport row. It records componentwise* hsame *transport for the two real seals, the regular readbacks, the finite windows, the positive tolerance ledger, replay, provenance, and local naming.*
6. *H is the displayed* Cont *continuation row. It replays a consumer request through $E_0, E_1, R_0, R_1, W_0, W_1, D, T, P,$ without adding a selected limit or an equality decision.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealApartness}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite positive-apartness packet. It has no coordinate for trichotomy, quotient stream equality, selected limits, countable choice, metric-space completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRealApartnessUp.CauchyRealApartnessTasteGate single carrier alignment`

Theorem 1881.2 (Cauchy real apartness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealApartness}^{\uparrow}$ *carrier*

$$A = (E_0, E_1, R_0, R_1, W_0, W_1, D, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealApartness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two Real seals, two regular rational readbacks, two finite StreamName windows, positive dyadic tolerance ledger, transport row, continuation row, provenance row, and local naming row;*
2. *positive tolerance stability, requiring the positive dyadic gap in* D *to remain positive under the displayed comparison ledger and the componentwise transports in* T*;*
3. *RegSeqRat handoff, requiring every apartness read to pass from the two finite windows* W_0, W_1 *through* R_0, R_1 *before the Real seal rows* E_0, E_1 *are consumed;*
4. *Real seal nonescape, requiring* E_0 *and* E_1 *to be terminal seals rather than carriers of equality, trichotomy, selected representatives, selected limits, or completeness;*
5. *ledger rows, requiring* T, H, P, N *to transport, replay, source, and name only the displayed rows of the packet.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1881.1. The accepted packet displays exactly the two terminal real seals, two regular rational readbacks, two finite window rows, one positive dyadic tolerance ledger, and the structural rows.

Positive tolerance stability is finite. The row D records the displayed positive gap and its slack comparisons, while T transports only the named rows componentwise, so no transport step can replace the gap with an undecided order comparison.

The handoff obligation follows the row order. The finite windows W_0, W_1 are read first, the regular rational witnesses R_0, R_1 interpret those windows, and only then may the real seals E_0, E_1 be consumed by an apartness reader.

Finally, the seal and ledger obligations are exhausted by E_0, E_1, T, H, P, N. Those rows preserve and name the displayed route; they do not add trichotomy, quotient stream equality, selected limits, countable choice, metric completeness, ambient Real completeness, Lean verification, or bridge data. □

Lean4 ✓ `BEDC.Derived.CauchyRealApartnessUp.CauchyRealApartnessCarrier namecert obligations`

Theorem 1881.3 (Cauchy real apartness RegSeqRat handoff)**.** *Every accepted* $\mathsf{CauchyRealApartness}^{\uparrow}$ *read reaching a* $\mathsf{Real}^{\uparrow}$ *apartness consumer factors through the finite route*

$$W_0, W_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto E_0, E_1 \longmapsto (T, H, P, N).$$

Thus the apartness witness reaches $\mathsf{Real}^{\uparrow}$ *only through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*

Proof. Start with a Real-facing apartness read of an accepted carrier. By Definition 1881.1, the only window data available to that read are W_0 and W_1.

The regular rational stage is forced next. The rows R_0 and R_1 read the two finite StreamName windows as regular rational witnesses, so the consumer receives no quotient stream equality or infinite stream comparison.

The positive gap is then read from D. This dyadic ledger supplies the finite positive tolerance and the displayed slack comparisons used by the apartness request.

Only after these rows are displayed can the read consume E_0 and E_1 as terminal Real seals. The structural rows T, H, P, N preserve the same route by transport, continuation, provenance, and local naming. □

Theorem 1881.4 (Cauchy real apartness nonescape)**.** *An accepted* $\mathsf{CauchyRealApartness}^{\uparrow}$ *carrier exports no row for order trichotomy, quotient stream equality, selected limits, countable choice, metric-space completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any consumer asking for one of those principles must leave the local packet and cannot obtain it from the carrier rows*

$$E_0, E_1, R_0, R_1, W_0, W_1, D, T, H, C, P, N.$$

Proof. Inspect the carrier rows. The StreamName rows are finite windows, the RegSeqRat rows are displayed readbacks, and the DyadicRatCore row is a positive tolerance ledger; none of these rows carries quotient stream equality or a selected limit.

The two Real rows are seals only. They are consumed after the regular rational and dyadic rows have been displayed, and their role is terminal naming rather than equality decision, order trichotomy, metric completeness, or ambient completeness.

The remaining rows are structural. Transport, continuation, provenance, and local naming preserve the displayed route, so countable choice, selected representatives, quotient equality, trichotomy, metric-space completeness, and $\mathsf{Real}^{\uparrow}$ completeness remain outside the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealApartness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1881.1, Definition 1881.2, Definition 1881.3, and Definition 1881.4 seed the finite positive-apartness route over two Real seals, regular rational readbacks, StreamName windows, and a positive DyadicRatCore tolerance ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, full order trichotomy, metric-space completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, positive tolerance stability, RegSeqRat handoff, Real seal nonescape, ledger exhaustion, and TasteGate field faithfulness for BEDC.Derived.CauchyRealApartnessUp.

Constructive story: A $\mathsf{CauchyRealApartness}^{\uparrow}$ packet is generated from two RealUp seals, two RegSeqRat readbacks, two StreamName windows, a positive DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont continuation, Pkg provenance, and a local NameCert row.

Chapter 1882

Rational Interval Cover NameCert Construction

Following Bishop–Bridges constructive analysis and the finite interval methods of Moore–Kearfott–Cloud, the $\mathsf{RationalIntervalCover}^{\uparrow}$ packet records finite rational interval covers as displayed endpoint, coverage, and refinement data. It sits between the rational interval surface of chapter 354, the refinement rows of chapter 1432, the located interval boundary of chapter 394, the dyadic tolerance core of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite cover ledger for Real and Completion consumers; it is not an open-cover compactness principle, a countable-choice construction, quotient equality of completed reals, selected-limit data, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1882.1 (RationalIntervalCover carrier)**.** *A* $\mathsf{RationalIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (I, F, R, W, H, K, P, N)$$

with the following displayed rows:

1. *I is the finite family of* $\mathsf{RationalInterval}^{\uparrow}$ *rows whose endpoint and containment surfaces are read through chapter 354.*
2. *F is the finite coverage ledger, recording exactly which rational samples, located interval requests, and regular rational windows are covered by rows of I.*
3. *R is the finite refinement ledger, displaying the* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *rows by which accepted subcovers and retained windows refine through the intervals in I.*
4. *W is the StreamName and* $\mathsf{RegSeqRat}^{\uparrow}$ *window boundary, naming the finite stream indices, rational tolerances, and regular-readback requests for which the cover is available.*
5. *H records componentwise* hsame *transport for interval-family rows, coverage rows, refinement rows, window-boundary rows, continuation rows, provenance, and local naming.*
6. *K records displayed* Cont *replay, so a consumer can reread I, F, R, W, H, P, N without changing the cover ledger.*
7. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalCover}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RationalIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalCover}^{\uparrow}}$ *row.*

The classifier compares accepted covers only through the displayed rows I, F, R, W, H, K, P, N. It has no coordinate for an arbitrary open cover, countable cover selection, quotient real equality, selected limit, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RationalIntervalCoverUp.RationalIntervalCoverTasteGate single carrier alignment`

Theorem 1882.2 (RationalIntervalCover NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalCover}^{\uparrow}$ *carrier*

$$C = (I, F, R, W, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalIntervalCover}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite rational interval family, coverage ledger, refinement ledger, StreamName and* $\mathsf{RegSeqRat}^{\uparrow}$ *boundary, transports, replay, provenance, and local naming;*
2. *interval-family exactness, requiring every cover read to expose its* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint and containment rows before any completion-facing consumer may use the cover;*
3. *coverage-ledger exactness, requiring every covered rational sample, located interval request, or regular rational window to appear as a displayed row of F;*
4. *refinement-ledger exactness, requiring every retained subcover or narrowed window to factor through displayed* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *rows in R;*
5. *window-boundary ordering, requiring the StreamName and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows in W to be read before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *ledger non-escape, requiring H, K, P, N to export no open-cover compactness, countable choice, quotient real equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No RationalIntervalCover obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1882.1. The accepted packet displays exactly one finite interval-family row, one finite coverage ledger, one finite refinement ledger, one finite window boundary, and the structural rows that transport, replay, package, and name them.

Interval-family exactness follows because I is the only coordinate containing $\mathsf{RationalInterval}^{\uparrow}$ packets. A consumer can therefore inspect interval endpoints and containment only through the displayed rational interval rows.

Coverage-ledger exactness is the row F. Every accepted cover request must be one of its displayed rational samples, located interval requests, or regular rational windows, and there is no second coordinate from which an unrecorded cover read could be obtained.

Refinement-ledger exactness is the row R. Its entries are the displayed $\mathsf{RationalIntervalRefinement}^{\uparrow}$ witnesses, so any retained subcover or narrowed window is read through those finite refinement rows.

The remaining rows W, H, K, P, N bind the cover to finite stream windows, regular rational readback, transport, replay, provenance, and local naming. Since the excluded compactness, choice, quotient, limit, and completeness objects are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1882.3 (RationalIntervalCover finite refinement)**.** *Every accepted* $\mathsf{RationalIntervalCover}^{\uparrow}$ *carrier $C = (I, F, R, W, H, K, P, N)$ refines through the displayed* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *rows in R. More precisely, each accepted subcover, retained window, or consumer-facing narrowed interval is obtained by reading a finite row of R against the interval family I, coverage ledger*

F, StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ *boundary W, componentwise* hsame *transport H, displayed* Cont *replay K,* Pkg *provenance P, and local* $\mathsf{NameCert}$ *row N. The refinement route does not use open-cover compactness, countable choice, quotient real equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet through Definition 1882.1. The interval family I supplies the finite rational interval rows, and F records which rational samples, located interval requests, and regular rational windows are covered by those rows.

The only refinement coordinate is R. Reading a subcover or narrowed window must therefore choose a displayed row of R, and that row is a $\mathsf{RationalIntervalRefinement}^{\uparrow}$ witness by the carrier definition.

The window boundary W fixes the StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ requests for which the refinement is being read. The structural rows H and K transport and replay the same finite data, while P and N bind provenance and local naming.

No carrier coordinate contains an arbitrary open cover, a countable selector, a quotient-real equality proof, a selected limit, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. Thus every accepted cover refinement is finite and factors through the displayed rational interval refinement ledger. □

Theorem 1882.4 (RationalIntervalCover finite consumer factorization)**.** *For every accepted* $\mathsf{RationalIntervalCover}^{\uparrow}$ *carrier*

$$C = (I, F, R, W, H, K, P, N),$$

every Real or Completion consumer of the cover factors through the displayed route

$$I \to F \to R \to W \to H, K \to P, N.$$

Here I supplies the $\mathsf{RationalInterval}^{\uparrow}$ *rows, F supplies the finite coverage ledger, R supplies the* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *rows, and W supplies StreamName and* $\mathsf{RegSeqRat}^{\uparrow}$ *boundary data before any* $\mathsf{Real}^{\uparrow}$ *seal is reachable. The factorization route has no coordinate for open-cover compactness, countable choice, quotient real equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 1882.1. The first admissible reads are the rational interval rows in I and the finite coverage ledger F, because the NameCert obligations require interval-family exactness and coverage-ledger exactness before a Real or Completion consumer can use the cover.

Next use Definition 1882.3. Any retained window or consumer-facing narrowed interval is forced through a displayed row of R, so the consumer cannot bypass the finite $\mathsf{RationalIntervalRefinement}^{\uparrow}$ ledger when it asks for a narrower cover view.

The window-boundary obligation then orders the StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ data in W before the terminal real-facing seal. The structural rows H and K transport and replay the same displayed data, and P, N bind the route to provenance and local naming.

No coordinate of C stores open-cover compactness, countable choice, quotient real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every accepted Real or Completion consumer reaches the cover only through the finite route $I \to F \to R \to W \to H, K \to P, N$. □

Falsifiable prediction: Every $\mathsf{RationalIntervalCover}^{\uparrow}$ read factors through a finite family of $\mathsf{RationalInterval}^{\uparrow}$ rows, one finite coverage ledger, one finite $\mathsf{RationalIntervalRefinement}^{\uparrow}$ ledger, one StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ window boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: rational-interval, rational-interval-refinement, located-interval, dyadicratcore, regseqrat, real: $\mathsf{RationalIntervalCover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite interval family, finite coverage ledger, finite refinement ledger, stream-window boundary, regular rational readback boundary, and terminal Real-facing provenance as one cover packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalCover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1882.1, Definition 1882.2, Definition 1882.3, and Definition 1882.4 seed the finite rational interval cover route from rational interval rows through finite coverage, displayed refinement, StreamName and regular rational windows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-family exactness, coverage-ledger exactness, refinement-ledger exactness, window-boundary ordering, ledger non-escape, and finite consumer factorization for BEDC.Derived.RationalIntervalCoverUp.

Constructive story: A $\mathsf{RationalIntervalCover}^{\uparrow}$ packet is generated from a finite family of $\mathsf{RationalInterval}^{\uparrow}$ rows, a finite coverage ledger, a finite $\mathsf{RationalIntervalRefinement}^{\uparrow}$ ledger, StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ window-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1883

A Concrete Naming Certificate for $\mathsf{RoundedIdealCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, Vickers-style formal topology, and the Edalat–Heckmann formal-ball domain presentation of metric completion, the $\mathsf{RoundedIdealCompletion}^{\uparrow}$ packet names completion data as rounded directed families of formal balls rather than quotient classes of Cauchy names. It sits after the formal-ball interface of chapter 1510, the metric source surface of chapter 57, the completion boundary of chapter 95, the stream-window interface of chapter 126, and the dyadic radius ledger of chapter 291.

The carrier is intended for completion consumers that can inspect finite lower information about an ideal. It records only finite BHist rows for roundedness, directedness, cofinal refinements, classifier transport, replay, provenance, and local naming, so the packet can be replayed without selecting a limit point or assuming that the ambient metric space is already complete.

Definition 1883.1 (Rounded ideal completion carrier)**.** *A* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, F, D, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including accepted point histories, metric-distance witnesses, and the point classifier used by every formal-ball center.*
2. *F is the finite* $\mathsf{FormalBall}^{\uparrow}$ *family row. Its entries are formal balls (x, ρ) read through the same metric row M, with radius requests exposed through finite windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger. It records positive-radius witnesses, strict comparison budgets, radius addition, and refinement inequalities for the rows of F.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to read finite center observations and finite ideal membership requests.*
5. *R is the roundedness row: every displayed ball in F is accompanied by a smaller displayed ball whose dyadic radius comparison is recorded in D and whose center window is read in S.*
6. *E is the directedness row: every displayed pair of balls in F has a common displayed refinement in F, with both comparison witnesses recorded in D over the same metric row M.*
7. *T records componentwise* hsame *transport for the metric source, formal-ball family, dyadic ledger, stream window, roundedness row, directedness row, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from finite ideal membership requests through $M, F, D, S, R, E, T, P, N$.*
9. *P is the* Pkg *provenance over* RoundedIdealCompletion$^{\uparrow}$, FormalBall$^{\uparrow}$, Met$^{\uparrow}$, Completion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RoundedIdealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $M, F, D, S, R, E, T, C, P, N$. The carrier has no coordinate for quotient completion, selected limits, countable choice, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RoundedIdealCompletionUp.TasteGate.RoundedIdealCompletionTasteGate single carrier alignment`

Theorem 1883.2 (RoundedIdealCompletion NameCert obligations)**.** *For every accepted* RoundedIdealCompletion$^{\uparrow}$ *carrier*

$$I = (M, F, D, S, R, E, T, C, P, N),$$

the local NameCert$_{\text{RoundedIdealCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, formal-ball family, dyadic ledger, stream window, roundedness row, directedness row, transport row, replay row, provenance row, and local naming row;*
2. *roundedness, requiring each displayed ideal member to admit a strictly smaller displayed formal ball in the same family, with the comparison recorded in D and the center read through S;*
3. *directedness, requiring every displayed pair of ideal members to admit a common displayed refinement in the same family, with both comparison witnesses recorded in D over M;*
4. *cofinal refinement stability, requiring any finite radius tightening accepted by D and replayed through C to remain inside the same ideal-family row F;*
5. *classifier transport, requiring* hsame *comparison of accepted packets to be componentwise through T and to preserve the displayed roundedness and directedness rows;*
6. *ledger non-escape, requiring every completion-facing read to pass through $M, F, D, S, R, E, T, C, P, N$ and to export no quotient completion, selected limit, countable-choice selector, open-cover compactness proof, or ambient completeness datum.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1883.1. The accepted packet displays exactly the metric source, formal-ball family, dyadic ledger, stream window, roundedness row, directedness row, transport, replay, provenance, and local naming row.

Roundedness is read from R. For each displayed ideal member, R names a smaller displayed formal ball, while D supplies the strict radius comparison and S supplies the finite center window.

Directedness is read from E. Given two displayed ideal members, E supplies a common formal-ball refinement in F, and D records the two comparison witnesses over the same metric row M.

Cofinal refinement stability and classifier transport are structural. The replay row C keeps finite tightening requests inside the same displayed route, and the transport row T compares packets componentwise without adding a second classifier.

Finally, P and N only source and name the displayed packet. Since quotient completion, selected limits, countable choice, open-cover compactness, and ambient completeness have no carrier coordinate, no replay edge, and no provenance row, the local NameCert surface is exactly the listed obligation surface. □

Theorem 1883.3 (RoundedIdealCompletion cofinal replay)**.** *Let $I = (M, F, D, S, R, E, T, C, P, N)$ be an accepted* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *carrier. Every finite completion-facing request for a tighter formal-ball neighbourhood is answered by the route*

$$M, F \longmapsto D, S \longmapsto R, E \longmapsto T, C, P, N.$$

The answer is a displayed member of the same rounded directed family F, not a selected limit, not a quotient representative, and not an ambient-completeness witness.

Proof. Begin with the metric source and formal-ball family. Projection gives M and F, so the request can inspect only the displayed centers, radii, and formal-ball rows of the accepted packet.

The requested tightening is checked against D and S. The dyadic ledger records the radius comparison budget, and the stream window records the finite center observations used by that comparison.

Roundedness and directedness then supply the internal answer. The row R handles a one-ball tightening request, while E handles the common-refinement demand generated by a pair of displayed members.

The structural rows preserve the route. The transport row T, replay row C, provenance row P, and naming row N add no field for quotient classes, selected limits, or completeness principles, so the answer remains a displayed member of the same rounded directed family. □

Theorem 1883.4 (RoundedIdealCompletion classifier transport)**.** *If two accepted* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *carriers are related by componentwise* hsame *transport through their transport rows, then their classifier-visible rounded ideal data agree on the metric source, formal-ball membership rows, dyadic comparisons, stream windows, roundedness witnesses, directedness witnesses, replay route, provenance, and local name.*

Consequently classifier transport preserves cofinal refinement stability and ledger non-escape for the rounded ideal completion surface.

Proof. Project the two accepted carriers. The only classifier-visible coordinates are the metric source, formal-ball family, dyadic ledger, stream window, roundedness row, directedness row, replay row, provenance row, and local name.

Apply componentwise hsame transport through the transport rows. The metric source remains the same source surface, formal-ball membership is compared row by row, dyadic comparison witnesses are preserved, and stream windows are transported with their finite observations.

The roundedness and directedness rows are transported with the family they certify. Hence a smaller displayed ball, or a common displayed refinement, remains a witness for the transported packet.

Replay, provenance, and naming preserve the same route. Since no excluded coordinate is available to either classifier, cofinal refinement stability and ledger non-escape are invariant under the displayed transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedIdealCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedIdealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1883.1, Definition 1883.2, Definition 1883.3, and Definition 1883.4 seed the rounded directed formal-ball ideal surface for choice-free completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedIdealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, roundedness, directedness, cofinal refinement stability, classifier transport, replay stability, provenance, local naming, and ledger non-escape for the same packet.

Constructive story: A RoundedIdealCompletion$^{\uparrow}$ packet is generated from a metric source, a finite FormalBall family, a DyadicRatCore radius ledger, StreamName windows, roundedness and directedness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1884

A Concrete Naming Certificate for $\mathsf{CompleteBaireSpace}^{\uparrow}$

Following Brouwer's spread semantics and the Baire-space practice of Troelstra–van Dalen and Bishop–Bridges, the $\mathsf{CompleteBaireSpace}^{\uparrow}$ packet records the complete-prefix-stream object by finite prefix data rather than by a host sequence space. It refines the $\mathsf{BaireSpace}^{\uparrow}$ carrier of chapter 334, reads the prefix metric rows of $\mathsf{BaireMetric}^{\uparrow}$ from chapter 1602, uses the finite-window interface of $\mathsf{StreamName}^{\uparrow}$ in chapter 126, keeps rational readback on the $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301, and exposes its completion boundary through $\mathsf{UniformCompletion}^{\uparrow}$ in chapter 1473 or $\mathsf{HausdorffCompletion}^{\uparrow}$ in chapter 402. The object is a concrete L10 completion surface for prefix streams; it is not countable choice, quotient equality of streams, a selected branch principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1884.1 (CompleteBaireSpace carrier)**.** *A* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (B, M, S, R, L, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *finite prefix row, naming the inspected natural-number prefixes and their extension order.*
2. *M is the* $\mathsf{BaireMetric}^{\uparrow}$ *prefix-metric row, recording the finite common-prefix comparisons and dyadic radii used by the carrier.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that schedules which prefix coordinates and metric comparisons are available to a consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows, dyadic radii, and prefix-metric comparisons.*
5. *L is the completion witness row, displayed as a* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{HausdorffCompletion}^{\uparrow}$ *handoff for prefix-Cauchy streams and not as an ambient complete-space theorem.*
6. *T is the prefix-limit trace ledger, recording the finite route from compatible prefix windows through the metric rows and regular readback into the completion witness.*
7. *H records componentwise* hsame *transport for prefix data, metric rows, stream windows, readback rows, completion witnesses, trace rows, continuation rows, provenance, and local naming.*

8. *C records displayed* Cont *replay, so a consumer rereads $B, M, S, R, L, T, H, P, N$ without changing the prefix-stream packet.*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteBaireSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteBaireSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $B, M, S, R, L, T, H, C, P, N$. It has no coordinate for countable choice, quotient stream equality, a selected infinite branch, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompleteBaireSpaceUp.CompleteBaireSpaceTasteGate single carrier alignment`

Theorem 1884.2 (CompleteBaireSpace NameCert obligations)**.** *For every accepted* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *carrier*

$$X = (B, M, S, R, L, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteBaireSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Baire prefix row, prefix metric row, stream-window row, regular rational readback, completion witness, trace ledger, transport, replay, provenance, and local naming;*
2. *prefix-metric exactness, requiring every accepted comparison to read the same displayed* $\mathsf{BaireSpace}^{\uparrow}$ *prefixes through the* $\mathsf{BaireMetric}^{\uparrow}$ *row M;*
3. *window-readback exactness, requiring every consumer-visible prefix request to pass through the* $\mathsf{StreamName}^{\uparrow}$ *row S and then the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. *completion-witness stability, requiring the prefix-Cauchy handoff to use only the displayed* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{HausdorffCompletion}^{\uparrow}$ *row L and trace ledger T;*
5. *nonescape, excluding countable choice, quotient stream equality, selected branches, ambient Real completeness, Lean verification, and bridge checking.*

No CompleteBaireSpace obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1884.1. The accepted tuple displays exactly the prefix row, prefix metric row, finite stream-window row, regular rational readback, completion witness, trace ledger, transport, replay, provenance, and local name.

Prefix-metric exactness is forced by B and M. The only prefix data are stored in B, and the only comparison row is M, so every accepted metric comparison is a displayed common-prefix comparison of the same finite Baire-space packet.

Window-readback exactness is forced by S and R. A consumer first reads the scheduled finite prefix windows in S and then reads the corresponding regular rational tolerance and radius comparisons in R.

Completion-witness stability is the pair L, T. The completion row is displayed as a uniform or Hausdorff completion handoff for prefix-Cauchy streams, while the trace ledger records how finite compatible windows reach that handoff.

The structural rows H, C, P, N transport, replay, source, and name only the displayed packet. Since the excluded choice, quotient, selected-branch, and ambient completeness data are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1884.3 (CompleteBaireSpace prefix-Cauchy limit extraction)**.** *Let $X = (B, M, S, R, L, T, H, C, P, N)$ be an accepted* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *carrier. Every prefix-Cauchy consumer read of X extracts its completion-facing limit witness through the displayed route*

$$\mathsf{BaireSpace}^{\uparrow}(B) \longrightarrow \mathsf{BaireMetric}^{\uparrow}(M) \longrightarrow \mathsf{StreamName}^{\uparrow}(S) \longrightarrow \mathsf{RegSeqRat}^{\uparrow}(R) \longrightarrow L.$$

The extraction uses finite compatible prefixes, prefix-metric comparisons, scheduled windows, and regular rational readback before reaching the completion witness. It does not use a selected infinite branch, quotient equality of streams, countable choice, or ambient Real completeness.

Proof. Begin with a prefix-Cauchy consumer read. By the carrier definition, the only source of stream data is the finite prefix row B, and the only metric evidence available for Cauchy comparison is the prefix-metric row M.

The scheduled request is then read through S. This step restricts the consumer to the displayed finite StreamName window rather than to an arbitrary host stream of choices.

The rational tolerance and radius readback is R. Thus the prefix-Cauchy claim is inspected only through the same finite windows and the same $\mathsf{RegSeqRat}^{\uparrow}$ regular readback row.

Finally the completion witness is L, with T recording the route from compatible prefix windows to that witness. Componentwise transport and replay in H and C preserve the same rows, while P and N bind provenance and local naming.

No row in the packet contains a selected branch, quotient stream equality, countable choice, or ambient Real completeness theorem. Therefore every accepted limit extraction factors through the displayed prefix-Cauchy route. □

Theorem 1884.4 (CompleteBaireSpace prefix-window stability)**.** *Let $X = (B, M, S, R, L, T, H, C, P, N)$ and $X' = (B', M', S', R', L', T', H', C', P', N')$ be accepted* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *carriers. Suppose the displayed* $\mathsf{BaireSpace}^{\uparrow}$ *prefix rows,* $\mathsf{BaireMetric}^{\uparrow}$ *prefix-metric rows,* $\mathsf{StreamName}^{\uparrow}$ *window rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows agree componentwise under* hsame *and replay through displayed* Cont *routes. Then the completion witness rows L, L' and trace ledgers T, T' transport to the same finite prefix-Cauchy route.*

Proof. Project both carriers through Definition 1884.1. The completion-facing data can only be reached after the rows B, M, S, R and B', M', S', R' have been displayed.

Use Definition 1884.3. It forces every prefix-Cauchy consumer read through the route B, M, S, R, L for X and through the corresponding route B', M', S', R', L' for X'.

The componentwise hsame hypotheses identify the displayed prefix rows, prefix-metric rows, StreamName windows, and regular readback rows. The displayed Cont replays keep those reads on the same finite windows, so the two prefix-Cauchy routes have the same visible source.

The completion witness and trace ledger are downstream of that source. Repack the transported rows with L, T, H, C, P, N and L', T', H', C', P', N'; the resulting completion witness rows and trace ledgers therefore describe the same finite prefix-Cauchy route. □

Theorem 1884.5 (CompleteBaireSpace Real-completion boundary)**.** *For an accepted* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *carrier $X = (B, M, S, R, L, T, H, C, P, N)$, every Real or Completion consumer route is exhausted by the displayed prefix packet*

$$B, M, S, R, L, T, H, C, P, N.$$

Such a consumer may inspect finite Baire prefixes, prefix-metric comparisons, StreamName windows, RegSeqRat readback, the displayed uniform or Hausdorff completion witness, componentwise transport, continuation replay, provenance, and local naming. It may not replace that route by

countable choice, quotient streams, selected branches, hidden limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The Real and Completion-facing rows are S, R, L, T together with the source prefix and metric rows B, M.

The finite source route is fixed before completion is read. The carrier requires the consumer to see the Baire prefix row, then the prefix metric row, then the scheduled finite StreamName windows and RegSeqRat readback.

The completion boundary is the displayed row L. It is either a uniform-completion or Hausdorff-completion handoff for the same prefix-Cauchy stream data, and T records that finite route inside the packet.

The remaining rows do not add analytic strength. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same prefix packet.

Because no carrier coordinate stores countable choice, quotient stream equality, a selected branch, a hidden limit selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every accepted Real or Completion consumer remains inside the displayed boundary. □

Falsifiable prediction: Every $\mathsf{CompleteBaireSpace}^{\uparrow}$ read factors through one finite $\mathsf{BaireSpace}^{\uparrow}$ prefix row, one $\mathsf{BaireMetric}^{\uparrow}$ prefix-metric row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one displayed completion witness, one trace ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: bairespace, bairemetric, streamname, regseqrat, uniformcompletion, hausdorffcompletion: $\mathsf{CompleteBaireSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries prefix-stream data, prefix-metric comparisons, finite window scheduling, regular rational readback, a completion witness, and a Real-completion refusal boundary as one local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteBaireSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteBaireSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1884.1, Definition 1884.2, Definition 1884.3, and Definition 1884.5 seed the complete prefix-stream route from Baire prefixes through prefix metrics, finite StreamName windows, RegSeqRat readback, displayed completion handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteBaireSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient stream equality, selected branches, hidden limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-metric exactness, window-readback exactness, completion-witness stability, prefix-Cauchy limit extraction, and Real-completion boundary proofs for BEDC.Derived.CompleteBaireSpace

Constructive story: A $\mathsf{CompleteBaireSpace}^{\uparrow}$ packet is generated from finite Baire prefix data, a BaireMetric prefix-metric row, StreamName finite windows, RegSeqRat readback, a UniformCompletionUp or HausdorffCompletionUp handoff, a trace ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1885

A Concrete Naming Certificate for $\mathsf{LocatedIntervalCover}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalCover}^{\uparrow}$ packet records a finite cover of a displayed located real interval by rational cover rows and dyadic refinement rows. It sits after the source interval surface of chapter 1709, the finite rational cover surface of chapter 1882, the dyadic mesh route of chapter 1428, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers one located-interval cover boundary; it is not an open-cover compactness theorem, a countable-choice construction, quotient equality of real names, selected-limit data, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1885.1 (LocatedIntervalCover carrier)**.** *A* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (I, Q, D, R, W, S, H, K, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, supplying the endpoint, radius, locator, locatedness, and metric-bracket data for the interval being covered.*
2. *Q is the finite* $\mathsf{RationalIntervalCover}^{\uparrow}$ *family whose rational interval rows, coverage ledger, and regular-window boundary are accepted for the source interval.*
3. *D is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *mesh and refinement row, recording the dyadic scale, radius ledger, finite membership rows, and visible real-name seal used to test the cover.*
4. *R is the finite refinement ledger comparing the rational cover family Q with the dyadic mesh row D over the located source I.*
5. *W is the StreamName and* $\mathsf{RegSeqRat}^{\uparrow}$ *window boundary, naming the finite stream windows and regular rational readbacks through which the cover is inspected.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the located interval, rational cover, dyadic mesh, refinement, and window rows have been replayed.*
7. *H records componentwise* hsame *transport for the source interval, rational cover family, dyadic cover row, refinement ledger, window boundary, terminal seal, replay, provenance, and local naming.*

8. *K records displayed* Cont *replay, so a consumer can reread $I, Q, D, R, W, S, H, P, N$ without changing the cover route.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RationalIntervalCover}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalCover}^{\uparrow}}$ *row.*

The classifier compares accepted located interval covers only through the displayed rows $I, Q, D, R, W, S, H, K, P, N$. It has no coordinate for arbitrary open covers, countable cover selection, quotient real equality, selected limits, or ambient Real completeness.

Theorem 1885.2 (LocatedIntervalCover NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *carrier*

$$C = (I, Q, D, R, W, S, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalCover}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located source interval, rational cover family, dyadic cover mesh, refinement ledger, window boundary, terminal seal, transports, replay, provenance, and local naming;*
2. *source-interval exactness, requiring every endpoint, radius, locator, locatedness, and metric-bracket request to pass through the displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row I;*
3. *cover-family exactness, requiring every rational interval, finite coverage read, and retained regular-window request to pass through the displayed* $\mathsf{RationalIntervalCover}^{\uparrow}$ *family Q;*
4. *refinement-route exactness, requiring every dyadic mesh read, finite membership row, and rational-to-dyadic narrowing to pass through D and the ledger R;*
5. *window and readback ordering, requiring W to expose StreamName windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks before the terminal* $\mathsf{Real}^{\uparrow}$ *seal S is available;*
6. *ledger non-escape, requiring H, K, P, N to export no open-cover compactness, countable choice, quotient real equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No located interval cover obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1885.1. The accepted packet displays exactly one located interval source, one rational cover family, one dyadic cover row, one refinement ledger, one window boundary, one terminal seal, and the structural rows that transport, replay, package, and name them.

Source-interval exactness follows because I is the only coordinate containing $\mathsf{LocatedRealInterval}^{\uparrow}$ data. Endpoint, radius, locator, locatedness, and metric-bracket reads therefore enter the cover packet through the displayed source interval and cannot be replaced by a host closed interval.

Cover-family exactness is supplied by Q. Its rational interval rows, coverage ledger, and regular-window boundary are the only rational-cover coordinates available to the packet, so every rational cover read is a finite projection from Q.

Refinement-route exactness is supplied jointly by D and R. The dyadic mesh, radius, and membership rows are read from D, while the comparison between those rows and the rational family Q is read from the finite ledger R.

The remaining rows W, S, H, K, P, N impose the readback order. StreamName windows and regular rational readbacks are exposed before the terminal real-name seal, and the transport, replay, provenance, and naming rows contain no excluded compactness, choice, quotient, limit, or completeness coordinate. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalCoverUp.TasteGate.LocatedIntervalCoverTasteGate single carrier alignment`

Theorem 1885.3 (LocatedIntervalCover refinement route)**.** *Every located interval cover read of an accepted* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *carrier factors through the displayed route*

$$I \longmapsto Q, D, R \longmapsto W, S, H, K, P, N.$$

Thus the consumer first receives the located interval source row, then the finite rational cover family, dyadic mesh, and refinement ledger, and only then the StreamName, $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, transport, replay, provenance, and local naming rows. The route exports no open-cover compactness, countable choice, quotient real equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $C = (I, Q, D, R, W, S, H, K, P, N)$. The only source interval coordinate is I, so every cover request begins with the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ endpoint, radius, locator, locatedness, and metric-bracket data.

The cover rows are then read through Q, D, R. The rational family Q supplies the finite rational cover ledger, the dyadic row D supplies the mesh and membership tests, and the refinement ledger R records how the two surfaces agree over the located source interval.

The window and seal rows are downstream of that refinement surface. The StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ boundary W is read before the terminal $\mathsf{Real}^{\uparrow}$ seal S, so a consumer cannot bypass finite readback by appealing directly to a completed real object.

Finally, H, K, P, N transport, replay, package, and name the same displayed route. Since the accepted packet contains no arbitrary open cover, countable selector, quotient real equality proof, selected limit, or Real completeness row, those objects cannot be exported by the factorization. □

Falsifiable prediction: Every $\mathsf{LocatedIntervalCover}^{\uparrow}$ read factors through one $\mathsf{LocatedRealInterval}^{\uparrow}$ source row, one finite $\mathsf{RationalIntervalCover}^{\uparrow}$ family, one $\mathsf{DyadicIntervalCover}^{\uparrow}$ mesh row, one finite refinement ledger, one StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ window boundary, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-real-interval, rational-interval-cover, dyadic-interval-cover, stream-name, regseqrat, real: $\mathsf{LocatedIntervalCover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located source interval, rational cover family, dyadic mesh, refinement ledger, finite readback boundary, terminal real seal, and local NameCert route as one finite cover packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalCover}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1885.1, Definition 1885.2, and Definition 1885.3 seed the finite located interval cover route from a located real interval source through rational cover rows, dyadic refinement rows, finite windows, terminal real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-interval exactness, cover-family exactness, refinement-route exactness, window and readback ordering, ledger non-escape, and finite consumer factorization for BEDC.Derived.LocatedIntervalCoverUp.

Constructive story: A $\mathsf{LocatedIntervalCover}^{\uparrow}$ packet is generated from a $\mathsf{LocatedRealInterval}^{\uparrow}$ source row, a finite $\mathsf{RationalIntervalCover}^{\uparrow}$ family, a $\mathsf{DyadicIntervalCover}^{\uparrow}$ mesh and refinement row, a finite refinement ledger, StreamName and $\mathsf{RegSeqRat}^{\uparrow}$ windows, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1886

A Concrete Naming Certificate for $\mathsf{CantorFanBarrier}^{\uparrow}$

Following Brouwer's finite fan arguments, Troelstra–van Dalen's treatment of decidable bars, and Bishop–Bridges constructive analysis, the $\mathsf{CantorFanBarrier}^{\uparrow}$ packet records the finite barrier layer between the fan certificate of chapter 400, the Cantor-space prefix surface of chapter 1475, and the Real and Completion modulus route of chapter 1707. It is a displayed finite packet over branch-prefix histories, StreamName windows, RegSeqRat readback, and a Real seal; it is not an open-cover compactness principle, a selected infinite branch, a quotient stream equality principle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1886.1 (Cantor fan barrier carrier)**.** *A* $\mathsf{CantorFanBarrier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, A, B, D, W, S, Q, R, H, C, P, N)$$

with the following visible rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *row, carrying the finite binary fan surface, prefix closure, decidable finite-bar read, and fan-depth bound.*
2. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *address row, naming the finite Boolean prefix cylinder on which the barrier is inspected without selecting an infinite branch.*
3. *B is the decidable barrier row, assigning a visible* $\mathsf{Bool}^{\uparrow}$ *decision to each displayed prefix in the retained Cantor cylinder.*
4. *D is the unary depth ledger, a finite* $\mathsf{Nat}^{\uparrow}$ *row recording the maximal fan depth and the Real-facing read depth associated with each retained barrier decision.*
5. *W is the finite witness window, listing exactly the prefixes, barrier decisions, and depth entries read from F, A, B, D.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that converts the finite prefix-depth ledger into the source windows inspected by downstream Real and Completion consumers.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed StreamName windows.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after the rows F, A, B, D, W, S, Q have been displayed.*

9. *H stores componentwise* hsame *transport for the fan row, Cantor address, decidable barrier, depth ledger, witness window, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from a consumer request through $F, A, B, D, W, S, Q, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CantorFanBarrier}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorFanBarrier}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares only the displayed rows $F, A, B, D, W, S, Q, R, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected infinite branches, quotient stream equality, selected Real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorFanBarrierUp.CantorFanBarrierTasteGate single carrier alignment`

Theorem 1886.2 (Cantor fan barrier NameCert obligations)**.** *For every accepted* $\mathsf{CantorFanBarrier}^{\uparrow}$ *carrier*

$$K = (F, A, B, D, W, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorFanBarrier}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed fan, Cantor-address, decidable-barrier, depth-ledger, witness-window, StreamName-window, RegSeqRat-readback, Real-seal, transport, replay, provenance, and local naming rows;*
2. *fan coverage, requiring every branch-prefix request to be bounded by the finite fan row F over the Cantor address surface A;*
3. *barrier decidability, requiring every retained prefix in W to read its barrier decision from the finite* $\mathsf{Bool}^{\uparrow}$ *row B;*
4. *depth exactness, requiring the unary ledger D to account for every fan-depth and Real-facing window-depth read used by S, Q, R;*
5. *Real-window handoff, requiring every downstream Real or Completion request to factor through S, then Q, then R;*
6. *transport, replay, provenance, and local naming stability, requiring H, C, P, N to preserve and name exactly the displayed packet.*

No Cantor fan barrier obligation is stored outside these six rows.

Proof. Proceed by structural induction on the displayed unary depth ledger D.

In the zero-depth case, the retained witness window is the root cylinder named by A. The fan row F supplies the root-prefix surface, the barrier decision is the corresponding entry of B, and the StreamName, RegSeqRat, and Real rows are read only through S, Q, R after that finite prefix has been displayed.

For the successor step, assume the obligation surface has been constructed through depth d. A depth $d + 1$ entry adds only the two immediate Boolean extensions of prefixes already present in the Cantor address row. The fan row F bounds these branch-prefix reads, B supplies the two displayed barrier decisions, and W records the finite witness entries attached to the new depth.

The StreamName window row S is then extended only by the windows named by the new ledger entries. RegSeqRat readback through Q and the Real seal through R are downstream of

the same finite schedule, so no quotient stream equality, selected branch, or ambient completeness object is introduced.

Finally, H, C, P, N transport, replay, record, and name the same finite rows. Coordinate exhaustion gives exactly the six obligation rows and excludes open-cover compactness, countable choice, selected infinite branches, quotient stream equality, selected Real limits, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{CantorFanBarrier}^{\uparrow}$ Real or Completion-facing read factors through a finite fan row, Cantor-prefix address row, decidable barrier row, unary depth ledger, finite witness window, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Independence witness: fantheorem, cantorspace, bishop-fan-modulus: $\mathsf{CantorFanBarrier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the fan row, Cantor address row, decidable barrier row, unary fan-depth ledger, finite witness window, StreamName window, RegSeqRat readback, Real seal, and structural support while refusing open-cover compactness, countable choice, selected branches, quotient stream equality, selected Real limits, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorFanBarrier}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorFanBarrier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1886.1 and Definition 1886.2 seed the finite barrier route through $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorFanBarrier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, quotient stream equality, countable choice, selected Real limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan coverage, barrier decidability, depth exactness, Real-window handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CantorFanBarrierUp.

Constructive story: A $\mathsf{CantorFanBarrier}^{\uparrow}$ packet is generated from a finite $\mathsf{FanTheorem}^{\uparrow}$ row, $\mathsf{CantorSpace}^{\uparrow}$ address row, decidable $\mathsf{Bool}^{\uparrow}$ barrier row, unary $\mathsf{Nat}^{\uparrow}$ depth ledger, finite witness window, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1887

A Concrete Naming Certificate for $\mathsf{WeaklyCauchySequence}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of Cauchy data, the $\mathsf{WeaklyCauchySequence}^{\uparrow}$ packet records finite weak-Cauchy evidence without turning it into a regular modulus or a located real limit. It sits between the finite StreamName windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal Real boundary of chapter 38, and the Specker-style obstruction surface of chapter 1406. The packet names the finite tail-comparison evidence visible to a BEDC consumer; it does not supply a regular modulus, selected limit, located supremum, quotient stream equality, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1887.1 (Weakly Cauchy sequence carrier)**.** *A* $\mathsf{WeaklyCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the inspected sequence indices and the stream observations available at those indices.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same inspected windows, recording the rational approximants read from the displayed stream data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii used in the inspected pairwise tail comparisons.*
4. *T is the weak-Cauchy tail-comparison ledger: for each displayed tolerance request it stores only the finite pairs of inspected tail indices and the dyadic comparison rows witnessed for those pairs.*
5. *E is an optional* $\mathsf{Real}^{\uparrow}$ *seal-boundary row, present only as a downstream consumer boundary after S, R, D, T have been displayed and never as a completed limit coordinate.*
6. *H records componentwise* hsame *transport for stream windows, rational readbacks, dyadic tolerances, tail-comparison rows, optional Real boundary rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite tolerance query through S, R, D, T and then through E, H, P, N when the optional Real boundary is read.*

8. *P is the* Pkg *provenance over* $\mathsf{WeaklyCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, T, E, H, C, P, N$. It has no coordinate for a regular modulus, selected limit, located supremum, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.WeaklyCauchySequenceUp.WeaklyCauchySequenceTasteGate single carrier alignment`

Theorem 1887.2 (Weakly Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyCauchySequence}^{\uparrow}$ *carrier*

$$W = (S, R, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeaklyCauchySequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, weak tail-comparison ledger, optional Real boundary, transport, replay, provenance, and local naming;*
2. *window exactness, requiring every inspected sequence coordinate to be read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S before any rational readback is used;*
3. *readback exactness, requiring the rational observations used by the tail comparisons to be the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. *tolerance exactness, requiring every pairwise comparison in T to cite a dyadic tolerance row in D;*
5. *weak-tail exposure, requiring T to store only finite inspected tail comparisons and not a global regular modulus;*
6. *boundary nonescape, excluding selected limits, located suprema, quotient stream equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No weak-Cauchy obligation is stored outside these rows.

Proof. Project the carrier of Definition 1887.1. The projection exposes exactly one finite StreamName window row, one RegSeqRat readback row, one dyadic tolerance ledger, one weak tail-comparison ledger, the optional Real boundary row, and the structural transport, replay, provenance, and naming rows.

Window and readback exactness are forced by S and R. Every inspected sequence coordinate is first scheduled by S, and every rational observation used downstream is then read through the corresponding regular rational row R.

Tolerance exactness is forced by D. Each pairwise tail comparison in T names a dyadic radius and comparison row already present in the tolerance ledger, so no hidden metric or host real comparison can be inserted.

The weak-tail obligation is exactly the ledger T. It records finite inspected tail comparisons, but it does not choose a threshold function for all tolerances and it does not package a regular Cauchy modulus.

The rows E, H, C, P, N only preserve or expose the same packet. Since the excluded limit, supremum, quotient, choice, trichotomy, completeness, verification, and bridge coordinates are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1887.3 (Weakly Cauchy finite-window boundary)**.** *Let $W = (S, R, D, T, E, H, C, P, N)$ be an accepted* $\mathsf{WeaklyCauchySequence}^{\uparrow}$ *carrier. Every consumer-visible weak-Cauchy read factors through the finite route*

$$\mathsf{StreamName}^{\uparrow}(S) \longrightarrow \mathsf{RegSeqRat}^{\uparrow}(R) \longrightarrow \mathsf{DyadicRatCore}^{\uparrow}(D) \longrightarrow T \longrightarrow H, C, P, N.$$

The route may compare finitely inspected tail windows at displayed dyadic tolerances. It cannot be strengthened into a regular modulus, quotient stream equality, selected limit, countable-choice tail selector, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with a consumer-visible weak-Cauchy read. The carrier definition gives S as the only row that schedules sequence observations, so the consumer first receives finite StreamName windows rather than an unrestricted host stream.

The rational observations are then read through R. This keeps every inspected value on the RegSeqRat route named by the packet.

The dyadic scale is read through D, and the actual weak-tail comparison is one of the finite entries of T. Thus the consumer obtains only a finite comparison between displayed tail indices at displayed tolerances.

The structural rows H, C, P, N transport, replay, source, and name that same route. No row produces a global threshold function, quotient equality, selected limit, choice selector, trichotomy decision, or ambient completeness theorem, so every accepted read remains a finite-window boundary read. □

Theorem 1887.4 (Weakly Cauchy regular-modulus refusal)**.** *Let*

$$W = (S, R, D, T, E, H, C, P, N)$$

be an accepted $\mathsf{WeaklyCauchySequence}^{\uparrow}$ *carrier. Any route that exports a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular modulus or a* $\mathsf{Real}^{\uparrow}$ *limit from W must factor through an additional modulus row not contained in $S, R, D, T, E, H, C, P, N$. The displayed weak-tail ledger T alone supplies only inspected pairwise tail comparisons at displayed dyadic tolerances.*

Proof. Project the carrier of Definition 1887.1. Its displayed inventory contains StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, the finite weak-tail ledger, the optional Real boundary row, transport, replay, provenance, and local naming; it contains no coordinate that chooses a threshold function for every tolerance.

Apply Definition 1887.2. The weak-tail exposure obligation identifies T as finite inspected tail evidence and explicitly prevents that ledger from being read as a global regular modulus.

Apply Definition 1887.3. Every consumer-visible read passes through

$$\mathsf{StreamName}^{\uparrow}(S) \longrightarrow \mathsf{RegSeqRat}^{\uparrow}(R) \longrightarrow \mathsf{DyadicRatCore}^{\uparrow}(D) \longrightarrow T,$$

before the structural rows replay or name the route, so a regular-modulus export needs data beyond the displayed finite route.

Finally apply Definition 1887.5. The Specker-facing boundary excludes selected limits, located suprema, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so no $\mathsf{Real}^{\uparrow}$ limit can be obtained from W unless an additional modulus row is supplied outside the accepted carrier. □

Theorem 1887.5 (Weakly Cauchy sequence Specker boundary)**.** *For an accepted* $\mathsf{WeaklyCauchySequence}^{\uparrow}$ *carrier $W = (S, R, D, T, E, H, C, P, N)$, every Specker-style or Real-facing consumer route is exhausted by the displayed rows*

$$S, R, D, T, E, H, C, P, N.$$

In particular, the packet may expose finite weak-Cauchy tail comparisons before a $\mathsf{Real}^{\uparrow}$ *boundary row is read, but it does not convert those comparisons into a located supremum, a regular Cauchy modulus, a selected limit, quotient stream equality, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The Specker-facing information is the finite schedule S, the rational readback row R, the dyadic ledger D, and the weak tail-comparison ledger T.

A Real-facing read can only use E after those finite rows have been displayed. The row E is therefore a boundary row for consumers of the evidence, not an independent completed real or located supremum coordinate.

The structural rows H, C, P, N do not add analytic strength. They preserve componentwise equality, replay the displayed continuation route, record provenance, and name the local certificate.

The Specker obstruction remains visible because the packet stops at finite weak-Cauchy evidence. Since no carrier coordinate stores a regular modulus, selected limit, located supremum, quotient stream equality, countable choice, trichotomy, or ambient completeness theorem, every accepted Specker-style or Real-facing route is exhausted by the displayed boundary. □

Falsifiable prediction: Every $\mathsf{WeaklyCauchySequence}^{\uparrow}$ read factors through finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a finite weak tail-comparison ledger, optional RealUp boundary exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, speckersequence: $\mathsf{WeaklyCauchySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries inspected sequence windows, regular rational readback, dyadic tolerance comparisons, finite weak-tail evidence, and a Specker-facing Real boundary refusal as one local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WeaklyCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{WeaklyCauchySequence}^{\uparrow}$ packet is generated from inspected StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, finite weak-Cauchy tail comparisons, an optional RealUp boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeaklyCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1887.1, Definition 1887.2, Definition 1887.3, Definition 1887.4, and Definition 1887.5 seed the finite weak-Cauchy boundary over inspected StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, finite tail comparisons, RealUp boundary exposure, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeaklyCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close regular moduli, selected limits, located suprema, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, readback exactness, tolerance exactness, weak-tail exposure, finite-window boundary, regular-modulus refusal, and Specker boundary proofs for BEDC.Derived.WeaklyCauchySequenceUp.

Chapter 1888

A Concrete Naming Certificate for $\mathsf{PicardLindelof}^{\uparrow}$

Following Picard and Lindelöf, the $\mathsf{PicardLindelof}^{\uparrow}$ packet records the local constructive existence-and-uniqueness route for ordinary differential equations with a Lipschitz vector field. It consumes the local-flow source of chapter 193, the Banach state classifier of chapter 90, the map-level Lipschitz ledger of chapter 410, the complete-metric convergence boundary of chapter 128, the finite iteration route of chapter 395, and the fixed-point endpoint discipline of chapter 396. The packet names a local time-state window and a displayed Picard iteration certificate; it is not a global ODE solver, a maximal-interval continuation theorem, a host function-space equality principle, or a choice-selected solution object.

Definition 1888.1 (Picard–Lindelof carrier)**.** *A* $\mathsf{PicardLindelof}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

with the following visible coordinates:

1. *I is the initial time-state cell, recording a displayed time row t_0, a state row x_0, and the shared* $\mathsf{Ode}^{\uparrow}$ *local-flow source in which both rows are interpreted;*
2. *F is the Lipschitz vector-field ledger, a* $\mathsf{LipschitzMap}^{\uparrow}$ *row for the vector field on the named local time-state window, including the displayed bound and graph rows used by ODE evaluations;*
3. *L is the Picard iteration route, a* $\mathsf{PicardContraction}^{\uparrow}$ *ledger that records the finite sequence of successive integral or step approximants starting at I and reading every vector-field value through F;*
4. *R is the complete-metric convergence row, supplied by* $\mathsf{CompleteMetric}^{\uparrow}$ *for the carried space of local approximants and containing the displayed Cauchy modulus, limit row, and late-observation comparisons for the Picard route;*
5. *Q is the local uniqueness classifier, recording that two displayed local-flow rows with the same initial cell and the same Lipschitz ledger are classified by the endpoint classifier inherited from* $\mathsf{Ode}^{\uparrow}$ *and the Banach state surface;*
6. *U is the nonescape window row, naming the local time interval and state ball in which the Picard iterates, the convergence limit, and the uniqueness comparison are all read;*

7. *H stores componentwise* hsame *transports for the initial cell, vector-field ledger, Picard route, convergence row, uniqueness classifier, nonescape window, replay rows, provenance row, and local naming row;*
8. *C stores the displayed* Cont *replay from the initial time-state cell through the vector-field ledger, Picard iteration route, complete-metric convergence row, uniqueness classifier, and local-flow endpoint;*
9. *G is the* Pkg *provenance row over* $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardLindelof}^{\uparrow}}$ *row.*

The carrier exposes only a local NameCert route from displayed ODE and Lipschitz data to a classified local-flow endpoint. It has no coordinate for global existence, maximal continuation, host equality of solution functions, selected representatives of solutions, or bridge-checked standardization.

Lean4 ✓ `BEDC.Derived.PicardLindelofUp.PicardLindelofTasteGate single carrier alignment`

Theorem 1888.2 (Picard–Lindelof NameCert obligations)**.** *For an accepted* $\mathsf{PicardLindelof}^{\uparrow}$ *carrier*

$$P = (I, F, L, R, Q, U, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PicardLindelof}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, initial time-state compatibility for I, Lipschitz vector-field stability for F, Picard iteration compatibility for L, complete-metric convergence visibility for R, local uniqueness classification for Q, nonescape-window stability for U, componentwise transport through H, displayed replay through C, package provenance through G, and local naming through N.*

Proof. Carrier admission is projection from Definition 1888.1. Each accepted packet displays the initial cell, vector-field ledger, Picard route, convergence row, uniqueness classifier, nonescape window, transport, replay, provenance, and local name.

The source-side obligations are local to I, F, U. The row I fixes the $\mathsf{Ode}^{\uparrow}$ time-state source, the row F supplies the $\mathsf{LipschitzMap}^{\uparrow}$ vector-field graph and bound rows on the named window, and U records the finite nonescape boundary in which those reads are valid.

The iterative and limiting obligations are then forced in order. The row L reads only the displayed Picard route supplied by $\mathsf{PicardContraction}^{\uparrow}$, and the row R reads the resulting regular Cauchy ledger through $\mathsf{CompleteMetric}^{\uparrow}$.

Finally Q classifies any competing local-flow row with the same initial cell and vector-field ledger. The rows H, C, G, N transport, replay, source, and name this same route, so the certificate cannot export a global continuation, a host function-space equality, or a selected solution. □

Theorem 1888.3 (Picard–Lindelof Picard iteration route)**.** *Every accepted* $\mathsf{PicardLindelof}^{\uparrow}$ *carrier factors each local-flow endpoint read through the finite route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{Banach}^{\uparrow} \longmapsto \mathsf{LipschitzMap}^{\uparrow} \longmapsto \mathsf{PicardContraction}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{BanachFixedPoint}^{\uparrow}$$

as instantiated by I, F, L, R, Q, U. The route first opens the ODE time-state source and Banach state classifier, then reads the Lipschitz vector-field ledger, then records the Picard iteration route, then reads the complete-metric convergence row, and only then exposes the local uniqueness classifier for the endpoint. No endpoint read bypasses these rows.

Proof. Read the carrier coordinates. The initial cell I is the only entrance to the $\mathsf{Ode}^{\uparrow}$ local-flow source, and the vector-field row F is the only Lipschitz ledger available on the named window.

The Picard approximants are supplied by L. Since L records the $\mathsf{PicardContraction}^{\uparrow}$ route using evaluations from F, every displayed iterate remains attached to the same ODE source and nonescape window.

The limiting step is supplied by R. It reads the Picard ledger as a regular Cauchy object in the carried complete metric and exposes the limit only through the displayed $\mathsf{CompleteMetric}^{\uparrow}$ convergence row.

The uniqueness boundary is supplied by Q and may be compared with the fixed-point endpoint discipline of $\mathsf{BanachFixedPoint}^{\uparrow}$ only after the previous rows have been displayed. Because the carrier lacks global continuation, host function-space equality, and choice-selected solution coordinates, the theorem exports only the stated local route. □

Theorem 1888.4 (Picard–Lindelof local existence handoff)**.** *Let*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

be an accepted $\mathsf{PicardLindelof}^{\uparrow}$ *carrier. A local-flow endpoint is exported only after the reader has opened the initial cell I, the Lipschitz vector-field ledger F, the Picard iteration route L, the complete-metric convergence row R, the nonescape window U, the componentwise transport row H, the displayed replay row C, the provenance row G, and the local naming row N. The endpoint is then classified by Q as a local endpoint row, without adding global continuation, maximal-interval data, host function-space equality, or a selected solution representative.*

Proof. Project the accepted carrier through Definition 1888.1. This exposes the initial cell, vector-field ledger, Picard route, convergence row, classifier, nonescape window, transport, replay, provenance, and local name.

Use Definition 1888.3 for L. The local endpoint read must pass through the displayed Picard iteration route, so the endpoint cannot be detached from the initial time-state cell or the Lipschitz vector-field ledger.

The convergence and locality checks are then read from R and U. The row R supplies the complete-metric convergence visibility for the Picard approximants, while U records the finite nonescape boundary in which the endpoint is read.

Finally expose Q only as the classifier row. The structural rows H, C, G, N transport, replay, source, and name the same local route, and no row supplies global continuation or a selected solution object. □

Theorem 1888.5 (Picard–Lindelof Gronwall–Osgood nonescape stability)**.** *Let*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

be an accepted $\mathsf{PicardLindelof}^{\uparrow}$ *carrier. If the Lipschitz ledger F is accompanied by a displayed* $\mathsf{GronwallInequality}^{\uparrow}$ *comparison row and the uniqueness classifier Q is accompanied by a displayed* $\mathsf{OsgoodCriterion}^{\uparrow}$ *modulus row, then every endpoint read classified by Q remains inside the same nonescape window U. The exported endpoint still factors through $I, F, L, R, Q, U, H, C, G, N$ and through the comparison rows; it does not introduce a host solver, a selected solution curve, an ambient completeness assertion, or a global continuation coordinate.*

Proof. Use Definition 1888.3. The endpoint read first passes through the initial cell, Lipschitz vector-field ledger, Picard iteration route, complete-metric convergence row, and nonescape window U before the classifier Q is exposed.

Apply Definition 2034.3 to the displayed Lipschitz ledger. The Gronwall row bounds the finite comparison envelope inside the same Picard-facing route, so it can tighten the read within U but cannot replace U by a new ambient interval or a host solution object.

Apply Definition 6159.3 to the uniqueness modulus. The Osgood row constrains competing endpoint reads through the same displayed ODE and Picard route, so the uniqueness comparison remains attached to the nonescape window already carried by P.

Finally replay the structural rows H, C, G, N. They transport, replay, source, and name the same finite certificate, and no row supplies a selected solution, host solver, ambient completeness principle, or continuation beyond U. □

Theorem 1888.6 (Picard–Lindelof Gronwall uniqueness handoff)**.** *Let*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

be an accepted $\mathsf{PicardLindelof}^{\uparrow}$ *carrier. If two displayed endpoint reads share the same initial cell I and the same Lipschitz ledger F, and the displayed* $\mathsf{GronwallInequality}^{\uparrow}$ *comparison row bounds their finite difference envelope inside the nonescape window U, then the local uniqueness classifier Q classifies the two endpoint reads as the same local endpoint of the packet. The handoff uses only $I, F, L, R, Q, U, H, C, G, N$ and the Gronwall comparison row; it does not add global continuation, a selected solution curve, host function-space equality, or an ambient completeness claim.*

Proof. Project the carrier rows of Definition 1888.1. The row Q is the only local uniqueness classifier, and it is keyed by the same initial cell I and Lipschitz vector-field ledger F named in the theorem statement.

Apply Definition 1888.5. The Gronwall comparison row keeps the finite difference envelope for the two displayed endpoint reads inside U, so the comparison remains within the same local time-state window carried by P.

Now read the uniqueness row Q. Because both endpoint reads share I and F, and the comparison envelope is bounded inside U, Q classifies them through the displayed ODE endpoint classifier rather than through a host function-space equality.

Finally transport and replay the classification through H and C, with provenance and naming supplied by G and N. These support rows do not add a selected solution curve, global continuation, or ambient completeness coordinate, so the uniqueness handoff stays local to the packet. □

Theorem 1888.7 (Picard–Lindelof local uniqueness induction)**.** *Let*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

be an accepted $\mathsf{PicardLindelof}^{\uparrow}$ *carrier, and let $W_0, \ldots, W_m$ be a finite list of Picard windows displayed by the route L inside the nonescape row U. If the initial window W_0 reads the same initial cell I and Lipschitz ledger F, and each successor window is obtained by the displayed* $\mathsf{PicardContraction}^{\uparrow}$ *step recorded in L, then every endpoint window W_i is classified by the same local classifier Q after the route has passed through L, R, H, C, G, N. The induction preserves the shared I, F, U rows at every stage and exports no host function equality, global solver, maximal continuation, or selected solution curve.*

Proof. The base window is W_0. By the carrier definition, W_0 is read from the initial cell I, the Lipschitz vector-field ledger F, and the nonescape window U before any endpoint classifier is visible.

For the successor step, use Definition 1888.3. The PicardContraction row L is the only available step rule, and every step in L reads vector-field values through F while remaining inside the same local window U.

The finite induction therefore preserves the three shared rows I, F, U along the whole displayed list. At each stage, the convergence-facing data is still the same complete-metric row R, and the support rows H, C, G, N transport, replay, source, and name the same packet.

Apply Definition 1888.6 at the endpoint stage. Since the endpoint read still shares I and F and remains inside U, the classifier Q supplies the local uniqueness read without introducing a host equality of functions, a global solver coordinate, or any continuation beyond the displayed finite windows. □

Theorem 1888.8 (Picard–Lindelof Cauchy completion route)**.** *Every completion-facing endpoint read of an accepted* $\mathsf{PicardLindelof}^{\uparrow}$ *carrier*

$$P = (I, F, L, R, Q, U, H, C, G, N)$$

must pass from the Picard route L through the complete-metric row R before the local uniqueness classifier Q is exposed. The displayed Cauchy modulus is stored only in the finite rows of L and R, is replayed only through H, C, G, N, and is not a claim of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit representative, a quotient equality, or a global ODE solution.*

Proof. Start with the Picard route. By Definition 1888.3, an endpoint read first opens I, F, L, U and reads each approximant through the $\mathsf{PicardContraction}^{\uparrow}$ sibling route of chapter 395.

The completion-facing read then enters R. The complete-metric row is the only carrier coordinate that can expose Cauchy convergence data, and it is supplied through the $\mathsf{CompleteMetric}^{\uparrow}$ sibling route of chapter 128.

Only after this route may Q classify the endpoint. The support rows H, C, G, N keep the Cauchy modulus attached to the displayed finite packet, so the public endpoint remains a local NameCert read rather than a selected limit, an ambient completeness theorem, or a global solution object. □

Falsifiable prediction: Every $\mathsf{PicardLindelof}^{\uparrow}$ local endpoint read factors through one initial time-state cell, one Lipschitz vector-field ledger, one PicardContraction route, one CompleteMetric convergence row, one local uniqueness classifier, one nonescape window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ode, lipschitzmap, completemetric, picardcontraction, banachfixedpoint: $\mathsf{PicardLindelof}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the initial time-state cell, vector-field Lipschitz ledger, Picard iteration route, complete-metric convergence row, local uniqueness classifier, nonescape window, and the transport/replay/provenance rows tying them together.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardLindelof}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardLindelof}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1888.1, Definition 1888.2, and Definition 1888.3 seed the local constructive ODE existence-and-uniqueness route over an initial time-state cell, a Lipschitz vector-field ledger, a Picard iteration route, a complete-metric convergence row, a local uniqueness classifier, a nonescape window, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardLindelof}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global ODE existence, maximal interval continuation, host function-space equality, choice-selected solutions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, initial time-state compatibility, Lipschitz vector-field stability, Picard iteration compatibility, complete-metric convergence visibility, local uniqueness classification, nonescape-window stability, transport, replay, provenance, and local naming for BEDC.Derived.PicardLindelofUp.

Constructive story: A PicardLindelof$^{\uparrow}$ packet is generated from one initial time-state cell, one Lipschitz vector-field ledger, one PicardContraction route, one CompleteMetric convergence row, one local uniqueness classifier, one nonescape window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1889

A Concrete Naming Certificate for $\mathsf{UniformCauchySequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformCauchySequence}^{\uparrow}$ packet records the finite NameCert surface for one regular rational sequence whose Cauchy comparisons are governed by a shared modulus schedule. It sits on the L10 route from the stream-window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the explicit threshold surface of chapter 332, and the terminal seal boundary of chapter 38. The packet names the sequence-level carrier consumed by completion routes; it does not select a limit, quotient streams, host real equality, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 1889.1 (UniformCauchySequence carrier)**.** *A* $\mathsf{UniformCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, Q, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window surface for the sequence observations;*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assigning rational names to the displayed stream windows;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every displayed Cauchy comparison;*
4. *M is the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *shared threshold row that binds all late-window comparisons;*
5. *R is the finite uniform Cauchy comparison row, reading pairs of sufficiently late windows through S, Q, D, M;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the shared modulus row and comparison row have been displayed;*
7. *H records* hsame *transport for the stream windows, regular readbacks, dyadic ledger, shared modulus, comparison row, real seal, replay row, provenance row, and local naming row;*
8. *C records displayed* Cont *replay from stream inspection through regular readback, dyadic tolerance, shared threshold, comparison, and real-seal delivery;*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySequence}^{\uparrow}}$ *row.*

The carrier stores no quotient stream, no selected host limit, no host equality of real names, no countable-choice selector, and no ambient completeness field.

Theorem 1889.2 (UniformCauchySequence NameCert obligations)**.** *For an accepted* $\mathsf{UniformCauchySequence}^{\uparrow}$ *carrier* $U = (S, Q, D, M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySequence}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed stream windows, regular rational readbacks, dyadic tolerance ledger, shared modulus row, comparison row, real seal, transports, replay route, provenance, and local naming row;*
2. *shared-modulus exactness, requiring every late-window Cauchy comparison in* R *to use the same* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *threshold row* M *and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*;*
3. *readback compatibility, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *to be the only rational readback consumed by the comparison row* R*;*
4. *route ordering, requiring* R *to be displayed only after* S, Q, D, M *and requiring* E *to be displayed only after* R*;*
5. *transport stability, requiring* H *and* C *to preserve the route* S, Q, D, M, R, E, P, N *without adding a hidden threshold, independent rational stream, quotient stream, or selected limit;*
6. *ledger exhaustion, stating that no quotient stream, selected host limit, host real equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle is exported.*

Proof. Carrier admission is projection from Definition 1889.1. The tuple displays the stream window row, regular readback row, dyadic tolerance ledger, shared modulus row, comparison row, real seal, transport, replay, provenance, and local name.

Shared-modulus exactness follows from the single coordinates M and D. Since every comparison row in R is read through those coordinates, the packet has no second threshold schedule and no hidden tolerance ledger.

Readback compatibility and route ordering are forced by the displayed coordinate order. The comparison row R consumes S, Q, D, M, while the real seal E is downstream of R.

Transport stability and ledger exhaustion are the role of H, C, P, N. These rows replay and name the same finite route, so they cannot introduce quotient streams, selected limits, host real equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.UniformCauchySequenceUp.TasteGate.UniformCauchySequenceTasteGate single carrier alignment`

Theorem 1889.3 (UniformCauchySequence RegSeqRat handoff)**.** *Let* $U = (S, Q, D, M, R, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformCauchySequence}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback used by a Cauchy comparison in* R *factors through the visible handoff*

$$S, Q, D, M, R, H, C, P, N.$$

In particular, a comparison cannot replace Q *by an independent rational stream, cannot replace* M *by a local threshold choice, and cannot replace* D *by a hidden host tolerance.*

Proof. Project the carrier coordinates. The only regular rational readback coordinate is Q, and the only shared threshold coordinate is M.

Apply the readback compatibility and shared-modulus clauses of Definition 1889.2. They force every comparison in R to read Q together with S, D, M before the comparison is accepted.

Finally use the transport rows H and C. They preserve the same displayed route with provenance P and local name N, so the handoff has no access to an independent rational stream, local threshold choice, or hidden host tolerance. □

Theorem 1889.4 (UniformCauchySequence Real seal boundary)**.** *For an accepted* $\mathsf{UniformCauchySequence}^{\uparrow}$ *carrier* $U = (S, Q, D, M, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal read reaches* E *only after passing through the finite stream row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *shared threshold* M*, and uniform Cauchy comparison row* R*. The seal boundary exports no quotient streams, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ seal read of U. By the carrier definition, the only terminal seal coordinate is E.

The NameCert obligations place E downstream of the comparison row R, and R downstream of S, Q, D, M. Hence the seal read must traverse the stream windows, regular readback, dyadic tolerance ledger, shared modulus, and comparison row first.

The rows H, C, P, N preserve and name the same route. Since the carrier lists no quotient-stream coordinate, selected-limit coordinate, countable-choice selector, host real equality, or ambient completeness row, the real seal boundary is exhausted by the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchySequence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1889.1, Definition 1889.2, Definition 1889.3, and Definition 1889.4 seed the L10 shared-modulus sequence packet over StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, ModulusOfConvergence thresholds, and the Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exactness, readback compatibility, route ordering, transport stability, ledger exhaustion, and Real seal nonescape for BEDC.Derived.UniformCauchySequenceUp.

Constructive story: A $\mathsf{UniformCauchySequence}^{\uparrow}$ packet is generated from $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{ModulusOfConvergence}^{\uparrow}$ shared threshold row, finite comparison rows, a $\mathsf{Real}^{\uparrow}$ seal boundary, hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1890

A Concrete Naming Certificate for $\mathsf{RealOrderTopology}^{\uparrow}$

Following Kelley, *General Topology*, and Bishop–Bridges constructive analysis, the $\mathsf{RealOrderTopology}^{\uparrow}$ packet records the finite order-topology route on BEDC real names. It binds the real-name carrier of chapter 38, the comparison rows of chapter 766, the generated-open surface of chapter 88, the ball-basis packet of chapter 1450, and the observable-open truth interface of chapter 1860. The packet gives later L10 consumers a BEDC-native topology interface for $\mathsf{Real}^{\uparrow}$ without treating host subsets, completeness, trichotomy, Dedekind cuts, or open-cover compactness as primitive structure.

Definition 1890.1 (Real order topology carrier)**.** *A* $\mathsf{RealOrderTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (R, A, B, S, T, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *point-name surface, exposing only finite real-name windows and their admitted seal rows.*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison row used to read rational and real-name order probes against the displayed point windows.*
3. *B is the interval-or-ball basis row, recording finite rays, bounded intervals, and* $\mathsf{MetricBall}^{\uparrow}$ *cells that are generated from the comparison service.*
4. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row, recording which displayed point-window probes certify membership in a basic open.*
5. *T is the* $\mathsf{Topology}^{\uparrow}$ *generated-open row, closing only under the finite generated-open operations displayed by B and S.*
6. *H records componentwise* hsame *transport for the real point rows, comparison rows, basis rows, observable truth rows, generated-open rows, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a real-name observation through comparison, basis generation, observable-open truth, generated-open formation, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RealOrderTopology}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, order trichotomy, Dedekind-cut construction, host subset equality, open-cover compactness, Lean verification, or bridge checking.

Definition 1890.2 (Real order topology classifier)**.** *Two accepted* $\mathsf{RealOrderTopology}^{\uparrow}$ *carriers*

$$O = (R, A, B, S, T, H, C, P, N) \quad \text{and} \quad O' = (R', A', B', S', T', H', C', P', N')$$

are classified by $\mathsf{msame}_{\mathsf{RealOrderTopology}^{\uparrow}}$ *exactly when their displayed real point rows, order-comparison rows, interval-or-ball basis rows, Sierpinski observable-open truth rows, generated-open rows, transports, replay routes, provenance rows, and local naming rows are matched componentwise by the visible* hsame *and* Cont *evidence. The classifier cannot inspect hidden host subsets, completeness witnesses, trichotomy decisions, Dedekind cuts, open-cover compactness data, Lean proof terms, or bridge certificates.*

Theorem 1890.3 (Real order topology NameCert obligations)**.** *For an accepted* $\mathsf{RealOrderTopology}^{\uparrow}$ *carrier* $O = (R, A, B, S, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealOrderTopology}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the real point-name rows, order-comparison rows, interval-or-ball basis rows, observable-open truth rows, generated-open topology rows, transport, replay, provenance, and local naming;*
2. *comparison-source exactness, requiring every interval endpoint, ray boundary, and ball-center comparison used by B to pass through the displayed* $\mathsf{RealAlgOrder}^{\uparrow}$ *row A and the displayed* $\mathsf{Real}^{\uparrow}$ *row R;*
3. *basis-generation exactness, requiring every basic open to be generated from the displayed interval-or-ball row B and not from a host subset predicate;*
4. *observable-open compatibility, requiring every membership read exported to* $\mathsf{SierpinskiSpace}^{\uparrow}$ *to be replayed through the same rows R, A, B before the truth row S is accepted;*
5. *topology-row stability, requiring the* $\mathsf{Topology}^{\uparrow}$ *row T to close only the generated-open operations displayed by B and S;*
6. *transport and replay stability, requiring H and C to preserve the route R, A, B, S, T, P, N without adding hidden completeness, trichotomy, Dedekind-cut, compactness, Lean, or bridge data;*
7. *ledger exhaustion, stating that no Real completeness, trichotomy, Dedekind-cut construction, open-cover compactness, Lean verification, or bridge checking is exported.*

No order-topology obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RealOrderTopologyUp.TasteGate.RealOrderTopologyTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1890.1. The accepted packet displays exactly one real point-name surface, one comparison row, one basis row, one observable-open truth row, one generated-open row, and the structural rows.

Comparison-source exactness follows from the pair R, A. Every endpoint, ray, and ball-center comparison consumed by the basis row has no second comparison coordinate and no hidden host-order field.

Basis generation and observable-open compatibility are forced by B and S. The basis row lists only finite interval-or-ball cells, and the observable truth row reads those cells through the same real-name and comparison rows.

Topology-row stability is the role of T. It records the generated-open operations admitted from B and S, so it cannot replace the generated surface with an ambient subset predicate.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the excluded completeness, trichotomy, Dedekind-cut, compactness, Lean, and bridge data are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1890.4 (Real order topology Cauchy-window basis)**.** *Every basic-open read of an accepted* $\mathsf{RealOrderTopology}^{\uparrow}$ *carrier factors through finite* $\mathsf{Real}^{\uparrow}$ *windows,* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparisons, and an interval-or-ball basis row before it reaches either the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row or the* $\mathsf{Topology}^{\uparrow}$ *generated-open row. In particular, a Cauchy-window consumer of real names can use the displayed route*

$$R, A, B \longmapsto S, T, H, C, P, N$$

without importing a host subset predicate, a selected limit, real-order trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $O = (R, A, B, S, T, H, C, P, N)$. The only point-name coordinate is R, so any real-name window opened by a Cauchy-style consumer must begin with that finite surface.

The only order service is A. Thus endpoint, ray, and ball-center tests used to recognize a basic open are read through the displayed comparison row.

The basis row B receives those finite comparison reads and records the interval-or-ball cells. The observable truth row S and the generated-open row T are downstream of that basis row, so neither can introduce an independent host subset.

The structural rows H, C, P, N preserve the same route. Because the packet has no selected-limit coordinate, trichotomy field, or completeness witness, the Cauchy-window consumer remains inside the stated finite basis route. □

Theorem 1890.5 (Real order topology Real seal nonescape)**.** *For an accepted* $\mathsf{RealOrderTopology}^{\uparrow}$ *carrier* $O = (R, A, B, S, T, H, C, P, N)$*, every read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal or a generated-open seal has already passed through the finite route*

$$R, A, B, S, T, H, C, P, N.$$

The read exports no Real completeness principle, no trichotomy decision, no Dedekind-cut construction, no open-cover compactness, no Lean verification, and no bridge checking.

Proof. A $\mathsf{Real}^{\uparrow}$ seal read can only inspect the point-name coordinate R and the downstream route displayed by the carrier. The packet contains no second real-name surface and no host equality coordinate.

A generated-open seal read must pass through A, B, S, T. The comparison row supplies finite order probes, the basis row supplies intervals or balls, the observable truth row supplies Sierpinski membership reads, and the topology row records generated-open formation.

Transport and replay are then supplied by H and C, with provenance and local naming supplied by P and N. These rows preserve the displayed route and cannot add the excluded completeness, trichotomy, Dedekind-cut, compactness, Lean, or bridge data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOrderTopology}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealOrderTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1890.1, Definition 1890.2, Definition 1890.3, Definition 1890.4, and Definition 1890.5 seed the finite order-topology route over Real point rows, RealAlgOrder comparisons, interval-or-ball bases, Sierpinski observable-open truth, and Topology generated-open rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealOrderTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, Dedekind-cut construction, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, comparison-source exactness, basis generation, observable-open compatibility, topology-row stability, Cauchy-window basis routing, and Real seal nonescape for BEDC.Derived.RealOrderTopologyUp.

Constructive story: A $\mathsf{RealOrderTopology}^{\uparrow}$ packet is generated from Real point rows, RealAlgOrder comparison rows, interval or MetricBall basis rows, Sierpinski observable-open truth rows, Topology generated-open rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1891

A Concrete Naming Certificate for $\mathsf{CompactIntervalLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactIntervalLocator}^{\uparrow}$ packet records finite locator data for a compact real interval through existing $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$, $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. The chapter binds the interval surface of chapter 1709, the comparison service of chapter 1669, and the locatedness budget of chapter 1627 as one finite consumer packet. It gives Real and Completion routes a compact-interval locator surface; it is not open-cover compactness, endpoint selection, real-order trichotomy, quotient-stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1891.1 (Compact interval locator carrier)**.** *A* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, \Lambda, M, D, S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source interval row, exposing the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, radius budget, endpoint compatibility, locator reads, and locatedness services already admitted by the interval packet.*
2. *Λ is the* $\mathsf{RealLocator}^{\uparrow}$ *comparison row used for rational probes against the displayed interval boundary.*
3. *M is the* $\mathsf{LocatednessModulus}^{\uparrow}$ *row that turns each positive tolerance request into finite endpoint windows, rational cells, dyadic refinements, and real-name readbacks.*
4. *D is the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *ledger for endpoint enclosure, interval refinement, containment comparison, and outward dyadic slack.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the Real and Completion consumer request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint and tolerance windows.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested positive dyadic scale and the rational comparison cells inspected by the locator.*
8. *H records componentwise* hsame *transport for the located interval, locator, modulus, dyadic interval ledger, stream windows, regular readback, dyadic tolerance ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-interval location request through* $I, \Lambda, M, D, S, R, Q, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalLocator}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{LocatednessModulus}^{\uparrow}$ $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalLocator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $I, \Lambda, M, D, S, R, Q, H, C, P, N$. It has no coordinate for open-cover compactness, selected endpoints, host closed-interval equality, trichotomy, quotient stream equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompactIntervalLocatorUp.CompactIntervalLocatorTasteGate single carrier alignment`

Theorem 1891.2 (Compact interval locator NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *carrier*

$$K = (I, \Lambda, M, D, S, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalLocator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval row, real locator row, locatedness modulus row, dyadic interval arithmetic ledger, StreamName window row, RegSeqRat readback row, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming;*
2. *interval-source exactness, requiring every endpoint, radius, containment, and boundary request to pass through the displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row I;*
3. *locator-modulus compatibility, requiring Λ and M to answer rational probes and tolerance requests through the same finite endpoint windows, dyadic cells, and real-name readback route;*
4. *dyadic ledger stability, requiring D and Q to store only displayed dyadic interval arithmetic, positive scales, and rational comparison cells;*
5. *consumer-window exhaustion, requiring S and R to expose finite windows and regular rational readback before any* $\mathsf{Real}^{\uparrow}$ *or Completion-facing seal is read;*
6. *nonescape, excluding open-cover compactness, selected endpoints, host interval equality, real-order trichotomy, quotient stream equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No compact interval locator obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1891.1. The accepted packet displays exactly one located interval source, one locator row, one locatedness modulus, one dyadic interval ledger, one finite stream-window row, one regular readback row, one dyadic tolerance ledger, and the structural rows.

Interval-source exactness is forced by I. Endpoint, radius, containment, separation, and refinement requests have no second interval coordinate, so every such read begins with the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ carrier.

Locator-modulus compatibility is the pair Λ, M. The locator row answers rational boundary probes, while the modulus row converts tolerance requests into the same finite endpoint windows, rational cells, dyadic refinements, and real-name readbacks.

Dyadic and consumer-window stability are supplied by D, Q, S, R. The dyadic rows name only displayed interval arithmetic, positive scales, and rational comparison cells; the window rows expose only finite StreamName windows and RegSeqRat readback.

The remaining rows H, C, P, N transport, replay, source, and name the same packet. Since the excluded compactness, endpoint-selection, order, quotient, choice, and ambient completeness data are absent from the carrier inventory, the listed rows exhaust the local NameCert surface. □

Theorem 1891.3 (Compact interval locator Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read of an accepted* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *carrier factors through the finite route*

$$I \longmapsto \Lambda, M, D, Q \longmapsto S, R \longmapsto H, C, P, N.$$

The read may inspect the located real interval, locator decisions, locatedness budgets, dyadic interval arithmetic, dyadic tolerance cells, finite stream windows, regular rational readback, transport, replay, provenance, and local naming. It may not replace that route by open-cover compactness, selected endpoints, host interval equality, trichotomy, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (I, \Lambda, M, D, S, R, Q, H, C, P, N)$. The only source interval coordinate is I, so every Real or Completion-facing request first reads the located interval row with its endpoint, radius, locator, and locatedness boundary.

The computational route is then forced through Λ, M, D, Q. These rows provide the finite locator decisions, tolerance-to-window budget, dyadic interval arithmetic, and dyadic rational comparison cells for the same displayed interval.

The consumer-facing observation is finite. The request opens the StreamName window S and reads it through the RegSeqRat row R before any Real-facing seal can be consumed.

Finally H, C, P, N preserve, replay, source, and name the displayed route. None of these rows contains open-cover compactness, selected endpoint functionals, host interval equality, trichotomy, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so every accepted read remains inside the stated route. □

Falsifiable prediction: Every $\mathsf{CompactIntervalLocator}^{\uparrow}$ read factors through one $\mathsf{LocatedRealInterval}^{\uparrow}$ source row, one $\mathsf{RealLocator}^{\uparrow}$ comparison row, one $\mathsf{LocatednessModulus}^{\uparrow}$ tolerance row, one $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ ledger, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-real-interval, real-locator, locatedness-modulus: $\mathsf{CompactIntervalLocator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source interval data, boundary locator decisions, tolerance-to-window budgets, dyadic interval arithmetic, finite observation windows, regular rational readback, and a Real or Completion-facing nonescape boundary as one local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalLocator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1891.1, Definition 1891.2, and Definition 1891.3 seed the finite compact-interval locator route over located real intervals, real locators, locatedness moduli, dyadic interval arithmetic, stream windows, regular rational readback, and dyadic tolerance ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected endpoints, host interval equality, real-order trichotomy, quotient stream equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exactness, locator-modulus compatibility, dyadic ledger stability, consumer-window exhaustion, and Real-route nonescape proofs for BEDC.Derived.CompactIntervalLocatorUp.

Constructive story: A CompactIntervalLocator$^{\uparrow}$ packet is generated from a LocatedRealIntervalUp row, a RealLocatorUp comparison row, a LocatednessModulusUp tolerance row, DyadicIntervalArithmeticUp rows, StreamNameUp windows, RegSeqRatUp readbacks, a DyadicRatCoreUp tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1892

A Concrete Naming Certificate for $\mathsf{UniformCompletionFunctor}^{\uparrow}$

Following Kelley on uniform spaces and Bishop–Bridges on constructive completion, the $\mathsf{UniformCompletionFunctor}^{\uparrow}$ packet names the functorial handoff from $\mathsf{UniformCompletion}^{\uparrow}$ data to completion consumers. It sits between the uniform-completion source of chapter 1473, the functorial Cauchy handoff of chapter 423, the universal-extension surface of chapter 397, the regular rational readback of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet records a finite functorial route for completion-facing consumers; it is not a quotient completion, selected limit, host complete uniform space, open-cover compactness theorem, or choice principle.

Definition 1892.1 (UniformCompletionFunctor carrier)**.** *A* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

with the following visible rows:

1. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row, supplying the displayed Cauchy-filter, Cauchy-net, universal-extension, classifier, transport, replay, provenance, and local naming data read by the functor.*
2. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row, recording the source-to-completion unit route, completion-facing bind route, and functorial classifier surface accepted for the same source.*
3. *E is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *universal-extension row, naming the finite extension and uniqueness ledger consumed after U and F have been projected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row used when the completion consumer asks for a regular source name or a regular output name.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite observation windows through which both source and completed rows are inspected.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision, comparison, and refinement budgets used by R and W.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the uniform-completion source, functorial handoff, universal-extension ledger, regular readback, stream windows, and dyadic tolerance rows have been replayed.*

8. *H records componentwise* hsame *transport for $U, F, E, R, W, D, S, C, P, N$.*
9. *C records displayed* Cont *replay, so finite completion-consumer requests reread $U, F, E, R, W, D, S, H, P, N$ without changing the route.*
10. *P is the* Pkg *provenance over* UniformCompletionFunctor$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted functor packets only through the displayed rows $U, F, E, R, W, D, S, H, C, P, N$. There is no coordinate for quotient completion equality, selected limits, host complete uniform spaces, open-cover compactness, or choice.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier definition surface`

Theorem 1892.2 (UniformCompletionFunctor NameCert obligations)**.** *For every accepted* UniformCompletionFunc *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N),$$

the local NameCert$_{\text{UniformCompletionFunctor}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed uniform-completion source, CauchyCompletionFunctor handoff, universal-extension row, regular readback row, stream-window row, dyadic tolerance row, Real seal row, transport, replay, provenance, and local naming;*
2. *source compatibility, requiring every completion-facing read to project the* UniformCompletion$^{\uparrow}$ *source row U before any functorial handoff is available;*
3. *handoff exactness, requiring F to expose the unit, bind, and classifier rows consumed by completion functor readers over the same source row;*
4. *universal-extension ordering, requiring E to be read after U and F and before any terminal* Real$^{\uparrow}$ *seal is exposed;*
5. *readback and tolerance exactness, requiring R, W, D to carry all regular rational, finite-window, and dyadic precision requests used by the handoff;*
6. *ledger non-escape, requiring H, C, P, N to export no quotient completion, selected limit, host complete uniform space, open-cover compactness proof, or choice principle.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1892.1. The accepted packet displays exactly the source, handoff, extension, readback, window, tolerance, seal, transport, replay, provenance, and local naming rows.

Source compatibility and handoff exactness are read from U and F. A completion consumer first reads the UniformCompletion$^{\uparrow}$ source row and then the CauchyCompletionFunctor$^{\uparrow}$ handoff row, so the packet has no separate entry point for a quotient completion or selected limit.

Universal-extension ordering is read from E, while readback and tolerance exactness are read from R, W, D. The seal row S is downstream of those rows, and H, C, P, N only transport, replay, source, and name the same displayed route. Since the excluded principles have no carrier coordinate, no replay edge, and no provenance row, the local NameCert surface is exactly the listed obligation surface. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorNamecertObligations`

Theorem 1892.3 (UniformCompletionFunctor source obligation)**.** *Every accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

must expose the UniformCompletion$^{\uparrow}$ *source row U before any completion-facing consumer may read the functorial handoff, universal-extension ledger, regular readback, stream window, dyadic tolerance, Real seal, transport, replay, provenance, or local naming rows. A consumer that bypasses U is not reading the displayed completion-functor packet.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier source factorization`

Proof. Project the displayed carrier of Definition 1892.1. The source row U is the only coordinate that supplies uniform-completion data to the packet.

Apply the NameCert obligations of Definition 1892.2. Their source-compatibility row requires each completion-facing read to project U before the handoff row F or any downstream row is public.

The sibling chapters named in the introduction supply the source and consumer surfaces: UniformCompletion$^{\uparrow}$ supplies U, while CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ are downstream rows. Since no separate source coordinate exists, the source obligation is exactly the projection through U. □

Theorem 1892.4 (UniformCompletionFunctor Cauchy handoff)**.** *Every* CauchyCompletionFunctor$^{\uparrow}$ *handoff consumed from an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier factors through the displayed rows*

$$U \longmapsto F \longmapsto E.$$

The row F may expose the unit, bind, and functorial classifier surface only for the same UniformCompletion$^{\uparrow}$ *source row U, and the universal-extension row E is read only after that handoff has been displayed.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier cauchy handoff`

Proof. Read the carrier rows U, F, E. The handoff row F is not an independent completion object; it is displayed as the CauchyCompletionFunctor$^{\uparrow}$ row attached to the source U.

Use Definition 1892.2. Handoff exactness confines the unit, bind, and classifier rows to the same source, while universal-extension ordering places E downstream of both U and F.

The introduction's CauchyCompletionFunctor and CompletionUniversalProperty siblings provide exactly those consumer surfaces. Nothing in the carrier adds quotient completion equality, a selected limit, host complete-uniform-space structure, or choice, so the Cauchy handoff is the displayed route $U \longmapsto F \longmapsto E$. □

Theorem 1892.5 (UniformCompletionFunctor bridge source lock)**.** *Every bridge read of the source coordinate in an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ factors through the ordered finite route*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D$$

before the terminal Real$^{\uparrow}$ *seal row S is exposed. The read cannot bypass the* UniformCompletion$^{\uparrow}$ *source row U, cannot treat F, E, R, W, D as independent completion sources, and cannot export a bridge surface that omits the displayed source before reaching S, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier bridge source lock`

Proof. Begin with the carrier of Definition 1892.1. The only source coordinate is U, and every downstream completion-facing row is displayed after it.

Use Definition 1892.3. It fixes U as the first public row of any completion-facing read, so a bridge cannot begin from F, E, R, W, D or from the terminal Real seal.

Next apply Definition 1892.4. The Cauchy-completion handoff F is attached to the same source row, and the universal-extension row E is downstream from that handoff.

Finally use Definition 1892.9. The readback, window, and dyadic rows R, W, D appear before the Real seal S, while H, C, P, N only transport, replay, source, and name the same route. Hence every bridge read is source-locked through U, F, E, R, W, D before any Real-facing seal is consumed. □

Theorem 1892.6 (UniformCompletionFunctor bridge target interface)**.** *Every target-side bridge read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ *factors through the displayed rows*

$$U, F, E, R, W, D, S, H, C, P, N.$$

In particular, the target interface preserves the $\mathsf{UniformCompletion}^{\uparrow}$ *source row* U*, the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row* F*, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* S *before any transport, replay, provenance, or local naming row is exported.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorBridgeTargetInterface`

Proof. Project the carrier of Definition 1892.1. The target-side bridge can read only the displayed coordinates $U, F, E, R, W, D, S, H, C, P, N$.

Use the source obligation, Definition 1892.3. It fixes U as the UniformCompletion source for every completion-facing read, so the bridge target cannot begin from a target seal or from an isolated handoff row.

Apply the Cauchy handoff theorem, Definition 1892.4, and the bridge source lock, Definition 1892.5. These place the CauchyCompletionFunctor row and the universal-property row downstream of the same source, then route the bridge through the regular readback, finite windows, and dyadic tolerance rows.

Finally use the Real-seal nonescape theorem, Definition 1892.9. It keeps S terminal for the displayed readback route and confines H, C, P, N to componentwise transport, replay, provenance, and local naming. Therefore every target-side bridge read exposes exactly the listed interface and no quotient completion, selected limit, host complete uniform space, open-cover compactness theorem, or choice principle. □

Theorem 1892.7 (UniformCompletionFunctor target-source order)**.** *Every target-side bridge read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet reaches the terminal target seal only after the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{StreamName}^{\uparrow}$ *window row, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row have been displayed. The target-side route therefore reads*

$$U \longmapsto F \longmapsto E \longmapsto R \longmapsto W \longmapsto D \longmapsto S$$

inside the carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ *before any terminal target seal, transport, replay, provenance, or local naming row is consumed.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorTargetSourceOrder`

Proof. Project the carrier of Definition 1892.1. The target-side bridge has no row other than $U, F, E, R, W, D, S, H, C, P, N$, so the terminal seal can only be reached through the displayed source-to-target route.

Apply Definition 1892.3. It places the $\mathsf{UniformCompletion}^{\uparrow}$ source row first for every completion-facing read and prevents the bridge from starting at the terminal seal.

Use Definition 1892.4 together with Definition 1892.5. These force the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ row to remain downstream of the source row before the bridge can read regular sequences, finite StreamName windows, or dyadic tolerances.

Finally apply Definition 1892.47. The existing target interface exposes the readback, window, tolerance, and terminal seal rows in the displayed carrier order and confines H, C, P, N to transport, replay, provenance, and local naming. Hence a target-side bridge read is source-before-target rather than a direct read of the terminal seal. □

Theorem 1892.8 (UniformCompletionFunctor Cauchy-completion handoff ordering)**.** *The* CauchyCompletionFunc *row F of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier is consumable only after the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row U has been displayed and only before the universal-extension row E is read. Any downstream* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer receives F only through the ordered route*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D \longmapsto S.$$

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCauchyCompletionHandoffOrdering`

Proof. Project the rows of Definition 1892.1. The Cauchy-completion handoff coordinate F is placed between the source coordinate U and the universal-extension coordinate E.

Apply Definition 1892.3 and Definition 1892.4. Together they require U before F and require E only after the handoff has been displayed.

For downstream consumers, use Definition 1892.10. It sends regular rational readback, stream windows, dyadic tolerance, and the Real seal through R, W, D, S after the same U, F, E prefix.

Thus F is neither a free-standing completion object nor a late Real-facing seal. It is the finite handoff row consumed after U and before E, with $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ strictly downstream. □

Theorem 1892.9 (UniformCompletionFunctor Real seal nonescape from root rows)**.** *For every accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row S can be consumed only after the rows R, W, D have been displayed downstream of U, F, E. The rows H, C, P, N may transport, replay, source, and name that same route, but they cannot turn S into a quotient completion, selected limit, host complete uniform space, open-cover compactness proof, or choice principle.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRealSealNonescape`

Proof. Project the carrier and isolate the terminal block R, W, D, S, H, C, P, N. The seal row S appears only after the readback, finite-window, and dyadic rows that mediate real-facing completion reads.

Apply Definition 1892.2. Readback and tolerance exactness assigns all regular rational, stream-window, and dyadic precision requests to R, W, D, while ledger non-escape confines the structural rows to the same packet.

The Real sibling named in the introduction is therefore reached only as a terminal seal for the displayed completion-consumer route. Since the remaining rows H, C, P, N preserve and name no additional coordinate, the excluded completion, compactness, and choice objects cannot escape from S. □

Theorem 1892.10 (UniformCompletionFunctor RegSeqRat and Real source handoff)**.** *Every completion-facing functor read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P,$ *that reaches the* $\mathsf{Real}^{\uparrow}$ *seal must first display the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row* U*, the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row* F*, the universal-extension row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S*. The structural rows* H, C, P, N *transport, replay, source, and name that same route, and no consumer may replace it by quotient completion equality, a selected limit, a host complete uniform space, open-cover compactness, or choice-selected representatives.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRegSeqRatRealSourceHandoff`

Proof. Start with the source obligation, Definition 1892.3. It fixes U as the first visible row for every completion-facing read.

Apply the Cauchy handoff theorem, Definition 1892.4. The functorial handoff F and universal-extension ledger E are downstream of the same source row, not independent completion objects.

Use the Real seal nonescape theorem above. It places the terminal seal S after the readback, finite-window, and dyadic rows R, W, D, and it confines H, C, P, N to transport and replay of that route.

Finally apply the universal handoff theorem, Definition 1892.23. The only completion-facing route is $U, F, E, R, W, D, S, H, C, P, N$, so the RegSeqRat and Real source handoff is finite, ordered, and free of quotient, selector, host-completeness, compactness, and choice coordinates. □

Theorem 1892.11 (UniformCompletionFunctor cofinal-window factorization)**.** *Every completion-facing cofinal-window read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ *factors through the ordered route*

$$U \longmapsto F \longmapsto E \longmapsto W, R, D \longmapsto S.$$

The structural rows H, C, P, N *preserve the same route under componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. No accepted consumer may replace the cofinal-window segment by quotient completion equality, a selected limit, a host complete uniform space, an open-cover compactness theorem, or choice-selected representatives.*

Proof. Start with the source obligation, Definition 1892.3. It fixes U as the first row of every completion-facing read, so a cofinal-window consumer cannot enter through W, R, D, or S directly.

Apply the Cauchy handoff theorem, Definition 1892.4. The handoff row F and universal-extension row E sit downstream of the same source row and upstream of the readback, window, tolerance, and seal rows.

Use the RegSeqRat and Real source handoff, Definition 1892.10. It places the cofinal-window service on the displayed W, R, D segment before the terminal seal S can be consumed.

Finally apply the Real seal nonescape theorem, Definition 1892.9. It confines H, C, P, N to transport, replay, provenance, and naming of the displayed route, so the cofinal-window factorization exports exactly $U, F, E, W, R, D, S, H, C, P, N$ and no hidden completion coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCofinalWindowFactorization`

Theorem 1892.12 (UniformCompletionFunctor Cauchy-filter nonescape)**.** *Let $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N$ be an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet. Any Cauchy-filter or completion-filter consumer that reads $\mathcal{F}$ receives only the displayed source, Cauchy handoff, extension, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance, Real seal, transport, replay, provenance, and local naming rows. It receives no quotient completion equality, selected limits, host complete uniform spaces, open-cover compactness, or choice-selected representatives.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCauchyFilterNonescape`

Proof. Project the carrier and apply Definition 1892.2. Carrier admission and ledger non-escape restrict every completion-filter read to the displayed rows $U, F, E, R, W, D, S, H, C, P, N$.

Use Definition 1892.10. It orders those rows before the Real seal and prevents a filter consumer from bypassing the RegSeqRat, StreamName, and DyadicRatCore source route.

Since no excluded completion, compactness, representative-selection, or host-completeness row occurs in the carrier, the Cauchy-filter read cannot escape the displayed finite packet. □

Theorem 1892.13 (UniformCompletionFunctor Real-RegSeqRat L10 nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P$ must expose the rows $U, F, E, R, W, D, S, H, C, P, N$, with* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *visible in that order along the readback-and-seal segment. The packet exports no quotient completion equality, selected limit, host complete uniform space, open-cover compactness, choice-selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the RegSeqRat and Real source handoff, Definition 1892.10. It forces any terminal Real-facing read to display U, F, E, R, W, D, S before the seal can be consumed, and it keeps H, C, P, N on the same transport, replay, provenance, and naming route.

Apply the Cauchy-filter nonescape result, Definition 1892.12. Completion-filter consumers receive only the displayed carrier rows, so the Real and RegSeqRat faces cannot be replaced by quotient completion equality, selected limits, host complete uniform spaces, open-cover compactness, or choice-selected representatives.

The scoped L10 route of Definition 1892.42 identifies the visible readback segment as the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ corridor. The public export theorem, Definition 1892.43, then repacks exactly that ordered corridor into the public NameCert surface, with no ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate added. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRealRegSeqRatL10Nonescape`

Theorem 1892.14 (UniformCompletionFunctor source factorization)**.** *Every completion-facing read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

factors through the $\mathsf{UniformCompletion}^{\uparrow}$ *source row U before the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row F is public. Thus the functorial unit, bind, and classifier reads cannot be sourced from quotient completion equality, a selected limit, a host complete uniform space, or a choice-selected representative.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorSourceFactorization`

Proof. Project the carrier of Definition 1892.1. The row U is the only source coordinate in the packet, and F is displayed as the handoff row attached to that source.

Apply Definition 1892.2. Its source-compatibility clause requires every completion-facing read to project U before any functorial handoff is available, while handoff exactness confines F to the same displayed source.

Since the carrier and obligation surface contain no quotient completion row, selected limit row, host complete-uniform-space row, or choice row, no consumer can bypass the source factorization through U. □

Theorem 1892.15 (UniformCompletionFunctor extension ordering)**.** *For every accepted* UniformCompletionFunctor *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$*, the universal-extension row* E *is consumed after the source and functorial handoff rows* U, F *and before the readback, window, dyadic, seal, transport, replay, provenance, and naming rows* R, W, D, S, H, C, P, N*. The ordered public route is therefore*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D \longmapsto S, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorExtensionOrdering`

Proof. Read the displayed carrier. The row E is the only $\mathsf{CompletionUniversalProperty}^{\uparrow}$ coordinate, and it sits between the source-handoff block U, F and the downstream readback block R, W, D, S.

Use the NameCert obligations of Definition 1892.2. Source compatibility and handoff exactness place U, F before E, and universal-extension ordering places E before any terminal $\mathsf{Real}^{\uparrow}$ seal can be exposed.

The remaining rows preserve the same order. The readback and tolerance clause accounts for R, W, D, while H, C, P, N only transport, replay, source, and name the displayed packet. Hence every public route has the stated ordering. □

Theorem 1892.16 (UniformCompletionFunctor readback seal exactness)**.** *In an accepted* UniformCompletionFunctor *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S *is exact only for readbacks that first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *row* W*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*. No completion-facing consumer may read* S *as a host real value, a quotient completion seal, or a selected limit independent of* R, W, D*.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorReadbackSealExactness`

Proof. Start from the carrier projection. The seal row S appears downstream of R, W, D, and there is no second Real-facing coordinate in the packet.

Apply Definition 1892.2. Its readback and tolerance exactness clause assigns all regular rational, finite-window, and dyadic precision requests to R, W, D, while universal-extension ordering keeps the seal downstream from U, F, E.

Thus a consumer reaches S only after the displayed readback surface has been consumed. The structural rows H, C, P, N preserve and name that same route, so the seal cannot be replaced by a host real value, quotient completion seal, selected limit, open-cover compactness proof, or choice principle. □

Theorem 1892.17 (UniformCompletionFunctor root obligation lattice)**.** *For every accepted* UniformCompletionFunctor *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N),$$

the root obligations form the ordered finite lattice

$$U \longmapsto F \longmapsto E \longmapsto (R, W, D) \longmapsto S, H, C, P, N.$$

The source row U is the unique root; carrier admission is the display of $\mathcal{F}$ as a single BHist *packet; source compatibility requires every consumer to read U before the handoff; the Cauchy handoff F is available only downstream of that source; universal-extension ordering puts E downstream of F and upstream of all readback rows; readback and tolerance exactness put R, W, D downstream of E and upstream of S; Real-seal nonescape keeps S terminal for the same route; and transport, replay, provenance, and local naming are exactly the terminal rows H, C, P, N. The lattice exports no quotient completion, selected limit, host complete uniform space, open-cover compactness theorem, or choice principle.*

Proof. Project the carrier of Definition 1892.1. Its row order displays one admitted BHist packet, one source coordinate U, one handoff coordinate F, one universal-extension coordinate E, the downstream readback-window-tolerance block R, W, D, and then S, H, C, P, N.

Apply the NameCert obligations of Definition 1892.2. Carrier admission accounts for the whole displayed packet. Source compatibility places U before any completion-facing handoff, Cauchy handoff exactness places F before any universal-extension read, universal-extension ordering places E before the terminal seal, and readback and tolerance exactness place R, W, D between E and the terminal rows.

Use the universal handoff theorem, Definition 1892.23, to identify the same order as the only consumer-visible route. The Real seal is read only as S after R, W, D, while H, C, P, N give transport, replay, provenance, and local naming for that route. Since the carrier has no coordinate outside this lattice, none of the excluded completion, compactness, or choice principles can be projected from the packet. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRootObligationLattice`

Theorem 1892.18 (UniformCompletionFunctor source-extension readback)**.** *Every* RegSeqRat$^{\uparrow}$ *or* StreamName$^{\uparrow}$ *readback consumed from an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier is downstream of both the* UniformCompletion$^{\uparrow}$ *source row U and the universal-extension row E. Concretely, each read of R or W factors through*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D$$

before the Real$^{\uparrow}$ *seal, transport, replay, provenance, or local naming rows are available.*

Proof. Read the carrier definition. The rows R and W occur in the same displayed packet as $U, F, E, D, S, H, C, P, N$, and no separate readback source is listed.

The NameCert obligations force the source and universal-extension order. Source compatibility makes U the first row for every completion-facing read, handoff exactness routes through F, and universal-extension ordering places E before any terminal seal can be exposed.

Now apply Definition 1892.23. Its route sends every completion-facing consumer through U, F, E before R, W, D. Hence a RegSeqRat or StreamName readback is a displayed downstream read of the UniformCompletion source and universal-extension ledger, not a quotient completion read, selected limit, host complete uniform space read, open-cover compactness proof, or choice-selected object. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorSourceExtensionReadback`

Theorem 1892.19 (UniformCompletionFunctor universal extension uniqueness ledger)**.** *Every uniqueness read of the universal-extension row in an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

factors through

$$U \longmapsto F \longmapsto E$$

before any regular-rational, stream-window, dyadic-tolerance, or terminal Real row is visible. The uniqueness ledger is therefore a displayed extension route over the $\mathsf{UniformCompletion}^{\uparrow}$ *source and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff, not a host uniqueness theorem about completed uniform spaces.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorUniversalExtensionUniquenessLe`

Proof. Project the carrier of Definition 1892.1. The extension row E is downstream of the source row U and the Cauchy handoff row F, while R, W, D, S, H, C, P, N are later readback and structural rows.

Apply the NameCert obligations and source obligation. Source compatibility forces every completion-facing read to start at U, and handoff exactness routes it through F before an extension ledger can be inspected.

Use the Cauchy handoff, universal handoff, and source-extension readback theorems. They keep E upstream of R, W, D and terminal Real sealing, so uniqueness is recorded only as the displayed U, F, E route and cannot import quotient completion equality, selected limits, host complete uniform spaces, compactness, or choice. □

Theorem 1892.20 (UniformCompletionFunctor readback tolerance terminal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier must expose the rows* R, W, D *as the regular-rational readback, stream-window readback, and dyadic tolerance ledger. Thus any route to* S *factors through*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D \longmapsto S$$

and no consumer may treat the seal as a host real value, a selected completion limit, or a quotient-completion endpoint.

Proof. Start from the readback seal exactness theorem. It already places the terminal seal S downstream of the regular rational row R, the stream window row W, and the dyadic tolerance row D.

Now apply the source obligation and universal handoff. The route to R, W, D is not free-standing; it first passes through U, F, E, so the readback and tolerance rows are terminal-route data for the same completion source.

Finally use the source-extension readback theorem. Since every R or W read is downstream of U, F, E and paired with D before S is visible, the Real seal remains a finite BEDC readback route rather than a host real, selected limit, quotient endpoint, compactness witness, or choice-selected completion. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorReadbackToleranceTerminalRoute`

Theorem 1892.21 (UniformCompletionFunctor functorial replay stability)**.** *Let* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P,$ *be an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier. Under functorial transport of the displayed source row* U*, the componentwise* hsame *row* H *and displayed* Cont *replay row* C *preserve the same route*

$$U, F, E, R, W, D, S, H, C, P, N.$$

The transported packet therefore exposes the same source, Cauchy handoff, universal-extension, readback, tolerance, Real seal, transport, replay, provenance, and local naming rows, with no additional completion object.

Proof. Project the accepted carrier and the transported source. The only source coordinate is U, and the handoff, extension, readback, tolerance, seal, and structural rows are attached to that same carrier.

Apply the NameCert obligations, source obligation, Cauchy handoff, and universal handoff. These order the consumer route as $U, F, E, R, W, D, S, H, C, P, N$ before any completion-facing data is exported.

Use H and C for the transported packet. Componentwise hsame moves each displayed row, while Cont replay presents the same row order to consumers. The provenance and local naming rows then cite the transported route without adding quotient completion equality, selected limits, host complete uniform spaces, compactness, or choice. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorFunctorialReplayStability`

Theorem 1892.22 (UniformCompletionFunctor completion consumer frontier)**.** *The completion-consumer frontier of an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier is exactly the displayed row family*

$$U, F, E, R, W, D, S, H, C, P, N.$$

A completion consumer may receive the source, handoff, universal-extension, readback, finite-window, dyadic, Real seal, transport, replay, provenance, and naming rows, and no further completion datum. In particular, quotient completions, selected limits, host complete uniform spaces, open-cover compactness, and choice are outside the frontier.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCompletionConsumerFrontier`

Proof. Carrier projection gives the candidate frontier. The definition of Definition 1892.1 lists exactly $U, F, E, R, W, D, S, H, C, P, N$ as visible rows, so any consumer-visible datum must be one of these rows or a replay through them.

The NameCert obligations identify how those rows are admitted. Carrier admission, source compatibility, handoff exactness, universal-extension ordering, readback and tolerance exactness, and ledger non-escape account for each row in the displayed family.

Finally use Definition 1892.23. It orders the same family as the completion-facing route and confirms that terminal structural rows only transport, replay, source, and name the displayed data. Because the carrier and its obligations contain no other coordinate, the excluded completion, compactness, and choice objects are not part of the consumer frontier. □

Theorem 1892.23 (UniformCompletionFunctor universal handoff)**.** *Every completion-facing consumer of an accepted* UniformCompletionFunctor$^{\uparrow}$ *carrier factors through the displayed route*

$$U \longmapsto F \longmapsto E \longmapsto R, W, D \longmapsto S, H, C, P, N.$$

Thus the consumer receives the uniform-completion source row, then the CauchyCompletionFunctor handoff, then the universal-extension ledger, and only then the regular rational, StreamName, DyadicRatCore, Real seal, transport, replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorUniversalHandoff`

Proof. Start with an accepted carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$. The only uniform-completion source coordinate is U, so every completion-facing request begins by projecting the displayed UniformCompletion$^{\uparrow}$ data.

The functorial handoff is then read through F. Its unit, bind, and classifier rows are attached to the same source row, and the universal-extension row E records the extension and uniqueness ledger available to the consumer after that handoff.

The readback rows are downstream of the extension ledger. Regular rational readback uses R, finite observation uses W, dyadic precision uses D, and the terminal real-name seal is exposed only through S after those requests have been replayed.

Finally H, C, P, N transport, replay, package, and name the same finite route. The carrier definition contains no coordinate for quotient completion equality, selected limits, host complete uniform spaces, open-cover compactness, or choice, so no completion-facing consumer can read such data from the handoff. □

Theorem 1892.24 (UniformCompletionFunctor Real seal route)**.** *Every accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *real-facing consumer must replay the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal in that order before exporting a completion result. The export route is therefore*

$$D \longmapsto W \longmapsto R \longmapsto S \longmapsto H, C, P, N$$

inside the accepted carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$*, downstream of the source, handoff, and universal-extension rows* U, F, E*.*

No real-facing consumer may replace this route by a host complete-space theorem, open-cover compactness argument, quotient completion, selected limit, or choice principle.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRealSealRoute`

Proof. Start with Definition 1892.23. It forces every completion-facing consumer through U, F, E before any readback, window, tolerance, or Real-seal row is available.

Use the carrier and obligation surface of Definition 1892.1 and Definition 1892.2. The dyadic tolerance row D supplies the precision budget for the subsequent finite-window read W; the window row then bounds the regular rational readback R; only after those rows have been displayed can the terminal Real seal S be read.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the carrier has no coordinate for host complete spaces, open-cover compactness, quotient completions, selected limits, or choice, none of those principles can be exported as a completion result. □

Theorem 1892.25 (UniformCompletionFunctor source-unit compatibility)**.** *Every accepted* $\mathsf{UniformCompletionFun}$ *packet reads the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row* U *before the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row* F*. Hence the functor unit is sourced from the displayed uniform-completion packet and cannot be sourced from a quotient completion, a selected limit, or a host complete uniform space.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorSourceUnitCompatibility`

Proof. Project the carrier of Definition 1892.1. The source coordinate U is the only row that supplies uniform-completion data to the packet, while F is explicitly the handoff row attached to that same source.

Apply Definition 1892.2. Its source-compatibility and handoff-exactness clauses require completion-facing reads to project U before any handoff through F is available.

Apply Definition 1892.23. The displayed route begins with U and then reads F, so the unit route is a ledger entry over the accepted source row rather than a datum recovered from quotient completion equality, selected limits, or a host complete uniform space. □

Theorem 1892.26 (UniformCompletionFunctor universal-extension uniqueness route)**.** *For every accepted* UniformCompletionFunctor$^{\uparrow}$ *packet, the universal-extension row E is consumed after U, F and before R, W, D, S. The uniqueness information therefore appears as a displayed ledger route from the source and functorial handoff into the readback, window, tolerance, and seal rows, not as a host complete-uniform-space theorem.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorUniversalExtensionUniquenessRou`

Proof. Project the accepted carrier

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N).$$

The row E is the only universal-extension coordinate, and the carrier places it between the source-handoff rows U, F and the downstream readback rows R, W, D, S.

Apply Definition 1892.2. The universal-extension ordering clause requires E to be read after the source row and CauchyCompletionFunctor handoff, before any terminal Real seal is exposed.

Apply Definition 1892.23. The consumer-visible route is $U \longmapsto F \longmapsto E \longmapsto R, W, D \longmapsto S, H, C, P, N$, so uniqueness is consumed as part of that finite ledger. Since the packet has no coordinate for a host complete-uniform-space theorem, quotient completion equality, selected limit, or choice principle, no stronger uniqueness source is exported. □

Theorem 1892.27 (UniformCompletionFunctor RegSeqRat readback totality)**.** *Every accepted completion-facing read that reaches the* RegSeqRat$^{\uparrow}$ *row R of a* UniformCompletionFunctor$^{\uparrow}$ *packet must first project the source row U, the functorial handoff row F, and the universal-extension row E, and must then expose the same* StreamName$^{\uparrow}$ *finite window W used by the readback. Thus R is a total displayed readback only for the route*

$$U, F, E, W, R,$$

not for quotient completion equality, selected representatives, host complete uniform spaces, open-cover compactness, or choice.

Proof. Project the carrier of Definition 1892.1. The row R occurs only after U, F, E have been displayed, and its window source is the same row W appearing in the carrier.

Apply Definition 1892.2. Its readback and tolerance clauses make R an obligation over the finite source, handoff, universal-extension, and window rows.

Use Definition 1892.23 and Definition 1892.26. Together they route every completion-facing consumer through U, F, E before any downstream readback row is inspected. Since no excluded completion or choice coordinate occurs in the carrier, the displayed readback route is total exactly over those rows. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.RegSeqRatReadbackTotality.UniformCompletionFunctorRegSe`

Theorem 1892.28 (UniformCompletionFunctor dyadic window stability)**.** *For every accepted* UniformCompletionFunctor$^{\uparrow}$ *packet, the* DyadicRatCore$^{\uparrow}$ *row D supplies the precision budget used by both the readback row R and the finite-window row W. Under componentwise* hsame *transport H and displayed* Cont *replay C, the same dyadic budget is preserved along the completion-facing route*

$$U, F, E, R, W, D, S.$$

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier dyadic window stability`

Proof. Read the carrier definition. The rows R, W, D occur together in the downstream part of $U, F, E, R, W, D, S, H, C, P, N$, so there is no separate tolerance source outside the displayed packet.

The NameCert obligations identify D as the tolerance row governing readback and window exactness. They also confine classifier-visible comparison to componentwise transport, which is the row H.

Finally apply the universal handoff and universal-extension uniqueness route. They force the consumer to replay R, W, D after U, F, E and before S. The displayed replay row C therefore preserves the same dyadic budget; no host complete-space or open-cover argument can replace it. □

Theorem 1892.29 (UniformCompletionFunctor Real seal nonescape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal row S of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet is reachable only after the source, handoff, universal-extension, readback, window, and dyadic rows*

$$U, F, E, R, W, D$$

have been displayed. The seal exports no quotient completion, selected limit, host complete uniform space, open-cover compactness, or choice principle.

Proof. Begin with the carrier and obligation surface. The seal row S is downstream from U, F, E, R, W, D, and the local NameCert obligations attach seal nonescape to that displayed order.

Use Definition 1892.23. It gives the completion-facing route from the source row through the functorial and universal-extension rows before readback, windows, tolerance, and the terminal seal are consumed.

Apply Definition 1892.26. Since uniqueness is already recorded as a finite ledger route before S, the seal cannot introduce a host completed object or selected limit. The excluded completion, compactness, and choice principles are not coordinates of the packet. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRealSealNonescapeFromDisplayedP`

Theorem 1892.30 (UniformCompletionFunctor ledger exactness)**.** *The carrier, obligation surface, and universal handoff of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet exhaust its completion-consumer ledger. Every exported route is a projection from*

$$U, F, E, R, W, D, S, H, C, P, N,$$

and every classifier-visible comparison is componentwise through the same rows. No exported route can bypass the displayed ledger to obtain quotient completion, selected limits, host complete uniform spaces, open-cover compactness, or choice.

Proof. Project the accepted carrier of Definition 1892.1. The displayed coordinates are exactly $U, F, E, R, W, D, S, H, C, P, N$, and the local classifier is stated only over those coordinates.

Apply Definition 1892.2 to account for carrier admission, source compatibility, handoff exactness, universal-extension ordering, readback and tolerance exactness, and ledger non-escape. Apply Definition 1892.23 to identify the order in which a completion-facing consumer can inspect those rows.

It remains to rule out escape from the ledger. Componentwise hsame transport is confined to H, displayed replay is confined to C, provenance is confined to P, and local naming is confined to N. Because no further coordinate is present, the packet exports exactly the displayed ledger and none of the excluded completion or choice principles. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorLedgerExactness`

Theorem 1892.31 (UniformCompletionFunctor carrier admission)**.** *Every accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet admits exactly one displayed carrier row*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

whose coordinates are read as $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows. Admission is refused for any completion-facing route that omits the* BHist *carrier row, bypasses* U*, or treats* Pkg *and* $\mathsf{NameCert}$ *as external annotations rather than displayed coordinates of the same packet.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier admission`

Proof. Project the carrier definition. Its rows are visible as one finite BHist packet, so admission is not a separate source-equivalence transport; it is the constructive projection of the displayed tuple.

The source row U is the unique $\mathsf{UniformCompletion}^{\uparrow}$ coordinate, and the handoff row F is the unique $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ coordinate attached to that source. The universal row E, readback row R, window row W, dyadic row D, and terminal seal S are then admitted only as downstream coordinates of the same packet.

Finally H, C, P, N expose hsame, Cont, Pkg, and $\mathsf{NameCert}$ inside the carrier. Since no row lies outside the tuple, a route without the displayed BHist packet, source coordinate, provenance coordinate, or naming coordinate is not an accepted $\mathsf{UniformCompletionFunctor}^{\uparrow}$ carrier. □

Theorem 1892.32 (UniformCompletionFunctor functoriality)**.** *Let a completion-facing request read an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N).$$

The functorial unit, bind, and classifier routes exposed by the packet are exactly the finite route compositions through $U, F, E, R, W, D, S, H, C, P, N$*. In particular, functoriality is witnessed by the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row* F*, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row* E*, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *observation rows* W, R*, the* $\mathsf{Real}^{\uparrow}$ *seal* S*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*; it is not transported from a source-equivalence theorem outside the packet.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorFunctoriality`

Proof. Read the packet from left to right. The source coordinate U determines the uniform-completion input, and F supplies the unit, bind, and classifier handoff rows for that same input.

Next, E records the extension and uniqueness ledger consumed by the handoff. The finite observation rows W, R, D provide stream windows, regular rational readback, and dyadic tolerance before the terminal $\mathsf{Real}^{\uparrow}$ seal S can be read.

The functorial comparison then composes through H, C, P, N. Componentwise hsame transport, displayed Cont replay, provenance, and local naming are all coordinates of the packet, so the composition is finite route composition over BHist rows rather than transport from an external source equivalence. □

Theorem 1892.33 (UniformCompletionFunctor completion handoff)**.** *Every completion consumer receiving an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet must factor its read through*

$$\mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRa}$$

Thus the packet hands completion data to downstream consumers by displayed rows only: the source row U*, functorial handoff* F*, universal-property row* E*, window and readback rows* W, R, D*, seal row* S*, transport* H*, replay* C*, provenance* P*, and naming* N*.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCompletionHandoff`

Proof. Start with the carrier row $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$. A completion consumer has no coordinate other than these displayed rows, so it first reads the $\mathsf{UniformCompletion}^{\uparrow}$ source U and then the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff F.

The universal handoff is mediated by E. Before a real-facing result is exposed, the consumer must read the finite $\mathsf{StreamName}^{\uparrow}$ window row W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, after which S supplies the terminal $\mathsf{Real}^{\uparrow}$ seal.

The remaining structural rows keep the route inside the packet. The BHist carrier is the ambient finite packet, H gives componentwise hsame transport, C gives displayed Cont replay, P gives Pkg provenance, and N gives local $\mathsf{NameCert}$ naming. This is a constructive completion handoff by finite projections and route composition, not a source-equivalence transport. □

Theorem 1892.34 (UniformCompletionFunctor root obligation surface)**.** *Before any completion consumer can read the functorial extension exported by an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N),$$

the packet must expose exactly the root obligation surface

$$U, F, E, R, W, D, S, H, C, P, N.$$

Here U *is the source uniformity row,* F *is the Cauchy-completion unit and handoff row,* E *is the universal-extension row,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* W *is the* $\mathsf{StreamName}^{\uparrow}$ *scheduling row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-comparison row,* S *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* H *is componentwise transport,* C *is replay,* P *is provenance, and* N *is local naming. No completion consumer can read the functorial extension before this surface is displayed, and the ledger-exactness row excludes quotient completions, selected limits, host complete uniform spaces, open-cover compactness, and choice.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRootObligationSurface`

Proof. Project the carrier of Definition 1892.1. It displays the source row U, handoff row F, universal-extension row E, readback row R, scheduling row W, tolerance row D, seal row S, and the structural rows H, C, P, N as one finite BHist packet.

Apply Definition 1892.2. Its carrier admission, source compatibility, handoff exactness, universal-extension ordering, readback and tolerance exactness, and ledger non-escape clauses assign each required obligation to one of the displayed rows.

Use Definition 1892.23 and Definition 1892.33. Together they force every completion-facing read to pass through U, F, E, R, W, D, S before transport, replay, provenance, and local naming are consumed.

Finally apply Definition 1892.30. Since every exported route is a projection from the same row family and no excluded completion or choice datum has a carrier coordinate, the displayed rows are exactly the root obligation surface needed before the functorial extension can be read. □

Theorem 1892.35 (UniformCompletionFunctor route obligations)**.** *Every accepted* UniformCompletionFunctor$^{\uparrow}$ *route must read the* CauchyCompletionFunctor$^{\uparrow}$ *handoff row, the* CompletionUniversalProperty$^{\uparrow}$ *universal-property row, the* DyadicRatCore$^{\uparrow}$ *tolerance row, the* Real$^{\uparrow}$ *seal row, the* RegSeqRat$^{\uparrow}$ *readback row, the* StreamName$^{\uparrow}$ *window row, and the* UniformCompletion$^{\uparrow}$ *source row before exporting a functorial completion handoff. Equivalently, every completion-facing handoff is a projection from*

$$U, F, E, R, W, D, S, H, C, P, N$$

inside the displayed BHist *carrier, with no host quotient completion or external selector exported by the packet.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier route obligations`

Proof. Project the accepted carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$. The carrier row already displays the UniformCompletion source, CauchyCompletionFunctor handoff, universal-property ledger, regular readback, stream window, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows as one finite packet.

Use the NameCert obligations and the root obligation surface. The source row U is read first, the handoff row F is attached to that source, the universal-property row E is downstream of both, and the readback block R, W, D must be visible before the terminal seal S.

Finally apply the universal handoff and ledger exactness theorems. They identify $U, F, E, R, W, D, S, H, C, P, N$ as the only consumer-visible route. Since the carrier has no coordinate for host quotient completion or selected representatives, the functorial completion handoff exports only the displayed BEDC rows. □

Theorem 1892.36 (UniformCompletionFunctor unit root obligation)**.** *The unit map of an accepted* UniformCompletionFunctor$^{\uparrow}$ *completion route must expose the source carrier row U, the* CauchyCompletionFunctor$^{\uparrow}$ *handoff row F, the Cauchy filter or* RegSeqRat$^{\uparrow}$ *window row R, the terminal* Real$^{\uparrow}$ *seal S, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before any completed point is exported.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorCarrier unit root obligation`

Proof. Start with the source obligation of Definition 1892.3. It fixes the source carrier row U as the first visible row of the completion route.

Use the Cauchy handoff of Definition 1892.4. The handoff row F and readback row R expose the Cauchy filter or regular rational window before the completed point is available.

The Real seal nonescape theorem Definition 1892.9 keeps the terminal row S from becoming ambient completeness or a hidden selected limit. The root obligation surface of Definition 1892.34 then adds only H, C, P, N for transport, replay, provenance, and local naming. □

Theorem 1892.37 (UniformCompletionFunctor extension root obligation)**.** *Every uniformly continuous extension read exported by an accepted* UniformCompletionFunctor$^{\uparrow}$ *packet factors through the displayed source-extension ledger*

$$U, F, E, R, W, D, S, H, C, P, N.$$

The read exports no selected limit, quotient equality, host function extensionality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorExtensionRootObligation`

Proof. Project the universal-extension row E from the carrier of Definition 1892.1. It is downstream of the source row U and the Cauchy handoff row F.

Apply Definition 1892.23. The extension read must pass through the source, handoff, readback, scheduling, tolerance, and Real seal rows before it reaches the structural rows.

Use Definition 1892.34. It identifies the same finite row family as the root surface, so the extension is a displayed source-extension ledger rather than a selected limit, quotient equality, host function-extensionality argument, or ambient completeness theorem. □

Theorem 1892.38 (UniformCompletionFunctor functorial root obligation)**.** *Composition of two accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packets preserves the displayed source, completion, extension, transport, replay, and provenance rows. The composite route may read only the two source rows, the two Cauchy-completion handoff rows, the two universal-extension rows, the displayed readback and tolerance rows, componentwise transport, continuation replay, provenance, and local naming rows already present in the packets.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorFunctorialRootObligation`

Proof. Start with the functoriality theorem Definition 1892.32. It states that unit, bind, and classifier routes are finite route compositions through the displayed carrier rows.

For each packet, use the source obligation and Cauchy handoff, Definition 1892.3 and Definition 1892.4. These keep the source and completion rows visible before any composite extension is read.

The extension root obligation above places uniformly continuous extension reads on the same $U, F, E, R, W, D, S, H, C, P, N$ route. Componentwise transport and displayed replay compose only those rows, while provenance records the two packet sources. Thus composition preserves the displayed source, completion, extension, transport, replay, and provenance data without importing an external completion principle. □

Theorem 1892.39 (UniformCompletionFunctor L10 source admission)**.** *An accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet admits an L10 completion source only through the displayed finite route*

$$\mathsf{UniformCompletion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Concretely, a completion-facing source read must project the $\mathsf{UniformCompletion}^{\uparrow}$ *row* U*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S*, the ambient* BHist *packet, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. It is not admitted by source-equivalence transport outside the packet.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorL10SourceAdmission`

Proof. Project the accepted carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$. The source row U is public only as a coordinate of the same finite BHist packet that carries R, W, D, S, H, C, P, N.

Use Definition 1892.14 for the first projection through U. Then use Definition 1892.16 to force the L10 readback through D, W, R before the Real seal S is consumed.

The structural rows finish the admission route. Componentwise hsame transport and displayed Cont replay preserve the projected rows, while Pkg provenance and local $\mathsf{NameCert}$ naming record the same finite source. No external source-equivalence object is a coordinate of the packet, so it cannot admit the L10 source. □

Theorem 1892.40 (UniformCompletionFunctor finite-window functoriality)**.** *Functorial composition of accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packets preserves the finite-window completion route through*

$$U, F, E, D, W, R, S, H, C, P, N.$$

For each input packet, the composite may read only the $\mathsf{UniformCompletion}^{\uparrow}$ *source row* U*, the Cauchy handoff row* F*, the universal-extension row* E*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*.*

Proof. Begin with Definition 1892.32. It identifies functorial unit, bind, and classifier reads with finite route composition through the displayed carrier rows.

For each composed packet, apply Definition 1892.33. The route first projects U, F, E and then reads the finite tolerance, window, and readback block D, W, R before the terminal Real seal.

It remains to check that composition does not add a hidden source. The rows H and C perform componentwise transport and replay over the same finite windows, while P and N preserve provenance and local naming. Thus functoriality is a finite-window induction over the displayed route, not transport from an external source-equivalence theorem. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorWindowFunctoriality`

Theorem 1892.41 (UniformCompletionFunctor Real-seal consumer route)**.** *Every Real-facing consumer of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet must reach the* $\mathsf{Real}^{\uparrow}$ *seal by the concrete L10 route*

$$\mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCe}$$

The consumer receives a sealed completion read only after the dyadic tolerance, finite stream window, regular rational readback, componentwise transport, replay, provenance, and local naming rows have been projected.

Proof. Start with Definition 1892.24. It places the Real seal downstream from the source, handoff, universal-extension, readback, window, and dyadic rows.

Apply Definition 1892.39. The source is admitted only through the same BHist packet and the displayed D, W, R, S, H, C, P, N rows.

Finally use Definition 1892.30. The ledger has no coordinate for selected limits, quotient completion equality, host complete uniform spaces, open-cover compactness, or choice. Therefore every Real-facing consumer route is the finite L10 route through the displayed rows. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRealSealConsumerRoute`

Theorem 1892.42 (UniformCompletionFunctor scoped L10 obligation route)**.** *The scoped obligation surface of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet is exactly the finite route*

$$\mathsf{UniformCompletion}^{\uparrow},\ \mathsf{CauchyCompletionFunctor}^{\uparrow},\ \mathsf{CompletionUniversalProperty}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},$$

Concretely, every source read must project the row U*, every target completion read must pass through the Cauchy-completion handoff* F *and universal-property row* E*, every regular and real-facing read must display* R, S, W*, and every structural replay must remain inside* H, C, P, N*. No quotient completion class, ambient completeness assumption, host complete uniform space, open-cover compactness principle, or choice-selected representative belongs to the scope.*

Proof. Start with the carrier and local NameCert obligations, Definition 1892.1 and Definition 1892.2. They list exactly the source row U, handoff row F, universal-extension row E, readback rows R, W, D, S, and structural rows H, C, P, N.

Use Definition 1892.23 and Definition 1892.34. These theorems order the same rows from the UniformCompletion source through the CauchyCompletionFunctor and CompletionUniversalProperty handoff before any RegSeqRat, StreamName, DyadicRatCore, or Real seal row can be consumed.

Finally apply Definition 1892.41 and Definition 1892.30. The Real-facing route remains inside the displayed L10 packet, and the ledger excludes quotient completion classes, ambient completeness, host complete uniform spaces, open-cover compactness, and choice. Hence the scoped obligation surface is the finite BEDC route named in the statement. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorScopedL10ObligationRoute`

Theorem 1892.43 (UniformCompletionFunctor public NameCert export)**.** *An accepted* UniformCompletionFunctor *packet exports its public* NameCert *only after reading the* CauchyCompletionFunctor$^{\uparrow}$ *route, the* UniformCompletion$^{\uparrow}$ *source,* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance rows, the* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The export refuses quotient completion classes, selected limits, countable choice, and ambient Real completeness.*

Proof. Begin with the carrier and the NameCert obligations. They admit exactly the source row U, handoff row F, universal-extension row E, readback rows R, W, D, S, and structural rows H, C, P, N.

Apply the completion handoff and L10 source-admission routes. The public consumer first reads the UniformCompletion$^{\uparrow}$ source and CauchyCompletionFunctor$^{\uparrow}$ handoff, then exposes StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ tolerance, and the terminal Real$^{\uparrow}$ seal.

Finally use ledger exactness. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same finite route, while quotient completion, selected limits, countable choice, and ambient Real completeness have no coordinate in the packet. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorPublicNamecertExport`

Theorem 1892.44 (UniformCompletionFunctor L10 bridge schema)**.** *An accepted* UniformCompletionFunctor$^{\uparrow}$ *packet supplies a bridge from its public* NameCert *export to the concrete L10 completion schema exactly through* UniformCompletion$^{\uparrow}$*,* CauchyCompletionFunctor$^{\uparrow}$*,* CompletionUniversalProperty$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The bridge schema is the finite route that first displays the public export and then reuses the same source, functorial handoff, universal-extension, finite-window, regular-readback, dyadic-tolerance, Real-seal, transport, replay, provenance, and local naming rows for L10 completion consumers.*

Proof. Start with the scoped L10 obligation route, Definition 1892.42. It identifies the finite route through the source, completion handoff, universal-property row, regular readback, Real seal, StreamName windows, and structural rows.

Apply the Real-seal consumer route and ledger exactness, Definition 1892.41 and Definition 1892.30. These results keep every completion-facing read inside the displayed dyadic, window, readback, Real, transport, replay, provenance, and local naming rows.

Finally use the public NameCert export, Definition 1892.43. The export supplies the public endpoint, while the previous routes provide the concrete L10 completion schema consumed downstream. No source-equivalence parameters or abstract carrier transport rows are introduced. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorBridgeSchema`

Theorem 1892.45 (UniformCompletionFunctor RegSeqRat-to-Real bridge)**.** *An accepted* UniformCompletionFunct *packet whose functorial handoff consumes* StreamName$^{\uparrow}$ *windows and* RegSeqRat$^{\uparrow}$ *readbacks reaches its* Real$^{\uparrow}$ *endpoint only through the same displayed uniform-completion functor rows, dyadic tolerance ledger, RegSeqRat handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The bridge exports no quotient completion equality, selected representative, ambient Real completeness theorem, or detached standard bridge.*

Proof. Start with the public export and functorial handoff routes, Definition 1892.43 and Definition 1892.44. They keep every completion-facing read inside the source row U, handoff row F, universal-extension row E, readback rows R, W, D, S, and structural rows H, C, P, N.

Use the L10 readback path already carried by Definition 1892.1. A finite StreamName$^{\uparrow}$ window is read through the RegSeqRat$^{\uparrow}$ handoff and the DyadicRatCore$^{\uparrow}$ tolerance ledger before the terminal Real$^{\uparrow}$ seal is exposed.

Finally apply the Real-seal consumer route of Definition 1892.41. Since the carrier has no coordinate for quotient completion equality, selected representatives, ambient Real completeness, or a detached standard bridge, the RegSeqRat-to-Real endpoint remains the displayed finite route through D, W, R, S, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorRegSeqRealBridge`

Theorem 1892.46 (UniformCompletionFunctor L10 status product noncollapse)**.** *An accepted* UniformCompletionFunctor$^{\uparrow}$ *packet exposes four separate local status faces for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *together with the* UniformCompletion$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, *and* CompletionUniversalProperty$^{\uparrow}$ *rows carried by the same completion route. No aggregate completion status route may replace the four face-local closurestatus, formalstatus, and bridge rows attached to those L10 faces.*

Proof. Start with the public export and bridge schema, Definition 1892.43 and Definition 1892.44. They expose the finite completion route through the source row, functorial handoff, universal-extension row, dyadic tolerance row, StreamName window row, RegSeqRat readback row, Real seal, and structural rows.

Use the RegSeqRat-to-Real bridge of Definition 1892.45. It keeps the readback path face-local: dyadic tolerance, stream windows, regular rational readback, and the terminal Real seal remain separately visible before the completion-facing endpoint is read.

The carrier rows in Definition 1892.1 supply no fused status coordinate. Therefore a downstream completion consumer may project the UniformCompletion, CauchyCompletion, and universal-property rows, but it cannot replace the four L10 face records by a single aggregate closurestatus, formalstatus, or bridge row. □

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorL10StatusProductNoncollapse`

Falsifiable prediction: Every UniformCompletionFunctor$^{\uparrow}$ completion-facing read factors through one UniformCompletion$^{\uparrow}$ source row, one CauchyCompletionFunctor$^{\uparrow}$ handoff row, one CompletionUniversalProperty$^{\uparrow}$ universal-extension row, one RegSeqRat$^{\uparrow}$ readback row, one StreamName$^{\uparrow}$ finite-window row, one DyadicRatCore$^{\uparrow}$ tolerance row, one terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: uniformcompletion, cauchycompletionfunctor, completionuniversalproperty, regseqrat, streamname, dyadicratcore, real: UniformCompletionFunctor$^{\uparrow}$ is not bijective to any

listed sibling because it jointly carries the source, functorial handoff, universal-extension, regular readback, finite-window, dyadic tolerance, Real seal, transport, replay, provenance, and local NameCert rows as one finite completion-consumer packet.

Theorem 1892.47 (UniformCompletionFunctor bridge target interface)**.** *Every target-side bridge read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier* $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ *factors through the displayed rows*

$$U, F, E, R, W, D, S, H, C, P, N.$$

In particular, the target interface preserves the $\mathsf{UniformCompletion}^{\uparrow}$ *source row* U*, the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row* F*, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* S *before any transport, replay, provenance, or local naming row is exported.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorBridgeTargetInterface`

Proof. Project the carrier of Definition 1892.1. The target-side bridge can read only the displayed coordinates $U, F, E, R, W, D, S, H, C, P, N$.

Use the source obligation, Definition 1892.3. It fixes U as the UniformCompletion source for every completion-facing read, so the bridge target cannot begin from a target seal or from an isolated handoff row.

Apply the Cauchy handoff theorem, Definition 1892.4, and the bridge source lock, Definition 1892.5. These place the CauchyCompletionFunctor row and the universal-property row downstream of the same source, then route the bridge through the regular readback, finite windows, and dyadic tolerance rows.

Finally use the Real-seal nonescape theorem, Definition 1892.9. It keeps S terminal for the displayed readback route and confines H, C, P, N to componentwise transport, replay, provenance, and local naming. Therefore every target-side bridge read exposes exactly the listed interface and no quotient completion, selected limit, host complete uniform space, open-cover compactness theorem, or choice principle. □

Theorem 1892.48 (UniformCompletionFunctor target-source order)**.** *Every target-side bridge read of an accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *packet reaches the terminal target seal only after the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{StreamName}^{\uparrow}$ *window row, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row have been displayed. The target-side route therefore reads*

$$U \longmapsto F \longmapsto E \longmapsto R \longmapsto W \longmapsto D \longmapsto S$$

inside the carrier $\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$ *before any terminal target seal, transport, replay, provenance, or local naming row is consumed.*

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorTargetSourceOrder`

Proof. Project the carrier of Definition 1892.1. The target-side bridge has no row other than $U, F, E, R, W, D, S, H, C, P, N$, so the terminal seal can only be reached through the displayed source-to-target route.

Apply Definition 1892.3. It places the $\mathsf{UniformCompletion}^{\uparrow}$ source row first for every completion-facing read and prevents the bridge from starting at the terminal seal.

Use Definition 1892.4 together with Definition 1892.5. These force the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ row to remain downstream of the source row before the bridge can read regular sequences, finite StreamName windows, or dyadic tolerances.

Finally apply Definition 1892.47. The existing target interface exposes the readback, window, tolerance, and terminal seal rows in the displayed carrier order and confines H, C, P, N to transport, replay, provenance, and local naming. Hence a target-side bridge read is source-before-target rather than a direct read of the terminal seal. □

Theorem 1892.49 (UniformCompletionFunctor bridge route)**.** *Every accepted* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *carrier*

$$\mathcal{F} = (U, F, E, R, W, D, S, H, C, P, N)$$

packages a bridge route from its public completion-facing NameCert *export to the L10 completion schema through exactly the displayed rows*

$\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Dyadi

The bridge first exposes the uniform-completion source U, then the Cauchy-completion handoff F, the universal-property row E, the regular readback R, the finite window row W, the dyadic tolerance ledger D, and the terminal Real seal S before any transport, replay, provenance, or local naming row is exported.

Lean4 ✓ `BEDC.Derived.UniformCompletionFunctorUp.UniformCompletionFunctorBridgeRoute`

Proof. Start with the public export of Definition 1892.43. It already binds every completion-facing consumer to the displayed source, functorial handoff, universal-extension, readback, finite-window, dyadic-tolerance, Real-seal, transport, replay, provenance, and local naming rows.

Apply the bridge schema of Definition 1892.44. That schema reads the same public route as a standard bridge surface: $\mathsf{UniformCompletion}^{\uparrow}$ supplies the source, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ supplies the handoff, and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ supplies the extension ledger before L10 readback rows are consumed.

Use the target interface of Definition 1892.47. It keeps the target-side bridge ordered through R, W, D, S and confines H, C, P, N to componentwise transport, displayed replay, provenance, and local naming.

Thus the bridge route is exactly the finite package named in the statement. The carrier contains no quotient completion equality, selected limit, host complete uniform space, open-cover compactness theorem, or choice-selected representative, so none can be exported by the bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionFunctor}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionFunctor}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1892.1, Definition 1892.2, Definition 1892.23, Definition 1892.34, Definition 1892.42, Definition 1892.43, Definition 1892.47, and Definition 1892.49 close the finite bridge route through $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host complete uniform spaces, open-cover compactness, choice principles, Lean verification, or bridge checking.

Upgrade path: The mature L10 functorial handoff is complete on the paper axis; Lean verification and bridge checking remain unclaimed.

Constructive story: A $\mathsf{UniformCompletionFunctor}^{\uparrow}$ packet is generated from a $\mathsf{UniformCompletion}^{\uparrow}$ source row, a $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff row, a $\mathsf{CompletionUniversalProperty}^{\uparrow}$ extension ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1893

A Concrete Naming Certificate for $\mathsf{NatRealEmbedding}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{NatRealEmbedding}^{\uparrow}$ packet records the finite route by which a displayed $\mathsf{Nat}^{\uparrow}$ unary source row becomes a $\mathsf{Real}^{\uparrow}$ name through an exact rational constant. It sits over the natural-number certificate of chapter 28, the rational source surface of chapter 37, the rational-to-real constant route of chapter 1849, the finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic zero-tail tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet routes a displayed $\mathsf{Nat}^{\uparrow}$ unary source row into a rational constant row, constant $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ zero-tail tolerance, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Definition 1893.1 (Nat-real embedding carrier)**.** *A* $\mathsf{NatRealEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (n, q, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *n is the* $\mathsf{Nat}^{\uparrow}$ *unary source row naming the natural-number input.*
2. *q is the* $\mathsf{Rat}^{\uparrow}$ *rational constant row obtained by reading n as $n/1$.*
3. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule whose admitted finite windows all read the same rational row q.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the constant schedule S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero-tail tolerance ledger attached to the finite reads of R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after n, q, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the natural source, rational constant row, constant stream schedule, regular readback, dyadic tolerance ledger, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a nat-real embedding request through $n, q, S, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{NatRealEmbedding}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NatRealEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $n, q, S, R, D, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host $\mathsf{Nat}^{\uparrow}$ *equality, host real equality, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1893.2 (Nat-real embedding NameCert obligations)**.** *For every accepted* $\mathsf{NatRealEmbedding}^{\uparrow}$ *carrier $K = (n, q, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NatRealEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the natural source, rational constant row, constant stream windows, regular rational readback, dyadic zero-tail tolerance ledger, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *source admission, requiring every exported constant to pass through the displayed* $\mathsf{Nat}^{\uparrow}$ *row n before the rational row q is read;*
3. *constant-window exactness, requiring every admitted* $\mathsf{StreamName}^{\uparrow}$ *window in S to replay the same rational constant row q and no independent tail schedule;*
4. *regular-readback admission, requiring R to expose the constant rational name only through the displayed windows in S;*
5. *dyadic zero-tail tolerance, requiring D to answer finite regularity requests by the zero-tail ledger attached to q, S, R;*
6. *Real seal nonescape, requiring E to be downstream of n, q, S, R, D and to expose no quotient stream, selected limit, host* $\mathsf{Nat}^{\uparrow}$ *equality, host real equality, trichotomy, countable-choice selector, ambient completeness theorem, Lean verification credential, or bridge credential;*
7. *ledger exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the same finite nat-real embedding packet.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.NatRealEmbeddingUp.NatRealEmbeddingTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1893.1. The accepted packet displays exactly the natural source, rational constant row, constant windows, regular readback, dyadic zero-tail ledger, terminal real seal, and structural rows.

Source admission and constant-window exactness are forced by row order. A real-facing constant first reads n, then the rational row q, and every window in S is attached to that same rational row rather than to a separate stream seed.

The regular-readback and dyadic-tolerance rows are downstream. The row R reads the constant windows as a regular rational name, while D supplies the zero-tail tolerance ledger for finite regularity tests.

The real seal and ledger rows cannot add external principles. The row E is reached only after n, q, S, R, D, and the rows H, C, P, N preserve, replay, source, and name the same displayed packet. Since none of the excluded objects appears as a coordinate, the listed rows exhaust the local surface. □

Theorem 1893.3 (Nat-real embedding Real seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{NatRealEmbedding}^{\uparrow}$ *carrier $K = (n, q, S, R, D, E, H, C, P, N)$ factors through the finite route*

$$n, q, S, R, D \longmapsto E$$

before transport, replay, provenance, or local naming can be read. Consequently the embedding of a natural-number constant into the real-name layer is witnessed by the displayed $\mathsf{Nat}^{\uparrow}$ *source, rational constant row, constant* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *zero-tail tolerance ledger, not by quotienting streams or selecting a limit.*

Proof. Start with an exported real seal. The carrier has only one real-facing coordinate, namely E, and that row is listed after the natural source, rational constant, constant-window, regular-readback, and dyadic-ledger rows.

The source row n fixes the natural-number input. The rational row q records the exact constant $n/1$, and the stream row S opens only finite windows over that same rational row.

The regular readback row R reads those windows as a constant regular rational name. The dyadic ledger D records the zero-tail tolerance facts needed by the displayed regularity requests.

Only after these five rows are fixed may E be read as a $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming preserve that same order, so the exported seal factors through n, q, S, R, D before any structural row is consulted. □

Closure status for $\mathsf{NameCert}_{\mathsf{NatRealEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NatRealEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1893.1, Definition 1893.2, and Definition 1893.3 seed the finite natural-constant embedding route from $\mathsf{Nat}^{\uparrow}$ through a rational constant row, constant $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ zero-tail tolerance, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NatRealEmbedding}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.NatRealEmbeddingUp.NatRealEmbeddingTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host $\mathsf{Nat}^{\uparrow}$ equality, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source admission, constant-window exactness, regular-readback admission, dyadic zero-tail tolerance, Real seal nonescape, ledger exhaustion, and factorization proofs for BEDC.Derived.NatRealEmbeddingUp.

Constructive story: A $\mathsf{NatRealEmbedding}^{\uparrow}$ packet is generated from a NatUp unary source row, RatUp rational constant row, constant StreamName windows, RegSeqRat constant readback, DyadicRatCore zero-tail tolerance ledger, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 1894

A Concrete Naming Certificate for $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ packet records the reverse-triangle estimate for displayed regular rational Cauchy real names as a finite route through subtraction, absolute-value readbacks, and a dyadic tolerance ledger. It sits over the regular source rows of chapter 301, the finite window discipline of chapter 126, the dyadic absolute-value surface of chapter 293, the regular absolute-value lift of chapter 1499, the subtraction route of chapter 1696, the real absolute-value boundary of chapter 1608, and the terminal real-name seal of chapter 38. The packet exposes the finite inequality route behind $||x| - |y|| \leq |x - y|$; it is not host real order, quotient equality of Cauchy streams, a selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1894.1 (Regular Cauchy reverse-triangle carrier)**.** *A* $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, S, A_X, A_Y, D, A_D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows for displayed regular rational Cauchy real names.*
2. *S is the* $\mathsf{RegularCauchySubtraction}^{\uparrow}$ *route for $X - Y$, exposing only its source rows, sign-flip-plus-sum route, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance rows, and subtraction readback.*
3. *A_X and A_Y are the two* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *routes for the source rows X and Y.*
4. *D is the* $\mathsf{RegularCauchySubtraction}^{\uparrow}$ *route for the displayed difference $|X| - |Y|$, using the readbacks exported by A_X and A_Y.*
5. *A_D is the* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *route for the regular readback of $|X| - |Y|$.*
6. *L is the dyadic comparison ledger whose finite rows read the endpoint-and-tolerance data from A_X, A_Y, D, A_D, S and record the inequality window $||x| - |y|| \leq |x - y|$ at each requested dyadic tolerance.*
7. *R is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the bounded absolute difference, assembled only after the subtraction and absolute-value rows have been displayed.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R and the finite comparison ledger L have been exposed.*

9. *H records componentwise* hsame *transport for the two source rows, subtraction routes, absolute-value routes, comparison ledger, readback, seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from any reverse-triangle-facing precision request through $X, Y, S, A_X, A_Y, D, A_D$*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{RegularCauchyAbs}^{\uparrow}$, $\mathsf{RegularCauchySubtraction}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReverseTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, A_X, A_Y, D, A_D, L, R, E, H, C, P, N$. The carrier has no coordinate for host real order, quotient Cauchy equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 (definition) `BEDC.Derived.RegularCauchyReverseTriangleUp.RegularCauchyReverseTriangleUp`

Theorem 1894.2 (Regular Cauchy reverse-triangle NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ *carrier*

$$T = (X, Y, S, A_X, A_Y, D, A_D, L, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReverseTriangle}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the $X-Y$ subtraction route, the absolute-value routes for both sources, the subtraction route for $|X|-|Y|$, the absolute-value route for that difference, the dyadic comparison ledger, the resulting readback, and the structural rows;*

2. *subtraction handoff, requiring S and D to expose their outputs only through the finite* $\mathsf{RegularCauchySubtraction}^{\uparrow}$ *route;*

3. *absolute-value handoff, requiring A_X, A_Y, A_D to expose their outputs only through the finite* $\mathsf{RegularCauchyAbs}^{\uparrow}$ *route and its* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint-and-tolerance ledger;*

4. *comparison exactness, requiring L to compare the displayed dyadic windows for $||x|-|y||$ and $|x-y|$ before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives a bounded read;*

5. *Real seal nonescape, requiring E to be downstream of R and L and to expose no host order, quotient equality, selected limit, trichotomy, or completeness row;*

6. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the same finite reverse-triangle packet.*

No reverse-triangle obligation is stored outside these finite rows.

Theorem 1894.3 (Regular Cauchy reverse-triangle RegSeqRat handoff)**.** *For every accepted* $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ *carrier $T = (X, Y, S, A_X, A_Y, D, A_D, L, R, E, H, C, P, N)$, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R is assembled only after the packet displays the source rows X, Y, the subtraction readback for $X-Y$, the absolute-value readbacks for X, Y, the subtraction readback for $|X|-|Y|$, the absolute-value readback for that difference, and the dyadic comparison ledger L. Thus a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of the reverse-triangle estimate reads the finite route*

$$X, Y \longmapsto S, A_X, A_Y \longmapsto D, A_D \longmapsto L \longmapsto R$$

through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{RegularCauchySubtraction}^{\uparrow}$, *and* $\mathsf{RegularCauchyAbs}^{\uparrow}$, *with componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Theorem 1894.4 (Regular Cauchy reverse-triangle Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealAbs}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ *carrier reaches the seal row* E *only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *and the comparison ledger* L *have been displayed. The real-facing boundary exposes the finite source rows, subtraction routes, absolute-value routes, dyadic tolerance comparison ledger for* $||x| - |y|| \leq |x - y|$*, regular readback, componentwise transport, continuation replay, provenance, and local naming. It exposes no host real order, quotient Cauchy equality, selected limit, trichotomy witness, ambient completeness principle, Lean verification, or public bridge row.*

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReverseTriangle}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReverseTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1894.1, Definition 1894.2, Definition 1894.3, and Definition 1894.4 seed the finite reverse-triangle route through two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, subtraction and absolute-value routes, dyadic comparison ledger, resulting readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReverseTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real order, quotient Cauchy equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subtraction handoff, absolute-value handoff, comparison exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyReverseTriangleUp.

Constructive story: A $\mathsf{RegularCauchyReverseTriangle}^{\uparrow}$ packet is generated from two RegSeqRat source rows, finite StreamName windows, subtraction routes for $X - Y$ and $|X| - |Y|$, RegularCauchyAbs routes for X, Y, and $|X| - |Y|$, DyadicAbsoluteValue tolerance rows, a comparison ledger for $||x| - |y|| \leq |x - y|$, a RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Chapter 1895

A Concrete Naming Certificate for $\mathsf{CantorFunction}^{\uparrow}$

Following Cantor and constructive analysis, the $\mathsf{CantorFunction}^{\uparrow}$ packet records the Cantor ternary-prefix to binary-prefix function as finite BEDC data. It depends on the retained-prefix and deleted-gap carrier of chapter 1530, the graph and pointwise-modulus surface of chapter 130, the compact source discipline of chapter 129, the dyadic readback ledger of chapter 418, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet exposes only finite ternary-prefix inspection, binary-prefix output, graph-row routing, transport, continuation, provenance, and local naming; it does not import measure theory, singularity analysis, host function extensionality, quotient real equality, or selected infinite branches.

Definition 1895.1 (Cantor function carrier)**.** *A* $\mathsf{CantorFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, B, G, E, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{CantorSet}^{\uparrow}$ *source-prefix row, naming a retained finite ternary prefix and the displayed deleted-gap checks inherited from the Cantor set certificate.*
2. *T is the ternary retained-prefix ledger, recording the left/right retained-third decisions that have been inspected and the finite depth at which the packet is read.*
3. *B is the binary output-prefix ledger, recording the corresponding finite binary prefix and the dyadic precision window consumed by* $\mathsf{BinaryExpansion}^{\uparrow}$ *readers.*
4. *G is the graph row, pairing the displayed source prefix with the displayed output prefix before any real-facing seal is opened.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the binary output ledger through the regular readback route exposed by* $\mathsf{BinaryExpansion}^{\uparrow}$*.*
6. *H stores componentwise* hsame *transport for the Cantor source prefix, ternary retained-prefix ledger, binary output-prefix ledger, graph row, real-seal row, continuation replay, provenance, and local naming row.*
7. *C stores displayed* Cont *replay from retained-prefix requests to binary-prefix output, from binary-prefix output to the graph row, and from the graph row through the continuous-map and real-seal handoff rows.*

8. *P is the* Pkg *provenance over* $\mathsf{CantorFunction}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BinaryExpansion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorFunction}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the source prefix is a retained $\mathsf{CantorSet}^{\uparrow}$ *prefix, the ternary ledger and binary ledger have the same inspected retained-branch content, the graph row pairs those displayed ledgers, and every* $\mathsf{ContinuousMap}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reads through G, E, H, C, P, N. It has no coordinate for measure, singularity, host equality of functions, quotient real equality, a selected infinite branch, or an ambient pointwise function outside the packet.*

Lean4 ✓ `BEDC.Derived.CantorFunctionUp.CantorFunctionTasteGate single carrier alignment`

Theorem 1895.2 (Cantor function NameCert obligations)**.** *For an accepted* $\mathsf{CantorFunction}^{\uparrow}$ *carrier $F = (S, T, B, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, prefix classifier stability, monotone prefix exactness, graph-row transport, continuous-map handoff, real-seal nonescape, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission projects the finite tuple of Definition 1895.1. The source row S and retained-prefix ledger T are accepted only through the $\mathsf{CantorSet}^{\uparrow}$ prefix classifier, so every source-side observation is already finite.

Prefix classifier stability is read componentwise. A shared retained ternary prefix transports through H, and the continuation row C sends it to the unique displayed binary prefix row B before any graph or real-seal row is inspected.

Monotone prefix exactness and graph-row transport are then forced by B and G. Extending a retained prefix appends only the corresponding binary output bits, and the graph row pairs the two displayed prefixes without adding a host function graph.

Finally, the continuous-map and real-facing obligations are downstream of the graph row. The rows E, H, C, P, N expose the $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BinaryExpansion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff route while preventing measure data, singularity data, host function extensionality, quotient real equality, selected infinite branches, or bridge checking from entering the certificate. □

Theorem 1895.3 (Cantor function prefix monotonicity)**.** *Let $F = (S, T, B, G, E, H, C, P, N)$ be an accepted* $\mathsf{CantorFunction}^{\uparrow}$ *carrier. If a retained ternary prefix row t' refines a retained ternary prefix row t inside T, then the binary output prefix row attached to t' refines the binary output prefix row attached to t inside B. This refinement is internal to the prefix ledgers and graph row: it cannot introduce host function equality, measure data, singularity data, quotient real equality, or a selected infinite branch.*

Proof. The retained-prefix relation is a finite comparison inside T. Since the carrier admits source prefixes only through S and the $\mathsf{CantorSet}^{\uparrow}$ classifier, both t and t' remain displayed retained-branch rows.

The output prefix attached to a retained row is read through the continuation route from T to B. Refining the source prefix therefore exposes a longer finite binary ledger entry rather than a different output object.

The graph row G only pairs the displayed source and output prefixes. It contains no coordinate for an ambient function, measure computation, singularity assertion, quotient real comparison, or branch selection, so the monotonic statement is exhausted by the two finite ledgers and their transport rows. □

Theorem 1895.4 (Cantor function continuous-map handoff)**.** *Every* $\mathsf{ContinuousMap}^{\uparrow}$ *read of an accepted* $\mathsf{CantorFunction}^{\uparrow}$ *packet factors through the finite graph and prefix rows before the* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, the read route is*

$$S \longmapsto T \longmapsto B \longmapsto G \longmapsto E$$

together with the componentwise transport, continuation replay, provenance, and local naming rows H, C, P, N*.*

Proof. A $\mathsf{ContinuousMap}^{\uparrow}$ consumer enters the packet through the displayed replay row C. The first available source data are the $\mathsf{CantorSet}^{\uparrow}$ source-prefix row S and the retained-prefix ledger T.

The continuation route then reads the binary output-prefix ledger B. By Definition 1895.3, stronger source requests remain on the same monotone prefix route.

Only after those two prefix ledgers have been displayed can the consumer inspect the graph row G. The row G is the handoff surface to $\mathsf{ContinuousMap}^{\uparrow}$, and the real-facing row E is downstream of it through $\mathsf{BinaryExpansion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$.

The transport, provenance, and local naming rows H, P, N record this same finite route. Since the carrier lacks host function extensionality, quotient real equality, measure and singularity coordinates, and selected infinite branches, every continuous-map read factors through the displayed graph and prefix rows before the real seal. □

Theorem 1895.5 (Cantor function uniform-modulus route)**.** *Every tolerance request for the* $\mathsf{ContinuousMap}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{CantorFunction}^{\uparrow}$ *packet is routed through a finite retained ternary-prefix depth, the corresponding binary-prefix ledger, the graph row, and the existing* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, the modulus-facing route is*

$$S, T \longmapsto B \longmapsto G \longmapsto E, H, C, P, N,$$

with the retained-prefix depth controlling the binary output window before any real-facing consumer reads the seal.

Proof. Begin with a tolerance request at the continuous-map or real-facing boundary. The carrier of Definition 1895.1 gives no direct host-function row, so the request must first expose the source prefix row S and the retained-prefix ledger T.

Apply Definition 1895.3. Refining the retained ternary prefix refines the binary output prefix inside B, so a finite retained-prefix depth supplies the binary window needed by the tolerance request.

Now use the continuous-map handoff of Definition 1895.4. The graph row G is inspected only after the source and output ledgers have been displayed, and the real-facing row E remains downstream through the $\mathsf{BinaryExpansion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ route.

The structural rows H, C, P, N transport and name the same finite route. Since measure data, singularity data, host function extensionality, quotient real equality, and selected infinite branches are absent from the carrier, the uniform-modulus read has no alternate escape from the retained-prefix ledger to the real seal. □

Falsifiable prediction: Every $\mathsf{CantorFunction}^{\uparrow}$ continuous-map or real-facing read factors through one CantorSet source prefix, one ternary retained-prefix ledger, one binary output-prefix ledger, one graph row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cantorset, continuousmap, compactmetric, binaryexpansion, real: $\mathsf{CantorFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Cantor source-prefix row, ternary retained-prefix ledger, binary output-prefix ledger, graph row, RealUp seal, transport, replay, provenance, and local naming for the ternary-to-binary prefix function.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1895.1, Definition 1895.2, Definition 1895.3, and Definition 1895.4 seed the finite Cantor ternary-prefix to binary-prefix function carrier through source-prefix, output-prefix, graph, continuous-map handoff, and $\mathsf{Real}^{\uparrow}$ seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure theory, singularity analysis, host function extensionality, quotient real equality, selected infinite branches, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix classifier stability, monotone prefix exactness, graph-row transport, continuous-map handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorFunctionUp.

Constructive story: A $\mathsf{CantorFunction}^{\uparrow}$ packet is generated from one CantorSet source prefix, one ternary retained-prefix ledger, one binary output-prefix ledger, one graph row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1896

A Concrete Naming Certificate for $\mathsf{CauchyBornology}^{\uparrow}$

Following Bourbaki and Kelley on bornologies and Bishop–Bridges on bounded constructive metric data, the $\mathsf{CauchyBornology}^{\uparrow}$ packet records the finite bounded-family surface needed by the Real and Completion route before any consumer asks for ambient completeness or a selected bound. It sits between the dyadic arithmetic of chapter 291, finite observations from chapter 126, regular rational readback from chapter 301, ball witnesses from chapter 1450 and chapter 355, effective Cauchy source data from chapter 1705, rate budgets from chapter 929, complete-metric consumers from chapter 128, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a bounded-family NameCert interface, not a host supremum theorem, quotient-stream equality, countable-choice schedule, selected bound, or ambient Real completeness principle.

Definition 1896.1 (CauchyBornology carrier)**.** *A* $\mathsf{CauchyBornology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B_{\mathrm{cau}} = (F, R, M, U, W, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded-family source row. It lists the finite family requests whose members may be inspected by Real-facing or Completion-facing consumers.*
2. *R is the dyadic radius-budget row read through* $\mathsf{DyadicRatCore}^{\uparrow}$*. It stores the displayed centers, radii, slack conversions, and comparison budgets assigned to the accepted family requests.*
3. *M is the* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{RationalBall}^{\uparrow}$ *witness ledger, recording that each accepted source request is routed through the corresponding displayed ball witness and radius comparison.*
4. *U is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite observation windows that may be opened for the accepted family before regular rational readback is exposed.*
5. *W is the* $\mathsf{CauchyRateBudget}^{\uparrow}$ *row. It records the monotone tolerance-depth schedule used to decide which windows of U are late enough for the displayed radius budget R.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the bounded-family source, radius budget, ball witness ledger, stream windows, and rate schedule have been displayed.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached downstream of F, R, M, U, W, Q.*
8. *H records componentwise* hsame *transport for the source, radius budget, ball witnesses, stream windows, rate schedule, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from any bounded-family request through $F, R, M, U, W, Q, A, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyBornology}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyRateBudget}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBornology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, M, U, W, Q, A, H, C, P, N$. The carrier has no coordinate for a host supremum, a selected bound, quotient-stream equality, countable choice, open-cover compactness, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyBornologyUp.CauchyBornologyTasteGate single carrier alignment`

Theorem 1896.2 (CauchyBornology NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBornology}^{\uparrow}$ *carrier*

$$B_{\mathrm{cau}} = (F, R, M, U, W, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyBornology}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the bounded-family source, dyadic radius budgets,* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{RationalBall}^{\uparrow}$ *witnesses,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{CauchyRateBudget}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *classifier stability, requiring accepted family reads in F to be preserved componentwise by the displayed transport row H;*
3. *bounded-family ledger exactness, requiring every accepted family request to pass through the dyadic radius budget R and the ball witness ledger M before any regular readback is exposed;*
4. *radius-budget monotonicity, requiring each deeper tolerance request in W to use a radius budget in R at least as late and at least as tight as the displayed predecessor row;*
5. *completion-facing handoff, requiring any* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *or* $\mathsf{CauchyRateBudget}^{\uparrow}$ *consumer to read Q and A only after F, R, M, U, W have been displayed;*
6. *non-escape, requiring P and N to export no host supremum, selected bound, quotient-stream equality, countable choice, open-cover compactness, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No CauchyBornology NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 1896.1. The projected rows are exactly the bounded-family source F, dyadic radius budget R, ball witness ledger M, stream windows U, rate schedule W, regular readback Q, Real seal A, and structural rows H, C, P, N.

Classifier stability is componentwise. The row H transports accepted family requests, radius budgets, ball witnesses, windows, schedules, readbacks, seals, replay, provenance, and local naming without adding a host-family predicate.

Ledger exactness is forced by the order of the displayed route. A family request first opens F, then reads its dyadic budget from R, then verifies the corresponding $\mathsf{MetricBall}^{\uparrow}$ or $\mathsf{RationalBall}^{\uparrow}$ witness in M before any $\mathsf{RegSeqRat}^{\uparrow}$ row can be consumed.

Radius-budget monotonicity is the local content of W read against R. Each deeper tolerance-depth request must replay the predecessor budget and then read the displayed later budget, so the schedule cannot jump to an unrecorded radius or to an ambient bound.

Finally, the completion-facing handoff is exhausted by Q and A. Since P and N package only the listed rows, the excluded host supremum, selected bound, quotient-stream equality, countable choice, open-cover compactness, trichotomy, and ambient Real completeness data have no coordinate from which to escape. □

Theorem 1896.3 (CauchyBornology bounded-tail handoff)**.** *Every completion-facing bounded-tail read of an accepted* $\mathsf{CauchyBornology}^{\uparrow}$ *carrier factors through the displayed route*

$$F, R, M, U, W, Q, A \longmapsto H, C, P, N.$$

*Here F, R, M provide the Cauchy filter or basis request, the **??** bounded-family row, and the ball-witness ledger; U provides finite* $\mathsf{StreamName}^{\uparrow}$ *windows; R, W provide the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and late-window schedule; Q provides* $\mathsf{RegSeqRat}^{\uparrow}$ *readback; A provides the* $\mathsf{Real}^{\uparrow}$ *seal; and H, C, P, N provide componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. The handoff does not select limits, form quotient filters, use countable choice, or appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. The completion-facing rows are exactly the bounded-family source F, dyadic radius budget R, ball witness ledger M, stream windows U, rate schedule W, regular readback Q, Real seal A, and structural rows H, C, P, N.

Read the bornology and metric rows next. The source and radius data are bounded only through F, R, M, so the tail request remains a displayed bounded-family read rather than a quotient filter or an ambient family predicate.

Use the sequence-facing rows U, W, Q to expose finite StreamName windows, late-window tolerance control, and RegSeqRat readback. These rows are the sibling Cauchy and metric handoff surface before the terminal Real seal A is available.

Finally replay through H, C, P, N. Componentwise transport, Cont replay, provenance, and local naming preserve the same finite route, and no row supplies selected limits, countable choice, quotient filters, or ambient Real completeness. □

Theorem 1896.4 (CauchyBornology completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*, or* $\mathsf{CauchyRateBudget}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyBornology}^{\uparrow}$ *carrier reads bounded-family data only through the displayed route*

$$F \longmapsto R \longmapsto M \longmapsto U \longmapsto W \longmapsto Q \longmapsto A \longmapsto H, C, P, N.$$

Consequently the consumer obtains finite bounded-family source rows, dyadic radius budgets, ball witnesses, stream windows, rate schedules, regular readback, the terminal Real seal, transport, replay, provenance, and local naming, and obtains no host supremum, selected bound, quotient-stream equality, countable choice, open-cover compactness, trichotomy, or ambient Real completeness.

Proof. Start from an accepted consumer request. By Definition 1896.1, the only bounded-family source coordinate is F, and every analytic row downstream of it is displayed inside the same finite packet.

The radius and ball data are next. The dyadic budget R supplies the radius, slack, and comparison rows, while M records the corresponding $\mathsf{MetricBall}^{\uparrow}$ and $\mathsf{RationalBall}^{\uparrow}$ witnesses. Thus no consumer can read boundedness before the displayed radius and ball ledgers are opened.

The sequence-facing data are downstream of those ledgers. The $\mathsf{StreamName}^{\uparrow}$ row U gives the finite windows, the $\mathsf{CauchyRateBudget}^{\uparrow}$ row W gives the late-window schedule, and the $\mathsf{RegSeqRat}^{\uparrow}$ row Q is available only after F, R, M, U, W have been displayed.

The terminal handoff then reaches the $\mathsf{Real}^{\uparrow}$ seal A and the structural rows H, C, P, N. These rows preserve the same route for $\mathsf{EffectiveCauchySequence}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers, so the packet exports only the listed bounded-family data and none of the excluded host principles. □

Theorem 1896.5 (CauchyBornology bounded-family non-escape)**.** *Let $B_{\mathrm{cau}} = (F, R, M, U, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{CauchyBornology}^{\uparrow}$ *carrier. Any bounded-family fact exported from B_{cau} is a row-wise consequence of the displayed source, dyadic radius budget, ball witness ledger, stream window, rate schedule, regular readback, Real seal, transport, replay, provenance, and local naming rows. It is not a host supremum, selected bound, quotient-stream equality, countable choice, open-cover compactness, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The analytic coordinates are exactly F, R, M, U, W, Q, A, and the structural coordinates are exactly H, C, P, N.

A bounded-family read has no other entry point. If the read concerns a member of the family, it begins at F; if it concerns a radius, it passes through R; if it concerns containment, it passes through M; and if it concerns Cauchy or completion data, it proceeds through U, W, Q, A.

The structural rows preserve only those coordinates. Componentwise hsame transport and displayed Cont replay cannot manufacture a host supremum or a selected bound, while provenance and local naming record only the finite packet.

Therefore every exported bounded-family fact is confined to the displayed rows, and each excluded host principle has no coordinate, replay edge, provenance entry, or local NameCert row. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBornology}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBornology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1896.1, Definition 1896.2, Definition 1896.4, and Definition 1896.5 seed the finite bounded-family NameCert surface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyRateBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBornology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host supremum theorem, selected bounds, quotient-stream equality, countable choice, open-cover compactness, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier stability, bounded-family ledger exactness, radius-budget monotonicity, completion-facing handoff, provenance, local naming, and non-escape for BEDC.Derived.CauchyBornologyUp

Constructive story: A $\mathsf{CauchyBornology}^{\uparrow}$ packet is generated from bounded-family source rows, displayed dyadic radius budgets, $\mathsf{MetricBall}^{\uparrow}$ and $\mathsf{RationalBall}^{\uparrow}$ witnesses, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{CauchyRateBudget}^{\uparrow}$ schedules, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1897

A Concrete Naming Certificate for $\mathsf{ContinuousIntervalImage}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ContinuousIntervalImage}^{\uparrow}$ packet records the finite route by which the image of a connected closed bounded real interval under a displayed continuous Real-facing map remains available as a connected Real-facing image surface. It sits over the closed bounded interval boundary of chapter 1591, the connected interval route of chapter 1462, the intermediate-value bisection discipline of chapter 1402, the graph and modulus rows of chapter 130, and the terminal real-name seal of chapter 38. The packet is a finite image certificate for Real and Completion consumers; it is not a host image set, an endpoint-selection principle, quotient equality of real names, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1897.1 (Continuous interval image carrier)**.** *A* $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, J, F, V, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing the displayed lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, rational bounds, endpoint-window requests, and interval membership ledger.*
2. *J is the* $\mathsf{ConnectedInterval}^{\uparrow}$ *row for the same source interval, recording the finite connectedness handoff consumed by image-connectedness reads.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and modulus row, carrying the displayed Real-facing map, finite graph observations, modulus budget, and compatibility with the source interval windows.*
4. *V is the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign-route row, naming the bisection and sign-change surface used whenever an image request must pass between two displayed values.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for source endpoint names, graph observations, bisection probes, and image output reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational approximants used by the map, intermediate-value route, and output seal.*
7. *E is the output* $\mathsf{Real}^{\uparrow}$ *seal row; it is reached only after the source interval, connectedness row, continuous-map row, intermediate-value route, finite windows, and regular readbacks have been replayed.*

8. *H records componentwise* hsame *transport for the closed bounded interval, connected interval row, continuous map, intermediate-value route, window row, readback row, output seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from an image request through $B, J, F, V, W, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* ContinuousIntervalImage$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, ConnectedInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, IntermediateValue$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ContinuousIntervalImage}^{\uparrow}}$ *row.*

The classifier compares accepted image packets only through the displayed rows $B, J, F, V, W, R, E, H, C, P, N$. It has no coordinate for a host image subset, selected extrema, endpoint-choice functionals, quotient equality of real names, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ContinuousIntervalImageUp.ContinuousIntervalImageTasteGate single carrier alignment`

Theorem 1897.2 (Continuous interval image NameCert obligations)**.** *For every accepted* ContinuousIntervalImage$^{\uparrow}$ *carrier*

$$I = (B, J, F, V, W, R, E, H, C, P, N),$$

the local NameCert$_{\text{ContinuousIntervalImage}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed bounded interval row, connected interval row, continuous-map graph and modulus row, intermediate-value sign route, finite window row, regular readback row, output Real seal, transport, replay, provenance, and local naming;*
2. *source-interval exactness, requiring every endpoint, rational bound, membership, and interval-window request to pass through the displayed* ClosedBoundedInterval$^{\uparrow}$ *row B;*
3. *connected-source exactness, requiring connectedness reads to pass through the displayed* ConnectedInterval$^{\uparrow}$ *row J and the same source interval boundary B;*
4. *map-modulus exactness, requiring graph observations and continuity budgets to pass through the displayed* ContinuousMap$^{\uparrow}$ *row F and its finite window requests;*
5. *intermediate-value routing, requiring every image handoff between displayed source values to pass through the* IntermediateValue$^{\uparrow}$ *sign-route row V rather than through host order completeness;*
6. *output-seal ordering, requiring W and R to expose StreamName windows and RegSeqRat readbacks before the terminal* Real$^{\uparrow}$ *seal E is available;*
7. *nonescape, excluding host image subsets, selected endpoints or extrema, quotient real equality, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No continuous interval image obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1897.1. The accepted packet displays exactly one closed bounded interval source, one connected interval row, one continuous-map graph and modulus row, one intermediate-value sign route, one finite window row, one regular readback row, one output real seal, and the structural rows.

Source-interval exactness follows from B. Endpoint, rational-bound, membership, and source-window reads have no second interval coordinate, so each such read enters the image packet through the displayed $\mathsf{ClosedBoundedInterval}^{\uparrow}$ carrier.

Connected-source exactness is supplied by J over the same source row B. Since the packet contains no independent connectedness object, connected image reads must consume the connected interval route already attached to the closed bounded interval boundary.

Map-modulus exactness is supplied by F. Graph observations, continuity budgets, and compatibility checks all pass through the displayed $\mathsf{ContinuousMap}^{\uparrow}$ row before any image-output seal can be inspected.

Intermediate-value routing is supplied by V. When a consumer asks for a value between two displayed image values, the sign-route row provides the bisection surface and prevents the request from being replaced by host order completeness or a selected preimage.

The remaining rows W, R, E, H, C, P, N impose readback order and local naming. StreamName windows and RegSeqRat readbacks precede the output Real seal, while transport, replay, provenance, and naming contain none of the excluded host image, choice, quotient, trichotomy, completeness, verification, or bridge data. □

Theorem 1897.3 (Continuous interval image Real seal route)**.** *Every Real-facing output read of an accepted* $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *carrier factors through the finite route*

$$B, J, F, V \longmapsto W, R \longmapsto E, H, C, P, N.$$

Thus the consumer first receives the closed bounded source interval, its connected interval handoff, the continuous-map graph and modulus data, and the intermediate-value sign route; only then may it read finite windows, regular rational approximants, the output $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. The route exports no host image set, selected endpoint or extremum, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $I = (B, J, F, V, W, R, E, H, C, P, N)$. The source side is forced through B and J: the closed bounded interval row supplies the endpoint and membership boundary, and the connected interval row supplies the connectedness handoff over that same boundary.

The image computation is then forced through F and V. The continuous-map row provides graph observations and modulus budgets, while the intermediate-value row supplies the sign-route surface needed to pass between displayed values.

The Real-facing output is downstream of finite observation. The window row W and readback row R expose the finite stream and regular rational data before E seals the output as a $\mathsf{Real}^{\uparrow}$ name.

Finally H, C, P, N transport, replay, source, and name the same route. Since no row contains a host image subset, endpoint selector, extremum selector, quotient-real equality, trichotomy, countable choice, or ambient completeness witness, every output read remains inside the displayed factorization. □

Theorem 1897.4 (Continuous interval image connected handoff)**.** *Every connectedness read exported by an accepted* $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *carrier factors through*

$$J \longmapsto F, V \longmapsto W, R, E, H, C, P, N.$$

The read uses the source $\mathsf{ConnectedInterval}^{\uparrow}$ *row, the continuous-map graph and modulus row, the intermediate-value sign route, finite windows, regular readbacks, the output* $\mathsf{Real}^{\uparrow}$ *seal, and the structural NameCert rows. It does not introduce a separate host connected image object or a choice-selected preimage.*

Proof. The source connectedness coordinate is J, and it is tied to the closed bounded interval row B in the carrier. A connectedness read therefore begins with the displayed $\mathsf{ConnectedInterval}^{\uparrow}$ handoff rather than a host connected-subset assertion.

Continuity transport is then read through F. The graph and modulus rows determine how source-window data are carried to image-window data, while V supplies the intermediate-value sign route needed to keep the image between displayed values connected at the finite certificate level.

The output side is read only after W, R, E have been replayed. These rows expose finite StreamName windows, RegSeqRat approximants, and the output Real seal before the structural rows H, C, P, N transport, replay, source, and name the packet.

Because the packet has no coordinate for a host image set, selected preimage, endpoint selector, quotient real equality, trichotomy, countable choice, or ambient completeness, the displayed handoff is the whole connectedness surface exported by the certificate. □

Falsifiable prediction: Every $\mathsf{ContinuousIntervalImage}^{\uparrow}$ read factors through one $\mathsf{ClosedBoundedInterval}^{\uparrow}$ source row, one $\mathsf{ConnectedInterval}^{\uparrow}$ source-connectedness row, one $\mathsf{ContinuousMap}^{\uparrow}$ graph and modulus row, one $\mathsf{IntermediateValue}^{\uparrow}$ sign-route row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one output $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closedboundedinterval, connectedinterval, continuousmap, intermediatevalue, real: $\mathsf{ContinuousIntervalImage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source interval boundary, connectedness handoff, continuous-map graph and modulus data, intermediate-value bisection route, finite readback boundary, output real seal, and local NameCert route as one finite image packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousIntervalImage}^{\uparrow}}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousIntervalImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host image-set construction, selected preimages, endpoint or extremum selection, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-interval exactness, connected-source exactness, map-modulus exactness, intermediate-value routing, output-seal ordering, Real-route nonescape, and connected-handoff proofs for BEDC.Derived.ContinuousIntervalImageUp.

Constructive story: A $\mathsf{ContinuousIntervalImage}^{\uparrow}$ packet is generated from a $\mathsf{ClosedBoundedInterval}^{\uparrow}$ source row, a $\mathsf{ConnectedInterval}^{\uparrow}$ source-connectedness row, a $\mathsf{ContinuousMap}^{\uparrow}$ graph and modulus row, an $\mathsf{IntermediateValue}^{\uparrow}$ sign-route row, StreamName windows, RegSeqRat readbacks, an output $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1898

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalCompactness}^{\uparrow}$

Following Bolzano, Weierstrass, and Bishop–Bridges constructive analysis, the $\mathsf{CauchyDiagonalCompactness}^{\uparrow}$ packet records the finite diagonal subsequence boundary used by the L10 Real and Completion route before any consumer may read a compactness-shaped seal. It sits downstream of the bounded-sequence source of chapter 1415, the finite subsequence compactness discipline of chapter 1254, the regular extraction boundary of chapter 381, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite diagonal window extraction route; it does not assert open-cover compactness, choice-selected infinite subsequences, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1898.1 (CauchyDiagonalCompactness carrier)**.** *A* $\mathsf{CauchyDiagonalCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row, carrying the bounded sequence windows available to the diagonal construction;*
2. *F is the finite net and refinement schedule, recording only the inspected cells and refinement levels used by the diagonal route;*
3. *W is the diagonal subsequence selector-window row, displaying for each visible precision request the finite window of selected indices consumed by the packet;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from B, F, W and read only through the finite windows of chapter 126;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic radius, slack, and comparison entries for the displayed net refinements and selected windows;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after B, F, W, Q, D have been displayed;*
7. *H records componentwise* hsame *transport for the bounded source, finite refinement schedule, selector windows, regular readback, dyadic ledger, Real seal, replay row, provenance row, and local naming row;*

8. *C records displayed* Cont *replay from each finite request through $B, F, W, Q, D, E, H, P, N$;*
9. *P is the* Pkg *provenance over* CauchyDiagonalCompactness$^{\uparrow}$, BolzanoWeierstrass$^{\uparrow}$, BoundedRealSequence$^{\uparrow}$, RegularCauchySubsequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* NameCert$_{\text{CauchyDiagonalCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, W, Q, D, E, H, C, P, N$. It contains no open-cover compactness field, no selected infinite subsequence, no quotient stream equality, no host real equality, no countable-choice row, and no ambient Real$^{\uparrow}$ *completeness datum.*

Lean4 ✓ BEDC.Derived.CauchyDiagonalCompactnessUp.TasteGate.CauchyDiagonalCompactnessTasteGate single carrier alignment

Theorem 1898.2 (CauchyDiagonalCompactness NameCert obligations)**.** *For an accepted* CauchyDiagonalCompact *carrier $K = (B, F, W, Q, D, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyDiagonalCompactness}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the bounded source, finite net and refinement schedule, selector-window row, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *bounded-source exactness, requiring every diagonal window to read the same* BoundedRealSequence$^{\uparrow}$ *row B that feeds the* BolzanoWeierstrass$^{\uparrow}$ *and* RegularCauchySubsequence$^{\uparrow}$ *routes;*
3. *finite-refinement exactness, requiring F to list the inspected net cells and refinement levels before any selector window is exposed;*
4. *readback compatibility, requiring Q to be the only* RegSeqRat$^{\uparrow}$ *readback obtained from the selected windows and requiring D to be the only dyadic tolerance ledger consumed by that readback;*
5. *Real seal ordering, requiring E to be displayed only after B, F, W, Q, D;*
6. *route stability, requiring H, C, P, N to preserve the displayed packet without adding open-cover compactness, choice-selected subsequences, quotient stream equality, host real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 1898.1. The tuple displays the bounded source, finite refinement schedule, selector windows, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local name.

Bounded-source exactness follows from the single coordinate B. Since the carrier has no second sequence source, every diagonal window and downstream readback must inspect the same bounded row used by the Bolzano–Weierstrass and regular-subsequence siblings.

Finite-refinement exactness is the projection to F. The schedule stores inspected cells and refinement levels before W, Q, D, or E is available, so the selector window cannot be supplied by an external compactness oracle.

Readback compatibility and Real seal ordering follow from W, Q, D, E. The readback row Q is downstream of the selected windows, the dyadic ledger D is the only tolerance row consumed by that readback, and the terminal seal E appears only after those rows are displayed.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite route, and the carrier has no coordinate for open-cover compactness, a choice-selected infinite subsequence, quotient stream equality, host real equality, countable choice, or ambient completeness. □

Theorem 1898.3 (CauchyDiagonalCompactness window extraction)**.** *Let $K = (B, F, W, Q, D, E, H, C, P, N)$ be an accepted* CauchyDiagonalCompactness$^{\uparrow}$ *carrier. Every finite precision request that reaches the diagonal route factors through the displayed extraction spine*

$$B, F, W \longmapsto Q, D \longmapsto E.$$

Thus the packet exposes a finite selector-window extraction over bounded real sequence data, not a choice-selected infinite subsequence, quotient stream, open-cover compactness proof, or ambient completion principle.

Proof. Begin with a finite precision request. Carrier admission provides B as the only bounded sequence source and F as the only refinement schedule.

The selector-window row W is then read from B and F. It stores visible windows of selected indices, rather than an infinite selected subsequence or a host choice function.

Next the packet reads Q and D. The regular rational readback is assembled from the selected windows, and the dyadic ledger records the tolerance data consumed by that readback.

The Real seal E is downstream of this spine. The structural rows H, C, P, N preserve the same finite extraction route, so no open-cover compactness field, quotient stream, selected infinite subsequence, or ambient completion datum can enter the consumer surface. □

Theorem 1898.4 (CauchyDiagonalCompactness Real seal non-escape)**.** *For an accepted* CauchyDiagonalCompactn *carrier $K = (B, F, W, Q, D, E, H, C, P, N)$, every* Real$^{\uparrow}$ *seal read reaches E only through the bounded source B, finite net and refinement schedule F, selector-window row W,* RegSeqRat$^{\uparrow}$ *readback Q, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger D. The seal exports no open-cover compactness, choice-selected subsequence, quotient stream equality, host real equality, countable-choice row, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with a Real$^{\uparrow}$ seal read. The carrier definition supplies E as the only terminal Real seal coordinate.

The NameCert obligations place E after B, F, W, Q, D. A consumer must therefore traverse the bounded source, finite refinement schedule, selector window, regular readback, and dyadic tolerance ledger before any Real seal can be read.

The transport and replay rows H and C preserve that same order, while P and N source and name the packet. Since the carrier contains no open-cover compactness field, selected infinite subsequence, quotient stream equality, host real equality, countable-choice row, or ambient completeness datum, the Real seal is exhausted by the displayed finite route. □

Closure status for NameCert$_{\text{CauchyDiagonalCompactness}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchyDiagonalCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 1898.1, Definition 1898.2, Definition 1898.3, and Definition 1898.4 seed the finite diagonal compactness packet over BoundedRealSequence sources, BolzanoWeierstrass refinement discipline, RegularCauchySubsequence windows, StreamName inspection, RegSeqRat readback, DyadicRatCore tolerances, and Real seals.

Formal verification: FormalStatus(NameCert$_{\text{CauchyDiagonalCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected infinite subsequences, quotient stream equality, host real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source exactness, finite-refinement exactness, selector-window extraction, readback compatibility, Real seal nonescape, and route stability for BEDC.Derived.CauchyDiagonalCompac

Constructive story: A CauchyDiagonalCompactness$^{\uparrow}$ packet is generated from a BoundedRealSequence$^{\uparrow}$ source, a finite net and refinement schedule, displayed diagonal selector windows, a RegSeqRat$^{\uparrow}$ readback row, a DyadicRatCore$^{\uparrow}$ tolerance ledger, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1899

A Concrete Naming Certificate for $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$

Following Picard, Lindelof, and Bishop–Bridges, the $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ packet records the local-flow part of constructive ODE existence and uniqueness as finite NameCert data. It refines the ODE source of chapter 193, the Lipschitz vector-field ledger of chapter 410, the contraction-map surface of chapter 1418, the finite Picard route of chapter 395, the complete-metric limit handoff of chapter 128, the stream naming discipline of chapter 126, and the regular rational sequence ledger of chapter 301. The packet names a local flow row over a displayed time-state window; it does not select a global solution curve, quotient completed paths, assert ambient real completeness, or compare host functions extensionally.

Definition 1899.1 (Picard–Lindelof local-flow carrier)**.** *A* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (O, F, K, L, M, S, R, H, C, G, N)$$

with the following visible rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *local-flow source row, including the initial time-state cell, the local time window, and the displayed endpoint row to be named;*
2. *F is the* $\mathsf{LipschitzMap}^{\uparrow}$ *vector-field ledger on the same local window, with graph reads and a displayed Lipschitz bound;*
3. *K is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row obtained by reading the Picard operator as a contraction on the local approximant surface;*
4. *L is the* $\mathsf{PicardContraction}^{\uparrow}$ *finite-iteration row, recording the successive Picard approximants and the one-step contraction comparisons that keep them inside the window;*
5. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row for the carried approximant space, containing the Cauchy modulus, limit row, and late-observation comparisons for the Picard stream;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the visible approximant stream without replacing it by a host sequence object;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational control row that records the local radius, time-step, and modulus budgets used by the contraction and completion rows;*

8. *H stores componentwise* hsame *transport for the ODE source, Lipschitz ledger, contraction row, Picard route, completion handoff, stream name, rational control row, replay rows, provenance row, and local naming row;*
9. *C stores the displayed* Cont *replay from the initial ODE row through the Lipschitz graph reads, Picard operator, finite iteration route, complete-metric handoff, and endpoint classifier;*
10. *G is the* Pkg *provenance row over* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalFlow}^{\uparrow}}$ *row.*

The carrier exposes only these finite rows. It has no coordinate for host function equality, quotient completion equality, choice-selected solution curves, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or maximal continuation.*

Lean4 ✓ `BEDC.Derived.PicardLindelofLocalFlowUp.PicardLindelofLocalFlowTasteGate single carrier alignment`

Theorem 1899.2 (Picard–Lindelof local-flow NameCert obligations)**.** *For an accepted* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ *carrier*

$$P = (O, F, K, L, M, S, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalFlow}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, ODE source compatibility for O, Lipschitz graph stability for F, contraction packaging for K, finite Picard iteration for L, complete-metric handoff for M, stream-name visibility for S, rational budget visibility for R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through G, and local naming through N.*

Proof. Carrier admission is projection from Definition 1899.1. Each accepted packet displays the ODE source row, vector-field ledger, contraction row, Picard route, completion row, stream name, rational budget, transport, replay, provenance, and local name.

The source rows O, F, R fix the local window. The ODE row supplies the initial time-state cell and endpoint row, the Lipschitz row supplies the graph reads and bound, and the rational control row supplies the time-step and radius budgets that keep the later rows inside the same window.

The iteration rows K, L, S are finite. The contraction row packages the Picard operator through chapter 1418, the Picard route records only finitely many displayed approximants through chapter 395, and the stream-name row names that visible approximant stream without selecting an external sequence.

The completion row M is a handoff to chapter 128. It contributes the Cauchy modulus, limit row, and late-observation comparisons needed by the local endpoint classifier, but it does not identify quotient representatives or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally H, C, G, N transport, replay, source, and name the same finite surface. Since all exported rows are fields of P, the certificate cannot assert host function equality, choose a solution curve, or extend the local window beyond the displayed nonescape data. □

Theorem 1899.3 (Picard–Lindelof local-flow Picard handoff)**.** *Every accepted* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ *carrier factors each local-flow endpoint read through the finite route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{LipschitzMap}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardContraction}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow}.$$

The route first opens the ODE source and Lipschitz vector-field ledger, then packages the Picard operator as a contraction, then records finite Picard iteration, then hands the resulting Cauchy stream to the complete-metric row. The local uniqueness boundary compares only local-flow rows that share the same O, F, R window data and the same displayed handoff rows K, L, M, S, H, C, G, N.

Proof. Start with O and F. The ODE source fixes the local-flow problem and the Lipschitz ledger supplies the only vector-field graph reads available to the packet.

Build the finite Picard stage next. The row K reads the Picard operator as a $\mathsf{ContractionMapping}^{\uparrow}$ packet, while L records the displayed finite approximants and one-step comparisons. No step is a host function application; each step is a BHist row replayed by C and transported componentwise by H.

Use S and R to keep the iteration visible. The stream-name row names the finite prefix and its continuing ledger, and the rational control row supplies the budgets used to keep the prefix inside the nonescape window.

The complete-metric handoff is the row M. It reads the Picard stream as a Cauchy object, records the limit row and late comparisons, and returns only the endpoint row licensed by the same local window.

For uniqueness, compare two accepted packets over the same O, F, R rows. Their endpoint comparison is the local classifier induced by the shared contraction, Picard, completion, stream, transport, replay, provenance, and naming rows. The comparison therefore stays inside the local NameCert surface and does not become host function equality, quotient completion equality, a selected solution curve, or a global continuation theorem. □

Falsifiable prediction: Every $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ endpoint read factors through one Ode row, one LipschitzMap vector-field ledger, one ContractionMapping Picard-operator row, one PicardContraction finite-iteration row, one CompleteMetric handoff row, one StreamName row, one RegSeqRat budget row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ode, lipschitzmap, contractionmapping, picardcontraction, complete-metric, streamname, regseqrat: $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries ODE source data, Lipschitz graph data, contraction packaging, finite Picard iteration, complete-metric handoff, stream naming, rational local-window budgets, and the transport/replay/provenance rows binding them into one local-flow certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalFlow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardLindelofLocalFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1899.1, Definition 1899.2, and Definition 1899.3 seed the constructive local-flow packet over ODE source rows, Lipschitz vector-field ledgers, contraction packaging, finite Picard iteration, complete-metric handoff, stream naming, rational local-window budgets, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardLindelofLocalFlow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global ODE existence, maximal interval continuation, host function equality, quotient completion equality, choice-selected solution curves, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ODE source compatibility, Lipschitz graph stability, contraction packaging, finite Picard iteration, complete-metric handoff, stream-name visibility, rational budget visibility, transport, replay, provenance, and local naming for BEDC.Derived.PicardLindelofLocalFlowUp.

Constructive story: A $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ packet is generated from one ODE local-flow source row, one LipschitzMap vector-field ledger, one ContractionMapping Picard-operator row, one PicardContraction finite-iteration row, one CompleteMetric handoff row, one StreamName row, one RegSeqRat local-window budget row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1900

A Concrete Naming Certificate for $\mathsf{RolleTheorem}^{\uparrow}$

Following Rolle and the Bishop–Bridges reading of constructive analysis, the $\mathsf{RolleTheorem}^{\uparrow}$ packet records the finite NameCert boundary behind the familiar stationary-point theorem without turning it into an ambient completeness principle. Its source rows are the terminal real-name surface of chapter 38, the pointwise continuity and modulus rows of chapter 130, the derivative quotient route of chapter 122, the sign-change and bisection ledger of chapter 1402, the regular rational readback of chapter 301, and the dyadic tolerance arithmetic of chapter 291. The chapter names the theorem-facing finite interface only: endpoint equality, interval localization, continuity, derivative inspection, rational readback, dyadic budgets, and a displayed zero-derivative handoff remain visible rows.

Definition 1900.1 (Rolle theorem carrier)**.** *A* $\mathsf{RolleTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, E, F, Q, D, I, Z, H, C, P, N)$$

with the following displayed rows:

1. *A, B are the two endpoint real-name rows, read through the* $\mathsf{Real}^{\uparrow}$ *surface and retained with their regular rational readbacks.*
2. *E is the endpoint-equality row, recording classifier equality of the two endpoint value seals rather than host equality of completed reals.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the displayed real-valued map over the located interval cells.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite endpoint and interior value inspections consumed by the theorem route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the inspected rational windows and derivative quotients.*
6. *I is the* $\mathsf{IntermediateValue}^{\uparrow}$ *handoff row that supplies the finite bisection-facing sign and location ledger used to isolate the stationary witness.*
7. *Z is the* $\mathsf{Derivative}^{\uparrow}$ *zero-handoff row, exposing a displayed derivative quotient whose terminal seal is the* $\mathsf{Real}^{\uparrow}$ *zero seal.*

8. *H records componentwise* hsame *transport for endpoint names, endpoint equality, map data, rational readbacks, dyadic tolerances, intermediate-value handoff, derivative quotient, zero seal, replay rows, provenance rows, and local naming rows.*
9. *C records displayed* Cont *replay from endpoint reads to map windows, from rational readbacks to dyadic tolerance checks, from the intermediate-value ledger to the derivative-zero handoff, and from the derivative quotient to the terminal real-name zero seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RolleTheorem}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RolleTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted theorem packets only through these rows. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy of real numbers, a selected root, host differentiability, quotient real equality, open-cover compactness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.RolleTheoremUp.RolleTheoremTasteGate single carrier alignment`

Theorem 1900.2 (Rolle theorem NameCert obligations)**.** *For every accepted* $\mathsf{RolleTheorem}^{\uparrow}$ *carrier*

$$T = (A, B, E, F, Q, D, I, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RolleTheorem}^{\uparrow}}$ *surface consists exactly of the finite obligation rows for endpoint real-name admission, endpoint-equality routing, continuous-map admission, regular rational readback, dyadic tolerance budgeting, intermediate-value handoff, derivative quotient inspection, terminal zero sealing, componentwise transport, displayed replay, provenance, and local naming. No obligation row may bypass the displayed* $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *sources.*

Proof. Carrier admission is projection from Definition 1900.1. The rows A, B, E supply the endpoint names and the equality route, while F supplies the sole continuous-map surface.

The arithmetic and localization rows are then fixed. The readback row Q and the tolerance ledger D are the only regular-rational and dyadic routes available to the packet, and I is the only intermediate-value handoff row.

Finally inspect the derivative-facing row Z. It is attached to the displayed derivative quotient and terminal zero seal, and it is transported and replayed only through H and C.

The provenance and local naming rows P, N add source and name data without adding mathematical coordinates. Since the carrier has no further field, the listed rows exhaust the NameCert surface. □

Theorem 1900.3 (Rolle theorem derivative-zero handoff)**.** *Every derivative-zero statement exported by an accepted* $\mathsf{RolleTheorem}^{\uparrow}$ *carrier factors through the ordered route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{IntermediateValue}^{\uparrow},\ \mathsf{Derivative}^{\uparrow}.$$

The exported conclusion is a displayed zero-handoff for the derivative quotient row Z, not a host differentiability claim and not a mean-value theorem over an ambient real function.

Proof. Start with an accepted carrier $T = (A, B, E, F, Q, D, I, Z, H, C, P, N)$. The endpoint real-name rows and the regular rational readback row are inspected before any derivative-zero read is available.

The dyadic ledger D bounds the finite readback windows, and the continuous-map row F fixes the displayed function data consumed by the theorem route. The intermediate-value handoff I supplies the finite bisection-facing location route used by the stationary witness.

Only after these rows are present can the derivative row Z be read. Transport through H and replay through C preserve the same order, while P and N add provenance and naming only.

Thus the derivative-zero export is the displayed handoff through Z over the named rows. The packet contains no host differentiability predicate, no ambient mean-value theorem, and no detached equality of completed functions. □

Theorem 1900.4 (Rolle theorem Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumed or exported by an accepted* $\mathsf{RolleTheorem}^{\uparrow}$ *carrier is routed through one of the displayed endpoint, readback, intermediate-value, or derivative-zero rows of Definition 1900.1. Consequently the carrier cannot export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, selected roots, host differentiability, quotient real equality, or standard-bridge data.*

Proof. Inspect the real-facing coordinates of the carrier. The endpoint rows A, B expose the initial real names, Q exposes regular rational readback, I exposes the intermediate-value handoff, and Z exposes the derivative-zero seal.

Each of these rows is paired with componentwise transport and displayed replay. The dyadic ledger D fixes the finite tolerance budget, and the continuous-map row F fixes the function surface that the route may inspect.

There is no additional coordinate for a completed-real selector, an order trichotomy witness, a selected root, a host differentiability predicate, or a bridge object. Provenance and local naming record the same row inventory.

Therefore every real seal remains inside the displayed packet boundary, and no Real or bridge claim can escape the carrier. □

Falsifiable prediction: Every $\mathsf{RolleTheorem}^{\uparrow}$ read factors through endpoint $\mathsf{Real}^{\uparrow}$ names, endpoint equality, $\mathsf{ContinuousMap}^{\uparrow}$ map data, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, $\mathsf{IntermediateValue}^{\uparrow}$ handoff, $\mathsf{Derivative}^{\uparrow}$ zero routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, continuousmap, derivative, intermediatevalue, regseqrat, dyadicratcore: $\mathsf{RolleTheorem}^{\uparrow}$ is not bijective to any listed sibling because it binds endpoint equality, theorem-facing continuity, rational readback, dyadic tolerance, intermediate-value handoff, derivative-zero routing, transport, replay, provenance, and local naming as one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RolleTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{RolleTheorem}^{\uparrow}$ packet is generated from endpoint real-name rows, endpoint equality, continuous-map data, regular rational readback, dyadic tolerance arithmetic, intermediate-value handoff, derivative-zero routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RolleTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1900.1, Definition 1900.2, Definition 1900.3, and Definition 1900.4 seed the finite theorem-facing Rolle boundary over displayed Real, continuous-map, derivative, intermediate-value, regular-rational, and dyadic rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RolleTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient RealUp completeness, trichotomy, selected roots, host differentiability, quotient real equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligation coverage, derivative-zero handoff, Real seal non-escape, and TasteGate field faithfulness for BEDC.Derived.RolleTheoremUp.

Chapter 1901

A Concrete Naming Certificate for $\mathsf{SecondCountable}^{\uparrow}$

Following Bourbaki and Kelley on general topology, the $\mathsf{SecondCountable}^{\uparrow}$ packet records a countable-base interface as finite BEDC rows. It sits over the metric source surface of chapter 57, the generated-open classifier of chapter 88, the finite observation windows of chapter 126, the dyadic precision ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed base enumeration, local basis reads, refinement rows, and transport ledgers; it does not identify host sets, assert open-cover compactness, select a basis by choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1901.1 (Second-countable carrier)**.** *A* $\mathsf{SecondCountable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, T, M, B, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the point or source carrier row whose visible histories supply the only points read by the packet.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-set classifier row, recording generated-open membership only through displayed BEDC histories.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *metric-ball witness row when the packet is metric-presented; if no metric row is present, M is the explicit empty witness row.*
4. *B is the displayed countable-base enumeration row, recording finite index windows and the basic-open cells exposed at those windows.*
5. *D is the dyadic radius and precision ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$ *used by metric-ball and boundary reads.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for finite inspection windows of the base enumeration and consumer probes.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *boundary and seal row used by radius, completion-facing, or real-valued classifier reads.*
8. *H stores componentwise* hsame *transport for the source, topology classifier, metric witness, base enumeration, dyadic ledger, stream windows, real seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a point or source read through the base enumeration, local basis test, refinement row, classifier transport, precision ledger, stream window, real seal, provenance, and local name.*

10. *P is the* Pkg *provenance row over* $\mathsf{SecondCountable}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SecondCountable}^{\uparrow}}$ *row.*

The carrier exposes no host set of opens, no selected countable basis, no countable-choice witness, no open-cover compactness proof, no Lindelof theorem, and no $\mathsf{Real}^{\uparrow}$ *completeness field.*

Lean4 ✓ `BEDC.Derived.SecondCountableUp.SecondCountableTasteGate single carrier alignment`

Theorem 1901.2 (Second-countable NameCert obligations)**.** *For an accepted* $\mathsf{SecondCountable}^{\uparrow}$ *carrier*

$$Q = (X, T, M, B, D, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SecondCountable}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the point or source row, topology classifier, optional metric-ball witness, displayed base enumeration, dyadic ledger, stream windows, real seal, transport, replay, provenance, and local name;*

2. *local-basis coverage, requiring every accepted point-window and open-classifier read to meet a displayed basic cell from B through the same source row X and topology row T;*

3. *basis refinement closure, requiring any two displayed basic cells accepted at a common point-window to refine through another displayed basic cell indexed by the same enumeration row B;*

4. *topology and metric classifier transport, requiring every open-set or metric-ball read to pass through T and, when present, M before it is exported to a consumer;*

5. *ledger nonescape, requiring every dyadic radius, stream-window, real-boundary, transport, replay, provenance, and local-naming read to remain inside the rows D, S, R, H, C, P, N.*

No second-countability obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.SecondCountableUp.SecondCountableCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1901.1. The accepted packet displays exactly one source row, topology classifier, metric witness slot, base enumeration, dyadic ledger, stream-window row, real-seal row, and structural rows.

Local-basis coverage is read from X, T, B. A consumer opens a point or source window in X, reads the generated-open classifier in T, and receives only a displayed basic cell from B that is witnessed at the same finite window.

Basis refinement closure is also internal to B. When two displayed basic cells are accepted at a common point-window, the refinement row is another finite base-enumeration entry, not a host intersection or a choice-selected neighborhood.

Topology and metric classifier transport are forced by T and M. The topology row supplies the open-set classifier, while the metric witness row supplies the ball route when the presentation has metric data; a non-metric packet exposes only the explicit empty metric slot.

Finally D, S, R, H, C, P, N keep the read inside the finite ledger. Dyadic precision, stream windows, real boundary reads, componentwise transport, replay, provenance, and local naming are

all packet fields, so no open-cover compactness theorem, Lindelof theorem, host basis, countable-choice witness, or $\mathsf{Real}^{\uparrow}$ completeness field can be exported. □

Theorem 1901.3 (Second-countable metric-base handoff)**.** *Every metric or topology consumer read of an accepted* $\mathsf{SecondCountable}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before any open-set or completion-facing read is accepted. A metric-presented packet first reads the $\mathsf{Met}^{\uparrow}$ *ball witness and dyadic radius ledger, then the* $\mathsf{StreamName}^{\uparrow}$ *inspection window, then the* $\mathsf{Topology}^{\uparrow}$ *generated-open classifier, and finally any* $\mathsf{Real}^{\uparrow}$ *boundary seal needed by a completion-facing consumer. A non-metric packet uses the same topology, stream, dyadic, and real-boundary rows while keeping the metric witness row empty.*

Lean4 ✓ `BEDC.Derived.SecondCountableUp.SecondCountableCarrier metric base handoff`

Proof. Start with the packet $Q = (X, T, M, B, D, S, R, H, C, P, N)$. A topology consumer has no open-set coordinate except T, so every open read begins with the displayed source row X, the topology classifier T, and the base enumeration row B.

If the consumer asks for a metric-ball presentation, the row M is the only metric witness. Its radius and precision reads must pass through the dyadic ledger D before the basic-open cell in B is accepted.

The stream row S names the finite inspection windows for the enumeration and consumer probes. It prevents the read from becoming a host sequence of basic opens or a selected countable basis.

The real boundary row R is the only endpoint-facing seal. Completion-facing consumers therefore see the route through M, D, S, T, B, R before any real-valued or completion-facing read is exported.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the packet has no host-set equality coordinate, open-cover compactness witness, countable-choice field, or $\mathsf{Real}^{\uparrow}$ completeness field, the handoff stays inside the stated BEDC rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{SecondCountable}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SecondCountable}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1901.1, Definition 1901.2, and Definition 1901.3 seed the finite countable-base interface over displayed source rows, topology classifiers, optional metric-ball witnesses, dyadic precision ledgers, stream windows, real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SecondCountable}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SecondCountableUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Lindelof theorems, selected bases as host sets, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-basis coverage, basis refinement, metric-base handoff, transport, replay, provenance, and local naming for BEDC.Derived.SecondCountableUp.

Constructive story: A $\mathsf{SecondCountable}^{\uparrow}$ packet is generated from one point or source carrier row, one Topology classifier row, an optional Metric ball witness row, one displayed countable-base enumeration row, one DyadicRatCore precision ledger, one StreamName finite-inspection row, one Real boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1902

A Concrete Naming Certificate for $\mathsf{Rolle}^{\uparrow}$

Following Rolle, Weierstrass, and Bishop–Bridges constructive analysis, the $\mathsf{Rolle}^{\uparrow}$ packet records the finite BEDC reading of Rolle's theorem for a continuous real-valued map on a compact interval whose endpoint values agree and whose interior derivative quotient admits a zero seal. It consumes the terminal real-name surface of chapter 38, the graph and pointwise-modulus rows of chapter 130, the compact interval locator of chapter 1891, the finite attainment route of chapter 1493, and the derivative metric quotient rows of chapter 122. The packet names a stationary-point certificate over displayed interval, endpoint, continuity, attainment, derivative, and zero-seal rows; it is not a host mean-value theorem, a classical differentiability principle, quotient real equality, open-cover compactness, or a choice-selected interior point.

Definition 1902.1 (Rolle carrier)**.** *A* $\mathsf{Rolle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, E, F, V, D, W, Z, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, exposing the located endpoint names, interval locator, finite windows, and compact-interval boundary data used by the theorem.*
2. *E is the endpoint-equality row, recording that the two endpoint value seals for the displayed map are classifier-equal through the same* $\mathsf{Real}^{\uparrow}$ *route.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the real-valued map on the compact interval source.*
4. *V is the* $\mathsf{ExtremeValue}^{\uparrow}$ *witness row, carrying the finite attainment route for the displayed continuous map on the compact interval data.*
5. *D is the* $\mathsf{Derivative}^{\uparrow}$ *metric quotient row, recording the inspected interior derivative quotient route rather than a host differentiability predicate.*
6. *W is the interior witness row, binding the stationary-point read to a displayed interior interval cell and excluding endpoint-only witnesses.*
7. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *zero-seal row for the derivative quotient named by D at the interior witness named by W.*
8. *H records componentwise* hsame *transport for the compact interval source, endpoint equality, continuous-map row, extreme-value witness, derivative quotient, interior witness, zero seal, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay from interval inspection to map windows, from endpoint equality to the extreme-value comparison route, from the attainment row to the interior witness, and from the derivative quotient route to the zero seal.*

10. *P is the* Pkg *provenance over* $\mathsf{Rolle}^{\uparrow}$, $\mathsf{CompactIntervalLocator}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ExtremeValue}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{Rolle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host real equality, open-cover compactness, arbitrary point choice, ambient differentiability, a full mean-value theorem, quotient real equality, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RolleUp.RolleUpTasteGate single carrier alignment`

Theorem 1902.2 (Rolle NameCert obligations)**.** *For every accepted* $\mathsf{Rolle}^{\uparrow}$ *carrier*

$$R = (I, E, F, V, D, W, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Rolle}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact interval source admission through I;*
2. *endpoint equality for the two displayed endpoint value seals through E;*
3. *continuous real-valued map admission through F;*
4. *extreme-value witness routing through V;*
5. *derivative metric quotient and interior zero-seal routing through D, W, Z.*

The structural rows H, C, P, N transport, replay, source, and name only these five rows. No Rolle obligation is stored outside the displayed carrier.

Proof. Carrier admission is projection from Definition 1902.1. The source row I supplies the compact interval data, and the endpoint row E supplies the equality of the two displayed endpoint value seals.

The map and attainment rows are then fixed. The row F is the only continuous-map surface, and V is the only extreme-value witness route attached to that map and interval source.

Finally inspect the derivative-facing rows. The quotient row D, the interior witness row W, and the zero-seal row Z form the only derivative-zero route in the packet.

The remaining rows H, C, P, N preserve, replay, source, and name the same data. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RolleUp.TasteGate.RolleTasteGate single carrier alignment`

Theorem 1902.3 (Rolle extreme-value stationary point)**.** *Every stationary witness exported by an accepted* $\mathsf{Rolle}^{\uparrow}$ *carrier factors through the extreme-value row V together with the endpoint-equality row E. The witness is therefore read as an interior stationary certificate produced from displayed attainment and equal-endpoint rows, not as a choice-selected point or an ambient compactness conclusion.*

Proof. Start with an accepted carrier $R = (I, E, F, V, D, W, Z, H, C, P, N)$. The compact interval source and continuous-map row expose the domain and graph data before any stationary read is available.

Read the endpoint equality E and the extreme-value row V. These are the only rows connecting the two endpoint value seals to the attained-value comparison route.

The interior witness W is downstream of that comparison. Transport and replay through H and C preserve the same row inventory, while P and N add only provenance and local naming.

Thus any exported stationary witness passes through the endpoint-equality and extreme-value rows before the derivative-zero seal can be displayed. The packet contains no separate selected point or host compactness conclusion. □

Theorem 1902.4 (Rolle derivative-zero seal boundary)**.** *The derivative-zero claim exported by an accepted* $\mathsf{Rolle}^{\uparrow}$ *carrier is only the displayed* $\mathsf{Real}^{\uparrow}$ *zero seal* Z *over the derivative quotient route* D *at the interior witness* W*. It does not assert host differentiability, a general mean-value theorem, quotient real equality, or an ambient equality of completed real functions.*

Proof. Project the derivative-facing part of Definition 1902.1. The packet contains a derivative metric quotient row D, an interior witness row W, and a terminal zero-seal row Z.

The derivative chapter supplies the quotient route, while the real chapter supplies the meaning of the displayed zero seal. Neither row stores a host differentiability predicate or an equality of completed functions.

The endpoint and extreme-value rows explain why this zero seal is exported for the Rolle packet, but they do not enlarge it into a mean-value theorem. The structural rows only transport and replay the displayed route.

Consequently the exported derivative-zero statement remains a $\mathsf{Real}^{\uparrow}$ seal over D and W, with no hidden host differentiability or ambient real-equality content. □

Falsifiable prediction: Every $\mathsf{Rolle}^{\uparrow}$ stationary read factors through a compact interval source row, endpoint equality row, $\mathsf{ContinuousMap}^{\uparrow}$ row, $\mathsf{ExtremeValue}^{\uparrow}$ witness row, $\mathsf{Derivative}^{\uparrow}$ metric quotient row, interior witness row, terminal $\mathsf{Real}^{\uparrow}$ zero seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, continuousmap, compact-interval-locator, extremevalue, derivative: $\mathsf{Rolle}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries equal endpoint value seals, a compact interval source, a continuous real-valued map, an extreme-value witness, an interior derivative quotient, a zero seal, transport, replay, provenance, and local naming as one stationary-point packet.

Closure status for $\mathsf{NameCert}_{\mathsf{Rolle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Rolle}^{\uparrow}$ packet is generated from a compact interval source row, an endpoint-equality row, a $\mathsf{ContinuousMap}^{\uparrow}$ graph row, an $\mathsf{ExtremeValue}^{\uparrow}$ witness row, a $\mathsf{Derivative}^{\uparrow}$ metric quotient row, an interior witness row, a terminal $\mathsf{Real}^{\uparrow}$ zero seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Rolle}^{\uparrow}}$, seed)

Scope closed: Definition 1902.1, Definition 1902.2, Definition 1902.3, and Definition 1902.4 seed the finite Rolle stationary-point reading over compact interval, endpoint equality, continuous-map, extreme-value, derivative quotient, interior witness, and Real zero-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Rolle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host differentiability, a general mean-value theorem, quotient real equality, open-cover compactness, selected interior points, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint equality, extreme-value factorization, derivative quotient zero-seal boundary, and TasteGate field faithfulness for BEDC.Derived.RolleUp.

Chapter 1903

A Concrete Naming Certificate for $\mathsf{CompactOpenMetric}^{\uparrow}$

Following Kelley and Bourbaki on the compact-open topology, and Bishop-style finite nets for compact metric spaces, the $\mathsf{CompactOpenMetric}^{\uparrow}$ packet names the constructive compact-open interface seen by continuous-map families. It records a sup-distance boundary over finite source nets rather than an ambient topology on all functions. The packet sits between the compact source rows of chapter 129, the continuous-map graph and modulus rows of chapter 130, the complete target rows of chapter 128, the finite handoff of chapter 388, the modulus ledger of chapter 369, and the Real-distance surface of chapter 1624.

The chapter isolates the function-family metric boundary consumed by compact-continuity arguments such as chapter 412. It does not construct an open-cover compactness theorem, does not install a host function-space topology, and does not choose subsequences or limits outside the displayed finite rows.

Definition 1903.1 (Compact-open metric carrier)**.** *A* $\mathsf{CompactOpenMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, F, G, M, D, S, H, C, P, N)$$

with the following displayed coordinates:

1. *X is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, including the compact metric distance surface and finite* $\mathsf{ProbeBundle}$ *net rows used for source inspection.*
2. *Y is the target* $\mathsf{CompleteMetric}^{\uparrow}$ *row whose distance witnesses and completion-facing reads receive every sampled value.*
3. *F is a finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows from X to Y.*
4. *G records the displayed graph rows of the maps in F on the finite source-net windows.*
5. *M records* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$ *handoff rows turning pointwise continuity data into uniform finite source windows.*
6. *D records finite target-distance samples for pairs of rows in F over the source-net windows, read through the target metric and the* $\mathsf{RealUniformStructure}^{\uparrow}$ *distance boundary.*
7. *S records the sup-distance comparison ledger obtained by taking the finite maximum of the sampled target-distance rows at each requested window.*

8. *H records componentwise* hsame *transport for source compact-metric rows, target complete-metric rows, continuous-map rows, graph rows, modulus rows, distance samples, sup-distance ledgers, replay rows, provenance, and local naming.*

9. *C records displayed* Cont *replay from a compact-open distance request through source-net selection, graph evaluation, target-distance sampling, finite maximum comparison, and modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactOpenMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, F, G, M, D, S, H, C, P, N$. No carrier coordinate names open-cover compactness, an ambient function-space topology, choice-selected subsequences, or Real completeness.

Lean4 ✓ `BEDC.Derived.CompactOpenMetricUp.CompactOpenMetricTasteGate single carrier alignment`

Theorem 1903.2 (Compact-open metric NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenMetric}^{\uparrow}$ *carrier $K = (X, Y, F, G, M, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenMetric}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the source compact-metric row, target complete-metric row, continuous-map family ledger, displayed graph rows, finite uniform-modulus rows, target-distance samples, finite sup-distance comparison rows, transport, replay, provenance, and local naming;*

2. *finite source inspection, requiring every compact-open distance request to choose its source windows from the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net coordinate X;*

3. *graph and distance sampling, requiring every sampled value to be read through G and every sampled distance to be read through Y and the* $\mathsf{RealUniformStructure}^{\uparrow}$ *distance boundary;*

4. *uniform handoff, requiring M to record the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$ *route that makes finite source-net samples stable for the requested tolerance;*

5. *classifier transport and non-escape, requiring H, C, P, N to preserve the same rows and to export no open-cover compactness, ambient function-space topology, choice-selected subsequence, or Real completeness.*

No NameCert obligation is stored outside those displayed rows.

Proof. Carrier admission is projection from Definition 1903.1. The packet exposes exactly the source compact-metric row, target complete-metric row, family ledger, graph rows, modulus rows, sampled-distance rows, finite sup-distance ledger, and structural rows.

Finite source inspection is forced by the coordinate X. A compact-open distance request first reads the compact-metric finite-net rows and cannot inspect source points through an unrecorded open cover.

Graph and distance sampling are then read from G, Y, and D. The family ledger supplies the named continuous-map graph rows, the target row supplies complete-metric distance witnesses, and the Real uniform-structure boundary names the distance surface used by the finite comparison.

The modulus handoff is the coordinate M. It records the compact-uniform-continuity and uniform-modulus rows that make the finite samples stable under the requested tolerance, so the sup-distance ledger is a finite certificate rather than a topology on all functions.

Finally, H, C, P, N transport and replay the same route. Because the carrier has no row for open-cover compactness, an ambient function-space topology, choice-selected subsequences, or Real completeness, the local certificate cannot export any of them. □

Theorem 1903.3 (Compact-open metric uniform-distance handoff)**.** *Every compact-continuity consumer reading an accepted* $\mathsf{CompactOpenMetric}^{\uparrow}$ *carrier obtains a finite uniform-distance handoff through the displayed rows*

$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{CompactUniformContinuity}^{\uparrow}, \mathsf{UniformModulus}^{\uparrow}, \mathsf{RealUniformStru}$

The handoff supplies source finite nets, continuous-map graph samples, target distance rows, finite sup-distance comparisons, and modulus stability. It supplies no open-cover compactness, ambient function-space topology, choice-selected subsequence, or Real completeness.

Proof. Begin with a compact-continuity consumer and project the accepted packet K. The source coordinate X supplies the finite ProbeBundle windows through the compact-metric row, and the family coordinate F names the continuous-map rows that may be sampled.

Next read the graph coordinate G and target coordinate Y. Each sampled value is a displayed graph read, and each target-distance comparison is a displayed complete-metric read whose Real-distance surface is recorded in D.

The finite comparison ledger S gathers those target-distance samples into the sup-distance boundary for the requested window. The modulus coordinate M records the compact-uniform-continuity and uniform-modulus route that makes this finite comparison stable for downstream tolerance requests.

The structural rows H, C, P, N preserve the same finite route under classifier transport and replay. Since no further coordinate is present, the handoff cannot add open-cover compactness, host function-space topology, choice-selected subsequences, or Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOpenMetric}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a CompleteMetricUp target row, ContinuousMapUp family and graph rows, CompactUniformContinuityUp and UniformModulusUp handoff rows, RealUniformStructureUp target-distance rows, finite sup-distance comparison rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1903.1, Definition 1903.2, and Definition 1903.3 seed the constructive compact-open sup-metric boundary for continuous-map families.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenMetric}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompactOpenMetricUp.CompactOpenMetricTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, ambient function-space topology, choice-selected subsequences, Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires carrier admission, finite source inspection, graph and distance sampling, uniform handoff, classifier transport, and non-escape proofs for the same packet.

Chapter 1904

A Concrete Naming Certificate for $\mathsf{RegularCauchyCancellation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyCancellation}^{\uparrow}$ packet records the finite cancellation boundary for displayed regular rational Cauchy names. It ties the pointwise sum route of chapter 417, the difference route of chapter 429, the zero route of chapter 624, the finite precision ledger of chapter 385, the regular source rows of chapter 301, and the terminal real-name seal of chapter 38 into one inspectable packet. The packet supplies a bounded route for cancelling a shared displayed summand before any $\mathsf{Real}^{\uparrow}$ consumer reads the result; it is not a completed-real additive group law, quotient stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1904.1 (Regular Cauchy cancellation carrier)**.** *A* $\mathsf{RegularCauchyCancellation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, S_X, S_Y, D, B, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. X, Y, Z *are the three* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, with* Z *the shared summand offered to both sum routes.*
2. S_X *is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *route for the displayed sum* $X + Z$*.*
3. S_Y *is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *route for the displayed sum* $Y + Z$*.*
4. D *is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *route comparing the two displayed sums and exposing the difference readback only through finite source windows, dyadic endpoint rows, and regular readback data.*
5. B *is the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger that accounts for the two sum budgets, the difference budget, and the cancellation tolerance requested by a downstream consumer.*
6. Q *is the* $\mathsf{RegularCauchyZero}^{\uparrow}$ *boundary row used to identify the shared* $Z - Z$ *contribution as the displayed zero route, with any* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *read confined to the sibling difference packet.*
7. R *is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite cancellation route from* $(X+Z)-(Y+Z)$ *to* $X - Y$*.*
8. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S_X, S_Y, D, B, Q, R *have been displayed.*

9. *H records componentwise* hsame *transport for the source rows, two sum routes, difference route, budget ledger, zero boundary, readback, seal, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a cancellation-facing precision request through $X, Y, Z, S_X, S_Y, D, B, Q, R,$*
11. *P is the* Pkg *provenance over* RegularCauchyCancellation$^\uparrow$, RegularCauchySum$^\uparrow$, RegularCauchyDifference$^\uparrow$, RegularCauchyZero$^\uparrow$, RegularCauchyNegation$^\uparrow$, FiniteErrorBudget$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{RegularCauchyCancellation}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, Y, Z, S_X, S_Y, D, B, Q, R, E, H, C, P, N$. The carrier has no coordinate for completed-real additive group laws, quotient stream equality, selected limits, trichotomy, countable choice, ambient Real$^\uparrow$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCancellationUp.TasteGate.RegularCauchyCancellationTasteGate`
`single carrier alignment`

Theorem 1904.2 (Regular Cauchy cancellation NameCert obligation surface)**.** *For every accepted* RegularCauchyCancellation$^\uparrow$ *carrier*

$$K = (X, Y, Z, S_X, S_Y, D, B, Q, R, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyCancellation}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the three* RegSeqRat$^\uparrow$ *source rows, two* RegularCauchySum$^\uparrow$ *routes, the* RegularCauchyDifference$^\uparrow$ *comparison route, the* FiniteErrorBudget$^\uparrow$ *ledger, the zero boundary row, the readback row, and the structural rows;*
2. *sum exactness, requiring S_X and S_Y to expose the two displayed sums only through aligned* StreamName$^\uparrow$ *windows,* DyadicRatCore$^\uparrow$ *endpoint rows, and their own finite error ledgers;*
3. *difference exactness, requiring D to compare the displayed sums through the sibling* RegularCauchyDifference$^\uparrow$ *route before any cancellation readback is available;*
4. *zero-boundary exactness, requiring Q to display the shared $Z-Z$ contribution through* RegularCauchyZero$^\uparrow$ *rather than through host real algebra;*
5. *budget exactness, requiring B to account for the two sum budgets, the difference budget, and the cancellation tolerance before R is consumed;*
6. *Real seal nonescape, requiring E to be downstream of R and to expose no completed-real additive group law, quotient stream equality, selected limit, trichotomy, countable choice, ambient completeness, Lean verification, or bridge row;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the same finite cancellation packet.*

No cancellation obligation is stored outside these rows.

Theorem 1904.3 (Regular Cauchy left cancellation finite route)**.** *Let $K = (X, Y, Z, S_X, S_Y, D, B, Q, R, E, H, C, P,$ be an accepted* RegularCauchyCancellation$^\uparrow$ *carrier. Every consumer that reads the cancellation of the shared left-hand summand factors through the finite route*

$$X, Y, Z \longmapsto S_X, S_Y \longmapsto D, B, Q \longmapsto R, E, H, C, P, N.$$

The consumer first reads the three source RegSeqRat$^{\uparrow}$ *rows and the two displayed sum routes, then the difference route between those sums, the finite budget ledger, and the zero boundary for the shared $Z - Z$ contribution, and only then obtains the regular readback and* Real$^{\uparrow}$ *seal. The route exports no completed-real additive group law, quotient stream equality, selected limit, trichotomy witness, countable-choice selector, or ambient completeness principle.*

Theorem 1904.4 (Regular Cauchy cancellation Real seal nonescape)**.** *Every* Real$^{\uparrow}$ *consumer of an accepted* RegularCauchyCancellation$^{\uparrow}$ *carrier reaches the seal row E only after the* RegSeqRat$^{\uparrow}$ *readback R has been assembled from the two* RegularCauchySum$^{\uparrow}$ *routes, the* RegularCauchyDifference$^{\uparrow}$ *route, the* RegularCauchyZero$^{\uparrow}$ *boundary row, and the* FiniteErrorBudget$^{\uparrow}$ *ledger. The real-facing boundary exposes the finite source rows, sum routes, difference route, zero route, budget ledger, readback, componentwise transport, continuation replay, provenance, and local naming. It exposes no completed-real additive group law, quotient stream equality, selected limit, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or public bridge row.*

Closure status for NameCert$_{\text{RegularCauchyCancellation}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCancellation}^{\uparrow}}$, seed)

Scope closed: Definition 1904.1, Definition 1904.2, Definition 1904.3, and Definition 1904.4 seed the finite cancellation boundary through three RegSeqRat$^{\uparrow}$ source rows, two sum routes, one difference route, one zero boundary row, one finite budget ledger, a regular readback, and a Real$^{\uparrow}$ seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCancellation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed-real additive group laws, quotient stream equality, selected limits, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sum exactness, difference exactness, zero-boundary exactness, budget exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCancellationUp.

Constructive story: A RegularCauchyCancellation$^{\uparrow}$ packet is generated from three RegSeqRat$^{\uparrow}$ source rows, two RegularCauchySum$^{\uparrow}$ routes, one RegularCauchyDifference$^{\uparrow}$ route, one RegularCauchyZero$^{\uparrow}$ boundary row, one FiniteErrorBudget$^{\uparrow}$ ledger, a RegSeqRat$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1905

A Concrete Naming Certificate for $\mathsf{RealApartnessOrderBridge}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ packet records the constructive route from positive real apartness evidence to order-facing comparison data. It consumes chapter 304, **??**, chapter 38, chapter 301, chapter 291, and chapter 126. The packet names the finite handoff by which a displayed positive radius can be read by order consumers without installing trichotomy, quotient real equality, a selected limit, or completeness for $\mathsf{Real}^{\uparrow}$.

Definition 1905.1 (RealApartnessOrderBridge carrier)**.** *A* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, A, L, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two endpoint* $\mathsf{Real}^{\uparrow}$ *rows, exposing only their terminal real-name seals and the finite comparison handles needed by downstream order consumers.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-radius witness row, binding the endpoint pair to an inspected radius seal and recording that the separation evidence is positive apartness data rather than an equality decision.*
3. *L records the* $\mathsf{LocatedReal}^{\uparrow}$ *refinement rows for the two endpoints, including the located dyadic refinements used to align the endpoint windows with the positive-radius witness.*
4. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for the rational regular sequences underlying the displayed endpoint names and refinement windows.*
5. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and comparison rows, including the positive radius token, dyadic lower-bound comparison, and finite order-facing comparison cell exported to consumers.*
6. *S records the* $\mathsf{StreamName}^{\uparrow}$ *finite window rows used to inspect the endpoint streams, radius stream, and comparison windows at the displayed precision.*
7. *H records componentwise* hsame *transport for the endpoint rows, apartness witness, located refinements, regular-sequence sources, dyadic-radius and comparison rows, stream windows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from endpoint names to stream windows, from stream windows to located dyadic refinements, from the positive-radius witness to the dyadic comparison cell, and from the comparison cell to the order-facing handoff row.*

9. *P is the* Pkg *provenance over* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApartnessOrderBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for equality-or-apartness decisions, total order, quotient real equality, selected real limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealApartnessOrderBridgeUp.RealApartnessOrderBridgeTasteGate single carrier alignment`

Theorem 1905.2 (RealApartnessOrderBridge NameCert obligations)**.** *For every accepted* RealApartnessOrderBrid *carrier*

$$G = (X, Y, A, L, R, D, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealApartnessOrderBridge}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *endpoint admission for the two displayed* $\mathsf{Real}^{\uparrow}$ *rows X, Y;*
2. *positive apartness witness admission through the* $\mathsf{ApartnessReal}^{\uparrow}$ *row A;*
3. *located dyadic refinement admission through the* $\mathsf{LocatedReal}^{\uparrow}$ *row L;*
4. *rational and dyadic comparison source admission through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows R, D;*
5. *finite stream-window admission through the* $\mathsf{StreamName}^{\uparrow}$ *row S.*

The structural rows H, C, P, N transport, replay, source, and name only these five obligation rows. No order-facing handoff obligation is stored outside the displayed carrier.

Proof. Carrier admission is projection from Definition 1905.1. The endpoint rows X, Y supply the two displayed real-name surfaces, and the apartness row A supplies the positive-radius witness attached to that endpoint pair.

The refinement and source rows are then fixed. The row L is the only located-refinement surface, while R and D are the only rational and dyadic rows that expose the radius and comparison data.

Finally inspect the finite-window row S. It is the only stream-name surface from which the endpoint, radius, and comparison windows are read.

The remaining rows H, C, P, N preserve, replay, source, and name the same data. Since the carrier has no additional coordinate, the listed five rows exhaust the local NameCert surface. □

Theorem 1905.3 (RealApartnessOrderBridge positive order handoff)**.** *Every order-facing consumer read exported by an accepted* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *carrier factors through the displayed positive-separation handoff formed by the* $\mathsf{ApartnessReal}^{\uparrow}$ *witness row A, the* $\mathsf{LocatedReal}^{\uparrow}$ *refinement row L, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row D, and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S. The consumer may read only this finite positive-separation handoff, not an ambient comparison principle.*

Proof. Start with an accepted carrier $G = (X, Y, A, L, R, D, S, H, C, P, N)$. The endpoint rows expose the two real names before any order-facing read is available.

Read the positive-radius witness A together with the located refinements L. These rows bind the apartness evidence to displayed dyadic windows rather than to a host comparison of completed reals.

The dyadic comparison row D and stream-window row S then provide the finite comparison cell consumed by an order-facing reader. Transport and replay through H and C preserve that same row inventory, while P and N add only provenance and local naming.

Thus every exported consumer read factors through the displayed positive-separation handoff. The packet contains no separate ambient comparison principle or selected real object. □

Theorem 1905.4 (RealApartnessOrderBridge no trichotomy)**.** *An accepted* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *carrier exports no equality-or-apartness decision, total order on* $\mathsf{Real}^{\uparrow}$*, quotient real, selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness principle. Its public content is only the finite positive-separation handoff described by the displayed endpoint, apartness, located-refinement, rational-source, dyadic-comparison, stream-window, transport, replay, provenance, and naming rows.*

Proof. Project the rows of Definition 1905.1. The endpoint rows, positive-radius witness, located refinements, rational sources, dyadic comparison rows, and stream windows are the only mathematical data coordinates in the carrier.

None of these rows stores a trichotomy branch, quotient constructor, equality decision, selected limit, or completeness witness. The apartness row records positive evidence, and the comparison row records only the finite handoff cell derived from that evidence.

The structural rows H, C, P, N cannot create new mathematical coordinates; they only transport, replay, source, and name the displayed rows. Therefore the packet exports the stated positive-separation handoff and none of the listed excluded principles. □

Falsifiable prediction: Every $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ order-facing read factors through two endpoint $\mathsf{Real}^{\uparrow}$ rows, an $\mathsf{ApartnessReal}^{\uparrow}$ positive-radius witness, $\mathsf{LocatedReal}^{\uparrow}$ refinement rows, $\mathsf{RegSeqRat}^{\uparrow}$ source rows, $\mathsf{DyadicRatCore}^{\uparrow}$ radius and comparison rows, $\mathsf{StreamName}^{\uparrow}$ finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: apartnessreal, locatedreal, real, regseqrat, dyadicratcore, streamname: $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint names, a positive apartness witness, located refinements, rational sequence sources, dyadic radius and comparison data, finite stream windows, transport, replay, provenance, and local naming as one order-facing handoff packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealApartnessOrderBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ packet is generated from two endpoint $\mathsf{Real}^{\uparrow}$ rows, an $\mathsf{ApartnessReal}^{\uparrow}$ positive-radius witness, $\mathsf{LocatedReal}^{\uparrow}$ refinement rows, $\mathsf{RegSeqRat}^{\uparrow}$ source rows, $\mathsf{DyadicRatCore}^{\uparrow}$ radius and comparison rows, $\mathsf{StreamName}^{\uparrow}$ finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealApartnessOrderBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1905.1, Definition 1905.2, Definition 1905.3, and Definition 1905.4 seed the finite positive-apartness route from endpoint real names to order-facing comparison data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealApartnessOrderBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close equality-or-apartness decisions, total order on RealUp, quotient real construction, selected limits, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius handoff, no-trichotomy boundary, and TasteGate field faithfulness for BEDC.Derived.RealApartnessOrderBridgeUp.

Chapter 1906

A Concrete Naming Certificate for $\mathsf{RegulatedFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegulatedFunction}^{\uparrow}$ packet names a regulated function by finite BHist rows of dyadic step-function approximation schedules. It sits over the dyadic mesh surface of chapter 358, the dyadic step-function carrier of chapter 428, the finite Darboux sum boundary of chapter 1880, the tagged-mesh Riemann route of chapter 1526, and the terminal real-name seal of chapter 38. The packet gives integration-facing consumers a displayed step-approximation handoff without importing host function quotients, measure-theoretic integration, open-cover compactness, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1906.1 (Regulated function carrier)**.** *A* $\mathsf{RegulatedFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, M, A, T, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain row, read through the terminal* $\mathsf{Real}^{\uparrow}$ *seal and its interval-facing data from chapter 38.*
2. *M is the finite dyadic mesh ledger, read through chapter 358, listing the displayed partitions used by the approximation schedule.*
3. *A is the dyadic step-function approximation schedule. Each row of A is a* $\mathsf{DyadicStepFunction}^{\uparrow}$ *packet over one mesh row of M, with its cells and values read through chapter 428.*
4. *T is the tolerance and tail ledger recording, for every displayed dyadic tolerance request, which later step rows are close enough to represent the same regulated read.*
5. *S is the finite sum handoff row connecting the step schedule to the* $\mathsf{DarbouxSum}^{\uparrow}$ *boundary of chapter 1880 and the* $\mathsf{RiemannIntegral}^{\uparrow}$ *tagged-mesh route of chapter 1526.*
6. *H records componentwise* hsame *transport for domain, mesh, step schedule, tolerance tail, finite sum handoff, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a domain request to a mesh row, from that mesh to a step-function approximant, from the approximant to the tail ledger, and from the tail ledger to the finite sum handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegulatedFunction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, M, A, T, S, H, C, P, N$. It has no coordinate for host function quotients, measure-theoretic integration, open-cover compactness, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedFunctionUp.RegulatedFunctionTasteGate single carrier alignment`

Theorem 1906.2 (Regulated function NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *carrier $F = (D, M, A, T, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, real-domain admission, dyadic mesh admission, dyadic step-function schedule admission, tolerance-tail routing, Darboux/Riemann finite-sum handoff, componentwise transport, continuation replay, provenance, local naming, and non-escape from host function quotients, measure-theoretic integration, open-cover compactness, selected limits, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1906.1. The accepted packet displays only the domain row D, mesh ledger M, step schedule A, tail ledger T, finite sum handoff S, transports H, continuations C, provenance P, and local name N.

The analytic rows are all finite. The real-facing domain row is read through chapter 38; each mesh row is read through chapter 358; and each approximant in A is read through the dyadic step-function carrier of chapter 428.

The tail and handoff rows impose the regulated-function route. The ledger T records which displayed approximants answer each tolerance request, while S exposes only the finite Darboux-sum and Riemann-mesh handoff named by chapter 1880 and chapter 1526. The rows H, C, P, N preserve and name this same route, so no excluded host object is available. □

Theorem 1906.3 (Regulated function step-approximation handoff)**.** *Every accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *packet exposes any integration-facing read through the finite route*

$$D, M, A, T \longmapsto S.$$

The row S can be consumed by Darboux and Riemann chapters only after the real-domain row, dyadic mesh ledger, dyadic step-function schedule, and tolerance-tail ledger have all been displayed.

Proof. Start with an integration-facing consumer request. The continuation row C first replays the real-domain row D and then selects a finite dyadic mesh row from M, so the request is already confined to displayed real and mesh data.

The chosen mesh row determines the visible step approximant in A. That approximant is a dyadic step-function packet, hence its cells, endpoint transports, and carried values are finite rows before any sum handoff is read.

It remains to reach S. The tail ledger T records that the selected approximant belongs to the displayed regulated schedule at the requested tolerance. Only then does C expose the finite sum handoff row S, whose consumers are the Darboux sum and Riemann integral surfaces. No carrier coordinate offers a host quotient of functions, a measure-theoretic integral, an open-cover compactness proof, a selected limit, or an ambient completeness witness for $\mathsf{Real}^{\uparrow}$. □

Theorem 1906.4 (Regulated function bounded step envelope)**.** *Every accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *packet exposes any boundedness-facing read only through*

$$D, M, A, T$$

before the finite-sum handoff row S can be consumed. The finite dyadic step approximants in A, indexed by the mesh ledger M and tolerance-tail ledger T, supply the only visible envelope rows available to downstream boundedness consumers.

Proof. Project the accepted carrier $F = (D, M, A, T, S, H, C, P, N)$ from Definition 1906.1. The rows preceding S are precisely the real-domain row, dyadic mesh ledger, dyadic step-function schedule, and tolerance-tail ledger.

Apply the step-approximation handoff of Definition 1906.3. Any consumer that reaches S has already read D, M, A, T, and the approximants in A are finite $\mathsf{DyadicStepFunction}^{\uparrow}$ packets over the displayed mesh rows.

Thus a boundedness-facing consumer can request envelope data only from the visible step schedule and its tolerance ledger. The carrier provides no host function quotient, selected supremum, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate from which another bound could be read. □

Theorem 1906.5 (Regulated function variation-control route)**.** *An accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *packet whose finite step schedule exposes compatible endpoint variation rows can be consumed by* $\mathsf{BoundedVariation}^{\uparrow}$ *and* $\mathsf{VariationMeasure}^{\uparrow}$ *only through the displayed route*

$$D, M, A, T, S, H, C, P, N$$

of Definition 1906.1, together with the sibling finite partition-variation ledger read by chapter 398 and chapter 3593. The route exports regulated step envelopes and finite partition variation data, not host total variation, measure completion, selected suprema, function quotients, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 1906.1. Its only analytic rows are the real-domain row D, finite dyadic mesh ledger M, dyadic step schedule A, tolerance-tail ledger T, and finite-sum handoff row S; the rows H, C, P, N only transport, replay, source, and name that same finite route.

Apply the step-approximation handoff of Definition 1906.3. Any consumer of the schedule first reads D, M, A, T before S is available, so compatible endpoint variation data can be attached only to the displayed finite step rows.

Now use the bounded step envelope of Definition 1906.4. It confines boundedness-facing reads to the visible step schedule and tail ledger, which is exactly the finite partition-variation surface consumed by $\mathsf{BoundedVariation}^{\uparrow}$ and then by $\mathsf{VariationMeasure}^{\uparrow}$.

Thus the cross-chapter handoff is the displayed regulated-function route plus the sibling finite partition ledger. No carrier coordinate supplies host total variation, measure completion, selected suprema, function quotients, or ambient real completeness. □

Theorem 1906.6 (Regulated function obligation closure package)**.** *The carrier of Definition 1906.1, the NameCert surface of Definition 1906.2, and the step-approximation handoff of Definition 1906.3 jointly supply the finite obligation surface for* $\mathsf{RegulatedFunction}^{\uparrow}$*. This surface consists exactly of carrier admission,* $\mathsf{Real}^{\uparrow}$ *domain admission,* $\mathsf{DyadicMesh}^{\uparrow}$ *admission,* $\mathsf{DyadicStepFunction}^{\uparrow}$ *schedule admission, tolerance-tail routing, Darboux/Riemann finite-sum handoff, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$ *admission, and non-escape from host function quotients, measure-theoretic integration, open-cover compactness, selected limits, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $F = (D, M, A, T, S, H, C, P, N)$. The carrier definition displays exactly the domain row, mesh ledger, step schedule, tail ledger, handoff row, transport row, continuation row, provenance row, and local naming row.

The NameCert-obligation theorem identifies these displayed rows as the full local obligation surface. In particular, D carries real-domain admission, M carries dyadic mesh admission, A carries dyadic step-function schedule admission, T carries tolerance-tail routing, and S carries the Darboux/Riemann finite-sum handoff.

The handoff theorem then supplies the integration-facing direction. It forces every consumer of S to pass through D, M, A, T first. Rows H, C, P, N preserve, replay, source, and name the same route, so the excluded host structures never become available as obligations. □

Theorem 1906.7 (Regulated function scoped kernel route)**.** *Every accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer read factors through the displayed route*

$$D, M, A, T, S, H, C, P, N$$

over $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicMesh}^{\uparrow}$*,* $\mathsf{DyadicStepFunction}^{\uparrow}$*,* $\mathsf{DarbouxSum}^{\uparrow}$*,* $\mathsf{RiemannIntegral}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. No accepted read factors through host function quotients, measure-theoretic integration, open-cover compactness, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier projection. The only analytic rows in an accepted packet are the real-domain row D, the dyadic mesh ledger M, the dyadic step-function schedule A, the tolerance-tail ledger T, and the finite-sum handoff row S.

The obligation closure package binds those analytic rows to the structural rows H, C, P, N. Thus componentwise transport, continuation replay, provenance, and local naming do not create a second carrier surface; they route the same finite data through the BEDC kernel objects listed in the statement.

Finally apply the step-approximation handoff. Any integration-facing consumer reaches S only after reading D, M, A, T, and any structural consumer reaches those rows only through H, C, P, N. This exhausts the scoped kernel route and leaves no coordinate for the excluded host objects. □

Theorem 1906.8 (Regulated function left–right limit consumer)**.** *Every accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer that reads paired one-sided limits must keep the source route*

$$D, M, A, T, S, H, C, P, N$$

visible before any $\mathsf{OneSidedLimit}^{\uparrow}$ *rows or terminal* $\mathsf{Real}^{\uparrow}$ *seals are consumed. Consequently a* $\mathsf{CadlagRealFunction}^{\uparrow}$ *or side-window consumer may use the regulated source as the displayed step-approximation schedule of chapter 5841 and chapter 5968, but it cannot replace that source with host function quotients, selected limits, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1906.1. The only source rows are the real-domain row D, dyadic mesh ledger M, dyadic step schedule A, tolerance-tail ledger T, finite-sum handoff S, and structural rows H, C, P, N.

Apply Definition 1906.7. It keeps every accepted consumer read inside those rows and refuses host function quotients, measure-theoretic integration, open-cover compactness, selected limits, and ambient Real completeness.

The one-sided-limit consumer can then read left and right side-window rows only downstream from that regulated source route. The cadlag chapter consumes the same paired side-window data after the regulated source has been displayed, so the paired limit handoff remains attached to $D, M, A, T, S, H, C, P, N$ rather than to an external function object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedFunction}^{\uparrow}$ packet is generated from a real-domain row, a finite dyadic mesh ledger, a dyadic step-function approximation schedule, a tolerance-tail ledger, a Darboux/Riemann finite-sum handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedFunction}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1906.1, Definition 1906.2, Definition 1906.3, Definition 1906.6, and Definition 1906.7 close the finite regulated-function surface over real-domain, dyadic mesh, dyadic step-function, tail-ledger, finite-sum handoff, transport, continuation, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function quotients, measure-theoretic integration, open-cover compactness, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires checked carrier admission, mesh and step-schedule admission, tolerance-tail routing, Darboux/Riemann handoff, non-escape, and field faithfulness for BEDC.Derived.RegulatedFunctionUp.

Chapter 1907

A Concrete Naming Certificate for $\mathsf{ConstructiveMeanValue}^{\uparrow}$

Following Cauchy, Lagrange, Rolle, and the Bishop–Bridges treatment of constructive analysis, the $\mathsf{ConstructiveMeanValue}^{\uparrow}$ packet records the finite BEDC boundary of the mean-value witness that is obtained by reducing a displayed secant comparison to the already named Rolle packet. It consumes the terminal real-name surface of chapter 38, the pointwise graph and modulus rows of chapter 130, the compact interval locator of chapter 1891, the finite attainment route of chapter 1493, the derivative metric quotient rows of chapter 122, and the stationary packet of chapter 1902. The chapter names only the finite witness surface: interval data, secant-slope rows, adjusted Rolle data, derivative quotient inspection, an interior witness, a terminal $\mathsf{Real}^{\uparrow}$ equality seal, transport, replay, provenance, and local naming.

Definition 1907.1 (Constructive mean-value carrier)**.** *A* $\mathsf{ConstructiveMeanValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, S, R, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, exposing located endpoint names, interval cells, and the finite boundary data inspected by the witness route.*
2. *S is the secant-slope row, recording the displayed endpoint-value difference, interval-width seal, and quotient route as* $\mathsf{Real}^{\uparrow}$ *data rather than as a host real quotient.*
3. *R is the adjusted* $\mathsf{Rolle}^{\uparrow}$ *packet obtained by subtracting the displayed secant line from the named* $\mathsf{ContinuousMap}^{\uparrow}$ *row over the same compact interval source.*
4. *D is the* $\mathsf{Derivative}^{\uparrow}$ *metric quotient row for the adjusted map together with the derivative quotient route of the original displayed map.*
5. *W is the interior witness row exported by the Rolle packet R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal saying that the derivative quotient read at W is classifier-equal to the secant-slope row S.*
7. *H records componentwise* hsame *transport for the interval source, secant slope, adjusted Rolle packet, derivative quotient, interior witness, equality seal, replay rows, provenance rows, and local naming rows.*

8. *C records displayed* Cont *replay from interval inspection to endpoint reads, from the secant row to the adjusted Rolle packet, from the Rolle stationary row to derivative inspection, and from the derivative quotient to the terminal equality seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveMeanValue}^{\uparrow}$, $\mathsf{Rolle}^{\uparrow}$, $\mathsf{CompactIntervalLocator}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ExtremeValue}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveMeanValue}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host differentiability, a choice-selected point, quotient real equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.ConstructiveMeanValueUp.ConstructiveMeanValueTasteGate single carrier alignment`

Theorem 1907.2 (Constructive mean-value NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveMeanValue}^{\uparrow}$ *carrier*

$$M = (I, S, R, D, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveMeanValue}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact interval admission through I;*
2. *secant-slope construction through S over displayed* $\mathsf{Real}^{\uparrow}$ *endpoint and interval-width seals;*
3. *adjusted Rolle admission through R over the same interval and continuous-map source;*
4. *derivative quotient routing through D and the interior witness row W;*
5. *terminal equality sealing through E;*
6. *structural stability through H, C, P, N.*

No mean-value obligation is stored outside the displayed carrier.

Proof. Carrier admission is projection from Definition 1907.1. The row I supplies the compact interval source, and S supplies the only secant-slope data available to the packet.

The adjusted theorem route is then fixed. The row R is the sole $\mathsf{Rolle}^{\uparrow}$ packet in the carrier, and it is built over the same interval and continuous-map source rather than over a detached host function.

Inspect the derivative-facing rows. The quotient row D, the interior witness row W, and the terminal equality row E are the only path from the adjusted Rolle stationary read back to the original secant-slope comparison.

Finally, the structural rows H, C, P, N transport, replay, source, and name the same row inventory. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 1907.3 (Constructive mean-value Rolle factorization)**.** *Every mean-value witness exported by an accepted* $\mathsf{ConstructiveMeanValue}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{Rolle}^{\uparrow}$ *stationary packet R. The exported witness is the interior row W together with the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal E between the derivative quotient route D and the secant-slope row S; it does not assert host differentiability, a selected point, quotient equality of completed reals, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $M = (I, S, R, D, W, E, H, C, P, N)$. The interval and secant data are visible before any witness is read, and the carrier exposes no other endpoint or quotient source.

Read the adjusted Rolle packet R. By chapter 1902, its stationary output is already constrained to the compact interval source, endpoint equality, continuous-map row, extreme-value witness, derivative quotient route, interior witness, and zero-seal boundary displayed inside the Rolle packet.

The mean-value carrier consumes exactly that stationary output. Its row W is the interior witness inherited from R, while D and E translate the adjusted zero-seal into the displayed equality between the original derivative quotient and the secant slope.

Transport and replay through H and C preserve this factorization, and P, N add only source and naming data. Thus every exported mean-value witness passes through R before it reaches D, W, E, with no hidden host differentiability, selected point, quotient equality, open-cover compactness, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{ConstructiveMeanValue}^{\uparrow}$ witness read factors through a compact interval source row, secant-slope row, adjusted $\mathsf{Rolle}^{\uparrow}$ packet, $\mathsf{Derivative}^{\uparrow}$ quotient route, interior witness row, terminal $\mathsf{Real}^{\uparrow}$ equality seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, continuousmap, compact-interval-locator, extremevalue, derivative, rolle: $\mathsf{ConstructiveMeanValue}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries secant-slope data, an adjusted $\mathsf{Rolle}^{\uparrow}$ stationary packet, derivative quotient comparison, an interior witness, a terminal equality seal, transport, replay, provenance, and local naming as one mean-value witness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveMeanValue}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveMeanValue}^{\uparrow}$ packet is generated from a compact interval source row, a secant-slope row, an adjusted $\mathsf{Rolle}^{\uparrow}$ packet, a $\mathsf{Derivative}^{\uparrow}$ quotient route, an interior witness row, a terminal $\mathsf{Real}^{\uparrow}$ equality seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveMeanValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1907.1, Definition 1907.2, and Definition 1907.3 seed the finite mean-value witness surface over compact interval, secant-slope, adjusted Rolle, derivative quotient, interior witness, and Real equality-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveMeanValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability, selected points, quotient equality of completed reals, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, secant-slope construction, adjusted Rolle factorization, derivative quotient equality sealing, and TasteGate field faithfulness for BEDC.Derived.ConstructiveMeanValueUp.

$\mathsf{Cauchy}^{\uparrow}$ is an L10 route whose regular-sequence, finite-window, dyadic-tolerance, and terminal seal reads are supplied through chapter 301, chapter 126, chapter 291, and chapter 38.

Chapter 1908

A Concrete Naming Certificate for $\mathsf{CauchyRealLocator}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRealLocator}^{\uparrow}$ packet records the finite locator surface by which a displayed Cauchy real answers Real-facing precision and side-location requests. It refines the modulus route of chapter 1423 and chapter 292, reads finite observations through chapter 126, uses the regular rational handoff of chapter 301, records dyadic tolerances through chapter 291, and reaches the terminal seal of chapter 38. The packet is a traditional constructive-analysis locator object reconstructed as finite NameCert data; it does not select a host limit, identify quotient streams, invoke countable choice, decide trichotomy, use open-cover compactness, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1908.1 (Cauchy real locator carrier)**.** *A* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row. It records the displayed RealCauchyModulus and CauchyModulus threshold data used for every locator request.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the locator at the requested precision and side test.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the positive dyadic scale, comparison cells, and slack budget for the displayed windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows into regular rational data before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *locator seal. It records only the Real-facing locator boundary delivered after M, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, stream windows, dyadic ledger, regular readback, terminal locator seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a locator request through M, S, D, Q, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$*, RealCauchyModulus, CauchyModulus,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $M, S, D, Q, R, H, C, P, N$. It has no coordinate for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Theorem 1908.2 (Cauchy real locator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier*

$$L = (M, S, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the modulus schedule, finite stream windows, dyadic tolerance ledger, regular rational readback, terminal Real locator seal, transport, replay, provenance, and local naming;*
2. *modulus exactness, requiring every locator request to use the displayed row M rather than an independent threshold, host convergence theorem, or selected limit;*
3. *window and tolerance compatibility, requiring the inspected windows in S to be compared only through the dyadic ledger D;*
4. *RegSeqRat readback, requiring the rational data consumed by the locator seal to pass through the displayed row Q;*
5. *route ordering, requiring R to be read only after M, S, D, Q have been displayed;*
6. *nonescape, excluding host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, and bridge checking.*

No local locator obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3410.1. The accepted packet displays exactly the modulus schedule, finite windows, dyadic ledger, regular readback, terminal locator seal, and structural rows.

Modulus exactness is forced by the single coordinate M. Every locator request reads its threshold from this row, so the packet has no second convergence witness, hidden host completeness theorem, or selected limit coordinate.

Window and tolerance compatibility are supplied by S and D. The stream row exposes only finite windows, while the dyadic row records the positive scale, comparison cells, and slack budget used to interpret those windows.

The readback and ordering clauses follow from Q and R. The regular rational row is the only rational readback coordinate, and the terminal Real locator seal occurs downstream of M, S, D, Q.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory contains no row for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 1908.3 (Cauchy real locator modulus route)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier factors each locator request through the displayed finite route*

$$M \longmapsto S, D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

Thus the request reaches the $\mathsf{Real}^{\uparrow}$ *locator seal only through the visible modulus schedule, finite stream windows, dyadic tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*

Proof. Begin with an accepted carrier $L = (M, S, D, Q, R, H, C, P, N)$ and a displayed locator request. The only threshold coordinate available to the request is M, so the modulus schedule is read first.

The finite observation step is next. The request opens the window row S and interprets its tolerance through D, whose dyadic ledger records the positive scale and comparison cells.

The rational handoff is then forced through Q. No independent stream or host rational approximation is present in the carrier, so the locator request reaches the Real-facing boundary only after the regular rational readback has been displayed.

Finally the terminal row R is consumed and the structural rows H, C, P, N preserve the same route. This proves the stated factorization and excludes a bypass through selected limits, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. □

Theorem 1908.4 (Cauchy real locator Real seal nonescape)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *locator-seal read reaches* R *only after the displayed rows* M, S, D, Q *have been consumed. The seal exports no host Real equality, quotient stream representative, selected limit, countable-choice selector, trichotomy branch, open-cover compactness witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*
