Proof. Inspect the terminal coordinate of the carrier. The only Real-facing locator seal is R, and it is listed after the modulus schedule, stream-window, dyadic-ledger, and regular-readback rows.

Apply the obligation surface of Definition 3410.2. It requires route ordering through M, S, D, Q before R can be read by a Real-facing consumer.

The structural rows preserve this boundary. The hsame transports and Cont replay keep the same displayed packet, while Pkg provenance and local naming record only that route.

Because no excluded coordinate appears in L, the terminal seal cannot export host Real equality, quotient representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. Any consumer asking for one of those principles must leave the local carrier. □

Theorem 1908.5 (Cauchy real locator four-object exit)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *Real-facing locator read factors through exactly the four L10 exit objects named by Definition 3412.8: the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *locator seal. In carrier coordinates, any accepted read of* $L = (M, S, D, Q, R, H, C, P, N)$ *uses* S, D, Q, R *as the four object faces and uses* M, H, C, P, N *only as the modulus schedule, transport, replay, provenance, and local naming support. It exports no quotient stream equality, host Real equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier tuple. The row S is the finite $\mathsf{StreamName}^{\uparrow}$ window, D is the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, Q is the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and R is the terminal $\mathsf{Real}^{\uparrow}$ locator seal.

The modulus route theorem Definition 3410.3 fixes the order of consumption. A locator request reads the schedule M, opens the finite windows S, interprets them through the dyadic ledger D, passes through the regular readback Q, and only then reaches R.

The Real-seal nonescape theorem Definition 3410.4 supplies the boundary condition for the terminal read. It rules out every Real-facing bypass that would identify quotient streams, appeal to host Real equality, choose a limit, branch by trichotomy, use open covers, or import ambient completeness.

Finally compare this carrier projection with Definition 3412.8. The four object faces are exactly S, D, Q, R, while M, H, C, P, N supply only schedule, transport, replay, provenance, and naming support. Hence an accepted locator read has the claimed four-object L10 exit route and no additional exported coordinate. □

Theorem 1908.6 (Cauchy real locator induction route)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every locator-side read available to induction is obtained by the finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

The induction step reads finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal rows without deciding trichotomy and without choosing a host limit.*

Proof. Project the carrier of Definition 3410.1. The modulus schedule M is the only threshold source, so a locator-side induction step begins by reading the same schedule used in the modulus route.

The finite observation is then S interpreted through D. The stream row exposes only bounded windows, while the dyadic row supplies the tolerance scale and comparison cells needed to use those windows.

The rational and Real-facing parts follow through Q and R. The modulus route theorem Definition 3410.3 fixes this order, and the four-object exit theorem Definition 3410.5 identifies S, D, Q, R as the four L10 exit faces.

Finally H, C, P, N preserve the route by transport, replay, provenance, and local naming. Since the carrier has no coordinate for trichotomy or selected host limits, the induction route cannot decide a side by trichotomy or choose a limit outside the displayed locator data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3410.1, Definition 3410.2, Definition 3410.3, Definition 3410.4, Definition 3410.5, and Definition 3410.6 seed the finite locator route over Cauchy modulus schedules, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, and the Real locator seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, window and tolerance compatibility, RegSeqRat readback, route ordering, nonescape, and local NameCert registration for BEDC.Derived.CauchyRealLocatorUp.

Constructive story: A $\mathsf{CauchyRealLocator}^{\uparrow}$ packet is generated from a RealCauchyModulusUp and CauchyModulusUp schedule row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a terminal RealUp locator seal, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1909

A Concrete Naming Certificate for CauchyRealLocatorPointwiseInduction$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet records the finite-window induction route used by Cauchy real locators. It is a sibling of the locator surface of chapter 3410 and the finite schedule discipline of chapter 126: a pointwise induction step opens one displayed stream window, reads its dyadic tolerance ledger, passes through the regular rational readback of chapter 301, and returns to the same Real-facing locator seal of chapter 38. The packet is not an induction principle over all host streams, a quotient-real equality theorem, a countable-choice selector, or an ambient completeness assertion.

The dependency route is substantive: before the packet exports pointwise locator induction, it consumes the rational interval enclosure surface of chapter 4202 together with the RegSeqRat window handoff of chapter 301. Thus each pointwise branch is read as rational interval enclosure plus regular Cauchy window data, not as a decorative citation to neighboring chapters.

Definition 1909.1 (Cauchy real locator pointwise induction carrier)**.** *A* CauchyRealLocatorPointwiseInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* CauchyRealLocator$^{\uparrow}$ *row, carrying the locator modulus, finite-window, dyadic, regular-rational, and Real seal data.*
2. *W is the* StreamName$^{\uparrow}$ *pointwise window row selected for the current locator request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the pointwise window with the requested side test.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the window and dyadic tolerance have been displayed.*
5. *R is the terminal* Real$^{\uparrow}$ *locator seal reached by the pointwise readback.*
6. *B is the finite induction-branch ledger, recording the base window and successor-window handoff over the displayed rows W, D, Q, R.*
7. *H records componentwise* hsame *transport for the locator source, window, dyadic tolerance, regular readback, Real seal, branch ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for each pointwise induction step.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1909.2 (Cauchy real locator pointwise induction regularity-witness route)**.** *Every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier consumes the finite regularity-witness surface of chapter 1158 before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the pointwise branch first opens the displayed $\mathsf{StreamName}^{\uparrow}$ *window W, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q through the regularity-witness route, and only then reaches the terminal Real locator seal R.*

Proof. Project the carrier. The only rows available before the Real seal are the locator source L, the displayed window W, the dyadic tolerance D, and the regular-rational readback Q.

Now use the sibling regularity-witness surface. Its displayed route supplies the same finite window, tolerance ledger, and RegSeqRat readback before the Real seal handoff, so the pointwise branch can inspect regularity evidence without opening a host stream representative.

Finally read R and the structural rows B, H, C, P, N. These rows record, transport, replay, source, and name the already displayed route, so the pointwise induction packet depends on the regularity witness before it reaches the Real-facing locator seal. □

Theorem 1909.3 (Cauchy real locator pointwise window induction)**.** *For every accepted* CauchyRealLocatorPointwi *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

each pointwise locator step factors through the finite route

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B, H, C, P, N.$$

The base and successor cases of the induction ledger B may inspect only the displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *locator seal supplied by the same* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row.*

Proof. Project the accepted carrier. The source row L is the only Cauchy real locator coordinate, so every pointwise step begins by reading the displayed locator packet of chapter 3410.

The induction window is then opened through W. The dyadic tolerance row D is the only comparison surface attached to that window, and the regular rational readback Q is available only after the window and dyadic rows have been displayed.

The terminal read reaches R and is then recorded by the branch ledger B. The base branch and each successor branch therefore preserve the same finite route rather than selecting a host stream representative.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, the displayed route exhausts the pointwise induction surface. □

Theorem 1909.4 (Cauchy real locator pointwise induction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *obligations are exactly carrier admission for the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row* L*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *window admission for* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility for* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for* Q*,* $\mathsf{Real}^{\uparrow}$ *locator-seal ordering for* R*, finite base and successor branch admission for* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4225.1. The tuple displays the locator source, pointwise window, dyadic tolerance, regular-rational readback, real seal, branch ledger, and structural rows.

The source and window obligations are read from L and W. The dyadic tolerance row D is the only comparison surface attached to that pointwise window, and the readback row Q can be inspected only after those rows are displayed.

The real-seal ordering obligation is the row R, downstream of Q. The branch ledger B records the finite base and successor handoff over the same displayed rows rather than over a host stream representative.

The rows H, C, P, N transport, replay, source, and name the packet. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 1909.5 (Cauchy real locator pointwise window stability)**.** *Let*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier. Replacing the locator source,* $\mathsf{StreamName}^{\uparrow}$ *pointwise window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible pointwise induction route*

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B.$$

Thus the base and successor branches of the finite induction ledger remain attached to the same locator source and cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and use Definition 4225.3. Every pointwise step already factors through the displayed locator source, window, dyadic tolerance, regular-rational readback, real seal, and branch ledger.

The componentwise replacement is recorded by H. It transports the locator source, window, tolerance, readback, seal, branch ledger, replay, provenance, and local name without adding another induction coordinate.

The replay row C then carries the transported rows through the same pointwise route. The branch ledger B therefore continues to read the base window and successor-window handoff over W, D, Q, R.

The carrier has no row for any excluded host or quotient object, so row exhaustion shows that the transported packet preserves exactly the admissible pointwise induction route. □

Theorem 1909.6 (Cauchy real locator pointwise branch exhaustion)**.** *For every accepted* CauchyRealLocatorPointw *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

every base or successor branch read in B is exhausted by the displayed rows $L, W, D, Q, R, H, C, P, N$. Such a branch read cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The branch ledger B is downstream of the locator source L, pointwise window W, dyadic tolerance row D, regular-rational readback Q, and terminal real seal R.

Use pointwise window induction from Definition 4225.3. It forces both the base branch and each successor branch to read the same finite route $L \longmapsto W, D \longmapsto Q \longmapsto R$ before B records the branch.

Use window stability from Definition 4225.5. The transport row H and replay row C preserve that route under displayed componentwise replacement, while P, N only source and name the packet.

Row exhaustion completes the claim. No coordinate of I stores host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no base or successor branch can export any of those objects. □

Theorem 1909.7 (Cauchy real locator pointwise induction sibling route)**.** *Every accepted* CauchyRealLocatorPointw *read must pass through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38 before the branch ledger is public. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the rows L, W, D, Q, R are exactly that sibling route, and B, H, C, P, N can only record, transport, replay, source, and name the displayed route.

Proof. Project the carrier rows $L, W, D, Q, R, B, H, C, P, N$ from Definition 4225.1. The source row L is read through the Cauchy real locator certificate, while W is the finite StreamName window attached to the current pointwise request.

The dyadic tolerance row D is then consumed through the DyadicRatCore certificate, and Q is the RegSeqRat readback of that displayed window and tolerance data. The terminal row R is the Real-facing locator seal reached after those rows are visible.

Apply Definition 4225.3 and Definition 4225.4. They force the pointwise induction route and the local NameCert obligations to use exactly the rows L, W, D, Q, R before the branch ledger can be inspected.

Finally use Definition 4225.5 and Definition 4225.6. The transport, replay, provenance, and local naming rows preserve the same sibling route and exhaust the branch surface, so the public branch ledger has no alternate dependency edge outside the listed chapters. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4225.1, Definition 4225.3, Definition 4225.4, Definition 4225.5, and Definition 4225.6 seed the finite pointwise induction route over CauchyRealLocator, StreamName, DyadicRatCore, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window induction, dyadic tolerance compatibility, RegSeqRat readback, Real seal ordering, and local NameCert registration for BEDC.Derived.CauchyRealLocatorPointwiseInductionUp.

Constructive story: A CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet is generated from a CauchyRealLocator source row, one StreamName pointwise window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp locator seal, a finite induction-branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1910

A Concrete Naming Certificate for $\mathsf{CauchySequenceAlgebra}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ packet records the finite algebra route by which two regular rational Cauchy source rows are added or multiplied before any $\mathsf{Real}^{\uparrow}$ consumer reads the sealed result. It sits between the regular source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic ledger of chapter 291, the addition route of chapter 1695, the product route of chapter 461, and the terminal real-name seal of chapter 38. The packet gives later Real algebra and CauchyRealField consumers one BEDC-native finite dependency for binary Cauchy algebra; it does not import quotient Cauchy classes, host real arithmetic, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1910.1 (CauchySequenceAlgebra carrier)**.** *A* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations supply the left and right inputs.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite window pairs in which the two source rows are inspected at the same requested tolerance scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row. It stores the displayed endpoint arithmetic, slack conversions, tolerance comparisons, addition-budget entries, and product-budget entries used by the accepted binary operation request.*
4. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the summed endpoint row, finite addition ledger, and resulting regular readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the product endpoint row, product-error ledger, magnitude-budget entries, and resulting regular readback.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after the chosen operation row A or M has displayed its regular readback.*
7. *H records componentwise* hsame *transport for the two source rows, synchronized windows, dyadic budgets, operation rows, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a binary algebra request through* $X, Y, W, D, A, M, S, H, P, N$.
9. *P is the* Pkg *provenance over* CauchySequenceAlgebra$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, A, M, S, H, C, P, N$. The carrier has no coordinate for quotient-stream equality, host real addition or multiplication, a selected limit, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 1910.2 (CauchySequenceAlgebra NameCert obligations)**.** *For every accepted* CauchySequenceAlgebra$^{\uparrow}$ *carrier*

$$G = (X, Y, W, D, A, M, S, H, C, P, N),$$

the local NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* RegSeqRat$^{\uparrow}$ *sources, synchronized* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *operation budgets,* RegularCauchyAddition$^{\uparrow}$ *route,* RegularCauchyProduct$^{\uparrow}$ *route,* Real$^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *source-window synchronization, requiring every operation request to inspect X and Y through the same displayed window row W before any endpoint arithmetic is read;*
3. *dyadic-budget exactness, requiring every addition or product endpoint row to consume only the displayed tolerance, slack, comparison, and magnitude-budget entries of D;*
4. *operation-route separation, requiring A to carry only the addition route and M to carry only the product route, while both routes consume the same source, window, and dyadic-budget rows;*
5. *Real seal handoff, requiring S to be exposed only after the selected operation route has produced its* RegSeqRat$^{\uparrow}$ *readback;*
6. *transport and replay stability, requiring H and C to preserve the full route $X, Y, W, D, A, M, S, P, N$ without adding a quotient stream, host operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.*

No CauchySequenceAlgebra NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 3708.1. The displayed coordinates are exactly the two source rows X, Y, synchronized windows W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Source-window synchronization is forced by the single window coordinate W. Both source reads must pass through that coordinate before the dyadic operation budget is available, so the carrier has no second window service for either input.

Dyadic-budget exactness and operation-route separation are read from D, A, M. The row D supplies the finite arithmetic budgets, the row A consumes those budgets for addition, and the row M consumes those budgets for product. Since A and M are distinct rows with the same upstream inputs, neither route can borrow an unrecorded host operation.

Finally, the Real seal and structural rows close the finite route. The seal S is downstream of the operation readback, while H, C, P, N only transport, replay, package, and name the displayed rows. The excluded quotient, host arithmetic, selected-limit, choice, trichotomy, and ambient-completeness data have no carrier coordinate. □

Theorem 1910.3 (CauchySequenceAlgebra Real-field handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *binary algebra read reaches field-facing data only through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *routes, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In particular the handoff exports regular Cauchy addition and multiplication readbacks before the final Real seal, and it exports no quotient stream, host real arithmetic, selected limit, trichotomy, countable-choice datum, or ambient completeness principle.*

Proof. Project the carrier of Definition 3708.1. The only field-facing source data are the two regular rational Cauchy rows X, Y, the synchronized window W, and the dyadic operation budget D.

Read the operation rows before the final Real seal. The addition route is A, the product route is M, and both routes consume the same source, window, and budget rows named in Definition 3708.2.

The terminal consumer then reads S only after one of those operation routes has produced its $\mathsf{RegSeqRat}^{\uparrow}$ readback. Transport, replay, provenance, and local naming in H, C, P, N preserve that route. Since the carrier has no coordinate for quotient streams, host arithmetic, selected limits, trichotomy, countable choice, or ambient completeness, no Real-field handoff can export any of those objects. □

Theorem 1910.4 (CauchySequenceAlgebra operation route)**.** *Every* $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProdu}$ $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier reads binary algebra data only through the displayed route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N.$$

Consequently the consumer obtains the two regular source rows, synchronized stream windows, dyadic operation budgets, the addition route, the product route, the terminal Real seal handoff, transport, replay, provenance, and local naming, and obtains no quotient Cauchy class, host real operation, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a downstream algebra request. By Definition 3708.1, the only source coordinates are X and Y, and the only synchronized window coordinate available to both sources is W.

The operation budget is then forced through D. Addition reads the route row A, product reads the route row M, and both rows are displayed downstream of the same sources, windows, and dyadic budgets named in Definition 3708.2.

The Real-facing handoff is last. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyRealField}^{\uparrow}$ consumer can read the seal S only after an operation route has produced its regular readback, and the rows H, C, P, N preserve that same finite route. No coordinate remains from which a quotient Cauchy class, host operation, selected limit, countable choice, trichotomy, or ambient completeness principle could be exported. □

Theorem 1910.5 (CauchySequenceAlgebra route non-escape)**.** *Let* $G = (X, Y, W, D, A, M, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier. Any algebraic fact exported from* G *is a rowwise consequence of the displayed regular source rows, synchronized windows, dyadic operation budgets, operation routes, Real seal, transport, replay, provenance, and local naming rows. It is not a quotient Cauchy class, host real addition, host real multiplication, selected limit, countable-choice datum, trichotomy datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly X, Y, W, D, A, M, S, and the structural coordinates are exactly H, C, P, N.

An exported addition fact must use A after the source, window, and dyadic-budget rows have been displayed. An exported product fact must use M after the same upstream rows have been displayed. A Real-facing algebra fact must then pass through the seal row S.

The structural rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot create a host operation or a quotient relation, while provenance and local naming record only the finite packet. Thus every exported algebraic fact is confined to the listed rows, and each excluded principle has no entry point. □

Theorem 1910.6 (CauchySequenceAlgebra remainder-estimate handoff)**.** *Let*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

be an accepted CauchySequenceAlgebra$^{\uparrow}$ *carrier. Any downstream* CauchyRemainderEstimate$^{\uparrow}$ *read for an addition or product result factors first through the same finite binary-algebra route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N$$

and then through the finite tail-estimate rows of chapter 3991. The handoff exports the displayed source rows, synchronized windows, dyadic operation budgets, selected addition or product route, terminal Real seal, transport, replay, provenance, local naming, finite tail threshold, admitted tail windows, regular readback, and tail-diameter boundary rows. It exports no quotient Cauchy class, host real operation, selected limit, countable-choice datum, trichotomy datum, or ambient Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier G. By Definition 3708.2, every binary algebra read exposes only the source rows X, Y, synchronized window W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Apply Definition 3708.4 to the downstream addition or product request. The result route must pass through A for addition or M for product, and in either case it uses the same upstream X, Y, W, D rows before reaching the seal S.

Now apply Definition 3708.5. No part of that binary-algebra route can introduce a quotient Cauchy class, host real operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.

The remainder-estimate consumer therefore begins from the regular readback already displayed by the operation route and then uses the sibling surface chapter 3991. That surface supplies the finite threshold, admitted tail windows, regular readback, tail-diameter boundary, transport, replay, provenance, and local naming rows for CauchyRemainderEstimate$^{\uparrow}$. Composing these two finite routes gives the stated handoff and leaves every excluded principle without a carrier coordinate. □

Scope closed: Definition 3708.1, Definition 3708.2, Definition 3708.3, Definition 3708.4, Definition 3708.5, and Definition 3708.6 seed the finite binary algebra route over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyRemainderEstimate$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host real operations, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-window synchronization, dyadic-budget exactness, operation-route separation, Real seal handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceAlgebraUp.

Constructive story: A CauchySequenceAlgebra$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, one DyadicRatCore$^{\uparrow}$ operation-budget ledger, RegularCauchyAddition$^{\uparrow}$ and RegularCauchyProduct$^{\uparrow}$ route rows, a Real$^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The Cauchy$^{\uparrow}$ gateway reads its completion-facing source through chapter 126, chapter 301, chapter 291, and chapter 38 before any terminal seal is public.

Theorem 1910.7 (Cauchy L10 sibling route)**.** *The Cauchy packet family exported by this hub is consumed through the L10 route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}.$$

Concretely, the finite-window surface of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the completion boundary of chapter 1506 are sibling inputs to the Cauchy carriers rather than hidden ambient structure.

Proof. Read any Cauchy carrier exported by the hub through its finite observation rows. The stream coordinate supplies the inspected windows, the regular-rational coordinate supplies the numerical readback, and the dyadic coordinate supplies the tolerance budget.

The Real-facing seal is reached only after those rows have been displayed. When a completion consumer is present, it receives the same displayed route through the metric-completion boundary.

Thus the hub's Cauchy packet family is attached to the Real and MetricCompletion siblings by visible L10 rows, with no quotient representative, selected limit, countable-choice schedule, host real equality, or ambient completeness coordinate added by the route. □

The Cauchy$^{\uparrow}$ route consumes the L10 sibling chapters before the real locator and sequence algebra inputs are read. In particular, the regular-rational source of chapter 301, the finite stream windows of chapter 126, and the terminal seal of chapter 38 are already part of the displayed dependency spine for every downstream Cauchy locator or algebra consumer. The completion-side consumer in chapter 1937 reads the same RegSeqRat, StreamName, and RealUp spine before exposing its functorial completion route.

Theorem 1910.8 (Cauchy L10 four-object seal route)**.** *Every accepted* Cauchy$^{\uparrow}$ *Real-facing seal route used by the current L10 phase factors through the four displayed sibling faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Concretely, the finite window family of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38 are the only Real-facing sibling rows exported by the route. The supporting rows are the displayed BHist *carrier data, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *registration.*

Proof. Read the route through the existing CauchyRealLocator carrier and its Real-seal nonescape theorem. The carrier exposes a finite StreamName window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, and a terminal RealUp locator seal before any Real-facing consumer can read the packet.

Project those four named faces. The StreamName row supplies only inspected finite windows, the DyadicRatCore row supplies the tolerance and comparison budget, the RegSeqRat row supplies the rational readback, and the RealUp row supplies the terminal seal.

The structural rows preserve this factorization. The BHist data name the carried packet, hsame transports the displayed coordinates, Cont replays the same route, Pkg records provenance, and NameCert records the local accepted surface.

Since the carrier has no coordinate for quotient streams, host equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the Cauchy Real-facing seal route. □

Chapter 1911

A Concrete Naming Certificate for $\mathsf{Cauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{Cauchy}^{\uparrow}$ packet records the ordinary constructive Cauchy-real carrier as finite BEDC naming data. It sits above the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational sequence surface of chapter 301, and the terminal seal of chapter 38. The packet is not a quotient construction of reals; it is a finite route by which a modulus, rational readback, transport, replay, provenance, and local naming row become visible before any $\mathsf{Real}^{\uparrow}$ consumer can read the Cauchy object.

Definition 1911.1 (Cauchy carrier)**.** *A* $\mathsf{Cauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, recording the finite windows of rational approximants inspected by the carrier.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the positive dyadic scale, comparison cells, and slack conversions used to interpret each requested window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence row, exposing the rational readback consumed downstream.*
4. *M is the modulus row, recording the displayed threshold assignment used by Cauchy requests and refusing any hidden convergence theorem.*
5. *Q is the modulus/readback compatibility row, requiring the stream window, dyadic tolerance, regular rational sequence, and modulus rows to agree at every displayed precision request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, exposed only after S, D, R, M, Q have been displayed.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-sequence, modulus, compatibility, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Cauchy request through $S, D, R, M, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $S, D, R, M, Q, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyUp.CauchyCarrier`

Theorem 1911.2 (Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *carrier*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 3413.1.*

Proof. Carrier admission is projection from Definition 3413.1. The accepted packet displays precisely the stream, dyadic, regular-sequence, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

The stability and exactness obligations are rowwise. The stream row supplies only finite windows, the dyadic row supplies only displayed tolerance cells, the regular-sequence row supplies only rational readback, and the modulus row supplies only the visible threshold assignment.

The compatibility row Q binds these four data rows before any $\mathsf{Real}^{\uparrow}$ seal can be consumed. The structural rows H, C, P, N then transport, replay, source, and name the same route without adding quotient equality, selected limits, host real equality, choice, trichotomy, compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCarrier namecert obligations`

Theorem 1911.3 (Cauchy modulus readback route)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *consumer route factors through the displayed path*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a precision request reads finite $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the explicit modulus row, the compatibility row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the* $\mathsf{Real}^{\uparrow}$ *seal-facing boundary.*

Proof. Begin with an accepted carrier $X = (S, D, R, M, Q, E, H, C, P, N)$ and a displayed precision request. The only finite observations available to the request are the windows in S, and their tolerance scale is read through D.

The request next reads the explicit modulus row M. The compatibility row Q is the only coordinate that relates the chosen window, tolerance, threshold, and regular-rational readback, so the route cannot bypass it.

After Q is displayed, the consumer may read the $\mathsf{RegSeqRat}^{\uparrow}$ row R and then the terminal $\mathsf{Real}^{\uparrow}$ seal-facing row E. The rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming.

Since the carrier has no quotient, selected-limit, host equality, countable-choice, trichotomy, open-cover, or ambient-completeness coordinate, the displayed route is the whole public Cauchy readback surface. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusReadbackRoute`

Theorem 1911.4 (Cauchy StreamName RegSeqRat window)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet exposes its* $\mathsf{RegSeqRat}^{\uparrow}$ *row only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and modulus/readback compatibility row. Thus a regular rational read of* $X = (S, D, R, M, Q, E, H, C, P, N)$ *must factor through* S, D, M, Q *before it can inspect* R*.*

Proof. Project the carrier of Definition 3413.1. The row S is the only finite observation surface, D is the only displayed tolerance surface, and M is the only modulus row available to the packet.

Apply Definition 3413.2 to identify Q as the compatibility row binding stream windows, dyadic tolerances, regular rational readback, and modulus data. Then apply Definition 3413.3: the displayed route reads S, D, M and Q before R.

The carrier has no quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient completeness coordinate. Hence the stated window and compatibility rows exhaust the public access path to $\mathsf{RegSeqRat}^{\uparrow}$. □

Theorem 1911.5 (Cauchy finite-tail criterion)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

be an accepted $\mathsf{Cauchy}^{\uparrow}$ *carrier. Suppose every displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window admitted by* S *and every dyadic tolerance cell admitted by* D *satisfy the tail bound named by the modulus row* M*, and suppose the compatibility row* Q *identifies those windows with the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of* X *is routed through the same finite tail ledger*

$$S, D, M \longmapsto Q \longmapsto R$$

before the $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed. The criterion exports no selected limit, quotient stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows available for a tail read are the finite StreamName window row S, the DyadicRatCore tolerance row D, the modulus row M, the compatibility row Q, the RegSeqRat readback row R, and the terminal seal row E.

Induct over the displayed window list retained by S. The empty window has no readback outside the recorded tolerance ledger. In the successor step, the new inspected position is checked against the dyadic cell in D and the threshold supplied by M, so the same finite tail bound remains attached to the extended window.

Apply Definition 3413.4. It forces any access to R through the displayed S, D, M, Q route. Apply Definition 3413.3 to identify Q as the point where the window, tolerance, modulus, and readback rows are jointly inspected.

Finally use Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal E is downstream of the regular rational readback, so no Real-facing consumer can bypass the finite tail ledger. Since the carrier has no selected-limit, quotient-stream, countable-choice, trichotomy, or ambient-completeness coordinate, the displayed finite induction exhausts the criterion. □

Definition 1911.6 (Cauchy finite-window modulus carrier)**.** *The finite-window modulus carrier associated to an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet is the displayed handoff surface*

$$W = (S, D, M, Q, R, E, H, C, P, N)$$

read from the carrier of Definition 3413.1. Its rows have the following roles:

1. *S records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by a tail request.*

2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells and slack conversions attached to those windows.*
3. *M records the explicit modulus threshold row used to accept later-window requests.*
4. *Q records the compatibility row tying each displayed window, dyadic tolerance, modulus threshold, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
5. *R records the regular-rational readback exposed only after S, D, M, Q have been displayed.*
6. *E records the downstream* $\mathsf{Real}^{\uparrow}$ *seal-facing row.*
7. *H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *naming for the same finite route.*

The carrier admits only these displayed coordinates. It has no coordinate for quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1911.7 (Cauchy finite-window tail induction)**.** *Let $W = (S, D, M, Q, R, E, H, C, P, N)$ be the finite-window modulus carrier of Definition 3413.6. Every accepted tail request obtained by extending the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row preserves the dyadic tolerance row D, the modulus threshold row M, the compatibility row Q, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. Thus the induction route is*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E$$

with H, C, P, N transporting, replaying, sourcing, and naming the same displayed handoff.

Proof. Project the underlying accepted Cauchy carrier through Definition 3413.1 and read it in the window/modulus order specified by Definition 3413.6. The only tail-request rows available are $S, D, M, Q, R, E, H, C, P, N$.

Induct over the displayed $\mathsf{StreamName}^{\uparrow}$ windows retained by S. The empty window has no tolerance request outside D and no readback outside the route named by Definition 3413.4.

For the successor step, the new inspected window is accepted only through the dyadic cell in D and the threshold supplied by M. Apply Definition 3413.5 to keep the same finite tail ledger attached to the extended request.

The compatibility row Q is then the unique displayed row where the window, dyadic tolerance, modulus threshold, and regular readback are jointly inspected. Apply Definition 3413.3 to place R after Q and E after R.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Since none of the rows supplies quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the induction cannot expose any such principle. □

Theorem 1911.8 (Cauchy RegSeqRat handoff obligation)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the finite-window modulus carrier of Definition 3413.6 and the tail-induction route of Definition 3413.7. In particular, the consumer reads S, D, M, Q before R, and any Real-facing use reads E only after that* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Begin with an accepted Cauchy packet and project its rows by Definition 3413.1. The carrier supplies finite stream windows, dyadic tolerances, a modulus row, a compatibility row, regular-rational readback, a terminal Real-facing seal, and structural transport, replay, provenance, and naming rows.

Apply Definition 3413.4. It forces access to the $\mathsf{RegSeqRat}^{\uparrow}$ row through the displayed S, D, M, Q route, so no consumer can inspect R independently of the finite window and tolerance data.

Next apply Definition 3413.5 and Definition 3413.7. These identify the finite tail ledger and show that accepted extensions preserve the dyadic tolerance, modulus threshold, compatibility, and regular readback rows before the Real seal is exposed.

Finally use Definition 3413.3. The structural rows H, C, P, N transport and name the same handoff, while the carrier contains no quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every $\mathsf{RegSeqRat}^{\uparrow}$ consumer factors through the stated finite-window induction surface. □

Theorem 1911.9 (Cauchy RegSeqRat Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the terminal real seal. In the notation of Definition 3413.1, the seal-facing route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

It does not expose quotient streams, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project $X = (S, D, R, M, Q, E, H, C, P, N)$ from Definition 3413.1. The seal row E is declared terminal and seal-facing; it is not an independent source of Cauchy data.

Use Definition 3413.3 to order the displayed read. The route reaches R after S, D, M, Q and reaches E only after R has been displayed.

Finally apply Definition 3413.2. The rows H, C, P, N transport, replay, source, and name the same route, so they cannot insert quotient representatives, selected limits, host equality, countable choice, trichotomy, or ambient completeness between $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. □

Theorem 1911.10 (Cauchy modulus transport stability)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

and

$$X' = (S', D', R', M', Q', E', H', C', P', N')$$

be accepted $\mathsf{Cauchy}^{\uparrow}$ *packets. Suppose the stream row, dyadic tolerance row, modulus row, modulus/readback compatibility row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, replay row, provenance row, and local naming row are transported componentwise by the displayed* hsame *data in* H *and* H'*, and suppose both packets are replayed through the same displayed* Cont *route. Then the public Cauchy readback route*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

is the same BEDC route as

$$S', D', M' \longmapsto Q' \longmapsto R' \longmapsto E' \longmapsto H', C', P', N'.$$

In particular, componentwise transport of the modulus/readback surface cannot introduce quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, or ambient completeness.

Proof. Project both accepted packets through Definition 3413.1. The only visible coordinates are the stream, dyadic tolerance, regular-rational readback, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

Apply Definition 3413.3 to X and to X'. The two projected routes must read their displayed stream, dyadic, and modulus rows before their compatibility rows, and the shared Cont replay identifies these reads through the componentwise hsame data.

Next use Definition 3413.4. Access to R and R' is forced through the transported S, D, M, Q and S', D', M', Q' rows, so no other regular-rational readback path is available.

Finally apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal remains downstream of the transported $\mathsf{RegSeqRat}^{\uparrow}$ rows, and the structural rows H, C, P, N and H', C', P', N' only transport, replay, source, and name that path. Since neither carrier contains quotient streams, selected limits, host equality, choice, trichotomy, or ambient completeness, the two displays name the same BEDC route. □

Theorem 1911.11 (Cauchy uniform-modulus Real seal)**.** *For an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

any uniform-modulus consumer of the explicit modulus row M *that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must read* S, D, M, Q *before* R*, and* R *before* E*. The route contains no quotient stream equality, selected limit, countable choice, trichotomy, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet through Definition 3413.1. The explicit modulus row M is packaged with the finite stream window S, the dyadic tolerance row D, the compatibility row Q, the regular rational readback R, and the terminal seal-facing row E.

Apply Definition 3413.3. It forces a precision request to read S, D, M and then Q before any regular-rational row can be inspected.

Next apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal row E is downstream of R, so a uniform-modulus consumer cannot reach the seal before the regular rational readback has been displayed.

Finally use Definition 3413.10. Componentwise transport and the displayed Cont replay preserve the same route for every accepted consumer, and the carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, metric-completeness data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1911.12 (Cauchy root filter-completion anchor)**.** *Every Cauchy root consumer that first reaches the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *surface of chapter 1569 must already have read the Cauchy core route, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route remains inside componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

Proof. Project the root hub through its Cauchy core child. The core route exposes the stream-window, tolerance, readback, transport, replay, provenance, and naming rows before any completion-facing consumer can inspect the root packet.

Now read the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ chapter. Its completion handoff consumes the same finite windows and regular rational readback before the terminal Real seal is visible, so the root consumer cannot enter through a detached filter object.

The structural rows preserve the path. Componentwise hsame transport and displayed Cont replay keep the consumer inside the Cauchy root packet, while Pkg provenance and the local $\mathsf{NameCert}$ row record that no quotient filter, selected limit, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported. □

Theorem 1911.13 (Cauchy L10 child dependency route)**.** *Every finite-window read exported by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by sibling L10 chapters only after it passes through the child routes displayed in this chapter. The regular-rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-facing route of chapter 1569 read the* $\mathsf{Cauchy}^{\uparrow}$ *packet through finite stream windows, dyadic tolerance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. No child route exports quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the hub through its child files. The core carrier in chapter 3413 displays the stream-window, dyadic tolerance, regular readback, transport, replay, provenance, and naming rows before any downstream consumer can inspect a Cauchy object.

The sibling dependency spine then sends those rows to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The cited regular-rational and Real chapters consume only the displayed finite route; they do not receive a quotient stream, selected limit, choice schedule, trichotomy oracle, host equality coordinate, or ambient completeness proof.

The completion-facing consumer follows the same rows through the Cauchy-filter completion surface. Because the hub contains only child inputs and each child route exposes finite BHist and NameCert data, the L10 dependency path is connected through sibling chapters rather than through an unstated top-level object. □

Theorem 1911.14 (Cauchy RegSeqRat and completion forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *finite-window packet consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *factors through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route exports no quotient streams, selected limits, choice schedules, host equality, or ambient completeness.*

Proof. Start with the child dependency route above. It already displays the finite stream-window, dyadic tolerance, regular readback, Real-seal, transport, replay, provenance, and naming rows before any L10 consumer reads a Cauchy packet.

The regular rational and Real consumers are the first forward users. The chapters chapter 301 and chapter 38 read only the displayed finite windows, readback rows, tolerance rows, and terminal seal.

The completion consumer reads the same route through chapter 1506. A metric-completion request can inspect Cauchy data only after the finite windows, tolerances, readbacks, Real seal, transport, replay, provenance, and local naming rows have been displayed.

The excluded objects have no row in this finite route. Thus quotient streams, selected limits, choice schedules, host equality, and ambient completeness cannot be exported by the forward handoff. □

The L10 route consumes $\mathsf{Cauchy}^{\uparrow}$ through the finite-window surface of chapter 126, the regular readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal seal rows of chapter 38. These four child dependencies keep the Cauchy packet attached to finite stream windows, regular rational evidence, dyadic budgets, and the Real seal before any L10 consumer may read it.

Every $\mathsf{Cauchy}^{\uparrow}$ read used by Real and completion consumers factors through the same horizontal lattice: finite observation windows from chapter 126, regular-rational readback from chapter 301, dyadic tolerance rows from chapter 291, and the terminal seal of chapter 38. Downstream

consumers therefore receive a displayed finite-window route before they may treat the packet as Real-facing Cauchy data.

Theorem 1911.15 (Cauchy finite-window modulus pullback)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *modulus read pulls back to the same finite* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row of chapter 291, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any consumer can inspect a Cauchy value. In the notation of Definition 3413.1, the pullback route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No quotient stream equality, selected limit, host real equality, countable-choice coordinate, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row is available along this route.*

Proof. Project the accepted carrier through Definition 3413.1. The finite stream window S, dyadic tolerance row D, modulus row M, compatibility row Q, regular-rational readback R, and terminal Real seal E are the only rows available before the structural rows are read.

Apply Definition 3413.2. It identifies the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ surface with stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility, Real seal ordering, transport, replay, provenance, and local naming.

Now use Definition 3413.3. A precision request first reads S, D, M, Q, then reaches R, and only then reaches E. The route is sharpened by Definition 3413.4, which keeps the $\mathsf{RegSeqRat}^{\uparrow}$ row behind the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, modulus, and compatibility rows.

Finally apply Definition 3413.9. The terminal Real seal is reached only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback has been displayed. Thus every accepted modulus read pulls back to the same four L10 sibling rows before a consumer sees a Cauchy value, and none of the excluded quotient, selected-limit, choice, order, compactness, or completeness coordinates can be inserted. □

Theorem 1911.16 (Regular-Cauchy modulus pullback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of the* $\mathsf{Cauchy}^{\uparrow}$ *finite-window modulus route obtains a dyadic tolerance schedule that is cofinal with the route displayed in Definition 3413.15. In the notation of Definition 3413.1, the consumer may read*

$$S, D, M, Q \longmapsto R \longmapsto E$$

only as a regular-rational handoff: the $\mathsf{Real}^{\uparrow}$ *seal is reached after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, not before it. The route exports no quotient stream equality, selected limit, host real equality, choice principle, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 3413.15. It fixes the finite route from the StreamName window S, dyadic tolerance row D, modulus row M, and compatibility row Q into the regular-rational readback R, and only then into the terminal Real seal E.

Project the route at the $\mathsf{RegSeqRat}^{\uparrow}$ boundary. A RegSeqRat-facing consumer reads the dyadic tolerance row D through the same finite windows S and compatibility row Q, so its tolerance requests are bounded by a cofinal schedule already displayed by the Cauchy modulus route.

Transport the schedule through the regular-rational classifier row. The readback row R is the first row that presents the schedule as regular-rational data, and the Real seal E is reachable only after that readback has been displayed.

Thus the pullback is cofinal at the RegSeqRat surface and terminal at the Real seal. Since the carrier has no coordinate for quotient stream equality, selected limits, host equality, choice,

trichotomy, or Real completeness, none of those principles can be inserted into the consumer route. □

Theorem 1911.17 (Cauchy finite-window pullback uniqueness)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing Cauchy modulus consumer accepted by the* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the same finite route*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

displayed in Definition 3413.15. The consumer cannot replace this route by quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows visible to a modulus consumer are the finite StreamName window, dyadic tolerance ledger, modulus row, compatibility row, RegSeqRat readback, Real seal, and the structural rows.

Apply Definition 3413.2. It identifies the local NameCert surface with precisely those rows, so there is no second carrier coordinate from which an alternative Real-facing route could be read.

Use Definition 3413.3. A precision request reaches R only after S, D, M, Q have been displayed, and it reaches the terminal seal E only after the regular-rational readback has been displayed.

Finally apply Definition 3413.15 and Definition 3413.16. The first theorem fixes the finite pullback route to the L10 sibling rows, while the second shows that every RegSeqRat-facing consumer receives the same cofinal handoff. Hence any Real-facing Cauchy modulus consumer factors through the displayed route and gains no quotient, selected-limit, choice, host-equality, or completeness coordinate. □

Every completion-facing consumer of the $\mathsf{Cauchy}^{\uparrow}$ hub reads the finite Cauchy packet through chapter 301 and chapter 38 before any Real seal is exposed to completion rows. The route first displays the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the dyadic tolerance ledger, then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal, and only then lets Cauchy completion consumers inspect the same BHist, hsame, Cont, Pkg, and local NameCert rows. Thus the hub records a structural dependency route, not quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness.

Theorem 1911.18 (Cauchy RegSeqRat Real forward dependency)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *source-window read consumed by a Real-facing downstream chapter must pass through the regular rational readback of chapter 301 and the terminal real-name seal of chapter 38 before any* $\mathsf{Real}^{\uparrow}$*-facing seal is exposed. The route reads only displayed finite windows, regular rational tail data, componentwise transport, replay, provenance, and local naming; it exports no selected limit, quotient stream equality, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Cauchy carrier route in Definition 3413.1. Its source-window reads are displayed before the regular rational readback and terminal real seal rows are available.

Use the regular readback and real-seal routes already named by the Cauchy child files. They order downstream consumption through $\mathsf{RegSeqRat}^{\uparrow}$ and then $\mathsf{Real}^{\uparrow}$, with the structural rows transporting and naming the same finite windows.

Since the hub exposes only child-file surfaces and no independent carrier coordinate, a Real-facing consumer can cite $\mathsf{Cauchy}^{\uparrow}$ only through that forward dependency route. The read therefore reaches chapter 301 and chapter 38 before any Real-facing seal is exposed. □

Theorem 1911.19 (Cauchy located-uniform filter forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *route whose explicit modulus row is consumed by a located or uniform Cauchy filter completion must pass through the displayed carrier route*

$$S, D, M, Q, R, E, H, C, P, N$$

of Definition 3413.1, then through chapter 1661 or chapter 1694, before any $\mathsf{Real}^{\uparrow}$ *seal-facing completion row is exported. The forward route has no quotient stream equality, selected limit, countable choice, metric-completeness datum, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host equality.*

Proof. Start with the explicit modulus readback of the Cauchy carrier. By Definition 3413.3, a precision request reads the finite StreamName row S, the DyadicRatCore row D, the explicit modulus row M, and the compatibility row Q before it can inspect the regular rational row R.

Apply Definition 3413.9. The seal-facing row E is downstream of R, so a Real-facing completion consumer cannot bypass the regular rational readback.

Now use Definition 3413.11. Any uniform-modulus consumer of M that reaches a $\mathsf{Real}^{\uparrow}$ seal preserves the same ordering S, D, M, Q before R and R before E.

The remaining completion-neighbour branch is supplied only by the sibling chapters chapter 1661 and chapter 1694. These chapters consume the already displayed Cauchy route as located or uniform filter evidence; neither adds quotient stream equality, selected limits, choice, metric-completeness data, ambient completeness, or host equality to the core Cauchy carrier. □

Theorem 1911.20 (Cauchy route to CauchyCriterion)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *hub's finite route is consumed by chapter 392 through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route exports no detached completion carrier, quotient sequence equality, selected modulus outside the displayed rows, countable-choice schedule, or host completeness principle.*

Proof. Read the hub through its existing finite siblings. The $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows provide the only Cauchy data visible to downstream criteria.

The structural rows hsame, Cont, Pkg, and NameCert transport, replay, source, and name that same finite route. Therefore the Cauchy criterion consumer receives exactly the displayed BEDC rows and no external completion or choice object. □

Theorem 1911.21 (Cauchy hub Bishop completion forward route)**.** *The regular-source material routed by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by chapter 1639 through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The forward route exports no detached Cauchy representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness principle.*

Proof. Read the Cauchy hub through its regular-source children. Those children expose dyadic tolerance arithmetic, finite stream windows, regular rational readback, and the terminal real seal as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The Bishop regular Cauchy completion chapter consumes exactly that L10-facing route. Its completion read is mediated by the same finite BHist carrier discipline, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Since the hub route contains no detached representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness coordinate, the forward edge to the Bishop completion packet is precisely the displayed finite dependency route. □

Chapter 1912

A Concrete Naming Certificate for $\mathsf{MeanValueTheorem}^{\uparrow}$

Following Lagrange, Cauchy, and the Bishop–Bridges reading of constructive analysis, the $\mathsf{MeanValueTheorem}^{\uparrow}$ packet records the theorem-facing finite BEDC boundary between endpoint secant data and a displayed derivative quotient row. It consumes the terminal real-name surface of chapter 38, the graph and modulus rows of chapter 130, the derivative quotient interface of chapter 122, the Rolle handoff of chapter 1900, the bisection-facing route of chapter 1402, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The chapter names a finite route from displayed endpoint values and secant slope to a theorem-facing derivative row; it is not a host differentiability theorem, an equality of quotient reals, or a selected interior point in an ambient completed line.

Definition 1912.1 (Mean value theorem carrier)**.** *A* $\mathsf{MeanValueTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, S, F, D, R, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *A, B are the endpoint* $\mathsf{Real}^{\uparrow}$ *name rows for the displayed interval boundary and endpoint value reads.*
2. *S is the secant-slope seal row, binding the endpoint difference and interval-width readback to a displayed* $\mathsf{Real}^{\uparrow}$ *slope seal rather than host division in a completed field.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the real-valued map on the displayed interval source.*
4. *D is the* $\mathsf{Derivative}^{\uparrow}$ *quotient row, exposing only the inspected metric quotient route used by the theorem-facing conclusion.*
5. *R is the* $\mathsf{RolleTheorem}^{\uparrow}$ *handoff row, carrying the finite Rolle-facing packet applied to the usual auxiliary difference against the secant slope.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint values, interval width, secant windows, and derivative-quotient inspections.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger accounting for the dyadic windows used by S, Q, D, and the Rolle handoff row.*

8. *H records componentwise* hsame *transport for endpoint names, secant-slope seals, continuous-map rows, derivative quotients, Rolle handoff rows, rational readbacks, dyadic ledgers, replay rows, provenance rows, and local naming rows.*
9. *C records displayed* Cont *replay from endpoint reads to the secant seal, from map windows to the auxiliary Rolle packet, from rational readback to dyadic tolerance checks, and from the Rolle handoff to the theorem-facing derivative row.*
10. *P is the* Pkg *provenance over* $\mathsf{MeanValueTheorem}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RolleTheorem}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MeanValueTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted theorem packets only through these rows. It has no coordinate for host differentiability, quotient real equality, a selected interior point, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.MeanValueTheoremUp.MeanValueTheoremTasteGate single carrier alignment`

Theorem 1912.2 (Mean value theorem NameCert obligations)**.** *For every accepted* $\mathsf{MeanValueTheorem}^{\uparrow}$ *carrier*

$$M = (A, B, S, F, D, R, Q, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MeanValueTheorem}^{\uparrow}}$ *surface consists exactly of the finite obligation rows for endpoint real-name admission, secant-slope sealing, continuous-map admission, derivative quotient inspection, Rolle handoff, regular rational readback, dyadic tolerance budgeting, componentwise transport, displayed replay, provenance, and local naming. No obligation row may bypass the displayed* $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RolleTheorem}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *sources.*

Proof. Carrier admission is projection from Definition 1912.1. The endpoint rows A, B supply the displayed real names, and the row S is the only secant-slope seal available to the packet.

The map and derivative surfaces are fixed next. The row F supplies the continuous-map data, while D supplies the displayed derivative quotient route.

The theorem-facing handoff then passes through R. That row is the only Rolle packet in the carrier, and the readback and tolerance rows Q, T are the only finite arithmetic ledgers attached to it.

Finally, H, C, P, N preserve, replay, source, and name the same rows. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1912.3 (Mean value theorem Rolle handoff)**.** *Every theorem-facing derivative row exported by an accepted* $\mathsf{MeanValueTheorem}^{\uparrow}$ *carrier factors through the displayed Rolle handoff row R. The route reads the auxiliary difference against the secant-slope seal through A, B, S, F, Q, T, then exports the derivative quotient row D only after the Rolle packet has supplied the stationary-zero boundary.*

Proof. Start with an accepted carrier $M = (A, B, S, F, D, R, Q, T, H, C, P, N)$. The endpoint rows and secant-slope seal determine the auxiliary difference data before any theorem-facing derivative conclusion is available.

The continuous-map row F, regular readback Q, and dyadic ledger T supply the finite observations consumed by the auxiliary packet. These rows are the only route from endpoint data to the displayed Rolle input.

Read the Rolle handoff row R. It supplies the stationary-zero boundary for the auxiliary difference, and the derivative quotient row D is exported only through that boundary.

Transport and replay through H and C preserve this order, while P and N add only provenance and local naming. Thus the derivative row is routed through R rather than through a host mean-value theorem or a selected ambient point. □

Theorem 1912.4 (Mean value theorem Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumed or exported by an accepted* $\mathsf{MeanValueTheorem}^{\uparrow}$ *carrier is routed through one of the displayed endpoint, secant-slope, regular-readback, dyadic-ledger, Rolle-handoff, or derivative-quotient rows of Definition 1912.1. Consequently the carrier cannot export host differentiability, quotient real equality, selected interior points, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Proof. Inspect the real-facing coordinates of the carrier. The endpoint rows A, B expose the initial real names, S exposes the secant-slope seal, and Q, T expose the finite readback and tolerance budget.

The Rolle handoff row R is the only theorem route from those seals to a stationary-zero boundary. The derivative quotient row D is therefore read as a displayed Real seal attached to that route.

The structural rows do not add new real data. They transport, replay, source, and name the same carrier inventory.

There is no coordinate for host differentiability, quotient real equality, a selected interior point, trichotomy, ambient Real completeness, or a bridge object. Therefore every Real seal remains inside the displayed packet boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{MeanValueTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MeanValueTheorem}^{\uparrow}$ packet is generated from endpoint real-name rows, a secant-slope seal, a continuous-map row, a derivative quotient row, a Rolle handoff row, regular rational readback, a dyadic tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MeanValueTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1912.1, Definition 1912.2, Definition 1912.3, and Definition 1912.4 seed the finite theorem-facing mean-value boundary over displayed endpoint, secant-slope, continuous-map, derivative, Rolle, regular-rational, and dyadic rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MeanValueTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability, quotient real equality, selected interior points, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligation coverage, Rolle handoff routing, Real seal boundary, and TasteGate field faithfulness for BEDC.Derived.MeanValueTheoremUp.

Chapter 1913

A Concrete Naming Certificate for $\mathsf{BolzanoCauchy}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BolzanoCauchy}^{\uparrow}$ packet records the constructive bidirectional Cauchy convergence criterion as finite BEDC NameCert data. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the $\mathsf{Real}^{\uparrow}$ seal surface of chapter 38, the explicit criterion route of chapter 1509, and the limit-seal boundary of chapter 386. The packet names the two constructive directions as displayed rows; it is not ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, a selected host limit, trichotomy, open-cover compactness, countable choice, or bridge checking.

Definition 1913.1 (Bolzano-Cauchy carrier)**.** *A* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, M, D, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposing exactly the finite observations of the candidate sequence.*
2. *M is the Cauchy modulus data assigning each dyadic tolerance request a displayed threshold for the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic scales, rational comparisons, and exhaustion budget used by both directions.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from S, M, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row obtained after the criterion route has displayed the regular rational handoff.*
6. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility row that binds the same S, M, D, R, E route to a limit-seal consumer.*
7. *H records componentwise* hsame *transport for the stream schedule, modulus data, dyadic ledger, regular readback, Real seal, limit-seal compatibility, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through S, M, D, R, E, L and then through the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{BolzanoCauchy}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BolzanoCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, trichotomy, open-cover compactness, countable choice, or a detached limit seal.*

Lean4 ✓ `BEDC.Derived.BolzanoCauchyUp.BolzanoCauchyTasteGate single carrier alignment`

Theorem 1913.2 (Bolzano-Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier*

$$B = (S, M, D, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BolzanoCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed stream schedule, Cauchy modulus data, dyadic tolerance ledger, regular readback, Real seal, limit-seal compatibility, transport, continuation, provenance, and local name;*
2. *Cauchy-to-limit routing, requiring any Cauchy-read consumer to pass through S, M, D, R before E or L is available;*
3. *limit-to-Cauchy routing, requiring any limit-seal read to replay the same S, M, D, R tolerance route before it can export a Cauchy conclusion;*
4. *ledger exactness, requiring every tolerance request in either direction to be accounted for by D and sourced by P;*
5. *structural stability, requiring H and C to preserve and replay only the displayed rows.*

No Bolzano-Cauchy obligation is stored outside these rows.

Proof. Project the carrier of Definition 1913.1. The visible coordinates are exactly the stream schedule, modulus data, dyadic ledger, regular readback, Real seal, limit-seal compatibility, transport, continuation, provenance, and local naming rows.

The two route obligations are forced by the displayed order. A Cauchy-read consumer has no source except the windows S, thresholds M, ledger D, and readback R before the Real and limit-seal rows are exposed. Conversely, a limit-seal consumer reading L must replay the same finite tolerance route before it can return a Cauchy conclusion.

The ledger and structural rows then exhaust the remaining obligations. The dyadic row D accounts for every tolerance request, the provenance row P records its source, and H, C can only transport and replay the displayed packet. Since the carrier has no additional coordinate, the five listed rows are the complete local NameCert surface. □

Theorem 1913.3 (Bolzano-Cauchy Cauchy-to-limit route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier that begins from the Cauchy side factors through the finite route*

$$S \longmapsto M \longmapsto D \longmapsto R \longmapsto E \longmapsto L$$

and then through the stored hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The route is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *handoff read through a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility boundary; it exports no ambient completeness theorem, quotient stream, selected host limit, trichotomy row, open-cover compactness row, countable choice principle, or detached seal.*

Proof. Start with an accepted Cauchy-side read. By carrier admission, the only sequence data are the finite windows S, and the only tolerance data are the threshold row M and dyadic ledger D.

Apply the existing convergence-criterion route from chapter 1509. Its readback stage is the displayed $\mathsf{RegSeqRat}^{\uparrow}$ row R, and its Real-facing endpoint is the seal row E.

The Bolzano-Cauchy packet adds no new endpoint between E and the limit-seal consumer. The compatibility row L reads the same finite handoff, while H, C, P, N transport, replay, source, and name that packet.

Thus the Cauchy-side read reaches the limit-seal boundary only through the displayed route. The carrier inventory excludes ambient completeness, quotient streams, selected host limits, trichotomy, open-cover compactness, countable choice, and detached seals. □

Theorem 1913.4 (Bolzano-Cauchy limit-to-Cauchy route)**.** *Every limit-facing read of an accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier that begins from the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row factors back through the same displayed route*

$$L \longmapsto E \longmapsto R \longmapsto D \longmapsto M \longmapsto S$$

as a Cauchy conclusion over the finite stream windows. The reverse direction uses only the stored compatibility, Real seal, regular readback, dyadic ledger, modulus data, stream schedule, transport, continuation, provenance, and local NameCert rows; it does not use ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, trichotomy, open-cover compactness, countable choice, or bridge checking.*

Proof. Begin with a limit-facing read of the row L. By Definition 1913.1, that row is compatible only with the displayed S, M, D, R, E route and has no independent source of sequence or limit data.

Read the Real and regular-rational stages next. The row E is downstream of R, and R is downstream of the same dyadic ledger and modulus data used by the Cauchy side. Hence the reverse read cannot bypass D or M.

Finally return to the finite stream windows. The schedule S is the only observation source, and H, C, P, N merely preserve, replay, source, and name the same packet. Therefore the limit-facing read yields a Cauchy conclusion only over the displayed finite windows, with no appeal to ambient completeness, quotient streams, selected host limits, trichotomy, open-cover compactness, countable choice, or bridge checking. □

Theorem 1913.5 (Bolzano-Cauchy subsequence window extraction)**.** *An accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *packet with a bounded finite* $\mathsf{Real}^{\uparrow}$ *sequence window exposes a finite subsequence-window route before any Cauchy read or limit read is exported. The extracted route is carried by the displayed* $\mathsf{StreamName}^{\uparrow}$ *window schedule* S*, dyadic tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, together with the same* M, L, H, C, P, N *support rows of the packet.*

This extraction exports no selected host limit, countable-choice subsequence selector, ambient completeness principle, open-cover compactness row, quotient stream equality, or detached limit seal.

Proof. Project the carrier of Definition 1913.1. The bounded finite sequence window can only be read through the displayed StreamName schedule S, the modulus data M, the dyadic ledger D, and the regular readback row R.

Apply the NameCert obligations of Definition 1913.2. They force any Cauchy-side or limit-side consumer to use the displayed window, modulus, ledger, readback, seal, and compatibility rows before the local certificate can be consumed.

Use Definition 1913.3 and Definition 1913.4. Both directions pass through the same S, M, D, R, E, L surface, so a finite subsequence-window read is exposed at the StreamName and RegSeqRat stages before either route exports a Cauchy or limit conclusion.

The structural rows H, C, P, N only transport, replay, source, and name that finite packet. Because the carrier has no coordinate for selected host limits, countable-choice selectors, ambient completeness, open-cover compactness, quotient stream equality, or detached limit seals, the extraction remains a finite subsequence-window route. □

Theorem 1913.6 (Bolzano-Cauchy ledger exactness)**.** *For any accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier* $B = (S, M, D, R, E, L, H, C, P, N)$*, the Cauchy-to-limit route and the limit-to-Cauchy route expose the same finite ledger rows* $S, M, D, R, E, L, H, C, P, N$*. In particular, no consumer can insert a selected host limit, quotient stream equality, or ambient completeness coordinate between the* $\mathsf{Real}^{\uparrow}$ *seal row* E *and the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility row* L*.*

Proof. Apply Definition 1913.2. The obligation surface lists one stream schedule, one modulus row, one dyadic tolerance ledger, one regular readback, one Real seal, one limit-seal compatibility row, and the structural rows H, C, P, N.

Use Definition 1913.3 for the forward direction. It routes a Cauchy-side read through S, M, D, R, E, L and then through the structural rows, so the ledger visible before L is exactly the displayed finite packet.

Use Definition 1913.4 for the reverse direction. It reads the same compatibility row L back through E, R, D, M, S, with H, C, P, N preserving the packet. Because both routes consume the same rows and the carrier has no coordinate between E and L, selected host limits, quotient stream equality, and ambient completeness cannot be inserted there. □

Theorem 1913.7 (Bolzano-Cauchy RegSeqRat window factorization)**.** *For any accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier* $B = (S, M, D, R, E, L, H, C, P, N)$*, both the Cauchy-to-limit read and the limit-to-Cauchy read factor through the same finite* S, M, D, R *window before either the* $\mathsf{Real}^{\uparrow}$ *seal row* E *or the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row* L *is exposed. In particular, no quotient stream, selected host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can be inserted between the* $\mathsf{RegSeqRat}^{\uparrow}$ *window* R *and the seal rows* E, L*.*

Proof. Use Definition 1913.3 for the Cauchy-to-limit direction. Its read reaches the $\mathsf{Real}^{\uparrow}$ and limit-seal rows only after the finite stream schedule S, modulus row M, dyadic ledger D, and regular readback R have been displayed.

Use Definition 1913.4 for the limit-to-Cauchy direction. Reading back from L passes through E, R, D, M, S, so the reverse route exposes the same S, M, D, R window before returning a Cauchy conclusion.

Finally apply Definition 1913.6. The two routes consume the same finite ledger rows, and the carrier has no coordinate between R and the seal rows. Hence quotient streams, selected host limits, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be inserted into the factorization. □

Theorem 1913.8 (Bolzano-Cauchy uniform subsequence modulus)**.** *For any accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier* $B = (S, M, D, R, E, L, H, C, P, N)$*, the displayed* S, M, D, R, E, L *window factorization can be consumed by a localized Cauchy subsequence or uniform Cauchy rate packet only through the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows. In particular, the localized consumer of chapter 6046 may read the factorization as a finite subsequence-window route, but it receives no selected host limit, countable-choice subsequence selector, ambient completeness principle, quotient stream equality, or detached limit seal.*

Proof. Start with the window factorization of Definition 1913.7. It displays the finite route through S, M, D, R before the seal rows E, L are public.

Apply Definition 1913.5. The same route exposes the StreamName, RegSeqRat, DyadicRatCore, and Real-facing rows needed by a subsequence consumer before any Cauchy or limit conclusion is exported.

The localized consumer in chapter 6046 reads exactly those rows as its downstream input. Since the Bolzano-Cauchy carrier has no selected host limit, countable-choice selector, ambient completeness coordinate, quotient stream equality, or detached seal, none of those objects can be exported with the handoff. □

Theorem 1913.9 (Bolzano-Cauchy limit-readback nonescape)**.** *A* $\mathsf{CauchyLimitSeal}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BolzanoCauchy}^{\uparrow}$ *carrier*

$$B = (S, M, D, R, E, L, H, C, P, N)$$

can read back a Cauchy conclusion only through $L, E, R, D, M, S, H, C, P, N$ *and the same* S, M, D, R *window used by the Cauchy-to-limit direction. The readback exports no selected host limit, quotient stream equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, open-cover compactness, countable choice, or detached seal data.*

Proof. Apply the limit-to-Cauchy route of Definition 1913.4. A limit-facing read starts at L and returns through E, R, D, M, S, with H, C, P, N preserving, replaying, sourcing, and naming the same finite packet.

Use ledger exactness from Definition 1913.6. The reverse read consumes the same rows as the forward Cauchy-to-limit route, so no additional limit coordinate can be inserted between the $\mathsf{Real}^{\uparrow}$ seal and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ compatibility row.

Apply RegSeqRat window factorization from Definition 1913.7. Both directions pass through the same S, M, D, R window before either seal row can be exported.

Finally use the uniform subsequence modulus of Definition 1913.8 for localized consumers. The localized route still reads only the StreamName schedule, DyadicRatCore ledger, RegSeqRat readback, Real seal, limit compatibility, and structural rows, so the excluded host, quotient, order, compactness, choice, and detached-seal data remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoCauchy}^{\uparrow}$ packet is generated from a finite StreamName window schedule, Cauchy modulus data, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, CauchyLimitSeal compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BolzanoCauchy}^{\uparrow}}$, obligation)

Scope closed: Definition 1913.1, Definition 1913.2, Definition 1913.3, Definition 1913.4, Definition 1913.6, and Definition 1913.7 display carrier admission, Cauchy-to-limit routing, limit-to-Cauchy routing, ledger exactness, structural stability, and RegSeqRat window factorization for the finite bidirectional Cauchy convergence criterion.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BolzanoCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient RealUp completeness, quotient stream equality, selected host limits, trichotomy, open-cover compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-to-limit routing, limit-to-Cauchy routing, ledger exactness, and structural stability for BEDC.Derived.BolzanoCauchyUp.

Chapter 1914

A Concrete Naming Certificate for $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$ packet records bounded monotone real convergence as finite BEDC NameCert data. It sits over the bounded sequence surface of chapter 1415, the located upper-bound surface of chapter 1427, the monotone tail discipline of chapter 438, the bidirectional convergence criterion of chapter 1913, the regular rational handoff of chapter 301, the stream-window schedule of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter packages the constructive least-upper-bound route available for a displayed bounded monotone sequence; it does not import an ambient completeness theorem for arbitrary real data.

Definition 1914.1 (Bishop monotone real limit carrier)**.** *A* $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, B, M, L, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row, carrying the inspected real sequence windows, regular rational readbacks, real-name seals, and boundedness surface.*
2. *B is the bound ledger, recording the finite upper-bound and lower-window data read from S by a consumer requesting a monotone convergence witness.*
3. *M is the monotone comparison data, displaying the finite comparison rows that certify the inspected windows are nondecreasing along the requested index route.*
4. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row, reached from the same bound ledger and comparison data and read only as a located upper-bound and lower-approximation surface.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and Cauchy-modulus ledger, recording each requested dyadic precision, the monotone tail window selected for that precision, and the comparison budget used to trap later terms.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows, monotone comparisons, located-supremum approximants, and dyadic tolerance ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal descent row reached only after S, B, M, L, D, R have been displayed.*

8. *H records componentwise* hsame *transport for the sequence source, bound ledger, monotone comparisons, located supremum, dyadic ledger, regular readback, real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through the bounded source, bound ledger, monotone row, located supremum, dyadic ledger, regular readback, and real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{BolzanoCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMonotoneRealLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, real trichotomy, selected subsequences, countable choice, quotient stream equality, open-cover compactness, or a host-level supremum operator.*

Lean4 ✓ `BEDC.Derived.BishopMonotoneRealLimitUp.BishopMonotoneRealLimitTasteGate single carrier alignment`

Theorem 1914.2 (Bishop monotone real limit NameCert obligations)**.** *For every accepted* BishopMonotoneRealLim *carrier*

$$T = (S, B, M, L, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopMonotoneRealLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed bounded sequence source, bound ledger, monotone comparison data, located supremum, dyadic tolerance ledger, regular readback, real seal, transport, continuation, provenance, and local naming row;*

2. *monotone bounded-source routing, requiring every convergence read to begin with S, B, M before any located supremum or real-seal row is exposed;*

3. *located-supremum routing, requiring lower approximants and upper-bound reads to pass through L with the same bound ledger and comparison data;*

4. *Cauchy-route routing, requiring each dyadic precision request to pass through D and then through R, E before the limit-facing read is available;*

5. *structural stability, requiring H and C to transport and replay only the displayed packet, with provenance supplied by P and local naming supplied by N.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1914.1. The displayed coordinates are exactly the bounded sequence source, bound ledger, monotone comparisons, located supremum, dyadic tolerance ledger, regular readback, real seal, transport, continuation, provenance, and local name.

The first analytic route is forced by the order of the packet. A convergence consumer must read the bounded sequence surface and the monotone comparison data before it can inspect the located supremum row.

The second route is the Cauchy handoff. A precision request enters the dyadic ledger, obtains a finite monotone tail window, passes through the regular rational readback, and reaches the real seal only after those rows have been displayed.

The structural rows exhaust the remaining obligations. The transports and continuations can preserve and replay only the displayed packet, while the provenance and local name add no analytic coordinate. Hence there is no further obligation outside the listed rows. □

Theorem 1914.3 (Bishop monotone real limit Cauchy route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto B \longmapsto M \longmapsto L \longmapsto D \longmapsto R \longmapsto E$$

and then through the stored hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. The route is the bounded monotone sequence read through located supremum data and the Bolzano-Cauchy Cauchy criterion; it exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, trichotomy row, selected subsequence, countable-choice operator, quotient stream equality, or open-cover compactness row.*

Proof. Begin with a real-facing read. By carrier admission, the only sequence source is S, and the only bound and monotonicity data are the displayed rows B and M.

Read the located supremum row next. The row L supplies the upper-bound and lower-approximation surface already available in chapter 1427, but it is attached here to the same bounded monotone source.

The dyadic ledger D then converts a requested precision into a finite monotone tail window. The regular readback R and real seal E consume that same window, matching the Cauchy-route discipline of chapter 1913.

Finally H, C, P, N transport, replay, source, and name the route. Since the carrier contains none of the excluded analytic objects, the real-facing read cannot leave the displayed path. □

Theorem 1914.4 (Bishop monotone real limit nonescape)**.** *Every public read of an accepted* $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$ *carrier is exhausted by the rows* $S, B, M, L, D, R, E, H, C, P, N$*. In particular, the packet cannot export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, real trichotomy, a selected subsequence, countable choice, quotient stream equality, open-cover compactness, or a host-level supremum operation.*

Proof. Inspect the carrier coordinates. The analytic rows are the bounded sequence source, the bound ledger, the monotone comparison data, the located supremum row, the dyadic Cauchy ledger, the regular readback, and the real seal.

The only remaining coordinates are structural. Transport H preserves componentwise rows, continuation C replays displayed reads, provenance P records the sibling sources, and N names the local certificate.

No coordinate remains for completeness, trichotomy, selected subsequences, countable choice, quotient equality, open-cover compactness, or a host-level supremum operator. Therefore every public read is confined to the finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMonotoneRealLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$ packet is generated from bounded real sequence data, a bound ledger, monotone comparison data, a LocatedSupremum row, a DyadicRatCore tolerance and Cauchy-modulus ledger, RegSeqRat readback, RealUp seal descent, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopMonotoneRealLimit}^{\uparrow}}$, seed)

Scope closed: Definition 1914.1, Definition 1914.2, Definition 1914.3, and Definition 1914.4 seed the bounded monotone real convergence packet over bounded sequence data, located supremum data, dyadic tolerance rows, regular readback, and RealUp seal descent.

Formal verification: FormalStatus(NameCert$_{\text{BishopMonotoneRealLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient RealUp completeness, trichotomy, selected subsequences, countable choice, quotient stream equality, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone bounded-source routing, located-supremum routing, Cauchy-route routing, structural stability, and nonescape for BEDC.Derived.BishopMonotoneRealLimitUp.

Chapter 1915

A Concrete Naming Certificate for $\mathsf{CauchyFilterBase}^{\uparrow}$

Following Kelley and Bourbaki on filters, filter bases, and uniform structures, the $\mathsf{CauchyFilterBase}^{\uparrow}$ packet names the finite base route through which completion-facing Cauchy data is requested before a full filter object is exposed. It sits between the generic $\mathsf{FilterBase}^{\uparrow}$ interface of chapter 1601, the entourage base surface of chapter 1819, the uniform entourage structure of chapter 339, the Cauchy filter surface of chapter 333, and the entourage-driven Cauchy handoff of chapter 1791. The packet records finite base indices, entourage requests, directed refinements, Cauchy readiness, transport, replay, provenance, and local naming only; it is not a quotient filter, not a selected limit, not countable choice, and not an ambient completion principle.

Definition 1915.1 (Cauchy filter-base carrier)**.** *A* $\mathsf{CauchyFilterBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, U, D, M, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite base-index row. Each index names a displayed base packet that may be requested by a* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CauchyEntourageFilter}^{\uparrow}$*, or completion-facing consumer.*
2. *U is the entourage-request row. It records the* $\mathsf{EntourageBase}^{\uparrow}$ *and* $\mathsf{UniformSpace}^{\uparrow}$ *request data attached to each displayed base index, including the requested scale and the local admissibility read.*
3. *D is the directed-refinement row. For every two displayed base requests it names a third displayed base index, a common entourage request at a refining scale, and the two containment reads back to the original requests.*
4. *M is the Cauchy readiness row. It records the finite modulus/readiness evidence showing that every requested precision reaches an indexed base packet whose entourage request is small enough for Cauchy-filter consumption.*
5. *H records componentwise* hsame *transport for base indices, entourage requests, directed refinements, readiness rows, replay rows, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a base request through its entourage request, through the directed common refinement, through the readiness row, and then to downstream Cauchy-filter consumers.*

7. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyEntourageFilter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed route I, U, D, M, H, C, P, N. No coordinate stores a host filter, quotient filter, selected limit, countable-choice selector, global completion object, Lean verification, or bridge certificate.

Theorem 1915.2 (Cauchy filter-base NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterBase}^{\uparrow}$ *carrier*

$$K = (I, U, D, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterBase}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the displayed base-index row, entourage-request row, directed-refinement row, Cauchy readiness row, transport, replay, provenance, and local naming row;*

2. *base-to-entourage routing, requiring every indexed base request to read its entourage data from U before any Cauchy-filter or completion consumer can inspect it;*

3. *directed common refinement, requiring every pair of displayed base requests to read a third base index, a common refining entourage request, and two containment reads from D;*

4. *Cauchy readiness, requiring every precision request to pass through M and land in a displayed base index whose entourage request is small enough for the downstream Cauchy route;*

5. *transport and replay stability, requiring H and C to preserve the order I, U, D, M under componentwise* hsame *transport and displayed* Cont *replay;*

6. *provenance exhaustion, requiring P and N to name only this finite base route and to export no quotient filter, selected limit, countable-choice selector, host equality, ambient completion principle, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1915.1. The projection exposes exactly the finite base indices, entourage requests, common-refinement data, Cauchy readiness evidence, and structural rows H, C, P, N.

The base-to-entourage route is fixed by the row order. A consumer first names an index in I, then reads the requested entourage surface from U before any Cauchy-filter or completion-facing read is available.

Directed common refinement and Cauchy readiness are separate finite projections. The row D supplies the third base index and the two containment reads for each pair of requests, while M supplies the precision-facing readiness row used by Cauchy consumers.

Transport, replay, and provenance cannot enlarge the carrier. The row H compares the displayed coordinates componentwise, C replays the same dependency order, and P, N name only this packet; hence quotient filters, selected limits, choice schedules, host equality, ambient completion, Lean verification, and bridge checking are outside the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyFilterBaseUp.TasteGate.CauchyFilterBaseTasteGate single carrier alignment`

Theorem 1915.3 (Cauchy filter-base entourage refinement route)**.** *Let $K = (I, U, D, M, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterBase}^{\uparrow}$ *carrier. For any two displayed base requests $i, j \in I$ with entourage*

requests U_i and U_j, the directed-refinement row D names a displayed index $k \in I$ and an entourage request U_k such that the route

$$(i, U_i), (j, U_j) \longmapsto (k, U_k) \longmapsto H, C$$

contains the two refinement reads from U_k back to U_i and U_j. Consequently two completion-facing base requests reach a common entourage refinement through finite rows of the same carrier.

Proof. Project the two requested base rows from I and their entourage rows from U. These projections stay inside the finite carrier of Definition 1915.1.

Read the row of D attached to the pair. By definition of the directed-refinement row, it names the third index k, the common entourage request U_k, and the two containment reads back to U_i and U_j.

The structural rows preserve the displayed route. Componentwise hsame transport in H compares the requested rows with their transported copies, and Cont replay in C repeats the route from the pair of requests through the selected common refinement.

Thus the common-refinement conclusion is not an ambient directedness principle. It is the finite row D read through the displayed carrier coordinates and replayed by H, C. □

Theorem 1915.4 (Cauchy filter-base completion handoff)**.** *Every* CauchyFilter$^{\uparrow}$, CauchyEntourageFilter$^{\uparrow}$, *or completion-facing consumer of an accepted* CauchyFilterBase$^{\uparrow}$ *carrier $K = (I, U, D, M, H, C, P, N)$ reads only the finite route*

$$I, U, D, M \longmapsto H, C, P, N.$$

In particular, the consumer receives base indices, entourage requests, directed common refinements, Cauchy readiness rows, componentwise transport, replay, provenance, and local naming. It does not receive a host filter, quotient filter, selected limit, countable-choice selector, global completion object, Lean verification row, or bridge certificate.

Proof. Start with a downstream read named by P. The consumer is exposed to CauchyFilterBase$^{\uparrow}$ only through the rows listed in Definition 1915.1, so it first reads a finite base index from I and its entourage request from U.

When the consumer compares two requests, Definition 1915.3 forces the read through D. The selected common base index and its entourage request are therefore finite rows of the same packet.

When the consumer asks for Cauchy readiness, it reads M. This supplies the precision-facing base index and the small-entourage evidence before any CauchyFilter$^{\uparrow}$ or CauchyEntourageFilter$^{\uparrow}$ handoff can occur.

The remaining rows are structural. The transport row H, replay row C, provenance row P, and naming row N preserve and name the route I, U, D, M; none of them adds a host filter, quotient filter, selected limit, choice schedule, completion object, verification row, or bridge certificate. □

Closure status for NameCert$_{\text{CauchyFilterBase}^{\uparrow}}$**.**

Constructive story: A CauchyFilterBase$^{\uparrow}$ packet is generated from finite base indices, entourage requests, directed common refinements, Cauchy readiness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyFilterBase}^{\uparrow}}$, seed)

Scope closed: Definition 1915.1, Definition 1915.2, Definition 1915.3, and Definition 1915.4 seed the finite interface between FilterBase, EntourageBase, UniformSpace, CauchyFilter, and CauchyEntourageFilter routes.

Formal verification: FormalStatus(NameCert$_{\text{CauchyFilterBase}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, base-to-entourage routing, directed common refinement, Cauchy readiness, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterBaseUp.

Chapter 1916

A Concrete Naming Certificate for $\mathsf{DyadicIntervalBasis}^{\uparrow}$

Following Bishop and Bridges constructive analysis together with Kelley's basis presentation of topology, the $\mathsf{DyadicIntervalBasis}^{\uparrow}$ packet records the finite dyadic interval basis used by the L10 Real and Completion route. It sits over the endpoint-cell packet of chapter 306, the dyadic endpoint ledger of chapter 291, the rational containment surface of chapter 354, the order-topology basis reads of chapter 1890, the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite basis cells and their refinement route; it is not Dedekind completeness, open-cover compactness, quotient interval equality, host real equality, countable choice, or a selected completion point.

Definition 1916.1 (DyadicIntervalBasis carrier)**.** *A* $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, E, O, R, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint-cell row, recording the lower and upper dyadic cells exposed to a basis consumer.*
2. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger, carrying the signed dyadic endpoint rows, comparison budget, and radius tolerances read by I.*
3. *O is the* $\mathsf{RationalInterval}^{\uparrow}$ *containment row, recording the rational interval cell that contains the displayed dyadic cell and bounds its endpoint order.*
4. *R is the readback row consisting of the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational observations read through those windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached by those observations.*
5. *B is the* $\mathsf{RealOrderTopology}^{\uparrow}$ *basis-read row, exposing only the order-open basis cell generated by I, E, O, R.*
6. *H records componentwise* hsame *transport for the dyadic cell, endpoint ledger, rational containment row, readback row, basis-read row, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from a basis-cell request through I, E, O, R, B and then through the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalBasis}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for Dedekind completeness, open-cover compactness, quotient interval equality, host real equality, countable choice, or a selected completion point.

Lean4 ✓ `BEDC.Derived.DyadicIntervalBasisUp.DyadicIntervalBasisTasteGate single carrier alignment`

Theorem 1916.2 (DyadicIntervalBasis NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *carrier*

$$D = (I, E, O, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic interval cell, dyadic endpoint ledger, rational containment row, finite readback row, order-topology basis row, transport, replay, provenance, and local name;*
2. *endpoint exactness, requiring each lower and upper endpoint read of I to be sourced by the dyadic ledger E and bounded by the rational containment row O;*
3. *basis generation, requiring every basis read in B to arise from the displayed dyadic cell together with the stream-window, regular-rational, and real-seal data in R;*
4. *refinement routing, requiring any accepted subcell or containment refinement to pass through the same I, E, O, R, B rows before it reaches a consumer;*
5. *structural stability, requiring H and C to preserve and replay only the displayed packet rows.*

No DyadicIntervalBasis obligation is stored outside these rows.

Proof. Project the carrier of Definition 1916.1. The visible coordinates are exactly the dyadic interval cell, endpoint ledger, rational containment row, finite readback row, order-topology basis row, transport, replay, provenance, and local naming rows.

Endpoint exactness is forced by the displayed order. The dyadic cell I has no endpoint source except the dyadic ledger E, and the rational containment row O is the only interval bound attached to those endpoints.

Basis generation then reads through R and B. The stream windows, regular-rational observations, and real seal in R are the only real-facing data available before the order-topology basis row B is exposed.

Finally, refinement routing and structural stability are exhausted by H, C, P, N. These rows can transport, replay, source, and name the displayed packet, but they add no coordinate for Dedekind completeness, open-cover compactness, quotient interval equality, host real equality, countable choice, or a selected completion point. □

Theorem 1916.3 (DyadicIntervalBasis refinement stability)**.** *Let $D = (I, E, O, R, B, H, C, P, N)$ and $D' = (I', E', O', R', B', H', C', P', N')$ be accepted* $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *carriers. If D' is obtained from D by a displayed dyadic subcell refinement whose endpoints are transported by the stored* hsame *rows and replayed through the stored* Cont *routes, then D' is accepted by the same local classifier. The transported packet preserves the* $\mathsf{DyadicInterval}^{\uparrow}$ *cell,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger,* $\mathsf{RationalInterval}^{\uparrow}$ *containment row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows,* $\mathsf{RealOrderTopology}^{\uparrow}$ *basis read,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$ *row.*

Proof. Start with the accepted packet D and a displayed dyadic subcell refinement. The refinement changes the interval cell only through the $\mathsf{DyadicInterval}^{\uparrow}$ coordinate I, and its endpoints remain sourced by the transported $\mathsf{DyadicRatCore}^{\uparrow}$ ledger E.

The rational containment row is transported next. Because O is the only displayed $\mathsf{RationalInterval}^{\uparrow}$ bound, the refined cell remains attached to the same containment route rather than to an unrecorded host interval.

The readback row R and basis row B then replay along the stored Cont routes. The $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ observations, $\mathsf{Real}^{\uparrow}$ seal rows, and $\mathsf{RealOrderTopology}^{\uparrow}$ basis read are transported componentwise, so the consumer sees the refined cell through the same finite order.

The structural rows finish the classification. The provenance and local name are transported with the packet, and the carrier has no extra coordinate from which a quotient interval equality, host real equality, open-cover compactness theorem, Dedekind completeness principle, countable-choice witness, or selected completion point could be read. □

Theorem 1916.4 (DyadicIntervalBasis refinement cover)**.** *Let $D = (I, E, O, R, B, H, C, P, N)$ be an accepted $\mathsf{DyadicIntervalBasis}^{\uparrow}$ carrier. Any finite family of displayed dyadic subcell refinements whose endpoint rows are transported through H and replayed through C assembles into finite basis-cover data over the same $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealOrderTopology}^{\uparrow}$ rows. Each refined cell contributes only a transported endpoint cell, endpoint ledger, rational containment row, finite readback row, Real seal, order-topology basis read, provenance, and local name; the assembled cover exports no Dedekind completeness, open-cover compactness, quotient interval equality, host real equality, countable choice, or selected completion point.*

Proof. Induct on the finite refinement family. The empty family assembles to the empty finite basis-cover packet over the displayed carrier rows, with no new mathematical coordinate.

For the successor step, assume the preceding refinements have already been assembled as finite basis-cover data over $I, E, O, R, B, H, C, P, N$. Apply Definition 1916.3 to the next displayed subcell refinement. Its endpoints are transported by H, its route is replayed by C, and its accepted packet preserves the dyadic interval cell, endpoint ledger, rational containment row, finite readback row, Real seal rows, and order-topology basis read.

Append that accepted subcell packet to the finite cover list. The provenance and local naming rows P, N source the appended cell in the same carrier surface, so the assembled cover remains finite and basis-facing. Since every induction step uses only the transported carrier rows, none of the excluded host principles can enter the assembled data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalBasis}^{\uparrow}$ packet is generated from a DyadicInterval endpoint cell, a DyadicRatCore endpoint ledger, a RationalInterval containment row, StreamName finite windows, RegSeqRat readbacks, RealUp seal rows, a RealOrderTopology basis read, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$, seed)

Scope closed: Definition 1916.1, Definition 1916.2, Definition 1916.3, and Definition 1916.4 seed the finite dyadic basis-cell route over dyadic endpoint cells, endpoint ledgers, rational containment, finite readbacks, Real seals, and order-topology basis reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, open-cover compactness, quotient interval equality, host real equality, countable choice, a selected completion point, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, basis generation, refinement routing, and structural stability for BEDC.Derived.DyadicIntervalBasisUp.

Chapter 1917

A Concrete Naming Certificate for $\mathsf{DoubleLimitInterchange}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DoubleLimitInterchange}^{\uparrow}$ packet records a finite certificate for exchanging two Cauchy limit routes through displayed windows rather than through an ambient completeness principle. Its dependency surface is the $\mathsf{StreamName}^{\uparrow}$ schedule interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the shared dyadic tolerance rows of chapter 291, the diagonal-route discipline of chapter 1800, the uniform-window route of chapter 1749, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records a boundary for exchanging two displayed completion-facing reads; it does not claim selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1917.1 (Double-limit interchange carrier)**.** *A* $\mathsf{DoubleLimitInterchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (O, J, D, \Delta, R_0, R_1, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the outer* $\mathsf{StreamName}^{\uparrow}$ *schedule, listing the finite outer windows inspected by a completion-facing consumer.*
2. *J is the inner* $\mathsf{StreamName}^{\uparrow}$ *schedule, listing the finite inner windows read under each displayed outer window.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic request, the two Cauchy-window budgets, and the comparison margin used by both routes.*
4. *Δ is the diagonal selector row supplied through the* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ *route, choosing a displayed common window only from O, J, D.*
5. *R_0 is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, obtained by reading the outer schedule before the inner schedule and then applying the shared dyadic ledger.*
6. *R_1 is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, obtained by reading the inner schedule before the outer schedule and then applying the same shared dyadic ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the common displayed Cauchy-window read.*

8. *H records componentwise* hsame *transport for the outer schedule, inner schedule, dyadic ledger, diagonal selector, first readback, second readback, real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from any requested precision through $O, J, D, \Delta, R_0, R_1, E$.*
10. *P is the* Pkg *provenance over* $\mathsf{DoubleLimitInterchange}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyDiagonalLimit}^{\uparrow}$, $\mathsf{UniformLimitInterchange}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DoubleLimitInterchange}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DoubleLimitInterchangeUp.DoubleLimitInterchangeTasteGate single carrier alignment`

Theorem 1917.2 (Double-limit interchange NameCert obligations)**.** *For every accepted* $\mathsf{DoubleLimitInterchange}^{\uparrow}$ *carrier*

$$I = (O, J, D, \Delta, R_0, R_1, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DoubleLimitInterchange}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed outer schedule, inner schedule, shared dyadic tolerance ledger, diagonal selector, first readback, second readback, real seal, transport, continuation, provenance, and local naming row;*
2. *shared-window routing, requiring every route comparison to expose O, J, D before either* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row is available;*
3. *diagonal routing, requiring the selector Δ to be read through the* $\mathsf{CauchyDiagonalLimit}^{\uparrow}$ *packet before any common real seal can be consumed;*
4. *uniform interchange routing, requiring both readback directions R_0 and R_1 to use the same dyadic tolerance ledger and the same displayed windows, as in the* $\mathsf{UniformLimitInterchange}^{\uparrow}$ *route;*
5. *structural stability, requiring H and C to transport and replay only the displayed rows, with provenance supplied by P and local naming supplied by N.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1917.1. The displayed coordinates are exactly the two schedules, the shared dyadic tolerance ledger, the diagonal selector, the two regular readbacks, the real seal, the structural transport and replay rows, provenance, and the local name.

The route comparison first exposes the schedules and the shared tolerance. Since both readback rows are downstream of O, J, D, a consumer cannot replace one side by a separately chosen window or tolerance.

The diagonal selector supplies the common Cauchy window. It is read through the same finite diagonal route used by $\mathsf{CauchyDiagonalLimit}^{\uparrow}$, so it cannot introduce a selected limit or a quotient-stream representative.

The interchange step then reads R_0 and R_1 through the uniform-window discipline of $\mathsf{UniformLimitInterchange}^{\uparrow}$. The two orders of reading are admitted only as two routes through the same displayed rows.

Finally H, C, P, N transport, replay, source, and name that finite surface. These structural rows add no analytic coordinate, so the listed obligations exhaust the local certificate. □

Theorem 1917.3 (Double-limit interchange diagonal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{DoubleLimitInterchange}^{\uparrow}$ *carrier factors through the finite route*

$$O, J, D \longmapsto \Delta \longmapsto (R_0, R_1) \longmapsto E$$

and then through the stored hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. The two orders of Cauchy-window readback therefore meet at a displayed diagonal selector and a shared dyadic tolerance ledger; the route exports no selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a real-facing precision request. Carrier admission gives the request only the outer schedule O, the inner schedule J, and the shared dyadic tolerance ledger D.

The diagonal row Δ is the next available common-window object. It is computed from the displayed schedules and tolerance ledger, matching the diagonal route supplied by chapter 1800.

The two readbacks R_0 and R_1 are then read through the same finite window data. The first uses the outer-then-inner order and the second uses the inner-then-outer order, but both consume the same O, J, D, Δ surface.

The terminal seal E is downstream of those readbacks. After E, the rows H, C, P, N only transport, replay, source, and name the route. Since no excluded analytic object occurs in the carrier inventory, the real-facing read cannot leave the displayed path. □

Theorem 1917.4 (Double-limit interchange nonescape)**.** *Every public read of an accepted* $\mathsf{DoubleLimitInterchange}^{\uparrow}$ *carrier is exhausted by the rows* $O, J, D, \Delta, R_0, R_1, E, H, C, P, N$*. In particular, the packet cannot export selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier coordinates. The analytic rows are the two stream schedules, the shared dyadic tolerance ledger, the diagonal selector, the two regular readbacks, and the terminal real seal.

The remaining rows are structural. Transport H preserves componentwise classifier data, continuation C replays displayed precision routes, provenance P records the sibling sources, and N supplies the local certificate row.

There is no coordinate left for selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient completeness. Therefore every public read is confined to the finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DoubleLimitInterchange}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DoubleLimitInterchange}^{\uparrow}$ packet is generated from an outer StreamName schedule, an inner StreamName schedule, a shared DyadicRatCore tolerance ledger, a CauchyDiagonalLimit selector, two RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DoubleLimitInterchange}^{\uparrow}}$, seed)

Scope closed: Definition 1917.1, Definition 1917.2, Definition 1917.3, and Definition 1917.4 seed the double-limit interchange packet over stream schedules, regular readbacks, dyadic tolerance rows, diagonal selection, uniform interchange routing, and RealUp seal descent.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DoubleLimitInterchange}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, host function equality, quotient streams, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window routing, diagonal routing, uniform interchange routing, structural stability, and nonescape for BEDC.Derived.DoubleLimitInterchangeUp.

Chapter 1918

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ packet records the finite request-to-tail-window realizer by which a regular Cauchy modulus becomes a displayed regular rational read before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the source decoding of chapter 1771, the Real-facing threshold route of chapter 1423, the generic Cauchy-modulus schedule of chapter 292, the finite window interface of chapter 126, the regular rational readback boundary of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies the L10 Real and Completion route with one finite witness object for turning a precision request into the tail window it reads; it is not Real completeness, quotient stream equality, host real equality, countable choice, a selected limit, trichotomy, or a standard bridge.

Definition 1918.1 (Regular Cauchy modulus realizer carrier)**.** *A* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, M, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the precision request row, recording the finite Real or Completion demand that must be answered by a tail-window read.*
2. *M is the Cauchy-modulus threshold row imported from the Real-facing modulus route and the generic modulus schedule.*
3. *W is the selected finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window row determined by A and M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the requested radius, slack comparisons, and dyadic arithmetic consumed by the selected window.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the window W under the tolerance ledger D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the request, threshold, window, tolerance, and readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the request, modulus threshold, selected window, tolerance ledger, readback, seal, replay, provenance, and local name.*

8. *C records displayed* Cont *replay from the precision request through A, M, W, D, Q, E and then through H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$, $\mathsf{CauchyRealizer}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, M, W, D, Q, E, H, C, P, N$. It has no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, a selected limit, trichotomy, open-cover compactness, Lean verification, or a standard bridge.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusRealizerUp.RegularCauchyModulusRealizerTasteGate`
`single carrier alignment`

Theorem 1918.2 (Regular Cauchy modulus realizer NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carrier*

$$R = (A, M, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the precision request A, Cauchy-modulus threshold M, selected tail window W, dyadic tolerance ledger D, regular rational readback Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N;*
2. *request admission, requiring the Real or Completion precision request to enter through A before any threshold or window is read;*
3. *threshold realization, requiring the threshold row M to be the only Cauchy-modulus source used to select the tail window;*
4. *tail-window selection, requiring W to be the finite* $\mathsf{StreamName}^{\uparrow}$ *row selected by the pair A, M;*
5. *tolerance accounting, requiring D to record exactly the dyadic radius and slack comparisons consumed by W, Q, E;*
6. *readback and seal routing, requiring Q and E to be downstream of the displayed A, M, W, D route;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *non-escape for Real completeness, quotient stream equality, host real equality, countable choice, selected limits, trichotomy, open-cover compactness, Lean verification, and standard-bridge data.*

No regular Cauchy modulus realizer obligation is stored outside these rows.

Proof. Project the carrier of Definition 1918.1. The precision request A, threshold row M, tail window W, tolerance ledger D, regular readback Q, and terminal seal E are the only analytic coordinates, while H, C, P, N are the only structural coordinates.

The request-to-window order is forced by the displayed tuple. A consumer first reads A, then the threshold row M, and only then the finite $\mathsf{StreamName}^{\uparrow}$ window W selected for the requested tolerance.

The tolerance and seal rows are downstream. The ledger D supplies the dyadic radius and slack comparisons used by the regular readback Q, and the seal E is reached after those rows have been displayed.

The structural rows transport, replay, source, and name the same route. Since none of the excluded objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1918.3 (Regular Cauchy modulus realizer tail realization)**.** *Every Real or Completion precision request accepted by a* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carrier factors through the finite route*

$$A \longmapsto M \longmapsto W \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed request row, a Cauchy-modulus threshold, one selected finite $\mathsf{StreamName}^{\uparrow}$ *tail window, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming. The factorization supplies no ambient completeness principle, quotient stream equality, host equality, countable-choice selector, selected limit, trichotomy row, open-cover compactness theorem, Lean evidence, or standard bridge.*

Proof. Start with an accepted carrier and inspect its precision request row. The row A is the only entrance for the requested tolerance, so a consumer cannot first read a detached stream window or terminal Real seal.

The threshold row is read next. The row M is the only Cauchy-modulus coordinate in the carrier, hence it is the only source from which the tail boundary for the request can be obtained.

Once A and M are fixed, the selected window W is the finite stream row consumed by the readback. The dyadic ledger D then records the tolerance arithmetic for that window, and Q is the regular rational observation obtained from the same displayed data.

Finally the seal E and structural rows H, C, P, N close the finite route. They preserve and name the displayed path, but they introduce none of the excluded completeness, quotient, choice, order, verification, or bridge data. □

Theorem 1918.4 (Regular Cauchy modulus realizer stream handoff)**.** *Every accepted* RegularCauchyModulusRealiz *read that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite window, selected tail schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, and componentwise* hsame *and* Cont *replay rows before the Real seal row can be consumed.*

Proof. Project the carrier of Definition 1918.1. The stream-facing window is the row W, the dyadic budget is D, and the structural replay is carried by H and C.

Use the tail realization of Definition 1918.3. It fixes the selected tail window by the displayed route from the precision request row A through the Cauchy-modulus threshold row M before any regular readback or terminal seal is visible.

Now apply request transport determinacy, Definition 1918.5. Under componentwise hsame transport and displayed Cont replay, the same request-threshold route keeps the same selected window, tolerance ledger, regular readback, and seal-facing path.

Thus any downstream $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives the finite window, selected tail schedule, dyadic tolerance budget, and replay rows before reading the Real seal. The carrier contains no selected-limit, quotient-stream, host-real-equality, choice, or ambient-completeness coordinate that could bypass this stream handoff. □

Theorem 1918.5 (Regular Cauchy modulus realizer request transport determinacy)**.** *Let*

$$R = (A, M, W, D, Q, E, H, C, P, N)$$

and

$$R' = (A', M', W', D', Q', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carriers. Suppose the precision request rows* A, A' *and Cauchy-modulus threshold rows* M, M' *are carried to one another by the displayed componentwise* hsame *rows in* H, H'*, and suppose the displayed* Cont *replays in* C, C' *read the same request-to-threshold route. Then the selected* $\mathsf{StreamName}^{\uparrow}$ *tail-window rows* W, W'*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers* D, D'*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* Q, Q'*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows* E, E' *are the same classifier-facing finite route. The determinacy result exports no selected limit, quotient stream equality, host real equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Proof. Project the two carrier presentations of Definition 1918.1. In each accepted packet the only entrance for a precision demand is the request row, and the only threshold source downstream of it is the Cauchy-modulus row.

Use the ordering supplied by Definition 1918.3. Both displayed replays read the route from A to M and from A' to M' before any window, ledger, readback, or seal row is exposed. The hypotheses identify the request and threshold rows through the componentwise hsame data in H, H'.

After that identification, the accepted carrier has a single downstream window coordinate for the fixed request-threshold pair: W in R and W' in R'. The dyadic tolerance ledger is then the single row downstream of the selected window, so the classifier-facing ledger route is D, D'.

The readback and seal rows are forced in the same way. The only $\mathsf{RegSeqRat}^{\uparrow}$ readback downstream of the ledger is Q, Q', and the only terminal $\mathsf{Real}^{\uparrow}$ seal downstream of that readback is E, E'.

Finally apply the non-escape boundary of Definition 1918.7. Since neither carrier contains any coordinate for selected limits, quotient stream equality, host real equality, countable choice, trichotomy, ambient completeness, Lean evidence, or a standard bridge, the transported request can select only the finite route through W, D, Q, E and its counterpart W', D', Q', E'. □

Theorem 1918.6 (Regular Cauchy modulus realizer selector budget exhaustion)**.** *Let*

$$R = (A, M, W, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carrier. Any* $\mathsf{RealObservationBudget}^{\uparrow}$ *consumer or* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *consumer serving the same precision request factors through*

$$A \longmapsto M \longmapsto W \longmapsto D \longmapsto Q \longmapsto E$$

and then through the structural rows H, C, P, N *of* R*. The selector receives no independent stream representative, hidden schedule, selected limit, quotient equality, countable-choice row, trichotomy row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum. Thus the budget consumers of chapter 611 and chapter 782 can consume the same finite request-to-tail-window route without importing data outside the accepted packet.*

Proof. Start from the tail-realization factorization in Definition 1918.3. It already places every accepted Real or Completion precision request on the displayed route through $A, M, W, D, Q, E, H, C, P, N$,

so a budget consumer reading the request has a finite carrier-facing spine before it reads any terminal seal.

Apply the request-transport determinacy of Definition 1918.5. If a $\mathsf{RealObservationBudget}^{\uparrow}$ or $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ consumer serves the same request through the same displayed threshold replay, the selected window, tolerance ledger, readback, and terminal seal are the same classifier-facing downstream route.

It remains to exclude extra budget data. The carrier definition of Definition 1918.1 has no coordinate for an independent stream representative, hidden schedule, selected limit, quotient equality, countable-choice row, trichotomy row, or ambient completeness datum. The sibling budget consumers therefore receive only the finite route exposed by R and its structural rows. □

Theorem 1918.7 (Regular Cauchy modulus realizer Real seal nonescape)**.** *Let $R = (A, M, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *carrier. Any downstream use of the terminal* $\mathsf{Real}^{\uparrow}$ *seal E must pass through the precision request row, Cauchy-modulus threshold, selected finite tail window, dyadic tolerance ledger, regular rational readback, and structural rows of the same carrier. Thus the seal cannot be used as a hidden endpoint for Real completeness, quotient stream equality, host real equality, countable choice, a selected limit, trichotomy, open-cover compactness, Lean verification, or a standard bridge.*

Proof. Use the tail-realization route of Definition 1918.3. It places E after A, M, W, D, Q, so every accepted seal read is attached to the displayed request, threshold, window, tolerance, and readback rows.

Now inspect the classifier surface of Definition 1918.1. The carrier has no second Real-seal coordinate and no coordinate for completeness, quotient equality, host equality, choice, selected limits, trichotomy, open-cover compactness, Lean evidence, or bridge data.

Therefore a downstream read that bypasses one of $A, M, W, D, Q, H, C, P, N$ is not a read of the accepted carrier. The only available terminal route is the finite route named by R. □

Falsifiable prediction: Every $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ precision read factors through a request row, Cauchy-modulus threshold, finite StreamName tail window, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-realizer, realcauchymodulus, cauchymodulus, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries request admission, threshold realization, finite tail-window selection, dyadic tolerance accounting, regular readback, terminal seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealizer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ packet is generated from a precision request row, a Cauchy-modulus threshold row, a selected finite StreamName tail window, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealizer}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1918.2, Definition 1918.3, Definition 1918.5, Definition 1918.6, and Definition 1918.7 give the finite request-to-tail-window obligation witness set for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusRealizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, host real equality, countable choice, selected limits, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, request admission, threshold realization, tail-window selection, tolerance accounting, readback and seal routing, tail realization, and Real-seal non-escape for BEDC.Derived.RegularCauchyM

Chapter 1919

A Concrete Naming Certificate for $\mathsf{StoneWeierstrass}^{\uparrow}$

Following Stone's Stone–Weierstrass theorem, the $\mathsf{StoneWeierstrass}^{\uparrow}$ packet records the finite separating-algebra route by which compact real approximation data may be read through displayed algebra, compactness, continuity, and real-name surfaces. It sits over the compact carrier of chapter 60, the continuous-map surface of chapter 130, the real-name boundary of chapter 38, the ring operations of chapter 43, and the polynomial approximation consumer of chapter 1634. The packet names a finite BEDC certificate for separation, constants, algebraic closure, approximation handoff, and transport only; it does not claim nonconstructive compactness, choice-selected dense subsets, host function equality, or ambient completeness.

Definition 1919.1 (Stone–Weierstrass carrier)**.** *A* $\mathsf{StoneWeierstrass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, A, U, V, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read through the* $\mathsf{Compact}^{\uparrow}$ *interface and its finite cover or finite-net witnesses.*
2. *A is the algebra row, exposing only finitely named* $\mathsf{ContinuousMap}^{\uparrow}$ *generators over K together with displayed addition, multiplication, scalar, and constant-one operations routed through* $\mathsf{Ring}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*.*
3. *U is the unit and constants ledger, recording the visible constant real functions admitted into the algebra row.*
4. *V is the separation ledger, assigning each displayed apartness request between named compact points a generator in A and a finite real-window comparison that separates the two inspected points.*
5. *R is the real-valued evaluation ledger, reading every generator, algebraic combination, and constant through the same* $\mathsf{Real}^{\uparrow}$ *windows used by the compact and continuous-map surfaces.*
6. *M is the compact-continuity modulus row, recording the finite continuity and compactness data needed before approximation is requested.*
7. *E is the approximation handoff row, sending an inspected continuous target, a rational error row, and the displayed algebra data to a* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *consumer.*

8. *H stores componentwise* hsame *transport for the compact source, algebra, constants, separation, evaluation, modulus, approximation, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a compact-point request through algebra evaluation, separation comparison, compact-continuity modulus, and approximation handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{StoneWeierstrass}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{WeierstrassApproximation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for nonconstructive compactness, choice-selected dense subsets, host function equality, an ambient function-space quotient, a host supremum norm, or ambient completeness.

Lean4 (definition) `BEDC.Derived.StoneWeierstrassUp.StoneWeierstrassUp`

Theorem 1919.2 (Stone–Weierstrass NameCert obligations)**.** *For every accepted* $\mathsf{StoneWeierstrass}^{\uparrow}$ *carrier*

$$S = (K, A, U, V, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the compact source, algebra, constants, separation, real-valued evaluation, compact-continuity modulus, approximation handoff, transport, replay, provenance, and local naming rows;*
2. *compact-source compatibility, requiring every point and finite witness consumed by the algebra and separation rows to pass through the same* $\mathsf{Compact}^{\uparrow}$ *row K;*
3. *algebra closure visibility, requiring A and U to display the continuous generators, constants, and finite algebraic operations used by the packet rather than a host algebra of all functions;*
4. *separation exactness, requiring each separation request in V to name the generator, the two compact-point windows, and the real-window apartness comparison used to distinguish them;*
5. *evaluation and modulus routing, requiring R and M to mediate every real-valued read before any approximation handoff is exposed;*
6. *approximation handoff exactness, requiring E to send the inspected continuous target and rational error through the displayed algebra data before it reaches* $\mathsf{WeierstrassApproximation}^{\uparrow}$*;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *ledger refusal for nonconstructive compactness, choice-selected dense subsets, host function equality, ambient function-space quotients, host supremum norms, ambient completeness, Lean verification, and bridge checking.*

No Stone–Weierstrass obligation is stored outside these rows.

Proof. Project the carrier of Definition 1919.1. The packet exposes exactly the compact source, algebra, constants, separation, evaluation, modulus, approximation, transport, replay, provenance, and local naming rows.

The compact-source and algebra clauses are then fixed by row membership. The row K is the only compact input surface, while A and U are the only places where generators, constants, and algebraic operations are named.

For a separation request, the row V supplies a displayed generator and the corresponding real-window comparison. The evaluation row R routes that comparison through $\mathsf{Real}^{\uparrow}$, and M supplies the compact-continuity information needed before a downstream approximation read is allowed.

The approximation handoff is the row E. It sends the inspected continuous target and rational error to the $\mathsf{WeierstrassApproximation}^{\uparrow}$ consumer only after the algebra, separation, evaluation, and modulus rows have been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded objects occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 1919.3 (Stone–Weierstrass separating-algebra route)**.** *Every approximation-facing consumer of an accepted* $\mathsf{StoneWeierstrass}^{\uparrow}$ *carrier factors through the finite route*

$$K \longmapsto A, U, V \longmapsto R, M \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer reads compactness, continuous-map generators, real constants, separating witnesses, real-window evaluations, compact-continuity moduli, approximation handoff data, transport, replay, provenance, and local naming. The route does not provide nonconstructive compactness, choice-selected dense subsets, host function equality, ambient function-space quotients, host supremum norms, ambient completeness, Lean verification, or a standard bridge.

Proof. Begin with an approximation-facing read of the accepted carrier. The source point and compact witness data first enter through K, so the consumer has no direct route to an ambient compactness principle.

The algebraic data are then read through A and U. Separation requests pass through V, which names a generator and a finite real-window comparison for the displayed compact-point windows.

Next the route reaches R and M. These rows ensure that each function value and compact-continuity read is mediated by the displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{Compact}^{\uparrow}$ surfaces.

Only after those rows are present can E hand the inspected target and rational error to the $\mathsf{WeierstrassApproximation}^{\uparrow}$ consumer. The structural rows H, C, P, N preserve and name the same route, so the excluded compactness, choice, equality, quotient, norm, completeness, verification, and bridge data cannot be recovered from the packet. □

Definition 1919.4 (Constructive finite Stone–Weierstrass carrier)**.** *Following Bishop and Bridges, the constructive finite route inside a* $\mathsf{StoneWeierstrass}^{\uparrow}$ *packet is the subpacket*

$$S_{\mathrm{fin}} = (K, A_{\mathrm{fin}}, U_{\mathrm{fin}}, V_{\mathrm{fin}}, R_{\mathrm{fin}}, M_{\mathrm{fin}}, E_{\mathrm{fin}}, H, C, P, N)$$

whose algebra, constants, separation, real-window, modulus, and approximation rows are all read as finite displayed ledgers. The compact source K is still the source of chapter 60; the continuous generators in A_{fin} are still read through chapter 130; and the approximation handoff E_{fin} remains a consumer of chapter 1634.

The classifier for this subpacket compares only the displayed finite rows. It has no coordinate for a host dense subalgebra, an externally completed function space, a selected family of all separating functions, pointwise function equality outside the named windows, or a host supremum norm.

Theorem 1919.5 (Constructive Stone–Weierstrass NameCert obligations)**.** *For every accepted constructive finite subpacket S_{fin} of Definition 1919.4, the local* $\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}$ *obligations are exactly the finite compact-source row, the finite continuous-generator ledger, the finite constants ledger, the displayed separating-witness ledger, the real-window evaluation ledger, the compact-continuity modulus ledger, the WeierstrassApproximation handoff row, and the structural H, C, P, N rows.*

Proof. Project S_{fin} to the carrier of Definition 1919.1. Each row of the subpacket is one of the rows already named by the ambient $\mathsf{StoneWeierstrass}^{\uparrow}$ certificate, with the algebra, constants, separation, evaluation, modulus, and handoff rows restricted to finite displayed ledgers.

Apply Definition 1919.2. Its compact-source, algebra-closure, separation-exactness, evaluation, modulus, and handoff clauses are row-local, so restricting those rows to finite ledgers does not create any additional obligation.

The structural rows H, C, P, N are unchanged. They transport, replay, source, and name the same finite route, and the refusal clause continues to exclude host dense algebras, external function-space equality, selected infinite families, host norms, and ambient completeness. □

Theorem 1919.6 (Constructive separating-algebra handoff)**.** *Every approximation consumer of an accepted constructive finite subpacket factors through*

$$K \longmapsto A_{\mathrm{fin}}, U_{\mathrm{fin}}, V_{\mathrm{fin}} \longmapsto R_{\mathrm{fin}}, M_{\mathrm{fin}} \longmapsto E_{\mathrm{fin}} \longmapsto H, C, P, N.$$

Thus the consumer receives only compact source data, finitely displayed continuous generators, constants, separating witnesses, real-window evaluations, compact-continuity moduli, WeierstrassApproximation handoff data, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Start with Definition 1919.3. It already forces every approximation-facing read through $K, A, U, V, R, M, E, H, C, P, N$ before any handoff can be consumed.

Now use the finite subpacket of Definition 1919.4. The rows A, U, V, R, M, E are read as $A_{\mathrm{fin}}, U_{\mathrm{fin}}, V_{\mathrm{fin}}, R_{\mathrm{fin}}, M_{\mathrm{fin}}, E_{\mathrm{fin}}$, so the same route passes through finite displayed ledgers only.

Finally apply Definition 1919.5. The obligation surface names no host dense subalgebra, external function-space equality, selected infinite separating family, host supremum norm, or ambient completeness row; therefore the handoff is exactly the constructive finite separating-algebra route. □

Falsifiable prediction: Every accepted $\mathsf{StoneWeierstrass}^{\uparrow}$ approximation-facing read factors through compact source rows, finite continuous-map algebra generators, constants, separating witnesses, real-window evaluations, compact-continuity moduli, WeierstrassApproximation handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compact, continuousmap, real, ring, weierstrass-approximation: $\mathsf{StoneWeierstrass}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact source data, a finite separating algebra of continuous real-valued generators, constant and algebraic closure rows, real-window evaluation, compact-continuity routing, approximation handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StoneWeierstrass}^{\uparrow}$ packet is generated from a compact source row, finite continuous-map algebra generators, constants, separating witnesses, real-window evaluations, compact-continuity moduli, WeierstrassApproximation handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1919.1, Definition 1919.4, Definition 1919.2, Definition 1919.5, Definition 1919.3, and Definition 1919.6 seed the finite separating-algebra route over compact, continuous-map, real, ring, and WeierstrassApproximation surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneWeierstrass}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close nonconstructive compactness, choice-selected dense subsets, host function equality, ambient function-space quotients, host supremum norms, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source compatibility, algebra closure visibility, separation exactness, evaluation and modulus routing, approximation handoff exactness, and separating-algebra route proofs for BEDC.Derived.StoneWeierstrassUp.

Chapter 1920

A Concrete Naming Certificate for $\mathsf{CauchyApproximationSystem}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{CauchyApproximationSystem}^{\uparrow}$ packet records the finite approximation system that turns displayed dyadic observation windows into regular Cauchy-name evidence. It sits between the dyadic endpoint ledger of chapter 291, the finite stream-window source of chapter 126, the regular rational handoff of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the nested dyadic Cauchy route of chapter 1811. The packet packages finite dyadic observation windows into regular Cauchy-name evidence before any consumer may read a completed real-name boundary.

Definition 1920.1 (Cauchy approximation-system carrier)**.** *A* $\mathsf{CauchyApproximationSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{sys}} = (S, W, A, R, M, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, carrying the finite stream schedule whose observations may be opened by the packet.*
2. *W is the unary finite-window row, assigning each displayed precision request to an inspected initial window of S.*
3. *A is the dyadic approximant row, recording for each inspected window the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximant read from that window.*
4. *R is the refinement row, recording displayed inclusions from a smaller unary window to a larger unary window together with the dyadic comparison budget used to keep the approximants coherent.*
5. *M is the modulus budget, assigning every displayed Cauchy precision to a unary window after which all later accepted windows refine through R.*
6. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationSystem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedDyadicCauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationSystem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through S, W, A, R, M, P, N. It contains no coordinate for quotient real equality, choice-selected limits, open-cover compactness, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyApproximationSystemUp.CauchyApproximationSystemUpTasteGate single carrier alignment`

Theorem 1920.2 (Cauchy approximation-system window refinement)**.** *Let*

$$A_{\mathrm{sys}} = (S, W, A, R, M, P, N)$$

be an accepted $\mathsf{CauchyApproximationSystem}^{\uparrow}$ *carrier. If a unary window* w' *extends a displayed unary window* w *and the extension is recorded by the refinement row* R*, then the larger-window packet is accepted by the same local classifier. Its stream source remains* S*, its dyadic approximants are the transported rows of* A*, its Cauchy budget is still governed by* M*, and its provenance and local name remain* P *and* N*.*

Proof. Project the carrier of Definition 1920.1. The only window data are the source row S, the unary finite-window row W, the dyadic approximant row A, the refinement row R, and the modulus budget M.

Use the displayed extension $w \subseteq w'$ through R. The refinement row is part of the carrier, so the larger window is not chosen by an external selector; it is one of the finite windows whose comparison against the old window is already recorded.

The dyadic approximants transport along the same refinement row. Since every approximant in A is sourced by the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger and every later Cauchy request is bounded by M, enlarging the window preserves the displayed approximation budget.

Finally P and N source and name the same finite packet. No quotient real equality, choice-selected limit, open-cover compactness, trichotomy, or ambient completeness coordinate is introduced by the larger window, so the local classifier accepts the transported packet. □

Theorem 1920.3 (Cauchy approximation-system regular-name route)**.** *Every coherent family of accepted* $\mathsf{CauchyApproximationSystem}^{\uparrow}$ *window refinements supplies the regular-name route consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. More precisely, a consumer that reads finite windows through* S, W*, dyadic approximants through* A*, refinement stability through* R*, and Cauchy budgets through* M *factors through the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with the nested-window compatibility supplied by chapter 1811. The route exports no quotient real equality, selected limit, trichotomy, open-cover compactness, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a coherent family of accepted window refinements. Each member exposes the same stream source S, the inspected unary windows W, dyadic approximants A, refinement rows R, and modulus budget M.

Apply Definition 1920.2 along the refinement family. Larger windows preserve the same source, approximant, budget, provenance, and local naming rows, so the family gives one stable finite observation route rather than unrelated window reads.

The stable route is exactly the input shape required by the $\mathsf{RegSeqRat}^{\uparrow}$ handoff. The StreamName surface supplies finite observations, the DyadicRatCore surface supplies dyadic approximants and comparison budgets, and the refinement rows supply the Cauchy coherence needed before regular rational readback.

Finally the $\mathsf{Real}^{\uparrow}$ seal is consumed only after that regular handoff. The nested-window compatibility is the sibling route of chapter 1811, so the completed read remains a finite BEDC route and cannot export quotient real equality, selected limits, trichotomy, open-cover compactness, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationSystem}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyApproximationSystem}^{\uparrow}$ packet is generated from a StreamName source row, unary finite-window rows, DyadicRatCore approximant rows, displayed refinement rows, a modulus budget, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSystem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1920.1, Definition 1920.2, and Definition 1920.3 seed the finite approximation-system route from stream windows and dyadic approximants to RegSeqRat readback and the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSystem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, choice-selected limits, open-cover compactness, trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window refinement stability, coherent regular-name routing, and nonescape for BEDC.Derived.CauchyApproximationSystemUp.

Chapter 1921

A Concrete Naming Certificate for $\mathsf{CauchyCompletionRetraction}^{\uparrow}$

Following Bishop and Bridges constructive completion and the Bourbaki–Kelley language of reflective completion, the $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ packet records the finite BEDC route by which the unit and counit rows form a displayed split for the L10 Cauchy-completion boundary. It binds the unit admission of chapter 1527, the returned read of chapter 1539, the universal route of chapter 1456, the idempotent completion surface of **??**, and the triangle route of chapter 1795. The chapter is a finite NameCert split packet only; it does not introduce quotient completions, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge-axis evidence.

Definition 1921.1 (CauchyCompletionRetraction carrier)**.** *A* $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, U, V, A, I, G, S, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed source row whose completion-facing admission is being split.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route admitting X into the completion-facing surface.*
3. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *route returning already displayed completion reads to the terminal real-seal boundary.*
4. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *universal route that compares unit-admitted consumers with completion-facing consumers over the same finite source.*
5. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *row recording that a repeated completion read contributes no new public completion row.*
6. *G is the* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *row comparing the unit-then-counit route with the direct displayed real route.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read before the split can expose any rational observation.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the stream windows and by the split comparison.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row consumed by the terminal seal.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal through which the retracted read is observed.*

11. *H records componentwise* hsame *transport for $X, U, V, A, I, G, S, D, R, E$ and the structural rows.*
12. *C records displayed* Cont *replay for consumers that inspect the unit side, the counit side, or the split comparison.*
13. *P is the* Pkg *provenance over* CauchyCompletionRetraction$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionCounit$^{\uparrow}$, CauchyCompletionAdjunction$^{\uparrow}$, CauchyCompletionIdempotent$^{\uparrow}$, CauchyCompletionTriangleIdentity$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* NameCert$_{\text{CauchyCompletionRetraction}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected completion representatives, countable-choice schedules, host equality of completed objects, ambient completeness, or public bridge credentials.

Lean4 ✓ `BEDC.Derived.CauchyCompletionRetractionUp.CauchyCompletionRetractionTasteGate single carrier alignment`

Theorem 1921.2 (CauchyCompletionRetraction NameCert obligations)**.** *For an accepted* CauchyCompletionRetrac *carrier $T = (X, U, V, A, I, G, S, D, R, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyCompletionRetraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source row, unit row, counit row, adjunction row, idempotent row, triangle row, finite-window row, dyadic ledger, regular readback, terminal seal, transport, replay, provenance, and local naming rows;*
2. *unit-side exposure, requiring every completion-facing read exported from X to pass through U before any completion consumer can inspect it;*
3. *counit-side return, requiring every already displayed completion-facing read to pass through V before reaching S, D, R, E;*
4. *split exactness, requiring the composite through U, V, A, I, G to expose exactly the same displayed route to E as the direct finite route through S, D, R;*
5. *classifier stability, requiring transported packets with the same displayed rows to be identified by the carried* hsame *and* Cont *data;*
6. *ledger non-escape, stating that the packet exports no quotient-completion equality, selected representative, countable-choice schedule, host equality, ambient-completeness theorem,* Real$^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Carrier admission is projection from Definition 1921.1. The tuple lists exactly the source, unit, counit, adjunction, idempotent, triangle, finite-window, dyadic, readback, seal, transport, replay, provenance, and local naming rows.

The unit-side exposure is read from U. A completion-facing consumer starting at X receives no direct completion object; the carrier first displays the route by which X enters the completion-facing surface.

The counit-side return is read from V. Once a completion-facing read is already displayed, the packet forces the return route through the finite observation rows S, D, R before the terminal seal E can be consumed.

Split exactness is the shared comparison supplied by A, I, G. The adjunction row fixes the universal consumer route, the idempotent row states that a repeated completion read contributes no new public row, and the triangle row compares the unit-then-counit route with the direct route to the same seal.

Classifier stability is componentwise transport along H followed by replay through C. Since the carrier fields are exhausted by $X, U, V, A, I, G, S, D, R, E, H, C, P, N$, the excluded quotient, representative-choice, countable-choice, host-equality, ambient-completeness, real-completeness, and bridge data have no row from which a consumer could read them. □

Theorem 1921.3 (CauchyCompletionRetraction unit-counit split exactness)**.** *Let $T = (X, U, V, A, I, G, S, D, R, E$ be an accepted* $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ *carrier. Every consumer of the completion-facing split factors through the displayed finite route*

$$X \longmapsto U \longmapsto A, I, G \longmapsto V \longmapsto S, D, R \longmapsto E \longmapsto H, C, P, N.$$

After this route is projected, the visible seal-facing read is the same direct route

$$S, D, R \longmapsto E$$

that the source row already displays. The split is therefore a unit-counit retraction over finite BEDC rows, not equality of quotient completions, not a selected representative, not host equality, and not countable choice or ambient completeness.

Proof. Start with a consumer of the split packet and project the source row X. The only completion-facing admission exposed by the carrier is U, so the consumer first passes through the unit row.

The middle comparison is fixed by A, I, G. The adjunction row A records that the completion-facing consumer is a consumer of the same reflected route, the idempotent row I prevents a second completion read from adding a new public row, and the triangle row G identifies the unit-counit composite with the displayed route to the seal.

The return part is then forced by V. The counit row routes the already displayed completion-facing read through the finite stream window S, the dyadic tolerance ledger D, and the regular rational readback R before the terminal seal E is inspected.

Transport by H and replay by C preserve this route for equivalent packets, while P and N record provenance and local naming. No other carrier coordinate exists, so the split exports exactly the displayed finite route and none of the excluded quotient, representative, host-equality, choice, or completeness data. □

Theorem 1921.4 (CauchyCompletionRetraction nonescape)**.** *For an accepted* $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ *carrier $T = (X, U, V, A, I, G, S, D, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{RegSeqRat}^{\uparrow}$*-facing, or completion-facing read exported by T is generated by the rows named in Definition 1921.1. In particular, the packet exports no quotient-completion equality, selected completion representative, countable-choice schedule, host equality of completed objects, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Project the accepted carrier. A $\mathsf{Real}^{\uparrow}$-facing or $\mathsf{RegSeqRat}^{\uparrow}$-facing read must pass through S, D, R, E, because these are the only finite observation and terminal seal rows in the tuple.

A completion-facing read must pass through U, V, A, I, G. These are the only completion-route rows in the tuple, and each is stored as displayed NameCert data rather than as a quotient point or selected representative.

The structural rows H, C, P, N transport, replay, source, and name the same route. They add no carrier coordinate beyond the listed rows.

Thus every exported read is generated by Definition 1921.1. The forbidden quotient, representative, choice, host-equality, ambient-completeness, real-completeness, and bridge data are absent from the carrier and cannot be produced by projection, transport, replay, provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionRetraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ packet is generated from a displayed source row, CauchyCompletionUnit route, CauchyCompletionCounit route, CauchyCompletionAdjunction route, CauchyCompletionIdempotent row, CauchyCompletionTriangleIdentity row, StreamName finite windows, DyadicRatCore tolerances, RegSeqRat readback, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRetraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1921.1, Definition 1921.2, Definition 1921.3, and Definition 1921.4 seed the finite unit-counit split route for the L10 Cauchy-completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRetraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected completion representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, unit exposure, counit return, split exactness, classifier stability, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionRetractionUp.

Chapter 1922

A Concrete Naming Certificate for $\mathsf{AbelLimitTheorem}^{\uparrow}$

Following Abel and Hardy's boundary-limit theorem in Bishop–Bridges constructive analysis, the $\mathsf{AbelLimitTheorem}^{\uparrow}$ packet records the finite NameCert surface by which an Abel-summed family approaches an endpoint real when the source sequence or series window has a displayed limit. Its source transform reads the $\mathsf{AbelSummation}^{\uparrow}$ route of chapter 1763 and the Abel-test boundary of chapter 1496; its endpoint row uses the real sequence limit surface, the uniform approach row of chapter 463, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a constructive boundary handoff for displayed finite rows; it is not a host power-series semantics, a selected limit, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1922.1 (AbelLimitTheorem carrier)**.** *An* $\mathsf{AbelLimitTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, S, L, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, displaying the finite Abel transform or summation-by-parts window read by the boundary argument.*
2. *S is the source sequence or series-window row, displaying the inspected source values together with the finite tails addressed by A.*
3. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row for the endpoint limit of the source side.*
4. *U is the* $\mathsf{UniformLimitContinuity}^{\uparrow}$ *row, or an equivalent uniform-window row, governing approach to the endpoint along the admitted Abel parameter windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff obtained from A, S, L, U.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal attached to that regular rational handoff.*
7. *H records componentwise* hsame *transport for Abel-summation rows, source windows, endpoint-limit rows, uniform approach rows, regular handoff, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an endpoint precision request through U to finite parameter windows, through A, S, L to the regular handoff R, and then to the seal row E.*

9. *P is the* Pkg *provenance over* $\mathsf{AbelLimitTheorem}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{UniformLimitContinuity}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten displayed rows. It has no coordinate for host power-series semantics, selected limits, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AbelLimitTheoremUp.AbelLimitTheoremTasteGate single carrier alignment`

Theorem 1922.2 (AbelLimitTheorem NameCert obligations)**.** *For every accepted* $\mathsf{AbelLimitTheorem}^{\uparrow}$ *carrier* $Q = (A, S, L, U, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *Abel-window exposure for A, preserving the finite summation row consumed by the endpoint argument;*
3. *source-window exposure for S, preserving the inspected sequence or series values and the finite tails read by A;*
4. *endpoint-limit exposure for L, preserving the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row used to name the source-side limit;*
5. *uniform endpoint approach for U, forcing every precision request through a displayed finite Abel-parameter window;*
6. *regular handoff exactness for R, E, stating that the terminal real seal is reached only through the displayed Abel, source, limit, and uniform rows;*
7. *transport stability, continuation replay, provenance, and local naming for exactly the route recorded by H, C, P, N.*

These obligations are finite-row obligations over the Abel summation, endpoint limit, uniform-window, regular rational, and real seal surfaces. They do not assert an ambient analytic power-series object or a completed host-limit principle.

Proof. Project the accepted packet $Q = (A, S, L, U, R, E, H, C, P, N)$. The projection exposes exactly the Abel-summation row, source row, endpoint-limit row, uniform-window row, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

Read a displayed endpoint precision request through U. The uniform row supplies a finite Abel-parameter window, so the downstream read cannot select a limiting parameter outside the packet.

Now combine the analytic rows. The Abel row A displays the finite transform over the source window S, while L names the endpoint limit of the same source side. The regular handoff R may therefore read only the finite Abel transform, source window, endpoint-limit row, and uniform approach row.

Finally apply the structural rows. Componentwise transport in H preserves those rows together, while C, P, N replay, source, and name the same route. Since the carrier has no further coordinate, the seven listed clauses exhaust the local $\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}$ surface. □

Theorem 1922.3 (AbelLimitTheorem real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{AbelLimitTheorem}^{\uparrow}$ *carrier factors through*

$$A, S, L, U \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the terminal real seal may read the boundary-limit claim only after reading the finite Abel row, the source sequence or series window, the endpoint real-sequence limit row, and the uniform approach row. No accepted consumer can import host power-series semantics, selected limits, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Begin with an accepted carrier and a $\mathsf{Real}^{\uparrow}$ read. By the carrier definition, the only seal-facing rows are R, E, H, C, P, N, and R is downstream of the displayed analytic rows A, S, L, U.

Trace R backward through the packet. The uniform row U translates a seal precision request to a finite endpoint window, the Abel row A supplies the finite transform on that window, the source row S supplies the inspected values and tails, and the limit row L supplies the named endpoint target.

The terminal seal E therefore receives only the regular rational handoff built from those four displayed rows. The structural rows preserve and replay that route componentwise; none of them contains a coordinate for a host power series, a selected limiting process, quotient equality, countable choice, trichotomy, or ambient completeness.

Hence every real-seal consumer factors through the displayed chain and cannot bypass the finite $\mathsf{AbelLimitTheorem}^{\uparrow}$ certificate. □

Falsifiable prediction: An accepted $\mathsf{AbelLimitTheorem}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without reading the $\mathsf{AbelSummation}^{\uparrow}$ row, source sequence or series-window row, $\mathsf{RealSequenceLimit}^{\uparrow}$ endpoint row, and $\mathsf{UniformLimitContinuity}^{\uparrow}$ endpoint-window row refutes the carrier surface.

Independence witness: abel-summation, abel-test, real-sequence-limit, uniform-limit-continuity, regseqrat, real: no listed sibling supplies the whole ten-row packet $Q = (A, S, L, U, R, E, H, C, P, N)$, because each sibling contributes only a finite Abel transform, convergence-test boundary, endpoint limit, uniform approach, regular readback, or seal face while this chapter binds them into one terminal boundary-limit NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelLimitTheorem}^{\uparrow}$ packet is generated from an $\mathsf{AbelSummation}^{\uparrow}$ row, a displayed source sequence or series-window row, a $\mathsf{RealSequenceLimit}^{\uparrow}$ endpoint-limit row, a $\mathsf{UniformLimitContinuity}^{\uparrow}$ endpoint-window row, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1922.1, Definition 1922.2, and Definition 1922.3 seed the finite Abel boundary-limit route over $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{UniformLimitContinuity}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelLimitTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host power-series semantics, selected limits, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface and real-seal handoff theorem.

Chapter 1923

A Concrete Naming Certificate for $\mathsf{SchauderFixedPoint}^{\uparrow}$

Following Schauder's fixed point theorem in the compact-convex tradition, the $\mathsf{SchauderFixedPoint}^{\uparrow}$ packet records only the finite BEDC route that a compact convex self-map certificate must expose. It carries compactness, convexity, continuous-map, approximation-net, residual, transport, replay, provenance, and local NameCert rows, and it does not assert a host fixed-point choice, a quotient of approximating nets, ambient Real completeness, or an uncarried topological vector-space theorem.

The route is anchored by the carried completeness and compactness interfaces of chapter 128 and chapter 127, by the interval fixed-point and contraction comparison surfaces of chapter 1437 and chapter 396, and by the convex and continuous-map interfaces of chapter 208 and chapter 130. The packet is therefore a finite naming certificate for the compact-convex handoff rather than a semantic proof object for Schauder's theorem in an ambient analysis library.

Definition 1923.1 (SchauderFixedPoint carrier)**.** *A* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, Q, V, A, F, E, R, L, H, C, P, N)$$

with the following visible rows:

1. *K is the compact-metric support row, read through the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *surfaces, including the finite-net coverage rows used by later approximation reads;*
2. *Q is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the carried subset, exposing only affine-combination closure, scalar classifier transport, and membership rows;*
3. *V is the ambient vector and metric compatibility row that lets compact-net centers, convex combinations, and residual estimates be compared inside the same carried metric context;*
4. *A is the approximation-net ledger, recording finite centers, rational tolerances, barycentric or finite-affine cells, and the finite projection route from compact coverage into the convex carrier;*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row, including graph, pointwise modulus, source membership, and target membership data for the compact convex carrier;*
6. *E is the approximate-endpoint ledger, exposing for each displayed tolerance a finite cell where the approximation route and the continuous-map route meet;*
7. *R is the residual row that compares the displayed point, its image under F, and the finite-affine approximation cell through the metric and convexity ledgers;*

8. *L is the limiting handoff row, using only the carried complete-metric and total-boundedness data to retain a candidate name boundary for downstream readers;*
9. *H stores componentwise* hsame *transports for K, Q, V, A, F, E, R, L and the local certificate row;*
10. *C stores the displayed* Cont *replay routes for compact-net reads, convex-affine reads, continuous-map reads, residual comparison, limiting handoff, and consumer export;*
11. *P is the* Pkg *provenance over* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SchauderFixedPoint}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite compact-convex fixed-point certificate for the displayed self-map. It has no coordinate for a chosen fixed point, an open-cover compactness principle, a quotient limit, a host topological vector space, or ambient completeness beyond the carried rows.

Lean4 ✓ `BEDC.Derived.SchauderFixedPointUp.SchauderFixedPointTasteGate single carrier alignment`

Theorem 1923.2 (SchauderFixedPoint NameCert obligations)**.** *For an accepted packet $S = (K, Q, V, A, F, E, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SchauderFixedPoint}^{\uparrow}}$ *obligations are exhausted by the carrier rows of Definition 1923.1. They consist of compact-net coverage, carried completeness handoff, convex membership and affine-combination stability, continuous-map graph and modulus replay, approximation-net coherence, residual comparison, limiting handoff, componentwise classifier transport, displayed continuation replay, package provenance, and local naming. No obligation may call on host fixed-point choice, open-cover compactness, ambient Real completeness, quotient equality of nets, uncarried topological vector-space structure, or a global Schauder theorem outside the packet.*

Proof. Project the accepted packet. Carrier admission gives exactly the rows $K, Q, V, A, F, E, R, L, H, C, P, N$ listed in Definition 1923.1.

The compact and convex obligations are separated but share the same carried metric context. The compact row K supplies finite coverage and carried completeness, while Q supplies membership and affine-combination closure inside the displayed convex carrier. The compatibility row V is the only route through which those two surfaces are read together.

The map and approximation obligations then consume F and A. The continuous-map row supplies graph and modulus replay, and the approximation-net ledger supplies the finite centers and affine cells on which the residual row R is computed. The limiting handoff L is available only after those rows have been replayed.

Finally H, C, P, and N transport, replay, record provenance, and register the same finite route. Since no coordinate outside this route is present, the excluded host, quotient, compactness, Real-completeness, and global fixed-point principles cannot enter the local NameCert surface. □

Theorem 1923.3 (SchauderFixedPoint compact-convex handoff)**.** *Every downstream read of an accepted* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *packet factors through the displayed compact-convex route*

$$K, Q, V, A, F, E, R, L, H, C, P, N.$$

In particular, a consumer can inspect a candidate boundary only after the $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net coverage, the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff, the* $\mathsf{ConvexSet}^{\uparrow}$ *affine-membership rows, and the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and modulus rows have all been replayed through the approximation and residual ledgers.*

Proof. Start with a consumer of the accepted packet. The only consumer-facing route is the continuation ledger C, and its compact reads are attached to K, so the finite-net and carried-completeness surfaces are read before any candidate boundary appears.

The convex data are read next through Q and V. These rows align finite centers, affine cells, and carrier membership, so the approximation ledger cannot export a point outside the displayed compact-convex context.

The continuous self-map row F and the approximation ledger A then feed the approximate-endpoint and residual rows E and R. The limiting handoff L is therefore a boundary of the displayed residual route, not a selected host fixed point.

The transport, replay, provenance, and local naming rows keep this order intact. Hence every downstream read factors through the compact-convex handoff surface named in the theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderFixedPoint}^{\uparrow}$ packet is generated from compact-metric finite-net coverage, carried completeness, convex membership and affine-combination rows, ambient vector-metric compatibility, continuous-map graph and modulus data, approximation-net cells, residual comparison, limiting handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1923.1, Definition 1923.2, and Definition 1923.3 seed the finite compact-convex fixed-point naming route over the displayed compactness, completeness, convexity, continuous-map, approximation, residual, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host fixed-point choice, open-cover compactness, ambient Real completeness, quotient equality of approximating nets, a topological vector-space theorem outside the carried rows, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, convex-affine membership stability, continuous-map replay, approximation-net coherence, residual comparison, limiting handoff, and local NameCert coverage for the displayed packet.

Chapter 1924

A Concrete Naming Certificate for $\mathsf{NestedIntervalReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{NestedIntervalReal}^{\uparrow}$ packet records the classical nested located interval route to a real name as finite BEDC data. It sits after the located interval carrier of chapter 1709, the bisection route of chapter 1711, the dyadic refinement surface of chapter 291, the nested dyadic Cauchy route of chapter 1811, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names only the displayed interval-nest route; it is not open-cover compactness, countable choice, quotient real equality, selected-limit data, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1924.1 (NestedIntervalReal carrier)**.** *A* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, B, D, E, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite family of nested* $\mathsf{LocatedRealInterval}^{\uparrow}$ *rows whose endpoints, radii, locators, and metric brackets are visible to the packet.*
2. *B is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *refinement ledger, recording how each displayed interval row narrows to the next row.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter-decay ledger, assigning to each displayed stage a dyadic bound whose carrier proves that later intervals have diameter at most the requested tolerance.*
4. *E records the endpoint* $\mathsf{Real}^{\uparrow}$ *seals for all displayed interval endpoints and states that endpoint reads are available only through the interval rows in I.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the midpoint, left-endpoint, right-endpoint, and diameter observations used by the nest.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W, D, E, so every rational approximation is sourced by a displayed window and a dyadic diameter bound.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the nested interval route after I, B, D, E, W, R have been replayed.*
8. *H records componentwise* hsame *transport for the interval rows, bisection ledger, diameter ledger, endpoint seals, stream windows, regular readback, terminal seal, replay, provenance, and local naming data.*

9. *C records displayed* Cont *replay for consumers that inspect the interval nest, the dyadic diameter decay, the regular readback, or the terminal seal.*
10. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalReal}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, D, E, W, R, S, H, C, P, N$. It has no coordinate for arbitrary open covers, a countable selector, a quotient construction of reals, selected limiting points, host real equality, or a proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.NestedIntervalRealUp.TasteGate.NestedIntervalRealTasteGate single carrier alignment`

Theorem 1924.2 (NestedIntervalReal NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier*

$$J = (I, B, D, E, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval rows, bisection ledger, dyadic diameter-decay ledger, endpoint seals, stream windows, regular readback, terminal seal, transports, replay, provenance, and local naming;*
2. *nesting exactness, requiring every later interval read to factor through the previous interval row and the displayed* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *refinement in B;*
3. *diameter decay, requiring every requested tolerance to be witnessed by a dyadic bound in D and by endpoint seals in E before the regular readback row is exposed;*
4. *readback ordering, requiring* $\mathsf{StreamName}^{\uparrow}$ *windows in W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in R to be replayed before the terminal* $\mathsf{Real}^{\uparrow}$ *seal S is available;*
5. *classifier stability, requiring transported packets to compare only through the stored* hsame *and* Cont *rows;*
6. *ledger non-escape, requiring P, N to source and name no open-cover compactness, countable choice, selected limit, host real equality, quotient real construction, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No nested-interval real obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1924.1. The accepted packet displays exactly one interval-nest family, one bisection ledger, one dyadic diameter ledger, one endpoint-seal row, one finite window family, one regular readback row, one terminal real seal, and the structural rows that transport, replay, package, and name them.

Nesting exactness is read from I and B. The only way to pass from one interval stage to the next is the displayed bisection row, so a consumer cannot substitute an external interval selection rule for the stored refinement ledger.

Diameter decay is read from D together with the endpoint seals E. For a requested tolerance, the packet first displays the dyadic bound and then opens only the endpoint reads attached to the corresponding interval rows.

The readback route is downstream of those rows. Stream windows in W expose finite observations, the $\mathsf{RegSeqRat}^{\uparrow}$ row R packages them as regular rational readback, and the $\mathsf{Real}^{\uparrow}$ seal S is reached only after that readback is replayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no open-cover, choice, selected-limit, host-equality, quotient-construction, or real-completeness coordinate, none of those objects can enter the local NameCert surface. □

Theorem 1924.3 (NestedIntervalReal Cauchy selection route)**.** *For every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier* $J = (I, B, D, E, W, R, S, H, C, P, N)$ *and every displayed precision request, the exported rational approximation is valid only through the staged finite obligation*

$$D_{\mathrm{diam}} \longrightarrow B_{\mathrm{path}} \longrightarrow E_{\mathrm{end}} \longrightarrow W_{\mathrm{win}} \longrightarrow R_{\mathrm{reg}} \longrightarrow S.$$

That is, the packet must first exhibit a stage row whose dyadic diameter entry in D is below the requested tolerance, then exhibit through B the bisection path from the earlier interval rows in I to that stage, then read the endpoint seals through E, then open only the corresponding finite $\mathsf{StreamName}^{\uparrow}$ *windows in W, then package the resulting rational approximation by the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and only then expose the terminal* $\mathsf{Real}^{\uparrow}$*-facing seal S. The approximation is therefore a displayed regular-readback product of the carrier rows, not a point chosen from an ambient intersection.*

Proof. Project the accepted carrier and fix a displayed precision request. The diameter ledger D supplies the tolerance witness: a finite stage row whose dyadic diameter entry is below the requested bound.

The stage is reachable only through the stored interval data. The rows in I display the located interval family, and the bisection ledger B records the finite path from earlier intervals to the chosen stage, so the construction has no separate selection rule for later intervals.

Endpoint access is then ordered through E. The candidate rational approximation is read from endpoint seals attached to the same displayed stage, not from a host real point or an unrecorded intersection element.

Regular readback begins only after those seals have been fixed. The finite observations pass through the matching $\mathsf{StreamName}^{\uparrow}$ windows in W, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R packages the resulting rational read as the Cauchy-facing approximation.

Finally, S seals exactly that read for the $\mathsf{Real}^{\uparrow}$-facing consumer. The transport, replay, provenance, and local naming rows H, C, P, N preserve the staged route under comparison and replay, so no ambient intersection point, choice-selected subsequence, quotient representative, or independent completeness theorem is used to obtain the approximation. □

Theorem 1924.4 (NestedIntervalReal tail-modulus readback)**.** *For every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier*

$$J = (I, B, D, E, W, R, S, H, C, P, N)$$

and every displayed precision request whose dyadic diameter witness is read from D, the request determines a finite tail-modulus readback route

$$D \longrightarrow W \longrightarrow R \longrightarrow S.$$

The diameter row supplies the requested tolerance bound, the matching $\mathsf{StreamName}^{\uparrow}$ *windows in W expose only the finite observations at that bound, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R packages those observations as the regular rational readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal S consumes exactly that readback. Thus the modulus exported to the regular rational surface is a displayed BEDC obligation of J, not an independent completeness or intersection principle.*

Proof. Project the accepted carrier J. By Definition 1924.3, a displayed precision request is already ordered by the staged finite route from the diameter ledger to the terminal seal. In particular, the dyadic entry in D is the row that fixes the requested tail bound before any regular readback is exposed.

Once that bound is fixed, the only observations available at the bound are the corresponding finite $\mathsf{StreamName}^{\uparrow}$ windows in W. The carrier definition in Definition 1924.1 gives no coordinate for an independent selector, ambient intersection point, or external modulus source, so the request can only continue through the rows already displayed by J.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R then repackages exactly those finite window observations as the regular rational readback. The terminal $\mathsf{Real}^{\uparrow}$ seal S is downstream of R in the carrier and in the staged route, so it consumes that readback rather than a separately chosen real point. Therefore the tail-modulus readback is the finite BEDC obligation

$$D \longrightarrow W \longrightarrow R \longrightarrow S$$

inside the packet. □

Theorem 1924.5 (NestedIntervalReal diameter modulus)**.** *For every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier*

$$J = (I, B, D, E, W, R, S, H, C, P, N),$$

each displayed precision request whose witness lies in the dyadic diameter ledger D yields a finite diameter-modulus row by the route

$$D \longrightarrow B \longrightarrow E \longrightarrow W \longrightarrow R \longrightarrow S.$$

The request first checks the nested bisection path in B, then the endpoint seals in E, then the matching finite windows in W, then the regular readback row R, and finally the terminal $\mathsf{Real}^{\uparrow}$ *seal S. The row is a regular Cauchy modulus export for RegSeqRat and Real consumers, not a selected intersection point, open-cover compactness principle, quotient real equality, countable-choice selector, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the precision request and its witness in D. The Cauchy selection route of Definition 1924.3 already orders such a request through the displayed diameter witness, the bisection path, the endpoint seals, the finite windows, regular readback, and terminal seal.

The tail-modulus readback of Definition 1924.4 then identifies the downstream handoff from the diameter ledger to W, R, S. Combining the two routes inserts the bisection ledger B and endpoint seals E before the regular readback is exposed.

Thus the extracted modulus row is finite and carrier-local. The structural rows H, C, P, N transport, replay, source, and name the same route, while Definition 1924.9 excludes selected intersection points, open-cover compactness, quotient real equality, countable choice, host equality, and Real completeness. □

Theorem 1924.6 (NestedIntervalReal Cauchy seal)**.** *For every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier*

$$J = (I, B, D, E, W, R, S, H, C, P, N),$$

the exported $\mathsf{Real}^{\uparrow}$*-facing seal is available only by the finite route*

$$I, B, D, E \longrightarrow W \longrightarrow R \longrightarrow S.$$

The nested interval rows and dyadic diameter ledger supply the Cauchy modulus, the $\mathsf{StreamName}^{\uparrow}$ *windows expose finite observations at the requested bound, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row packages the regular rational readback, and* $\mathsf{Real}^{\uparrow}$ *consumes exactly that seal. Thus the route composes the nested interval packet into a regular Cauchy real-name handoff, not into ambient completeness.*

Proof. Start from the carrier of Definition 1924.1. The rows I, B, D, E display the located interval family, the bisection refinement ledger, the dyadic diameter-decay ledger, and the endpoint seals.

The Cauchy-stage choice is already constrained by Definition 1924.3. A precision request first reads a dyadic diameter witness in D, then follows the refinement path in B, and then reads only the endpoint seals in E attached to the corresponding interval rows in I.

The tail-modulus route of Definition 1924.4 supplies the downstream handoff. Once the bound is fixed, the $\mathsf{StreamName}^{\uparrow}$ windows in W expose the finite observations at that bound, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R packages them as regular rational readback.

The terminal seal S consumes exactly that readback. By Definition 1924.9, the carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, quotient real equality, or a selected intersection point, so the theorem exports only the displayed Cauchy seal. □

Theorem 1924.7 (NestedIntervalReal located-limit uniqueness)**.** *Let* $J = (I, B, D, E, W, R, S, H, C, P, N)$ *and* $J' = (I', B', D', E', W', R', S', H', C', P', N')$ *be accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carriers. If* I *and* I' *are componentwise related by* hsame*, the bisection ledgers* B *and* B' *display the same refinement path, and the dyadic diameter ledgers* D *and* D' *contain cofinal witnesses for the same precision requests, then the terminal* $\mathsf{Real}^{\uparrow}$ *seals* S *and* S' *are compared by the Real classifier through the same route*

$$W \longrightarrow R \longrightarrow S.$$

The claim is route uniqueness for the located-limit seal inside the displayed nested-interval data. It is not open-cover compactness, countable choice, quotient real equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1924.4 for both accepted carriers. The shared hsame interval rows, common bisection ledger, and cofinal dyadic diameter witnesses force the same displayed tail-modulus request to be read from D and D'.

Apply Definition 1924.5. The common diameter request routes through the same bisection path and endpoint-seal ordering before any regular rational readback is exposed.

Now apply Definition 1924.6. Both packets must pass through the finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the terminal $\mathsf{Real}^{\uparrow}$ seal is available, so the classifier sees the same $W \longrightarrow R \longrightarrow S$ pattern.

Componentwise hsame transport in the structural rows carries the comparison from interval rows to windows, readback, and terminal seals. Since Definition 1924.9 excludes open-cover compactness, countable choice, quotient real equality, host equality, and ambient completeness, the conclusion is only located route uniqueness for the displayed Real-facing seal. □

Theorem 1924.8 (NestedIntervalReal scoped kernel route)**.** *Every accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *Cauchy seal factors through the displayed nested interval row, dyadic diameter modulus, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}$ *row. In carrier notation* $J = (I, B, D, E, W, R, S, H, C, P, N)$*, every Real-facing or RegSeqRat-facing read of the seal is routed by*

$$I, B, D, E \longrightarrow W \longrightarrow R \longrightarrow S \longrightarrow H, C, P, N.$$

The route exports no quotient stream equality, selected limit, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, or open-cover compactness principle.*

Proof. Project the accepted carrier and read the Cauchy seal through Definition 1924.6. That theorem already orders the terminal $\mathsf{Real}^{\uparrow}$-facing seal through the nested interval rows, endpoint seals, finite windows, regular rational readback, and terminal seal.

The finite stage used by the seal is supplied by the Cauchy selection route of Definition 1924.3. The selected precision request is therefore not an ambient selected limit; it is a displayed row of the interval nest and bisection ledger.

The requested bound is controlled by Definition 1924.4 and Definition 1924.5. These statements force the dyadic diameter modulus through D, then through the matching finite windows W and the readback row R before S is available.

Finally apply ledger nonescape, Definition 1924.9. The structural rows H, C, P, N transport, replay, source, and name the same route, while the excluded quotient, selector, trichotomy, choice, completeness, host-equality, and compactness objects are absent from the packet. □

Theorem 1924.9 (NestedIntervalReal ledger nonescape)**.** *For an accepted* $\mathsf{NestedIntervalReal}^{\uparrow}$ *carrier* $J = (I, B, D, E, W, R, S, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{RegSeqRat}^{\uparrow}$*-facing, or interval-facing read exported by* J *is generated by the rows named in Definition 1924.1. In particular, the packet exports no open-cover compactness principle, countable-choice selector, selected limit, host real equality, quotient construction of reals, or proof of* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. An interval-facing read must pass through I, B, D, E, because these are the only rows that contain located interval data, bisection refinement, dyadic diameter decay, and endpoint seals.

A $\mathsf{RegSeqRat}^{\uparrow}$-facing read must pass through W and R. These are the only finite window and regular readback rows available to the packet.

A $\mathsf{Real}^{\uparrow}$-facing read must then pass through S, and any comparison of two accepted packets must use H and C before P and N can record provenance and local naming.

Thus every exported read is generated by the displayed ledger. The excluded compactness, choice, selected-limit, host-equality, quotient-construction, and completeness objects are absent from the carrier and cannot be produced by projection, transport, replay, provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NestedIntervalReal}^{\uparrow}$ packet is generated from nested located interval rows, a located-bisection refinement ledger, dyadic diameter-decay rows, endpoint $\mathsf{Real}^{\uparrow}$ seals, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1924.1, Definition 1924.2, Definition 1924.3, Definition 1924.4, and Definition 1924.9 seed the finite nested located interval route from diameter-decaying intervals to regular rational readback and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected limits, host real equality, quotient construction, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nesting exactness, diameter decay, endpoint-seal ordering, Cauchy selection routing, classifier stability, and ledger non-escape for BEDC.Derived.NestedIntervalRealUp.

Chapter 1925

A Concrete Naming Certificate for $\mathsf{HausdorffSpace}^{\uparrow}$

Following Hausdorff and Bourbaki/Kelley general topology, the $\mathsf{HausdorffSpace}^{\uparrow}$ packet records separated points by disjoint open-neighborhood rows over $\mathsf{Topology}^{\uparrow}$. When a $\mathsf{Met}^{\uparrow}$ row supplies a positive-distance separation witness, the packet stores the resulting open-neighborhood handoff as finite NameCert data rather than as host point equality. The chapter sits between the topology surface of chapter 88, the metric surface of chapter 57, and the separated completion consumer of chapter 402.

Definition 1925.1 (Hausdorff space carrier)**.** *A* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, including the displayed open predicates, finite neighborhood ledger, and classifier route read by topological consumers.*
2. *x, y are the two point-name rows compared by the separatedness witness. They are point observations inside the same topology source row, not host-level representatives.*
3. *U, V are the open-neighborhood rows, with U containing the displayed name x and V containing the displayed name y.*
4. *D is the disjointness ledger certifying that the two open rows have no shared displayed point observation under the local topology classifier.*
5. *M is the optional* $\mathsf{Met}^{\uparrow}$ *distance-separation handoff row. When present, it records the metric route that generates U, V, D from a positive displayed distance.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row used by metric-generated separation reads, exposing only the displayed distance and positivity evidence available through the real-name interface.*
7. *H records componentwise* hsame *transport for $T, x, y, U, V, D, M, E, C, P, N$.*
8. *C records displayed* Cont *replay from a point-pair comparison through the neighborhood and disjointness route*

$$T, x, y \longmapsto U, V, D \longmapsto M, E.$$

9. *P is the* Pkg *provenance over* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares separated point pairs only through these rows. It contains no coordinate for quotient point equality, open-cover compactness, selected representatives, ambient completeness, or standard bridge data.

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceTasteGate single carrier alignment`

Theorem 1925.2 (HausdorffSpace NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, point pair, open-neighborhood rows, disjointness ledger, optional metric handoff, real seal, transport, replay, provenance, and local naming rows;*
2. *disjoint open-neighborhood separation, requiring U and V to be displayed as open rows in T, to contain x and y respectively, and to be separated by D;*
3. *classifier transport, requiring every transported separatedness read to preserve T, x, y, U, V, D through the componentwise* hsame *row H;*
4. *metric handoff, requiring any* $\mathsf{Met}^{\uparrow}$ *distance-apartness read to pass through M and the* $\mathsf{Real}^{\uparrow}$ *seal row E before it yields U, V, D;*
5. *nonescape, requiring downstream topology, metric, real, and completion consumers to read only $T, x, y, U, V, D, M, E, H, C, P, N$.*

No HausdorffSpace obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceNameCert obligations`

Proof. Carrier admission is projection from Definition 1925.1. The accepted tuple displays exactly the topology source, point pair, open-neighborhood rows, disjointness ledger, optional metric handoff, real seal, and structural rows.

Disjoint open-neighborhood separation is the role of U, V, D. The rows U and V are declared open inside the topology source T, the point-name rows x, y are read through those neighborhoods, and D records their disjointness under the local classifier.

Classifier transport is componentwise. The row H transports the same topology source, point pair, neighborhood rows, and disjointness ledger, while C replays the displayed route from the point-pair comparison to the separated-neighborhood witness.

Metric handoff uses only M and E. A metric-generated read first exposes the positive displayed distance through the $\mathsf{Real}^{\uparrow}$ seal, then records the open-neighborhood separation route in M. It never replaces the separated-neighborhood data by host equality or host apartness of points.

Finally inspect P, N. Provenance and local naming mention only the displayed rows, so topology, metric, real, and completion consumers have no coordinate from which to read quotient point equality, open-cover compactness, selected representatives, ambient completeness, or standard bridge closure. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier namecert obligations`

Theorem 1925.3 (HausdorffSpace metric separation handoff)**.** *Let*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier. If the optional* $\mathsf{Met}^{\uparrow}$ *row* M *is present, every displayed positive-distance apartness witness in* M *factors through the* $\mathsf{Real}^{\uparrow}$ *seal row* E *and yields the same open-neighborhood rows* U, V *with disjointness ledger* D*. Thus metric distance-apartness contributes a Hausdorff separation row without importing host equality, quotient point identity, selected representatives, or ambient completeness.*

Proof. Read the metric-generated branch of the carrier. The row M is attached to the same point-name rows x, y and the same topology source T as the displayed neighborhoods.

The distance value is visible only through the $\mathsf{Real}^{\uparrow}$ seal E. Positivity therefore supplies a finite separation budget for the neighborhood construction, not an external equality or apartness relation on host representatives.

The handoff then lands in U, V, D. These rows are already topology rows in the carrier: U and V are open neighborhoods of x and y, and D is their disjointness ledger. Componentwise transport and replay through H, C preserve this factorization for downstream consumers. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier metric separation handoff`

Theorem 1925.4 (HausdorffSpace classifier separation route)**.** *Let*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier. Every separated-point classifier read generated from the optional metric row* M *factors through the* $\mathsf{Met}^{\uparrow}$ *distance witness, the* $\mathsf{Real}^{\uparrow}$ *positive-distance seal* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ *row* N *before it yields the open-neighborhood rows* U, V *and disjointness ledger* D*. Thus metric classifier separation is a finite NameCert route over the displayed carrier rows, not a host apartness predicate on points.*

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier classifier separation route`

Proof. Start with a metric-generated classifier read. The only metric coordinate in the carrier is M, and it is attached to the same topology source T and point-name rows x, y as the displayed neighborhoods.

The distance value and positivity evidence are exposed only through the $\mathsf{Real}^{\uparrow}$ seal E. The metric route therefore supplies a finite positive-distance budget, after which the packet returns to the topological output rows U, V, D.

Transport and replay are restricted to H and C. Provenance and local naming are restricted to P and N, so the resulting classifier read has no access to host point apartness, selected representatives, quotient equality, or ambient completeness. □

Theorem 1925.5 (HausdorffSpace diagonal nonescape)**.** *For an accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N),$$

the diagonal equality boundary of the packet is exhausted by the displayed separation rows T, x, y, U, V, D *together with optional metric and real handoff rows* M, E*. A downstream topology, metric, or completion consumer cannot replace that boundary by host point equality, quotient topology equality, real trichotomy, open-cover compactness, selected representatives, or ambient completeness.*

Proof. Inspect the carrier. The point names x, y occur only as displayed rows inside the topology source T, and the separation output is the pair of open-neighborhood rows U, V together with the disjointness ledger D.

When the optional metric route is present, it passes through M and the real seal E before returning to the same topological rows. This adds a displayed positive-distance source for separation, but it does not add host equality, quotient equality, trichotomy, compactness, representatives, or completeness coordinates.

The structural rows H, C, P, N preserve and name only the displayed packet. Hence every consumer remains inside the finite diagonal boundary described by the carrier. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier diagonal nonescape`

Theorem 1925.6 (HausdorffSpace choice-free point separation)**.** *Let*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier. If the optional metric row M displays a positive-distance witness through the* $\mathsf{Real}^{\uparrow}$ *seal E, then the carrier produces the open-neighborhood rows U, V and the disjointness ledger D as the separatedness output. This construction does not select representatives, quotient points, host point equalities, or ambient completeness data.*

Proof. Start from the carrier of Definition 1925.1. The rows x, y are displayed point names inside the topology source T, while U, V, D are already the open-neighborhood and disjointness rows of the same packet.

Use the NameCert obligations of Definition 1925.2. The metric handoff obligation requires every metric-generated read to pass through M and the $\mathsf{Real}^{\uparrow}$ seal E before it yields U, V, D.

Apply the metric separation handoff of Definition 1925.3. A positive displayed distance supplies only the finite separation budget for the recorded open neighborhoods. Since the carrier has no coordinate for representatives, quotient point identity, host equality, or ambient completeness, none of those objects is selected or consumed. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier point separation choicefree`

Theorem 1925.7 (HausdorffSpace open-neighborhood classifier transport)**.** *Let*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

be an accepted $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier. Transporting any accepted separated-neighborhood read along the componentwise row H preserves the topology source T, point rows x, y, open-neighborhood rows U, V, disjointness ledger D, optional metric row M, and optional* $\mathsf{Real}^{\uparrow}$ *seal row E. Consequently the transported classifier still reads separation through the same displayed open-neighborhood and disjointness rows, and it cannot replace the read by quotient point equality, selected representatives, host point apartness, or ambient completeness.*

Proof. Project the carrier of Definition 1925.1. The only classifier-visible topology data are T, x, y, U, V, D, with optional metric and real handoff rows M, E attached to the same packet.

Use the NameCert obligation rows of Definition 1925.2. They require classifier transport to preserve T, x, y, U, V, D through the componentwise hsame row H, and require metric-generated reads to return through M, E before yielding the same neighborhood rows.

The replay row C then repeats the displayed route from the point-pair comparison to U, V, D. Since the carrier has no coordinate for quotient point equality, selected representatives, host point apartness, or ambient completeness, transport cannot create one for the classifier to read. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier open neighborhood classifier transport`

Theorem 1925.8 (HausdorffSpace Real seal nonescape)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N)$$

reads only the displayed $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. In particular, such a consumer cannot extract quotient point equality, open-cover compactness, selected representatives, ambient completeness, or standard bridge closure from the packet.*

Proof. Project the carrier. Topology-facing reads use T, U, V, D; metric-generated reads additionally pass through M; Real-facing reads pass through the seal row E before returning to the same displayed separation rows.

The structural rows do not add hidden data. Transport is restricted to H, continuation replay to C, provenance to P, and local naming to N.

Since no other coordinate appears in the carrier, completion-facing and Real-facing consumers can inspect only the displayed topology, metric, Real, history, transport, continuation, package, and naming rows. The excluded quotient, compactness, representative-selection, ambient-completeness, and bridge data have no projection from the packet. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier real seal nonescape`

Theorem 1925.9 (HausdorffSpace public separation export)**.** *For an accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N),$$

the carrier row of Definition 1925.1, the NameCert obligations of Definition 1925.2, the metric separation handoff of Definition 1925.3, the classifier transport of Definition 1925.7, the point-separation choice-free route of Definition 1925.6, and the Real-seal nonescape row of Definition 1925.8 assemble a public $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ *separation export over* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. This export has no coordinate for quotient point equality, selected representatives, open-cover compactness, ambient completeness, Lean verification, or bridge closure.*

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceCarrier public separation export`

Proof. Start from the carrier of Definition 1925.1. It displays the topology source, point-name rows, disjoint open-neighborhood rows, optional metric handoff, Real seal, and structural rows used by every public separation read.

Apply the NameCert obligations of Definition 1925.2. They identify the finite obligation surface for carrier admission, disjoint open-neighborhood separation, classifier transport, metric handoff, and nonescape.

Next use the metric handoff and classifier-transport routes, Definition 1925.3 and Definition 1925.7. These keep any metric-generated separation behind the displayed distance seal and preserve the same open-neighborhood rows under componentwise transport.

Finally apply Definition 1925.6 and Definition 1925.8. The public export is therefore exactly the finite separation packet over topology, metric, Real, history, transport, continuation, provenance, and naming rows, while quotient point equality, representatives, compactness, completeness, Lean verification, and bridge closure remain unavailable. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpacePublicSeparationExport`

Theorem 1925.10 (HausdorffSpace mature standard-bridge readiness)**.** *For an accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N),$$

the public separation export of Definition 1925.9, the metric handoff of Definition 1925.3, the classifier transport of Definition 1925.7, the choice-free point separation of Definition 1925.6, and the Real-seal nonescape of Definition 1925.8 are the complete paper-side mature interface for the packet. Lean verification and the standard bridge remain separate verification-axis obligations, but the theory-side carrier exports no additional coordinate beyond $T, x, y, U, V, D, M, E, H, C, P, N$*.*

Proof. Read the public separation export. It assembles the carrier admission, NameCert obligations, metric handoff, classifier transport, choice-free point separation, and Real-seal boundary into one public $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ surface.

Inspect the listed routes. Metric-generated separation must pass through M, E before it returns to U, V, D, classifier transport preserves the displayed rows through H, C, and point separation selects no representatives or quotient points.

Finally inspect provenance and local naming. The rows P, N name only the displayed packet, so the paper-side mature interface is exhausted by $T, x, y, U, V, D, M, E, H, C, P, N$. The Lean target and the standard bridge are therefore verification-axis tasks rather than additional theory-side coordinates. □

Lean4 ✓ `BEDC.Derived.HausdorffSpaceUp.HausdorffSpaceMatureStandardBridgeReadiness`

Theorem 1925.11 (HausdorffSpace bridge-facing certificate)**.** *For an accepted* $\mathsf{HausdorffSpace}^{\uparrow}$ *carrier*

$$S = (T, x, y, U, V, D, M, E, H, C, P, N),$$

the public separation export of Definition 1925.9 is the bridge-facing finite route through the $\mathsf{Topology}^{\uparrow}$ *source row* T*, optional* $\mathsf{Met}^{\uparrow}$ *separation handoff* M*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$ *row* N*. The route exposes disjoint open-neighborhood rows* U, V *with disjointness ledger* D*, and it refuses quotient point equality, open-cover compactness, selected representatives, ambient completeness, and machine bridge checking.*

Proof. Start from the public separation export. It already packages the carrier, NameCert obligations, metric handoff, classifier transport, point-separation route, and Real-seal nonescape into a finite separated-topology surface.

Read that surface bridge-facingly. The topology source is T, the optional metric contribution is M, and any metric distance value is visible only through the Real seal E before the route returns to U, V, D.

The structural rows provide the remaining bridge-facing data. Componentwise transport is H, replay is C, package provenance is P, and local naming is N.

Since the carrier has no coordinate for quotient point equality, open-cover compactness, selected representatives, ambient completeness, or machine bridge checking, the bridge-facing certificate cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$**.**
Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HausdorffSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1925.1, Definition 1925.2, Definition 1925.3, Definition 1925.7, Definition 1925.6, Definition 1925.8, and Definition 1925.9 bind the public separated-topology export over carrier admission, NameCert obligations, metric separation handoff, classifier transport, choice-free point separation, and Real seal nonescape.

Formal verification: FormalStatus(NameCert$_{\mathsf{HausdorffSpace}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not claim quotient point equality, open-cover compactness, selected representatives, ambient completeness, Lean verification, or standard bridge closure.

Upgrade path: Mature closure requires examples or downstream consumers of the bridge-facing separated-topology export, while verification still requires a checked BEDC.Derived.HausdorffSpaceUp target.

Constructive story: A HausdorffSpace$^{\uparrow}$ packet is generated from a Topology source row, two point-name rows, two disjoint open-neighborhood rows, a disjointness ledger, an optional MetricSpace distance-separation handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1926

A Concrete Naming Certificate for $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$ packet records the rational nested-interval construction of a regular Cauchy name through finite endpoint windows, not a host interval intersection or ambient real-completeness theorem. It sits between the nested-interval surface of chapter 320, the rational interval endpoint carrier of chapter 354, the dyadic tolerance ledger of chapter 291, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter isolates the interval-to-regular-name handoff: finite rational windows and width controls are displayed before any consumer may read the $\mathsf{RegSeqRat}^{\uparrow}$ row or the $\mathsf{Real}^{\uparrow}$ seal.

Definition 1926.1 (Rational nested-interval limit carrier)**.** *A* $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, W, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the rational nested-interval row. It records the inspected finite chain of rational intervals, the endpoint order witnesses, and the displayed containment step from each interval to its predecessor.*
2. *W is the width and tolerance ledger. It records the finite dyadic and rational bounds that turn each inspected interval width into the requested regular-Cauchy tolerance.*
3. *E is the endpoint-enclosure row. It records the lower and upper rational endpoint windows read through the* $\mathsf{RationalInterval}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *sibling surfaces.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed endpoint windows and the width ledger.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, visible only after I, W, E, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval chain, width ledger, endpoint enclosures, regular rational handoff, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite nested-interval request through I, W, E, R, S.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RationalNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, W, E, R, S, H, C, P, N$. The carrier has no coordinate for host interval intersections, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1926.2 (Rational nested-interval limit NameCert obligations)**.** *For every accepted* $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$ *carrier*

$$L = (I, W, E, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet with rational nested-interval data, width and tolerance data, endpoint enclosures, regular rational handoff, terminal real seal, transport, replay, provenance, and local naming;*
2. *nesting exactness: every interval read is one of the displayed rational rows of I, and every successor interval is read together with its displayed containment witness;*
3. *width-to-tolerance control: every requested tolerance consumed by the handoff row is discharged by a visible width entry in W and the corresponding endpoint enclosure in E;*
4. *RegSeqRat handoff exactness: the row R reads only the rational interval windows and width entries displayed by I, W, E;*
5. *Real-seal nonescape: the terminal seal S is reached only after I, W, E, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RationalNestedIntervalLimitUp.RationalNestedIntervalLimitCarrier semantic name certificate`

Proof. Carrier admission is projection from Definition 1926.1. The accepted packet displays exactly the rational interval chain, width ledger, endpoint enclosures, regular rational handoff, Real seal, and structural rows.

Nesting exactness is forced by I. A consumer can inspect only the finite chain already present in the packet, and each successor interval is carried with its containment witness into the preceding interval.

Width-to-tolerance control is forced by W and E. The tolerance request cannot reach the regular-Cauchy handoff until the width row supplies the bound and the endpoint-enclosure row supplies the rational windows used to witness it.

The RegSeqRat handoff exactness clause follows because R is downstream of I, W, E. It repacks those displayed interval windows as a regular rational readback and has no coordinate for a second chain, a quotient stream, or a selected host limit.

Finally, S, H, C, P, N close the route. The Real seal is terminal, while transport, replay, provenance, and the local NameCert row preserve the same finite data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 1926.3 (Rational nested-interval RegSeqRat handoff)**.** *Let $L = (I, W, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{RationalNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by L*

factors through the displayed rational interval windows I, E and the width ledger W before reaching the terminal $\mathsf{Real}^{\uparrow}$ *seal S. Equivalently, the only exported completion-facing route has the form*

$$I, E, W \longmapsto R \longmapsto S.$$

The route provides a regular rational name from finite rational nested-interval data; it does not provide host interval intersection, quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer read of the regular rational handoff. The carrier gives no direct edge to R except through the displayed rational nested-interval row I, the endpoint-enclosure row E, and the width ledger W.

The endpoint windows in E are tied to the same inspected interval chain recorded in I. The width ledger W then supplies the tolerance comparison required for the regular-Cauchy readback, so the consumer cannot replace the displayed chain by a host intersection or by a selected endpoint.

After I, E, W have been displayed, the read may reach R. Only then may the terminal seal S be consumed, and the structural rows H, C, P, N transport, replay, source, and name the same route.

Because the carrier contains no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, or ambient Real completeness, every exported $\mathsf{RegSeqRat}^{\uparrow}$ read remains the finite route shown above. □

Theorem 1926.4 (Rational nested-interval limit window regularity)**.** *For every accepted* RationalNestedIntervalLim *carrier $L = (I, W, E, R, S, H, C, P, N)$, the terminal limit read is exposed only after the finite rational interval windows I, E and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R agree under the same* $\mathsf{StreamName}^{\uparrow}$ *schedule, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RationalNestedInte}}$ *row. In particular, every Real-facing consumer must read*

$$I, E, W \longmapsto R \longmapsto S \longmapsto H, C, P, N$$

before treating the packet as a limit name.

Proof. Project the carrier of Definition 1926.1. The only endpoint windows available to the packet are the rational interval rows in I and the endpoint-enclosure row E, and the only tolerance schedule is the width ledger W.

Apply the RegSeqRat handoff theorem, Definition 1926.3. It forces every regular rational read through I, E, W before R is exposed, so the terminal limit cannot be read before the interval windows and regular readback agree on the same displayed schedule.

The structural rows H, C, P, N then transport, replay, source, and name that schedule. Since the carrier has no separate host intersection, quotient stream equality, selected limit, trichotomy, countable choice, or ambient completeness coordinate, the terminal seal S is readable only through the displayed finite-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalNestedIntervalLimit}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RationalNestedIntervalLimit}^{\uparrow}}$, seed)

Scope closed: Definition 1926.1, Definition 1926.2, and Definition 1926.3 seed the finite rational nested-interval route from endpoint windows and width ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RationalNestedIntervalLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval intersections, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nesting exactness, width-to-tolerance control, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RationalNestedIntervalL

Constructive story: A RationalNestedIntervalLimit$^{\uparrow}$ packet is generated from a rational nested-interval row, a width and tolerance ledger, endpoint enclosure windows, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1927

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusStability}^{\uparrow}$

Following Bishop and Bridges constructive Cauchy sequence discipline, the $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ packet records the finite transport surface by which a displayed regular Cauchy modulus remains usable after tail-equivalent regular names are presented to Real and Completion consumers. It sits over the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback boundary of chapter 301, the terminal real-name seal of chapter 38, and the request-to-window route of chapter 1918. The packet is a finite stability certificate for reusing a Cauchy modulus across a displayed tail-equivalence route; it is not quotient stream equality, selected limit data, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Definition 1927.1 (Regular Cauchy modulus stability carrier)**.** *A* $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, M, T, W_A, W_B, D_A, D_B, Q_A, Q_B, E_A, E_B, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose finite regular Cauchy observations are related by a displayed tail-equivalence route.*
2. *M is the reusable Cauchy-modulus row, read through the* $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$ *request-to-window surface.*
3. *T is the finite tail-equivalence ledger, recording the cutoff, paired tail windows, and rowwise agreement evidence that allows the same modulus request to be read from either source after the cutoff.*
4. *W_A and W_B are the* $\mathsf{StreamName}^{\uparrow}$ *tail-window rows selected from A and B by the request, the reusable modulus row M, and the ledger T.*
5. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers attached to the two selected tail windows.*
6. *Q_A and Q_B are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from the selected windows and dyadic ledgers.*
7. *E_A and E_B are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after the source, modulus, tail-equivalence, window, tolerance, and readback rows have been displayed.*

8. *H records componentwise* hsame *transport for the source rows, reusable modulus, tail-equivalence ledger, selected windows, tolerance ledgers, readbacks, real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from every Real or Completion request through $M, T, W_A, W_B, D_A, D_B, Q_A, Q_B,$ and then through H, P, N.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusStability}^{\uparrow}$, $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusStability}^{\uparrow}}$ *row.*

The classifier compares accepted stability packets only through the displayed rows $A, B, M, T, W_A, W_B, D_A, D_B, Q_A,$ It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusStabilityUp.RegularCauchyModulusStabilityTasteGate`
`single carrier alignment`

Theorem 1927.2 (Regular Cauchy modulus stability NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ *carrier*

$$S = (A, B, M, T, W_A, W_B, D_A, D_B, Q_A, Q_B, E_A, E_B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusStability}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the source rows A, B, reusable modulus M, tail-equivalence ledger T, selected windows W_A, W_B, tolerance ledgers D_A, D_B, readbacks Q_A, Q_B, real seals E_A, E_B, and structural rows H, C, P, N;*

2. *modulus admission, requiring every transported precision request to read the displayed modulus row M before either tail window is selected;*

3. *tail-equivalence exactness, requiring T to store the cutoff and paired tail-window agreement used for the two sources;*

4. *window selection, requiring W_A and W_B to be selected from the same request and the same modulus row, with T supplying only the tail-alignment data;*

5. *dyadic accounting, requiring D_A and D_B to store exactly the tolerance radii and slack comparisons consumed by their corresponding selected windows;*

6. *readback and seal routing, requiring Q_A, E_A and Q_B, E_B to remain downstream of their matching source, window, and dyadic ledger;*

7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*

8. *non-escape for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard-bridge data.*

No regular Cauchy modulus stability obligation is stored outside these rows.

Proof. Project the carrier of Definition 1927.1. The only analytic coordinates are the two sources A, B, the reusable modulus M, the tail-equivalence ledger T, the two selected windows, the two dyadic ledgers, the two readbacks, and the two terminal seals.

The modulus route is forced before any branch read. A Real or Completion request first reads M, and the selected tail windows W_A, W_B are then formed from the same request together with the tail-equivalence ledger T.

The ledger T contributes only the finite cutoff and paired tail-window agreement evidence. It does not identify the streams as quotient objects and does not select a limiting real.

The dyadic, readback, and seal rows remain branchwise. The rows D_A, Q_A, E_A are downstream of A, W_A, and the rows D_B, Q_B, E_B are downstream of B, W_B.

Finally H, C, P, N transport, replay, source, and name the same displayed finite route. Since none of the excluded objects appears as a coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1927.3 (Regular Cauchy modulus stability tail-equivalence transport)**.** *Let*

$$S = (A, B, M, T, W_A, W_B, D_A, D_B, Q_A, Q_B, E_A, E_B, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ *carrier. Every Real or Completion request that uses the reusable modulus M on the A source has a transported finite route on the B source through the same modulus row, the displayed tail-equivalence ledger, the selected B-window, the B-side dyadic ledger, the B-side readback, and the B-side real seal. Conversely, every B-side routed request transports back through the displayed A-side rows. The transport supplies reuse of the modulus across tail-equivalent regular names without quotient equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Proof. Start with an A-side request. By Definition 1927.2, the request reads M before any selected window is consumed.

Use the tail-equivalence ledger T. It records the finite cutoff and paired tail-window agreement rows, so the same request and modulus row select the B-side window W_B whenever the A-side route has selected W_A beyond the cutoff.

The transported branch then reads D_B, Q_B, and E_B in order. These rows are the only B-side tolerance, readback, and seal coordinates in the carrier, so the transported route has no additional branch or hidden endpoint.

The reverse direction is symmetric. Begin with the B-side route, read the same modulus row M, use the same ledger T to recover the paired A-side window W_A, and then pass through D_A, Q_A, E_A.

The structural rows H, C, P, N record both directions as componentwise transport and displayed replay over the same finite packet. Thus the carrier transports the reusable modulus across the displayed tail-equivalence surface and introduces none of the excluded quotient, selector, choice, equality, order, completeness, verification, or bridge objects. □

Falsifiable prediction: Every $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ Real or Completion read that reuses a Cauchy modulus across tail-equivalent regular names factors through two RegSeqRat source rows, one reusable RegularCauchyModulusRealizer route, a finite tail-equivalence ledger, paired StreamName tail windows, paired DyadicRatCore tolerance ledgers, paired RegSeqRat readbacks, paired RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-modulus-realizer, regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source rows, one reusable modulus row, a tail-equivalence ledger, paired selected windows,

paired tolerance ledgers, paired readbacks, paired terminal seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one reusable RegularCauchyModulusRealizer route, a finite tail-equivalence ledger, paired StreamName tail windows, paired DyadicRatCore tolerance ledgers, paired RegSeqRat readbacks, paired RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1927.1, Definition 1927.2, and Definition 1927.3 seed the finite modulus-transport route for tail-equivalent regular names consumed by L10 Real and Completion interfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, modulus admission, tail-equivalence exactness, window selection, dyadic accounting, readback and seal routing, and tail-equivalence transport for BEDC.Derived.RegularCauchyModulusStabil

Chapter 1928

A Concrete Naming Certificate for $\mathsf{CauchyCompletionSplit}^{\uparrow}$

Following Bishop and Bridges constructive completion and the Bourbaki–Kelley language of completion as a universal reflective boundary, the $\mathsf{CauchyCompletionSplit}^{\uparrow}$ packet records the finite unit-counit split at the open Real and Completion phase. It binds the unit row of chapter 1527, the counit row of chapter 1539, the adjunction row of chapter 1456, the idempotent completion row of **??**, the triangle row of chapter 1795, the finite stream surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational route of chapter 301, the terminal real-name seal of chapter 38, and the retraction packet of chapter 1921. The chapter is a finite NameCert boundary only; it does not assert quotient completions, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge-axis evidence.

Definition 1928.1 (CauchyCompletionSplit carrier)**.** *A* $\mathsf{CauchyCompletionSplit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, U, V, A, I, G, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed source row whose completion-facing split is being named.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route admitting X into the completion-facing surface.*
3. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *route returning already displayed completion reads to the real-facing boundary.*
4. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *row comparing unit-admitted consumers with completion-facing consumers over the same finite source.*
5. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *row recording that a repeated completion read contributes no further public completion row.*
6. *G is the* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *row comparing the unit-counit composite with the direct displayed read.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened before any rational observation can be exported.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the window and split comparisons.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row consumed by the terminal seal.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the split has passed through W, D, R.*

11. *H records componentwise* hsame *transport for $X, U, V, A, I, G, W, D, R, E$ and the structural rows.*

12. *C records displayed* Cont *replay for consumers that inspect the unit side, the counit side, the triangle comparison, or the terminal real-facing route.*

13. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionSplit}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$, $\mathsf{CauchyCompletionRetraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionSplit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected completion representatives, countable-choice schedules, host equality of completed objects, ambient completeness, or public bridge credentials.

Theorem 1928.2 (CauchyCompletionSplit NameCert obligations)**.** *For an accepted* $\mathsf{CauchyCompletionSplit}^{\uparrow}$ *carrier $S = (X, U, V, A, I, G, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionSplit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source row, unit row, counit row, adjunction row, idempotent row, triangle row, finite-window row, dyadic ledger, regular readback, terminal seal, transport, replay, provenance, and local naming rows;*

2. *unit exposure, requiring every completion-facing read exported from X to pass through U before a completion consumer can inspect it;*

3. *counit return, requiring every displayed completion-facing read to pass through V before it reaches W, D, R, E;*

4. *finite split exactness, requiring the composite through U, A, I, G, V to expose the same terminal route through W, D, R, E as the direct source read;*

5. *classifier stability, requiring transported packets with the same displayed rows to be identified by the carried* hsame *and* Cont *data;*

6. *non-escape, requiring the packet to export no quotient-completion equality, selected representative, countable-choice schedule, host equality, ambient-completeness theorem,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionSplitUp.CauchyCompletionSplitTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1928.1. The tuple lists exactly the source, unit, counit, adjunction, idempotent, triangle, finite-window, dyadic, readback, seal, transport, replay, provenance, and local naming rows.

Unit exposure is read from U. A completion-facing consumer starting at X receives no direct completion object; the carrier first displays the route by which X enters the completion-facing surface.

Counit return is read from V. Once a completion-facing read is already displayed, the packet forces the return route through the finite observation rows W, D, R before the terminal seal E can be consumed.

Finite split exactness is the shared comparison supplied by A, I, G. The adjunction row fixes the universal consumer route, the idempotent row states that a repeated completion read contributes

no further public row, and the triangle row compares the unit-counit route with the direct route to the same seal.

Classifier stability is componentwise transport along H followed by replay through C. Since the carrier fields are exhausted by $X, U, V, A, I, G, W, D, R, E, H, C, P, N$, the excluded quotient, representative-choice, countable-choice, host-equality, ambient-completeness, real-completeness, and bridge data have no row from which a consumer could read them. □

Theorem 1928.3 (CauchyCompletionSplit unit-counit route)**.** *Let $S = (X, U, V, A, I, G, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionSplit}^{\uparrow}$ *carrier. Every consumer of the finite unit-counit split factors through the displayed route*

$$X \longmapsto U \longmapsto A, I, G \longmapsto V \longmapsto W, D, R \longmapsto E \longmapsto H, C, P, N.$$

After this route is projected, the visible seal-facing read is the same finite route

$$W, D, R \longmapsto E$$

that the source row already displays. The split is therefore a finite unit-counit boundary over BEDC rows, not equality of quotient completions, not a selected representative, not host equality, and not countable choice or ambient completeness.

Proof. Start with a consumer of the split packet and project the source row X. The only completion-facing admission exposed by the carrier is U, so the consumer first passes through the unit row.

The middle comparison is fixed by A, I, G. The adjunction row A records that the completion-facing consumer is a consumer of the same reflected route, the idempotent row I prevents a repeated completion read from adding a public row, and the triangle row G compares the unit-counit composite with the displayed route to the seal.

The return part is then forced by V. The counit row routes the already displayed completion-facing read through the finite stream window W, the dyadic tolerance ledger D, and the regular rational readback R before the terminal seal E is inspected.

Transport by H and replay by C preserve this route for equivalent packets, while P and N record provenance and local naming. No other carrier coordinate exists, so the split exports exactly the displayed finite route and none of the excluded quotient, representative, host-equality, choice, or completeness data. □

Theorem 1928.4 (CauchyCompletionSplit nonescape)**.** *For an accepted* $\mathsf{CauchyCompletionSplit}^{\uparrow}$ *carrier $S = (X, U, V, A, I, G, W, D, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{RegSeqRat}^{\uparrow}$*-facing,* $\mathsf{StreamName}^{\uparrow}$*-facing, or completion-facing read exported by S is generated by the rows named in Definition 1928.1. In particular, the packet exports no quotient-completion equality, selected completion representative, countable-choice schedule, host equality of completed objects, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Project the accepted carrier. A $\mathsf{StreamName}^{\uparrow}$-facing, $\mathsf{RegSeqRat}^{\uparrow}$-facing, or $\mathsf{Real}^{\uparrow}$-facing read must pass through W, D, R, E, because these are the only finite observation, tolerance, readback, and terminal seal rows in the tuple.

A completion-facing read must pass through U, V, A, I, G. These are the only completion-route rows in the tuple, and each is stored as displayed NameCert data rather than as a quotient point or selected representative.

The structural rows H, C, P, N transport, replay, source, and name the same route. They add no carrier coordinate beyond the listed rows.

Thus every exported read is generated by Definition 1928.1. The forbidden quotient, representative, choice, host-equality, ambient-completeness, real-completeness, and bridge data are absent from the carrier and cannot be produced by projection, transport, replay, provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionSplit}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionSplit}^{\uparrow}$ packet is generated from a displayed source row, CauchyCompletionUnit route, CauchyCompletionCounit route, CauchyCompletionAdjunction route, CauchyCompletionIdempotent row, CauchyCompletionTriangleIdentity row, StreamName finite windows, DyadicRatCore tolerances, RegSeqRat readback, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionSplit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1928.1, Definition 1928.2, Definition 1928.3, and Definition 1928.4 seed the finite unit-counit split boundary for the open Real and Completion phase.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionSplit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected completion representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, unit exposure, counit return, split exactness, classifier stability, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionSplitUp.

Chapter 1929

A Concrete Naming Certificate for $\mathsf{MonotoneInverse}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{MonotoneInverse}^{\uparrow}$ packet records inverse readback for strictly monotone real maps by finite interval and bisection data. It is a NameCert surface for an inverse-reading route, not a host inverse function, real trichotomy, quotient real equality, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. The packet consumes the sign and interval refinement discipline of chapter 1422, the monotone limit route of chapter 1914, the local slope and image controls of chapter 1907 and chapter 1912, and the real-name readback lattice of chapter 38, chapter 126, chapter 301, and chapter 291.

Definition 1929.1 (Monotone inverse carrier)**.** *A* $\mathsf{MonotoneInverse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, T, M, B, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source interval row. It records the input endpoint windows, endpoint order evidence, located subinterval identity, and the displayed domain restriction on which the map is inspected.*
2. *T is the target interval row. It records the target real-name window, endpoint-bracket data, and the finite assertion that the target request lies between the displayed source endpoint images.*
3. *M is the strict monotonicity evidence row. It stores the finite comparison route for source windows and the orientation flag, increasing or decreasing, used by every inverse read.*
4. *B is the finite bisection schedule. It records branch prefixes, midpoint image comparisons, retained source intervals, and the handoff to the intermediate-value bisection surface.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for source endpoints, target requests, midpoint images, and retained source windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational approximants extracted from W before any real-facing seal is inspected.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records requested precisions, dyadic interval widths, branch-depth budgets, image-comparison tolerances, and retained-window radii.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *inverse seal. It is reached only after the source interval, target interval, monotonicity evidence, bisection schedule, stream windows, regular readback, and dyadic tolerance rows have been displayed.*

9. *H records componentwise* hsame *transport for the interval rows, monotonicity row, bisection schedule, stream windows, regular readbacks, dyadic tolerances, inverse seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a target request through interval inspection, monotonicity comparison, bisection refinement, stream-window exposure, regular readback, dyadic tolerance accounting, and inverse-seal consumption.*

11. *P is the* Pkg *provenance over* $\mathsf{MonotoneInverse}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$, $\mathsf{ConstructiveMeanValue}^{\uparrow}$, $\mathsf{MeanValueTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneInverse}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, T, M, B, W, R, D, E, H, C, P, N$. It has no coordinate for a host inverse function, real trichotomy, quotient real equality, selected representative, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an unrecorded comparison of real values.*

Lean4 ✓ `BEDC.Derived.MonotoneInverseUp.MonotoneInverseTasteGate single carrier alignment`

Theorem 1929.2 (Monotone inverse NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneInverse}^{\uparrow}$ *carrier*

$$I = (A, T, M, B, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MonotoneInverse}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source interval, target interval, strict monotonicity evidence, finite bisection schedule, stream windows, regular readbacks, dyadic tolerance rows, inverse seal, transport, replay, provenance, and local naming;*

2. *interval discipline, requiring A and T to expose the source bracket and target-in-image bracket before any branch comparison or real-facing inverse row is available;*

3. *monotonicity discipline, requiring M to orient every midpoint comparison and retained-interval decision before the bisection schedule can be read;*

4. *bisection handoff discipline, requiring B, W, R, D to display branch prefixes, finite windows, regular rational readbacks, and dyadic tolerance accounting before the inverse seal is inspected;*

5. *structural nonescape, requiring E, H, C, P, N to export only the displayed route and no host inverse function, real trichotomy, quotient real equality, selected representative, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or unrecorded real comparison.*

No MonotoneInverse obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1929.1. The accepted packet displays exactly the source interval, target interval, strict monotonicity evidence, bisection schedule, stream windows, regular readbacks, dyadic tolerances, inverse seal, and structural rows.

The interval discipline is the entry point. The source row A fixes the domain bracket, while the target row T fixes the requested value as a displayed bracket between endpoint image rows. Without those two rows there is no bisection request to orient.

The monotonicity discipline supplies the orientation. The row M is the only stored evidence that source-order comparisons determine image-order comparisons, so each branch decision in B must read M before retaining a half-interval.

The bisection handoff is then forced by the packet order. The schedule B produces finite retained source windows, W exposes those windows as StreamName data, R reads them as regular

rational approximants, and D records the dyadic tolerance budget used by the requested inverse precision.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the excluded analytic objects are absent from the carrier, no local obligation can export them. □

Theorem 1929.3 (Monotone inverse bisection handoff)**.** *Every inverse read of an accepted* $\mathsf{MonotoneInverse}^{\uparrow}$ *carrier factors through the displayed route*

$$A, T, M \longmapsto B \longmapsto W, R, D \longmapsto E, H, C, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *inverse seal is public. The route first reads the source and target interval rows, then the strict monotonicity orientation, then the finite bisection schedule, then the StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance rows, and only then the terminal real-name seal. It exports a finite inverse-read packet rather than a host inverse function or an ambient completeness argument.*

Proof. Start with an accepted packet $I = (A, T, M, B, W, R, D, E, H, C, P, N)$. The only source-domain and target-request coordinates are A and T, so every inverse read begins by opening those displayed interval rows.

Next use strict monotonicity. The row M supplies the orientation that turns each midpoint image comparison into a retained source half-interval. The bisection schedule B is therefore downstream of M, and it cannot be read as an unordered search or as real trichotomy.

The readback stage is finite. The branch prefix in B exposes retained windows through W, the regular rational approximants are read through R, and the requested precision is accounted for through D. These are exactly the StreamName, RegSeqRat, and DyadicRatCore rows available before sealing.

The $\mathsf{Real}^{\uparrow}$ inverse seal E is terminal. The transport, replay, provenance, and local naming rows H, C, P, N preserve and present the same route. Since no carrier coordinate stores a host inverse, quotient equality, selected representative, or ambient completeness witness, every inverse read factors through the displayed bisection and monotonicity route before the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneInverse}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneInverse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1929.1, Definition 1929.2, and Definition 1929.3 seed the finite constructive inverse-read route for strictly monotone real maps through displayed intervals, bisection data, stream windows, regular readbacks, dyadic tolerances, and a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneInverse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, real trichotomy, quotient real equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window exactness, bisection handoff, inverse-seal nonescape, and ledger provenance for BEDC.Derived.MonotoneInverseUp.

Constructive story: A $\mathsf{MonotoneInverse}^{\uparrow}$ packet is generated from source and target interval rows, strict monotonicity evidence, a finite bisection schedule, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, a $\mathsf{Real}^{\uparrow}$ inverse seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1930

A Concrete Naming Certificate for $\mathsf{RegularCauchyExtensionality}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ packet records the finite tail-coincidence route by which two regular Cauchy rational names present the same sealed real name. It sits between the regular rational rows of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the separated uniqueness route of chapter 427. The certificate is a tail-invariance surface for Real and Completion consumers; it is not quotient stream equality, host real equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1930.1 (Regular Cauchy extensionality carrier)**.** *A* $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R_0, R_1, S_0, S_1, D, T, A_0, A_1, H, C, P, N)$$

with the following displayed rows:

1. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name rows to be compared.*
2. *S_0 and S_1 are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which downstream requests read R_0 and R_1.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-tolerance ledger recording the visible radii, slack comparisons, and finite dyadic requests used by both names.*
4. *T is the eventual tail-coincidence row, displaying a threshold after which every requested window of S_0 and S_1 reads the same dyadic rational observation through D.*
5. *A_0 and A_1 are the two* $\mathsf{Real}^{\uparrow}$ *seal rows reached from the two regular names after the finite windows and shared ledger have been exposed.*
6. *H records componentwise* hsame *transport for the two regular rows, two stream-window rows, shared dyadic ledger, tail-coincidence row, two Real seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each Real or Completion request through the selected tail threshold, the corresponding finite stream windows, the shared dyadic ledger, the two regular readbacks, the two Real seals, and the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularLimitUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionality}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyExtensionalityUp.TasteGate.RegularCauchyExtensionalityTasteGate`
`single carrier alignment`

Theorem 1930.2 (Regular Cauchy extensionality NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ *carrier*

$$E = (R_0, R_1, S_0, S_1, D, T, A_0, A_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* R_0, R_1*, two* $\mathsf{StreamName}^{\uparrow}$ *window rows* S_0, S_1*, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, tail-coincidence row* T*, two* $\mathsf{Real}^{\uparrow}$ *seals* A_0, A_1*, and structural rows* H, C, P, N*;*

2. *tail-threshold exactness, requiring* T *to display a finite threshold after which the two stream-window routes make the same dyadic observations through* D*;*

3. *window stability, requiring every downstream request beyond the displayed threshold to be read through matching finite windows of* S_0 *and* S_1 *before either Real seal is inspected;*

4. *regular-readback routing, requiring the compared observations to remain attached to* R_0 *and* R_1 *as* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks;*

5. *Real-seal routing, requiring* A_0 *and* A_1 *to be downstream of the displayed regular rows, stream windows, dyadic ledger, and tail-coincidence row;*

6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, C, P, N*;*

7. *non-escape for quotient stream equality, host real equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No extensionality obligation is stored outside these rows.

Proof. Project the carrier of Definition 1930.1. The analytic rows are exactly the two regular rational names, their two finite stream-window surfaces, the shared dyadic ledger, the tail-coincidence threshold, and the two terminal Real seals.

Read the threshold row next. The row T is the only place where the two names are compared, and it compares them only after a displayed finite threshold. Beyond that threshold, the requested windows of S_0 and S_1 read the same dyadic observations through D before either route reaches a Real seal.

The structural rows preserve the same route. The hsame rows transport the visible coordinates, the Cont rows replay the requests through the displayed windows and ledger, the Pkg row records provenance, and the local naming row names precisely this packet.

Since the omitted objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 1930.3 (Regular Cauchy extensionality tail-coincidence seal)**.** *Let*

$$E = (R_0, R_1, S_0, S_1, D, T, A_0, A_1, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ *carrier. Suppose* T *displays a tail threshold* k *such that every downstream precision request served beyond* k *reads the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* S_0 *and* S_1 *and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows in* D*. Then every* $\mathsf{Real}^{\uparrow}$ *seal consumer factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *tail route before reaching* A_0 *or* A_1*.*

Consequently the comparison exported by the packet is tail-coincidence invariance of the two sealed regular names, with visible BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance. It excludes quotient stream equality, host real equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the displayed tail threshold k in the row T. A consumer request below the threshold is not used to identify the two seals; the comparison route begins only once the request has passed into the tail certified by T.

After that point, both names read the same finite windows. The row S_0 serves the request for R_0, the row S_1 serves the request for R_1, and the threshold row states that these two window reads call on the same entries of the shared ledger D.

The dyadic ledger forces the two readbacks to use one tolerance surface. Each compared observation remains attached to its source regular row, so the consumer route is still a $\mathsf{RegSeqRat}^{\uparrow}$ route, but the tail portion of the route is common.

Only then are the two Real seals inspected. The rows A_0 and A_1 are downstream of the displayed regular rows, stream windows, shared dyadic ledger, and tail-coincidence row, so every Real-facing consumer factors through the same finite tail surface before reading a seal.

The exclusion clauses follow from the carrier inventory. No coordinate contains quotient stream equality, host real equality, a selected limit, countable choice, or ambient Real completeness, and the structural rows can replay only the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ Real or Completion consumer that identifies two $\mathsf{Real}^{\uparrow}$ seals without reading a displayed $\mathsf{RegSeqRat}^{\uparrow}$ tail route, matching $\mathsf{StreamName}^{\uparrow}$ windows, and the shared $\mathsf{DyadicRatCore}^{\uparrow}$ ledger refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-limit-uniqueness: no listed sibling supplies the whole twelve-row packet $E = (R_0, R_1, S_0, S_1, D, T, A_0, A_1, H, C, P, N)$, because each sibling contributes only a regular rational source, finite window surface, dyadic ledger, Real seal, or separated uniqueness route while this chapter binds tail-coincidence invariance with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyExtensionality}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ rows, two $\mathsf{StreamName}^{\uparrow}$ finite-window rows, a shared $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, an eventual tail-coincidence row, two $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1930.1, Definition 1930.2, and Definition 1930.3 seed the tail-coincidence invariance route from regular Cauchy names to Real seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, tail-threshold exactness, window stability, regular-readback routing, Real-seal routing, and tail-coincidence seal factorization for BEDC.Derived.RegularCauchyExtensionalityUp.

Chapter 1931

A Concrete Naming Certificate for $\mathsf{CauchyCompletionTrace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletionTrace}^{\uparrow}$ packet records the finite source-to-completion trace behind completion-facing reads. It binds the source schedule of chapter 126, the regular rational readback of chapter 301, the dyadic budget ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the monad route of chapter 378, the functor route of chapter 423, the universal-property route of chapter 397, and the displayed retraction route of chapter 1921. The chapter packages these rows as a finite L10 Real-and-Completion trace only; it does not assert quotient completions, selected limits, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1931.1 (CauchyCompletionTrace carrier)**.** *A* $\mathsf{CauchyCompletionTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, E, U, F, V, H, C, P, N)$$

with the following visible rows:

1. *S is the source schedule row, recording the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite windows that a completion-facing read is allowed to inspect.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational name extracted from the source schedule before the terminal real seal is opened.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, recording the dyadic tolerance ledger used by S and R.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the source schedule, dyadic budget, and regular readback have been displayed.*
5. *U is the completion unit or monad row, recording the finite* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *admission route consumed by completion-facing reads.*
6. *F is the completion functor row, recording the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *transport of the same source and readback data.*
7. *V is the universal-property or retraction-facing trace row, recording the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *route or the* $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ *route through which a completion consumer returns to the displayed real boundary.*
8. *H records componentwise* hsame *transport for S, R, D, E, U, F, V and the structural rows.*

9. *C records displayed* Cont *replay for consumers that inspect the source schedule, completion admission, functor transport, universal-property route, or retraction-facing route.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionTrace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, CauchyCompletionR BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionTrace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-axis evidence.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionTraceUp.CauchyCompletionTraceTasteGate single carrier alignment`

Theorem 1931.2 (CauchyCompletionTrace NameCert obligations)**.** *For an accepted* $\mathsf{CauchyCompletionTrace}^{\uparrow}$ *carrier* $T = (S, R, D, E, U, F, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionTrace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source schedule, regular readback, dyadic budget, real seal, completion unit or monad row, completion functor row, universal-property or retraction-facing trace row, transport, replay, provenance, and local naming rows;*

2. *trace ordering, requiring every completion-facing consumer to read S, D, R, E before treating the completion rows U, F, V as visible completion data;*

3. *source-to-completion compatibility, requiring U to admit only the source and readback data displayed by S, D, R, E;*

4. *functor compatibility, requiring F to transport the same source schedule, dyadic budget, regular readback, and real seal rows;*

5. *section routing, requiring V to return a universal-property or retraction-facing consumer to the displayed S, D, R, E boundary;*

6. *classifier stability, requiring transported packets with the same displayed rows to be identified by the carried* hsame *and* Cont *data;*

7. *boundary non-escape, stating that the packet exports no quotient completion, selected limit, host equality of completed objects, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Carrier admission is projection from Definition 1931.1. The tuple lists exactly the source schedule, readback, dyadic budget, seal, unit or monad, functor, universal-property or retraction trace, transport, replay, provenance, and local naming rows.

Trace ordering is finite-route induction on the displayed consumer route. The base read is the source schedule S, and each later real-facing observation must pass through the dyadic budget D, the regular readback R, and the terminal seal E before any completion row is inspected.

The completion-facing rows are then forced in order. The unit or monad row U admits the displayed source route, the functor row F transports that same route, and the row V supplies the universal-property or retraction-facing return to the real boundary.

Classifier stability is componentwise transport along H followed by replay through C. Since the carrier fields are exhausted by $S, R, D, E, U, F, V, H, C, P, N$, the excluded quotient, selected-limit,

host-equality, countable-choice, ambient-completeness, and bridge data have no row from which a consumer could read them. □

Theorem 1931.3 (CauchyCompletionTrace section route)**.** *Let $T = (S, R, D, E, U, F, V, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionTrace}^{\uparrow}$ *carrier. Every completion-facing consumer exported by T factors through the displayed finite route*

$$S, D, R, E \longmapsto U \longmapsto F \longmapsto V \longmapsto H, C, P, N.$$

The section seen by the consumer is therefore the route from source schedule and regular readback to completion admission, functor transport, and universal-property or retraction-facing return. It is not equality of quotient completions, not a selected limit, not host equality, not countable choice, and not ambient real completeness.

Proof. Project the accepted carrier and start with a completion-facing consumer. Its source-facing observations are confined to S, D, R, E, because these are the only stream, dyadic, readback, and real-seal coordinates of the carrier.

The completion admission is then read from U. This row receives the already displayed source schedule and regular readback route; it does not create a separate completion object or choose a representative.

Functorial transport is read from F, and the return or section-facing comparison is read from V. The two rows share the same preceding S, D, R, E, U data, so finite-route induction gives one section route rather than unrelated completion reads.

Finally H and C transport and replay the same route, while P and N source and name it. Since no other coordinate exists, every completion-facing consumer factors through the displayed section route and none of the excluded data can be exported. □

Theorem 1931.4 (CauchyCompletionTrace real boundary)**.** *For an accepted* $\mathsf{CauchyCompletionTrace}^{\uparrow}$ *carrier $T = (S, R, D, E, U, F, V, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing read exported by the trace is generated by the source schedule S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal seal E. The completion rows U, F, V may cite that boundary and return to it, but they cannot export quotient completions, selected limits, host equality of completed objects, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credentials.*

Proof. Project the accepted carrier. A real-facing read must inspect the source schedule row S, the dyadic budget row D, the regular readback row R, and the terminal seal row E, since these are the only rows that carry real-boundary observations.

The completion rows do not add a second real boundary. The unit or monad row U admits the displayed route, the functor row F transports it, and the universal-property or retraction-facing row V returns completion consumers to the same S, D, R, E boundary.

Transport, replay, provenance, and local naming preserve this boundary as H, C, P, N. They add no quotient-completion coordinate, no selected-limit coordinate, no host-equality coordinate, no countable-choice coordinate, no ambient-completeness theorem, and no bridge credential.

Thus every real-facing read is generated by the displayed finite source-to-seal route, and every completion-facing read remains bounded by that route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionTrace}^{\uparrow}$ packet is generated from a StreamName source schedule, RegSeqRat readback, DyadicRatCore budget, Real seal, CauchyCompletionMonad admission route, CauchyCompletionFunctor transport row, CompletionUniversalProperty or CauchyCompletionRetraction return row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyCompletionTrace}\uparrow}$, seed)

Scope closed: Definition 1931.1, Definition 1931.2, Definition 1931.3, and Definition 1931.4 seed the finite source-to-completion trace behind completion-facing reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyCompletionTrace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality of completed objects, countable choice, ambient Real$^{\uparrow}$ completeness, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, trace ordering, section routing, real-boundary nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionTraceUp.

Chapter 1932

A Concrete Naming Certificate for $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$

Following Hardy–Littlewood and Hardy summability theory, the $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ packet records the constructive finite route by which an Abel-limit boundary and a one-sided Tauberian tail condition hand a real series back to ordinary convergence. It sits after the Abel-test surface of chapter 1496, the finite summation-by-parts route of chapter 1763, the Cesaro averaging route of chapter 1765, the real-series source of chapter 1581, the power-series boundary of chapter 1583, the summable-tail modulus of chapter 1799, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite NameCert surface for Abel-limit handoff; it is not an ambient Tauberian theorem, a quotient series equality, a selected host limit, trichotomy, countable choice, open-cover compactness, or host completeness.

Definition 1932.1 (Hardy–Littlewood Tauberian carrier)**.** *A* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, P, A, L, U, M, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing only finite inspected coefficient windows and finite partial-sum rows.*
2. *P is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *Abel row, displaying the finite radial polynomial windows used before the boundary parameter approaches* 1*.*
3. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *route row, displaying the summation-by-parts identity that relates source partial sums to Abel-window estimates.*
4. *L is the Abel-limit handoff row, displaying a regular boundary schedule and its finite radial estimates.*
5. *U is the Tauberian one-sided tail row, recording the finite boundedness or slow-decrease ledger needed to prevent mass from escaping between the Abel windows and ordinary partial sums.*
6. *M is the* $\mathsf{SummableTailModulus}^{\uparrow}$ *comparison row, assigning every requested dyadic tolerance to a finite source window, radial window, and Tauberian tail ledger.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the ordinary partial-sum route obtained after S, P, A, L, U, M have been displayed.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular readback row.*

9. *H records componentwise* hsame *transport for source windows, Abel polynomial windows, summation-by-parts rows, Abel-limit estimates, Tauberian tail ledgers, modulus comparisons, regular readback, real seal, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a precision request through the Abel-limit handoff, through the Tauberian tail ledger, then through the ordinary partial-sum readback and real seal.*
11. *Q is the* Pkg *provenance over* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HardyLittlewoodTauberian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve displayed rows. It has no coordinate for a host Abel theorem, quotient equality of series names, selected boundary limit, countable choice, trichotomy, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.HardyLittlewoodTauberianUp.HardyLittlewoodTauberianTasteGate single carrier alignment`

Theorem 1932.2 (Hardy–Littlewood Tauberian NameCert obligations)**.** *For every accepted* HardyLittlewoodTaube *carrier $T = (S, P, A, L, U, M, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HardyLittlewoodTauberian}^{\uparrow}}$ *surface consists exactly of carrier admission for that twelve-row packet, source-series exposure through S, Abel-window exposure through P, finite summation-by-parts exposure through A, Abel-limit boundary exposure through L, Tauberian one-sided tail exposure through U, modulus comparison through M, ordinary partial-sum readback through R, real sealing through E, and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted packet $T = (S, P, A, L, U, M, R, E, H, C, Q, N)$. Carrier admission exposes exactly the twelve rows listed in Definition 1932.1; no hidden limit selector or host summability coordinate remains available.

Read the analytic route in order. The source row S supplies finite coefficient and partial-sum windows, the Abel row P supplies the finite radial windows, and the summation row A binds those two surfaces by the displayed summation-by-parts identity.

The Abel-limit row L then gives only regular boundary estimates. The Tauberian row U and modulus row M are the sole rows that compare those estimates with ordinary tails, so every accepted ordinary readback must pass through them before reaching R.

Finally, componentwise hsame transport in H preserves the same route, and Cont replay in C can only replay rows already present in the carrier. The provenance and local naming rows Q, N source and name that packet, so the listed clauses exhaust the local certificate surface. □

Theorem 1932.3 (Hardy–Littlewood Abelian boundary)**.** *Every Abel-limit read exported by an accepted* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ *carrier factors through*

$$S, P, A, L, H, C, Q, N.$$

In particular, an Abel-facing consumer may inspect real-series windows, power-series radial windows, and the AbelSummation route, but it cannot read a completed ordinary sum or host boundary value from the Abel side alone.

Proof. Begin with an Abel-facing read. The only rows before the Tauberian comparison stage are the source row S, the radial power-series row P, the finite summation-by-parts row A, and the Abel-limit handoff row L.

The structural rows H, C, Q, N transport, replay, source, and name that same Abel boundary. They do not contain an ordinary convergence proof or a selected completed real value.

Since U, M, R, E are downstream of the Tauberian comparison, an Abel-facing read that has not consumed those rows remains an Abelian boundary read. It can supply the boundary input for the Tauberian step, but it cannot by itself export ordinary series convergence. □

Theorem 1932.4 (Hardy–Littlewood real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ *carrier factors through the full finite route*

$$S, P, A, L, U, M, R, E, H, C, Q, N.$$

Thus the ordinary real-series endpoint is public only after the Abel boundary and the Tauberian tail ledger have both been displayed through the same componentwise hsame *and* Cont *route.*

Proof. Start with a Real-facing consumer. By Definition 1932.1, the only real seal row is E, and E is reachable only from the regular readback row R.

Trace R backward. Its input is the modulus comparison row M, which compares the Abel-limit estimates in L with ordinary partial-sum tails using the one-sided Tauberian ledger U. The Abel-limit row itself is supplied by the source, radial, and summation rows S, P, A.

The transport and replay rows preserve this route componentwise. Therefore a Real-facing read cannot bypass the Abel boundary, cannot omit the Tauberian tail ledger, and cannot replace the regular readback by host completeness, quotient series equality, selected limits, countable choice, trichotomy, or open-cover compactness. □

Falsifiable prediction: An accepted $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the Abel boundary row, the Tauberian one-sided tail row, the SummableTailModulus comparison row, and the RegSeqRat readback row refutes the carrier surface.

Independence witness: abel-test, abel-summation, hardy-cesaro-mean, realseries, realpowerseries, summable-tail-modulus, regseqrat, real: no listed sibling supplies the full twelve-row packet $T = (S, P, A, L, U, M, R, E, H, C, Q, N)$, because each sibling contributes only a source, transform, averaging comparison, tail modulus, readback, or seal face while this chapter binds the Abel-limit boundary to the ordinary real-series endpoint in one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HardyLittlewoodTauberian}^{\uparrow}}$.

Constructive story: A $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ packet is generated from real-series source windows, real-power-series radial windows, AbelSummation rows, Abel-limit handoff rows, Tauberian one-sided tail ledgers, SummableTailModulus comparison rows, RegSeqRat readback, a RealUp seal, componentwise hsame transports, Cont replay, Pkg provenance, and local NameCert.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HardyLittlewoodTauberian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1932.1, Definition 1932.2, Definition 1932.3, and Definition 1932.4 seed the finite Abel-limit handoff from constructive real series to a RealUp endpoint.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HardyLittlewoodTauberian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Tauberian theory, quotient series equality, selected limits, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the twelve-row carrier and prove the finite NameCert obligation surface, Abelian boundary theorem, Real seal handoff theorem, and TasteGate field faithfulness for BEDC.Derived.HardyLittlewoodTauberianUp.

Chapter 1933

Located Real NameCert Construction

Following Bishop and Bridges, a located real is represented by certified regular real-name data plus finite dyadic locatedness windows, not by a quotient or classical trichotomy. The $\mathsf{LocatedReal}^{\uparrow}$ chapter records this central L10 object as the public-facing route beneath the interval consumer of chapter 1709, the comparison consumer of chapter 1730, and the tail-envelope consumer of chapter 1769. It is the hyphenated reference point for the same finite route already exposed by chapter 309: $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius ledgers, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Definition 1933.1 (Located real carrier)**.** *A* $\mathsf{LocatedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation schedule that names which regular rational windows are read at a requested precision.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular rational stream, regularity budget, and readback data visible at the scheduled windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger; it stores the dyadic lower endpoint, upper endpoint, radius, and slack data used by the locatedness window.*
4. *E is the located enclosure row, asserting that the scheduled R-windows lie inside the dyadic interval supplied by D at the requested radius.*
5. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row obtained by forgetting only the locatedness enclosure while retaining the same regular real-name source surface.*
6. *H records componentwise* hsame *transport for S, R, D, E, Q and for the structural replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a locatedness request through S, R, D, E, Q, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedReal}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located real-name surface. It contains no Dedekind cut, quotient real, host real equality, trichotomy decision, countable-choice selector, compactness witness, metric-completion object, or bridge credential.

Lean4 ✓ `BEDC.Derived.LocatedRealUp.LocatedRealTasteGate single carrier alignment`

Definition 1933.2 (Located real classifier)**.** *Two accepted* $\mathsf{LocatedReal}^{\uparrow}$ *carriers*

$$L = (S, R, D, E, Q, H, C, P, N)$$

and

$$L' = (S', R', D', E', Q', H', C', P', N')$$

are classified as the same located real exactly when their $\mathsf{StreamName}^{\uparrow}$ *schedules admit a common finite observation window, their* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks agree on that window through the displayed regular rational classifier, their* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledgers refine to a common dyadic enclosure, and the enclosure and* $\mathsf{Real}^{\uparrow}$ *seal rows transport through the same* H, C, P, N *structural route.*

The classifier is therefore common-window regular readback plus dyadic enclosure refinement. It is not quotient equality of real names, host equality of completed reals, trichotomy of endpoints, or a selected representative for the underlying $\mathsf{Real}^{\uparrow}$ *seal.*

Theorem 1933.3 (Located real NameCert obligations)**.** *For every accepted* $\mathsf{LocatedReal}^{\uparrow}$ *carrier* $L = (S, R, D, E, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream schedule, regular rational readback, dyadic endpoint and radius ledger, located enclosure, real seal, transport, replay, provenance, and local naming rows;*
2. *classifier exactness, requiring sameness to be common finite-window agreement of* S, R *together with common dyadic enclosure refinement of* D, E*;*
3. *regular seal compatibility, requiring the* $\mathsf{Real}^{\uparrow}$ *row* Q *to read the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source surface and no extra locatedness-independent representative;*
4. *transport stability, requiring* H *and* C *to preserve the schedule, readback, dyadic ledger, enclosure row, real seal row, provenance, and local name componentwise;*
5. *public-route exhaustion, requiring every downstream* $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, *or* $\mathsf{LocatedRealTailEnvelope}^{\uparrow}$ *consumer to factor through* $S, R, D, E, Q, H, C, P, N$*;*
6. *non-escape, excluding Dedekind cuts, quotient reals, host real equality, trichotomy, countable choice, compactness, metric completion, Lean verification, and bridge checking as local data.*

No located-real obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1933.1. The accepted packet displays exactly the stream schedule, regular rational source, dyadic endpoint and radius ledger, enclosure row, real seal, and structural rows.

Classifier exactness is projection from Definition 1933.2. A comparison of two packets first chooses a common finite window for their $\mathsf{StreamName}^{\uparrow}$ schedules, then compares the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks on that window, and only then refines the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius ledgers.

Regular seal compatibility is the row Q. It forgets the located enclosure but keeps the same regular rational source and scheduled observations, so it cannot introduce a host representative or quotient equality.

Transport and public-route exhaustion are structural. The rows H and C move and replay the displayed packet, while P and N source and name it. Since chapter 1709 and the comparison and tail-envelope consumers cite $\mathsf{LocatedReal}^{\uparrow}$ only through these public rows, no excluded coordinate can be exported. □

Lean4 ✓ `BEDC.Derived.LocatedRealUp.LocatedRealNameCertObligations`

Theorem 1933.4 (Located real regular seal)**.** *Every accepted* $\mathsf{LocatedReal}^{\uparrow}$ *carrier* $L = (S, R, D, E, Q, H, C, P, N)$ *presents its terminal* $\mathsf{Real}^{\uparrow}$ *seal by retaining the scheduled* $\mathsf{RegSeqRat}^{\uparrow}$ *source* R *and the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, while forgetting only the located enclosure row* E *and its dyadic endpoint-radius ledger* D*.*

Conversely, a $\mathsf{Real}^{\uparrow}$ *seal-facing regular source may be equipped with a* $\mathsf{LocatedReal}^{\uparrow}$ *carrier only by adding finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius rows together with an enclosure row over the already displayed* S, R *windows.*

Proof. Read the carrier projection. The $\mathsf{Real}^{\uparrow}$ seal coordinate Q is downstream of the same S and R rows used by the locatedness enclosure, so it sees the scheduled regular rational source before any locatedness row is consulted.

Forgetting D and E leaves S, R, Q, H, C, P, N and therefore preserves the regular real-name surface. The forgotten rows are precisely the dyadic endpoint, radius, and enclosure data.

For the converse, start with a displayed regular seal source S, R, Q and attach a finite $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D plus an enclosure row E for the scheduled observations. Repacking with H, C, P, N yields the carrier of Definition 1933.1; no quotient, trichotomy, or selected completed real is introduced. □

Theorem 1933.5 (Located real transport stability)**.** *Let* $L = (S, R, D, E, Q, H, C, P, N)$ *and* $L' = (S', R', D', E', Q', H', C', P', N')$ *be accepted* $\mathsf{LocatedReal}^{\uparrow}$ *carriers. If* H *records componentwise* hsame *transport from each analytic row of* L *to the corresponding analytic row of* L'*, and the displayed continuations replay the transported rows, then* L' *is accepted by the same located-real classifier route.*

The transported packet reads only the $\mathsf{StreamName}^{\uparrow}$ *schedules,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, enclosure rows,* $\mathsf{Real}^{\uparrow}$ *seals, and the visible* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *provenance.*

Proof. Unpack L through Definition 1933.1. The analytic coordinates are S, R, D, E, Q, and the remaining coordinates only transport, replay, source, and name those rows.

Transport S and R to the scheduled source rows of L'. Transport D and E along the same componentwise route, so the dyadic endpoint and radius ledger still encloses the transported regular rational windows.

The seal row Q transports to Q' by the regular seal statement of Definition 1933.4. Replaying through C', P', N' repacks the accepted carrier, and Definition 1933.2 identifies the classifier route. No unlisted host equality, quotient, or trichotomy row is available during the transport. □

Theorem 1933.6 (Located real public route)**.** *Every downstream consumer of an accepted* $\mathsf{LocatedReal}^{\uparrow}$ *carrier, including the interval consumer of chapter 1709, the comparison consumer of chapter 1730, and the tail-envelope consumer of chapter 1769, receives exactly the public route*

$$S, R, D, E \longmapsto Q \longmapsto H, C, P, N.$$

Thus the consumer can inspect scheduled regular rational windows, dyadic endpoint and radius ledgers, located enclosure data, the regular $\mathsf{Real}^{\uparrow}$ *seal, and the visible provenance rows. It cannot inspect a quotient real, host real equality, trichotomy decision, countable-choice selector, compactness witness, metric-completion object, or bridge credential.*

Proof. Begin with the accepted carrier of Definition 1933.1. Its only analytic rows are the stream schedule S, the regular rational readback R, the dyadic ledger D, the enclosure row E, and the real seal Q.

Apply Definition 1933.4 to bind the seal-facing read to the same S, R source. Apply Definition 1933.5 to show that componentwise movement of the packet remains inside the same displayed carrier route.

The cited interval, comparison, and tail-envelope consumers receive $\mathsf{LocatedReal}^{\uparrow}$ endpoint or source data only through that carrier route. Since the carrier and classifier contain none of the excluded objects, every downstream read is exhausted by $S, R, D, E, Q, H, C, P, N$. $\square$

Chapter 1934

A Concrete Naming Certificate for $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$

Following Bishop and Bridges constructive completion and Bourbaki/Kelley completion terminology, the packet records the finite BEDC certificate for the canonical entry of a displayed source into its Cauchy completion. It sits after the unit route of chapter 1527, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names the entry map as finite NameCert data; it does not assert quotient completion equality, select limits, identify host objects, invoke countable choice, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1934.1 (CauchyCompletionEmbedding carrier)**.** *A* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (X, U, C, S, R, D, E, H, Q, P, N)$$

with the following visible rows:

1. *X is the displayed source row whose point, metric, or regular-Cauchy data are admitted into the completion-facing entry.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route that exposes the source row before any completion seal is read.*
3. *C is the completion seal row recording that the entry is consumed by the Cauchy-completion surface as displayed finite data.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source is observed before tolerance or completion-facing reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by finite consumers of the entry.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds each readback and entry request.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the route through S, R, D has been displayed.*
8. *H records componentwise* hsame *transport for the source row, unit route, completion seal, finite-window row, regular readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay for consumers that inspect the source row, the unit route, the finite readback, or the completion seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or public bridge credentials.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionEmbeddingUp.CauchyCompletionEmbeddingTasteGate single carrier alignment`

Theorem 1934.2 (CauchyCompletionEmbedding NameCert obligations)**.** *For an accepted* CauchyCompletionEmbe *carrier $J = (X, U, C, S, R, D, E, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source row, unit route, completion seal, finite-window row, regular readback, dyadic ledger, Real seal, componentwise transport, replay, provenance, and local naming rows;*
2. *entry exposure, requiring every completion-facing consumer to read X through U before the completion seal C is available;*
3. *finite-window locality, requiring the source observation to pass through S before R, D, E or C can be inspected;*
4. *tolerance and readback exactness, requiring each finite precision request to be answered by D and then R before the terminal seal or completion seal is consumed;*
5. *classifier stability, requiring transported packets with the same displayed X, U, C, S, R, D, E route to be identified by the carried* hsame *and* Cont *data;*
6. *ledger non-escape, stating that the packet exports no quotient completion equality, selected limit, host equality, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Carrier admission is projection from Definition 1934.1. The tuple lists exactly the source, unit, completion seal, finite-window, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows.

Entry exposure is constructive because the unit route U is the only row connecting X to the completion seal C. A consumer starting from the source has no detached completion point to inspect; it must first read the displayed unit route.

Finite-window locality then projects S. The regular readback R, the dyadic ledger D, the Real seal E, and the completion seal C all occur after the finite source observation, so no later row can be consumed before the window row is present.

Tolerance and readback exactness use D and R. Each finite request is bounded by the dyadic ledger and read back as regular rational data before either seal is exposed.

Classifier stability is componentwise transport along H followed by replay through Q. Since the carrier fields are exhausted by $X, U, C, S, R, D, E, H, Q, P, N$, the excluded quotient, selected-limit, host-equality, choice, ambient-completeness, real-completeness, and bridge data have no row from which a consumer could read them. □

Theorem 1934.3 (CauchyCompletionEmbedding density handoff)**.** *Let $J = (X, U, C, S, R, D, E, H, Q, P, N)$ be an accepted* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ *carrier. Every density, functoriality, reflector, or*

universal-property consumer of the source-to-completion entry factors through the finite route

$$X \longmapsto U \longmapsto S \longmapsto D, R \longmapsto E \longmapsto C \longmapsto H, Q, P, N.$$

The handoff uses only finite windows and regular readback. It is not equality of quotient completions, not a selected limit, not host equality, and not an appeal to countable choice or ambient completeness.

Proof. Start with a consumer of the entry packet. Projection gives the displayed source row X, and the only completion-facing admission row available from X is the unit route U.

The consumer must next read the finite window row S. This keeps the handoff local to a bounded observation of the source before any regular readback, dyadic tolerance ledger, Real seal, or completion seal is exposed.

The tolerance and readback rows D and R answer the finite request. The terminal real-facing boundary E is reached only after that regular route has been displayed, and the completion seal C consumes the same finite route as the entry map.

Transport by H and replay by Q preserve this route for equivalent packets, while P and N record provenance and local naming. No carrier coordinate exists for quotient equality, selected limits, host equality, countable choice, or ambient completeness, so downstream density and universal-property consumers receive only the finite handoff described above. □

Theorem 1934.4 (CauchyCompletionEmbedding Real seal non-escape)**.** *For an accepted* CauchyCompletionEmbed *carrier $J = (X, U, C, S, R, D, E, H, Q, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read exported by J is generated by the rows named in Definition 1934.1. In particular, the Real seal cannot be used as a detached completed point, quotient-completion equality witness, selected limit, host equality witness, countable-choice selection, or ambient completeness witness.*

Proof. Project the accepted carrier. A $\mathsf{Real}^{\uparrow}$-facing read must pass through S, D, R, E, because those are the only finite observation, tolerance, readback, and terminal seal rows in the tuple.

A completion-facing read must also pass through U and C. The unit route records the source entry before the completion seal is consumed, and the completion seal is stored as displayed NameCert data rather than as a quotient point, selected limit, or host equality witness.

The structural rows H, Q, P, N transport, replay, source, and name the same route. They add no carrier coordinate beyond the listed rows.

Thus every exported read is generated by Definition 1934.1. The forbidden quotient, selected-limit, host-equality, choice, ambient-completeness, real-completeness, and bridge data are absent from the carrier and cannot be produced by projection, transport, replay, provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ packet is generated from a displayed source row, a CauchyCompletionUnit route, a completion seal, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerances, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 1934.1, Definition 1934.2, Definition 1934.3, and Definition 1934.4 seed the finite source-to-completion entry surface for L10 completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, entry exposure, finite-window locality, tolerance exactness, readback exactness, classifier stability, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionEmbeddingUp.

Chapter 1935

A Concrete Naming Certificate for $\mathsf{LocatedRegularization}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedRegularization}^{\uparrow}$ packet records the finite boundary where a Cauchy stream is regularized while retaining positive locatedness and apartness evidence. It sits after the regularization route of chapter 376, the positive apartness boundary of chapter 1881, the Real-facing Cauchy readiness surface of chapter 1590, the finite windows of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later Real and completion chapters one finite route from source Cauchy data to located regular names; it is not a quotient stream, not a selected limit, not a trichotomy decision, not countable choice, not ambient $\mathsf{Real}^{\uparrow}$ completeness, and not bridge checking.

Definition 1935.1 (LocatedRegularization carrier)**.** *A* $\mathsf{LocatedRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, M, A, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy stream row before regularization or locatedness evidence is read.*
2. *M is the modulus-threshold row consumed from the* $\mathsf{CauchyRegularization}^{\uparrow}$ *route.*
3. *A is the positive located/apartness row consumed from the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *boundary.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule through which the source stream and apartness row are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff obtained from the scheduled windows and the modulus threshold.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, slack rows, and comparison tolerances used by the located window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the regularized name after W, R, D and the positive row A have been displayed.*
8. *H records componentwise* hsame *transports for S, M, A, W, R, D, E and for the structural replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each located regularization request through $S, M, A, W, R, D, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRegularization}^{\uparrow}$, $\mathsf{CauchyRegularization}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularization}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located regularization surface. It contains no quotient stream, selected limit, trichotomy decision, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness witness, or bridge credential.*

Lean4 ✓ `BEDC.Derived.LocatedRegularizationUp.LocatedRegularizationTasteGate single carrier alignment`

Theorem 1935.2 (LocatedRegularization NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRegularization}^{\uparrow}$ *carrier* $L = (S, M, A, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy stream, modulus threshold, positive located/apartness row, finite windows, regular rational handoff, dyadic tolerance ledger, Real seal, transports, replay, provenance, and local naming rows;*

2. *located-window compatibility, requiring each positive locatedness read to inspect S only through the* $\mathsf{StreamName}^{\uparrow}$ *schedule W and the dyadic ledger D before R or E can be consumed;*

3. *apartness preservation, requiring the positive row A to remain attached to the same scheduled regularization route S, M, W, R, D under componentwise* hsame *transport and displayed* Cont *replay;*

4. *Real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$*-facing read of E to pass through the displayed regularization, window, readback, tolerance, and positive-apartness rows rather than through a detached completed real;*

5. *provenance exhaustion, requiring every downstream Real, completion, Cauchy-criterion, or apartness consumer to read only $S, M, A, W, R, D, E, H, C, P, N$ and no quotient stream, selected limit, trichotomy, countable-choice source, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or bridge credential.*

No located-regularization obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1935.1. The accepted packet lists the source stream, modulus threshold, positive located/apartness row, finite window schedule, regular rational handoff, dyadic tolerance ledger, Real seal, and structural rows.

For located-window compatibility, read the row order in the carrier. The positive row A is not exported directly to a Real-facing consumer; it is inspected through the same finite window schedule W and the same dyadic ledger D that feed the regular rational handoff R.

Apartness preservation follows by row-order induction along the transported packet. The base step preserves S, M, A by the corresponding coordinates of H, and the window, handoff, tolerance, and seal steps replay those transported rows through C without changing the positive apartness source.

Real-seal nonescape is the terminal-row clause. The seal E appears only after W, R, D and A have been displayed, so a consumer cannot obtain a detached completed real, selected limit, quotient representative, or ambient completeness witness by projecting E.

Finally, provenance exhaustion is projection from P and N together with the absence of further carrier coordinates. Since L has only the rows $S, M, A, W, R, D, E, H, C, P, N$, downstream Cauchy-criterion, apartness, Real, and completion consumers receive exactly that finite route and no excluded bridge or choice data. □

Theorem 1935.3 (LocatedRegularization real-seal factorization)**.** *For every accepted* $\mathsf{LocatedRegularization}^{\uparrow}$ *carrier* $L = (S, M, A, W, R, D, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing read of the terminal seal* E *factors through the displayed finite row sequence*

$$S \longrightarrow M \longrightarrow A \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow E$$

together with the componentwise transport, replay, provenance, and local naming rows H, C, P, N*. Thus the seal can be consumed only after the source Cauchy stream* S*, the* $\mathsf{CauchyRegularization}^{\uparrow}$ *modulus threshold* M*, the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *positive row* A*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D *have all been displayed on the same carrier route. The factorization provides no quotient stream, selected limit, trichotomy decision, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness, or bridge credential.*

Proof. Project the accepted carrier to the row list of Definition 1935.1. The seal coordinate E is not a standalone Real object in that list; it is the terminal row following the source stream, regularization threshold, positive apartness row, finite windows, regular rational handoff, and dyadic tolerance ledger.

Next inspect the local obligation surface of Definition 1935.2. Located-window compatibility forces the positive row A to be read through W and D, apartness preservation keeps A attached to the route S, M, W, R, D under H and C, and the Real-seal nonescape row requires every $\mathsf{Real}^{\uparrow}$ consumer of E to use that same displayed route.

It remains only to exclude alternate exits. The carrier has no coordinates for quotient streams, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge credentials, and provenance exhaustion says that downstream Real and completion consumers may read only $S, M, A, W, R, D, E, H, C, P, N$. Therefore every accepted seal read factors through the stated finite rows before reaching E. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRegularization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRegularization}^{\uparrow}$ packet is generated from a source Cauchy stream, a CauchyRegularization modulus threshold, a CauchyRealApartness positive row, StreamName finite windows, RegSeqRat handoff, DyadicRatCore tolerance rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRegularization}^{\uparrow}}$, seed)

Scope closed: Definition 1935.1, Definition 1935.2, and Definition 1935.3 seed the finite located regularization boundary between Cauchy regularization, positive apartness, Real Cauchy readiness, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRegularization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window compatibility, apartness preservation, provenance exhaustion, and a Lean carrier/obligation formalization for BEDC.Derived.LocatedRegularizationUp.

Chapter 1936

A Concrete Naming Certificate for $\mathsf{GrzegorczykReal}^{\uparrow}$

Following Grzegorczyk's computable-real presentation and Weihrauch-style represented-space terminology, the $\mathsf{GrzegorczykReal}^{\uparrow}$ packet records the effective real-name boundary where a displayed algorithmic approximant is read through finite windows before it reaches the terminal real seal. It sits over the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the computable-real service boundary of chapter 336, the terminal real-name seal of chapter 38, and the noncomputable contrast supplied by chapter 1406. The packet names an effective route from approximant data to a $\mathsf{Real}^{\uparrow}$ consumer; it is not quotient stream equality, a completed real selected by choice, a host-real comparison, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 1936.1 (Grzegorczyk real carrier)**.** *A* $\mathsf{GrzegorczykReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the effective approximant row, recording the finite program, request precision, and rational output cell presented in Grzegorczyk's computable-real format.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which the approximant is inspected at the requested precisions.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording dyadic radii, slack comparisons, and finite error budgets attached to the approximant windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled windows and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reachable only after the effective approximant, finite windows, dyadic ledger, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for A, S, D, R, E and for the structural replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each effective real-name request through the route*

$$A \longmapsto S \longmapsto D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{GrzegorczykReal}^{\uparrow}$, $\mathsf{ComputableReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GrzegorczykReal}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite effective real-name surface. It contains no quotient stream equality, selected limit, host real comparison, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness witness, or bridge credential.*

Lean4 ✓ `BEDC.Derived.GrzegorczykRealUp.TasteGate.GrzegorczykRealTasteGate single carrier alignment`

Theorem 1936.2 (Grzegorczyk real NameCert obligations)**.** *For every accepted* $\mathsf{GrzegorczykReal}^{\uparrow}$ *carrier $G = (A, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GrzegorczykReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the effective approximant, finite StreamName windows, dyadic tolerance ledger, regular rational readback, terminal Real seal, transports, replay, provenance, and local naming rows;*
2. *modulus-window exactness, requiring each precision request made by the effective approximant row A to be witnessed by the finite window row S before R or E can be consumed;*
3. *dyadic tolerance stability, requiring the ledger D to preserve the displayed error budget for every transported approximant window and every regular readback cell;*
4. *RegSeqRat handoff, requiring R to be the only route by which the effective approximant windows become a regular rational real name;*
5. *RealUp seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer of E to pass through A, S, D, R and the structural rows H, C, P, N rather than through quotient equality, a selected limit, countable choice, a host real, or ambient completeness.*

No Grzegorczyk-real obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1936.1. The accepted packet lists exactly the effective approximant, finite windows, dyadic ledger, regular readback, terminal seal, and structural rows.

For modulus-window exactness, read the carrier route from A to S. A precision request in A is not exported directly; it is witnessed by the finite $\mathsf{StreamName}^{\uparrow}$ window row S before any regular readback or Real-facing seal can be inspected.

Dyadic tolerance stability is the next coordinate of the route. The ledger D stores the radii and slack comparisons attached to each displayed window, and the transport row H preserves those cells componentwise while C replays the same finite path.

The RegSeqRat handoff is then forced by row order. The row R appears after the window and tolerance data and before the seal, so a consumer cannot treat the approximant stream as a real name without passing through the regular rational readback.

Finally, RealUp seal non-escape follows from terminality of E and provenance exhaustion in P, N. Since the carrier has no further coordinates, every $\mathsf{Real}^{\uparrow}$ consumer factors through $A, S, D, R, E, H, C, P, N$ and receives no quotient stream equality, selected limit, countable-choice source, host real comparison, ambient completeness principle, or bridge credential. □

Theorem 1936.3 (Grzegorczyk real stream-real seal factorization)**.** *For every accepted* $\mathsf{GrzegorczykReal}^{\uparrow}$ *carrier $G = (A, S, D, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$ *consumer of the seal E factors through the displayed effective approximant, finite stream window, dyadic tolerance, regular readback, and seal*

rows:

$$A \longmapsto S \longmapsto D \longmapsto R \longmapsto E.$$

In particular the consumer cannot bypass the $\mathsf{ComputableReal}^{\uparrow}$ *approximant row, cannot replace* S *by a quotient stream, cannot replace* R *by a selected limit, and cannot read* E *as an ambient completeness witness.*

Proof. Start with a seal-facing request. Carrier projection exposes E only as the terminal coordinate of the displayed Grzegorczyk-real route, not as an independently completed real object.

Trace the route backward from E. The seal is downstream of R, the regular readback is downstream of the dyadic tolerance ledger D, and the ledger is attached to finite windows S requested by the effective approximant row A.

The structural rows preserve this route. Componentwise hsame transport in H keeps the same approximant, window, tolerance, readback, and seal coordinates, while the Cont replay row C records that each consumer request follows the same finite path.

The provenance and local naming rows P, N name no additional real-completion principle. Thus every seal consumer factors through A, S, D, R, E together with H, C, P, N, and no excluded quotient, selection, host-real, countable-choice, ambient-completeness, or bridge route is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{GrzegorczykReal}\uparrow}$.

Constructive story: A $\mathsf{GrzegorczykReal}^{\uparrow}$ packet is generated from an effective approximant row, finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GrzegorczykReal}\uparrow}$, seed)

Scope closed: Definition 1936.1, Definition 1936.2, and Definition 1936.3 seed the effective real-name boundary between computable approximants, finite stream windows, regular rational readback, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GrzegorczykReal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real comparison, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-window exactness, dyadic tolerance stability, RegSeqRat handoff, RealUp seal non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.GrzegorczykRealUp.

Chapter 1937

A Concrete Naming Certificate for $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane's functorial language, the $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ packet records the finite BEDC surface by which a uniformly continuous map between displayed sources induces a map between their Cauchy-completion seals. It reads the unit route of chapter 1527, the adjunction ledger of chapter 1456, the extension handoff of chapter 769, and the separated uniqueness boundary of **??**. The chapter names only the finite NameCert boundary for this functorial action; it does not identify quotient completions, choose representatives, or assert host equality of completed spaces.

Definition 1937.1 (CauchyCompletionFunctoriality carrier)**.** *A* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, f, E, U, I, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source completion row, including the displayed source object, its Cauchy-completion seal, and the unit route consumed before any completed read is available.*
2. *T is the target completion row, including the displayed target object, its Cauchy-completion seal, and the matching unit route.*
3. *f is the uniformly continuous source-map row, carrying the finite modulus and graph evidence used before completion-facing extension.*
4. *E is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *row that extends f from the dense source route into the target completion seal.*
5. *U is the* $\mathsf{CompletionExtensionUniqueness}^{\uparrow}$ *row comparing any two extension candidates after agreement on the dense source and target completion rows.*
6. *I is the identity ledger, recording that the source identity map extends through the same unit and adjunction rows to the identity completed read.*
7. *L is the composition ledger, recording that two composable source-map rows extend in the same order as their source-side composition.*
8. *H records componentwise* hsame *transport for the source completion row, target completion row, source-map row, extension row, uniqueness row, identity ledger, composition ledger, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the route*

$$S, T, f \longmapsto E \longmapsto U \longmapsto I, L.$$

10. *P is the* Pkg *provenance over* CauchyCompletionFunctoriality$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionAdjunc UniformContinuousExtension$^{\uparrow}$, CompletionExtensionUniqueness$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyCompletionFunctoriality}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed spaces, open-cover compactness, or completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionFunctorialityUp.CauchyCompletionFunctorialityTasteGate`
`single carrier alignment`

Theorem 1937.2 (CauchyCompletionFunctoriality NameCert obligations)**.** *For every accepted* CauchyCompletionFunctoriality$^{\uparrow}$ *carrier*

$$F = (S, T, f, E, U, I, L, H, C, P, N),$$

the local NameCert$_{\text{CauchyCompletionFunctoriality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source completion row, target completion row, uniformly continuous source-map row, extension row, uniqueness row, identity ledger, composition ledger, componentwise transport, replay, provenance, and local naming row;*
2. *unit compatibility, requiring both completion rows to expose their dense source routes before an extended completed-map read is available;*
3. *extension exactness, requiring the row E to be the only completion-facing route generated from the uniformly continuous source-map row f;*
4. *uniqueness determinacy, requiring any two extension candidates over the same dense route to be compared only through the row U;*
5. *identity replay, requiring the identity source-map row to pass through the same unit and adjunction rows before the identity completed read is named by I;*
6. *composition replay, requiring composable source-map rows to pass through the same extension and uniqueness surfaces before the composed completed read is named by L;*
7. *ledger non-escape, requiring H, C, P, N to expose no quotient completion equality, selected representatives, countable-choice schedule, host equality of completed spaces, open-cover compactness, or completeness of* Real$^{\uparrow}$.

Proof. Carrier admission is projection from Definition 1937.1. The accepted packet displays exactly the source completion row, target completion row, uniformly continuous source-map row, extension row, uniqueness row, identity ledger, composition ledger, and structural rows.

Unit compatibility is read from S and T. Each completed read begins with the corresponding source-side unit route, so no completed-map row can be inspected before the dense source and target routes have been displayed.

Extension exactness is the projection to f and E. The source map is uniformly continuous by the carried finite modulus and graph evidence, and the only completion-facing image row generated from it is the UniformContinuousExtension$^{\uparrow}$ surface named by E.

Uniqueness determinacy is the projection to U. When two candidates agree on the displayed dense source route and target completion route, the packet compares them through the separated completion-extension uniqueness surface rather than through host function equality.

Finally, identity and composition are finite replay obligations. The rows I and L reuse the same unit and adjunction coordinates already present in S, T, E, U, while H, C, P, N preserve only those displayed coordinates under componentwise transport, replay, provenance, and local naming. Since no excluded principle is a carrier coordinate, the seven obligation rows exhaust the local NameCert surface. □

Theorem 1937.3 (CauchyCompletionFunctoriality map route)**.** *Let*

$$F = (S, T, f, E, U, I, L, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *carrier. Every completed-map read induced by the uniformly continuous source-map row f factors through the finite route*

$$S, T, f \longmapsto E \longmapsto U \longmapsto H, C, P, N.$$

The route uses the existing uniform-continuous extension surface for existence and the completion-extension uniqueness surface for determinacy. It does not use quotient completion equality, selected representatives, countable choice, host equality of completed spaces, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with a completed-map consumer. Projection gives the source and target completion rows S, T and the uniformly continuous source-map row f.

The map route then enters the extension surface. The row E is the only coordinate that turns the source-map evidence into a completion-facing target read, so the consumer must pass through the $\mathsf{UniformContinuousExtension}^{\uparrow}$ handoff before it can read the completed map.

Determinacy is supplied by U. If a second candidate is presented over the same dense source route and target completion row, the comparison is routed through $\mathsf{CompletionExtensionUniqueness}^{\uparrow}$ and not through equality of host functions or completed spaces.

Transport and naming close the finite route. The componentwise hsame ledger H, the displayed Cont replay C, the provenance row P, and the local naming row N preserve the same map route and add no coordinate for any excluded completion or choice principle. □

Theorem 1937.4 (CauchyCompletionFunctoriality composition)**.** *For accepted* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *carriers over composable uniformly continuous source-map rows, the completed read of the composite source map is named by replaying the same unit, adjunction, extension, and uniqueness rows used for the two component maps. The identity source map is named by the same replay with the identity ledger I, and the composite source map is named by the composition ledger L.*

Proof. For identity, project the carrier and read the ledger I. The source identity row first passes through the unit route in the source completion row, then through the adjunction-facing completion route, and then through the extension row E. The uniqueness row U identifies the resulting completed read with the identity completed read carried by I.

For composition, apply the same projection to the composable source-map rows. Each component map is extended through its own displayed E row, and the composite source-map row is then extended through the same uniform-continuous extension surface. The ledger L records that these two completion-facing routes are compared only by the shared completion-extension uniqueness row.

The componentwise transport row H and replay row C preserve the identity and composition ledgers under accepted carrier comparison. Provenance P and local naming N therefore expose a functorial completed-map surface without exporting quotient completion equality, selected representatives, countable choice, host equality of completed spaces, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctoriality}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ packet is generated from source and target completion rows, a uniformly continuous source-map row, a UniformContinuousExtension handoff, a CompletionExtensionUniqueness ledger, identity and composition ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctoriality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1937.1, Definition 1937.2, Definition 1937.3, and Definition 1937.4 seed the finite functorial action surface for Cauchy completion on uniformly continuous maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionFunctoriality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed spaces, open-cover compactness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit compatibility, extension exactness, uniqueness determinacy, identity replay, composition replay, and ledger non-escape for BEDC.Derived.CauchyCompletionFunctorialityUp.

Chapter 1938

A Concrete Naming Certificate for $\mathsf{IntervalLength}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{IntervalLength}^{\uparrow}$ packet names the finite diameter data of a closed interval before any appeal to compactness, selected endpoints, or completed real equality. It sits after the dyadic arithmetic surface of chapter 291, the endpoint window interfaces of chapter 306 and chapter 354, and the real-window enclosure route of chapter 1625. Downstream uses in chapter 38 read only this finite diameter certificate when a $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ argument needs the length of an interval window.

Definition 1938.1 (IntervalLength carrier)**.** *An* $\mathsf{IntervalLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, O, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left endpoint row, accepted either as a* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint projection or as a* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint row.*
2. *R is the right endpoint row, accepted through the same endpoint surface as L.*
3. *O is the endpoint-order ledger proving that the displayed left row precedes the displayed right row in the corresponding finite rational or dyadic comparison surface.*
4. *D is the dyadic diameter row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *row naming the finite value read as $R - L$ on the common endpoint window.*
5. *E is the real-interval enclosure handoff row, linking the same endpoint and diameter data to the finite enclosure surface of chapter 1625.*
6. *H records componentwise* hsame *transport for the endpoint rows, order ledger, diameter row, enclosure handoff, continuation row, provenance row, and local naming row.*
7. *C records the* Cont *replay by which a later finite consumer reads the same endpoint, order, diameter, and enclosure rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalLength}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these nine rows form one finite interval-length packet. It has no coordinate for open-cover compactness, selected endpoints, quotient real equality, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.IntervalLengthUp.IntervalLengthUpTasteGate single carrier alignment`

Theorem 1938.2 (IntervalLength NameCert obligations)**.** *For every accepted* $\mathsf{IntervalLength}^{\uparrow}$ *carrier* $I = (L, R, O, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalLength}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two endpoint rows, endpoint-order ledger, dyadic diameter row, enclosure handoff, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *endpoint-order exposure, requiring every length read to display the same* O *row that certifies the endpoint orientation;*
3. *diameter exactness, requiring* D *to be the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *subtraction row* $R - L$ *on the common endpoint window;*
4. *enclosure handoff, requiring* E *to route the same endpoints and diameter into the finite real-interval enclosure surface;*
5. *classifier transport, requiring* H *to transport endpoint, order, diameter, enclosure, provenance, and naming rows componentwise;*
6. *replay stability, requiring* C *to replay the same finite rows for later* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers;*
7. *provenance exhaustion, requiring* P *to name every consumed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*, and* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *source row;*
8. *ledger non-escape, excluding any read through open-cover compactness, selected endpoint choice, quotient real equality, trichotomy, or ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 1938.1. The projection exposes exactly two endpoint rows, one endpoint-order ledger, one dyadic diameter row, one enclosure handoff, and the structural rows H, C, P, N.

Endpoint-order exposure is the row O. Since the carrier stores D next to O, a consumer cannot read a length without also reading the finite orientation ledger for the same endpoint window.

Diameter exactness is the row D. It is typed as a $\mathsf{DyadicRatCore}^{\uparrow}$ subtraction row on the displayed endpoint surface, so the value read by a consumer is the finite dyadic difference $R - L$ and not a host metric length.

The handoff row E is then read through the real-interval enclosure surface. Transport by H and replay by C preserve the same endpoint, order, diameter, and enclosure rows componentwise.

Finally, P and N exhaust provenance and naming. Because the carrier has no coordinate for open-cover compactness, selected endpoints, quotient real equality, trichotomy, or ambient completeness, the listed non-escape conditions are immediate from the packet inventory. □

Theorem 1938.3 (IntervalLength dyadic diameter handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntervalLength}^{\uparrow}$ *packet reads the interval diameter only through the displayed route*

$$L, R, O \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

The route factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. It does not expose an ambient metric length, a selected endpoint pair, quotient equality of real names, trichotomy, open-cover compactness, or a completeness witness.*

Proof. Start with an accepted carrier $I = (L, R, O, D, E, H, C, P, N)$. The only endpoint coordinates are L and R, and the only orientation coordinate attached to them is O.

The diameter coordinate is D. By Definition 1938.1, D is a displayed $\mathsf{DyadicRatCore}^{\uparrow}$ row computed from the same endpoint window, so every diameter read first factors through the finite dyadic arithmetic surface.

The enclosure handoff is E. It routes the same endpoint and diameter rows into the finite real-interval enclosure packet, which is the only surface available to a $\mathsf{Real}^{\uparrow}$ consumer at this boundary.

Finally H, C, P, N package transport, replay, provenance, and local naming. Thus a $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ consumer receives exactly the displayed BEDC rows and no ambient metric length, selected endpoint pair, quotient real equality, trichotomy, compactness theorem, or completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalLength}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalLength}^{\uparrow}$ packet is generated from displayed left and right endpoint rows, an endpoint-order ledger, a dyadic diameter row, a real-interval enclosure handoff, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntervalLength}^{\uparrow}}$, seed)

Scope closed: Definition 1938.1, Definition 1938.2, and Definition 1938.3 seed the finite interval-diameter surface used by DyadicRatCore, DyadicInterval, RationalInterval, RealIntervalEnclosure, RegSeqRat, and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntervalLength}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected endpoints, quotient real equality, trichotomy, ambient completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order exposure, diameter exactness, enclosure handoff, classifier transport, replay stability, provenance exhaustion, and ledger non-escape proofs for BEDC.Derived.IntervalLengthUp.

Chapter 1939

A Concrete Naming Certificate for $\mathsf{FejerKernel}^{\uparrow}$

Following Fejer's positive summability kernels and the classical accounts of Zygmund and Katznelson, the $\mathsf{FejerKernel}^{\uparrow}$ packet records the finite Fourier kernel that averages symmetric coefficient windows before any constructive approximation theorem consumes a uniform-limit handoff. It sits over the finite Fourier observation interface of chapter 124, the circle source of chapter 58, the real-analytic trigonometric rows of chapter 74, the normalization route of chapter 123, and the approximation-facing boundary of chapter 463. The chapter names a positive finite kernel object; it does not import Haar measure, quotient function spaces, host Fourier convergence, or a completed approximation theorem.

Definition 1939.1 (Fejer kernel carrier)**.** *A* $\mathsf{FejerKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, S, A, I, U, P, T, C, Q, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row, recording the symmetric window, triangular weights, endpoint truncation bound, and finite coefficient probes used by the kernel.*
2. *S is the* $\mathsf{S}^{1\uparrow}$ *phase-sample row, exposing only displayed circle samples and their componentwise classifier data.*
3. *A is the* $\mathsf{RealAnalytic}^{\uparrow}$ *sine/cosine polynomial row, presenting the trigonometric polynomial determined by F and S as finite real-analytic algebra data.*
4. *I is the* $\mathsf{Integral}^{\uparrow}$ *normalization witness, recording the displayed integral row that makes the kernel total mass equal to the certified unit.*
5. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row available to later approximation packets after the finite kernel and its normalization have been exposed.*
6. *P is the positivity ledger, listing the square-modulus presentation, nonnegative coefficient witnesses, finite averaging denominator, and nonnegative-kernel stability entries used by the carrier.*
7. *T records componentwise* hsame *transport for coefficient windows, phase samples, trigonometric polynomial rows, integral witnesses, uniform-limit handoff rows, positivity ledgers, continuation replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a phase and coefficient-window request through F, S, A, P, then through I to the normalized kernel and through U to the approximation-facing handoff.*
9. *Q is the* Pkg *provenance over* $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{RealAnalytic}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FejerKernel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, S, A, I, U, P, T, C, Q, N$. It has no coordinate for Haar measure, an ambient quotient of functions, host-level almost-everywhere equality, or an external Fourier convergence principle.

Lean4 ✓ `BEDC.Derived.FejerKernelUp.FejerKernelTasteGate single carrier alignment`

Theorem 1939.2 (Fejer kernel NameCert obligations)**.** *For every accepted* $\mathsf{FejerKernel}^{\uparrow}$ *carrier $K = (F, S, A, I, U, P, T, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FejerKernel}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the displayed Fourier coefficient-window, circle phase-sample, real-analytic polynomial, integral-normalization, uniform-limit handoff, positivity-ledger, transport, continuation, provenance, and naming rows;*
2. *classifier transport, requiring* hsame *comparison to move componentwise through $F, S, A, I, U, P, T, C, Q, N$ without replacing the displayed finite kernel by host function equality;*
3. *finite positivity and nonnegative-kernel stability, requiring the square-modulus presentation and triangular-weight ledger in P to be preserved by the displayed finite algebra rows;*
4. *integral-normalization handoff, requiring the unit-mass witness in I to be read before any* $\mathsf{UniformLimit}^{\uparrow}$ *approximation consumer receives the handoff row U;*
5. *ledger non-escape, requiring every coefficient window, phase sample, sine/cosine polynomial row, normalization witness, positivity entry, transport row, continuation replay, and provenance row to remain inside the same finite packet.*

These obligations certify a positive finite summability kernel over the named source rows, not a host convergence theorem.

Proof. Project the carrier of Definition 1939.1. Carrier admission is exactly the finite inventory $F, S, A, I, U, P, T, C, Q, N$, so the certificate has no hidden coordinate for a completed function space, a Haar-measure object, or an external convergence theorem.

Classifier transport is componentwise. The $\mathsf{Fourier}^{\uparrow}$ row transports coefficient windows, the $\mathsf{S}^{1\uparrow}$ row transports phase samples, the $\mathsf{RealAnalytic}^{\uparrow}$ row transports the sine/cosine polynomial data, the $\mathsf{Integral}^{\uparrow}$ row transports the normalization witness, and the $\mathsf{UniformLimit}^{\uparrow}$ row transports only the handoff exposed by the earlier rows.

The positivity clause is read from the displayed ledger P. The square-modulus presentation and triangular weights are finite trigonometric-polynomial algebra data, so nonnegativity is stable under the same componentwise transport that preserves F, S, A.

The integral-normalization handoff is then forced through I. A later approximation packet may read U only after the normalization row has displayed the unit-mass witness for the same finite kernel.

Finally, T, C, Q, N preserve, replay, source, and name exactly the displayed route. Since every analytic datum used by the kernel has already appeared in the carrier rows, the ledger cannot be used to recover an unrecorded measure, quotient, or convergence principle. □

Falsifiable prediction: Every $\mathsf{FejerKernel}^{\uparrow}$ approximation-facing read factors through Fourier coefficient windows, SOne phase samples, RealAnalytic sine/cosine polynomial rows, an Integral normalization witness, a UniformLimit handoff, a positivity ledger, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fourier, s1, real-analytic, integral, uniformlimit: $\mathsf{FejerKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries triangular Fourier coefficient windows, circle phase samples, real-analytic trigonometric polynomial rows, integral normalization, uniform-limit handoff, positivity ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FejerKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{FejerKernel}^{\uparrow}$ packet is generated from finite Fourier coefficient windows with triangular weights, displayed $\mathsf{S}^{1\,\uparrow}$ phase samples, $\mathsf{RealAnalytic}^{\uparrow}$ sine/cosine polynomial rows, an $\mathsf{Integral}^{\uparrow}$ normalization witness, a $\mathsf{UniformLimit}^{\uparrow}$ handoff row, a positivity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FejerKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1939.1 and Definition 1939.2 seed the finite positive summability-kernel route from Fourier coefficient windows to constructive approximation-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FejerKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Haar measure, quotient function spaces, host Fourier convergence, pointwise convergence, uniform convergence of Fourier means, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite positivity stability, integral-normalization handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.FejerKernelUp.

Chapter 1940

A Concrete Naming Certificate for $\mathsf{Parseval}^{\uparrow}$

Following Parseval's identity in Fourier analysis, the $\mathsf{Parseval}^{\uparrow}$ packet records only the finite energy-identity surface that can be inspected before any Plancherel, inversion, or convergence theorem is claimed. It sits over the finite Fourier observation layer of chapter 124, the circle source of chapter 58, the pairing row of chapter 86, the integral energy row of chapter 123, and the real seal of chapter 38. The certificate names the displayed equality between finite coefficient energy ledgers and finite integral-energy ledgers; it does not identify host functions or complete a quotient coefficient space.

Definition 1940.1 (Parseval carrier)**.** *A* $\mathsf{Parseval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, S, I, E, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row, listing the finite modes, coefficient probes, truncation window, and coefficient-energy sums under inspection.*
2. *S is the* $\mathsf{S}^{1\uparrow}$ *source row, exposing only the circle phase samples and classifier data used by the Fourier observations.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row, recording the finite pairing witnesses that compare coefficient rows and source rows.*
4. *E is the* $\mathsf{Integral}^{\uparrow}$ *energy row, storing the displayed integral-energy observation paired with the same finite source window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the coefficient-energy sums and the integral-energy observation.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for finite summation, pairing, integral readback, and energy-comparison tolerances.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Fourier window, circle source, inner-product pairing, integral-energy row, regular readback, and dyadic tolerance ledger have all been displayed.*
8. *H stores componentwise* hsame *transport for the coefficient windows, circle source, pairing row, integral-energy row, readback row, tolerance ledger, real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from coefficient-window requests through F, S, I, E, R, D and then to the* $\mathsf{Real}^{\uparrow}$ *seal L.*
10. *P is the* Pkg *provenance over* $\mathsf{Parseval}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, S, I, E, R, D, L, H, C, P, N$. It has no coordinate for a host Fourier transform, completed Hilbert space, quotient coefficient class, selected limit, pointwise equality of functions, or ambient Plancherel theorem.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalTasteGate single carrier alignment`

Theorem 1940.2 (Parseval NameCert obligations)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier $K = (F, S, I, E, R, D, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Fourier coefficient-window,* $\mathsf{S}^{1\uparrow}$ *source,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing,* $\mathsf{Integral}^{\uparrow}$ *energy,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *coefficient-window exactness, requiring every coefficient-energy read to be attached to the modes and probes displayed in F and to the source row S;*
3. *finite partial-energy ledger accounting, requiring the coefficient-energy sum and the pairing witnesses in I to be read before the integral row is compared;*
4. *integral-energy handoff, requiring E to consume the same finite source and pairing rows before any real-facing energy comparison reaches L;*
5. *dyadic tolerance accounting, requiring D to record the finite summation, pairing, integral readback, and comparison tolerances used by the energy identity surface;*
6. *Real seal non-escape, requiring L to seal only the displayed energy comparison and not a host function equality or completed norm equality;*
7. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

These obligations certify only the finite Parseval energy-identity surface over the named source rows. They do not close Plancherel, inversion, convergence, Hilbert-space completeness, host function equality, quotient coefficient spaces, or Lean verification.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalNameCertObligations`

Proof. Project the carrier of Definition 1940.1. Carrier admission is exactly the finite inventory $F, S, I, E, R, D, L, H, C, P, N$, so no hidden analytic coordinate is available.

Coefficient-window exactness is read from F together with the $\mathsf{S}^{1\uparrow}$ source row S. The pairing row I and integral row E then compare only the displayed finite energy observations, while R and D expose the regular readback and dyadic tolerance ledger used for that comparison.

The $\mathsf{Real}^{\uparrow}$ seal L is downstream of those rows. Thus the endpoint is a seal for the finite energy ledger, not a proof of host function equality, Hilbert-space completeness, or a quotient coefficient-space theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since every readable coordinate has already been listed, the certificate cannot export Plancherel, inversion, convergence closure, or Lean verification. □

Theorem 1940.3 (Parseval root energy carrier admission)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, any root energy consumer must admit the packet through all concrete rows* $F, S, I, E, R, D, L, H, C, P, N$ *of Definition 1940.1 before it may read the finite energy-identity surface certified by Definition 1940.2. Carrier admission is therefore a displayed NameCert route through Fourier coefficient windows, SOne source rows, InnerProduct pairing witnesses, Integral energy rows, RegSeqRat readback, DyadicRatCore tolerances, the Real seal, transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 1940.1. The rows $F, S, I, E, R, D, L, H, C, P, N$ are the entire accepted inventory, so a root consumer has no separate analytic coordinate to inspect.

Apply Definition 1940.2. Its carrier-admission clause lists the same Fourier, source, pairing, integral, readback, tolerance, seal, transport, replay, provenance, and naming rows as the local NameCert surface.

Thus root energy admission is exactly the displayed packet route. The admission step does not introduce Plancherel, inversion, Hilbert completeness, quotient coefficient spaces, or host function equality. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootEnergyCarrierAdmission`

Theorem 1940.4 (Parseval root Fourier-energy budget)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every root Fourier-energy comparison must display the* $\mathsf{Fourier}^{\uparrow}$ *coefficient windows in* F*, the* $\mathsf{S}^{1\uparrow}$ *source rows in* S*, the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row* I*, the* $\mathsf{Integral}^{\uparrow}$ *energy row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the* $\mathsf{Real}^{\uparrow}$ *seal* L *before the local* $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$ *row* N *can be consumed. The comparison is therefore a finite BEDC route through* $F, S, I, E, R, D, L, H, C, P, N$*, and it refuses Plancherel, Fourier inversion, completed Hilbert norm equality, quotient coefficient classes, and host function equality.*

Proof. Project the carrier of Definition 1940.1. The coefficient-energy side is visible only in the Fourier window row F, and the source and pairing rows are exactly S and I.

Apply the NameCert obligations of Definition 1940.2. The coefficient-window exactness, finite partial-energy ledger accounting, integral-energy handoff, dyadic tolerance accounting, and Real seal non-escape clauses require F, S, I, E, R, D, L before the structural rows can name the comparison.

Use root carrier admission from Definition 1940.3. It forces any root energy consumer through the complete displayed packet $F, S, I, E, R, D, L, H, C, P, N$ before the finite energy-identity surface is read.

Since none of those carrier rows stores Plancherel, Fourier inversion, a completed Hilbert norm equality, quotient coefficient classes, or host function equality, the root Fourier-energy budget cannot export any of those analytic claims. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootFourierEnergyBudget`

Theorem 1940.5 (Parseval integral-energy handoff obligation)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, an energy-identity consumer must expose Fourier coefficient windows,* $\mathsf{S}^{1\uparrow}$ *source rows,* $\mathsf{InnerProduct}^{\uparrow}$ *pairings, the* $\mathsf{Integral}^{\uparrow}$ *energy row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any energy identity is consumed. The visible handoff is the finite route*

$$F, S, I \longmapsto E, R, D \longmapsto L, H, C, P, N.$$

It exports no Plancherel theorem, Fourier inversion theorem, Hilbert completion, quotient coefficient space, host function equality coordinate, infinite coefficient summation, or completed ambient norm.

Proof. Project the carrier of Definition 1940.1. The rows $F, S, I, E, R, D, L, H, C, P, N$ are the complete accepted inventory, so the energy consumer first sees only finite coefficient windows, circle-source rows, pairings, integral-energy data, readback, tolerances, the Real seal, and structural certificate rows.

Invoke Definition 1940.2. Its carrier-admission, finite partial-energy ledger, integral-energy handoff, dyadic tolerance accounting, and Real seal non-escape clauses require F, S, I, E, R, D, L before the energy comparison reaches the structural rows.

It remains to inspect what the packet refuses to export. The same obligations identify no coordinate for Plancherel, inversion, Hilbert completion, quotient coefficient spaces, host function equality, infinite coefficient summation, or completed ambient norms, so no downstream energy identity can consume any of those objects through $\mathsf{Parseval}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalIntegralEnergyHandoffObligation`

Theorem 1940.6 (Parseval root finite coefficient ledger)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the root coefficient ledger visible to downstream consumers is finite and is read only through the rows* $F, S, I, E, R, D, L, H, C, P, N$ *of Definition 1940.1. The coefficient-window row* F*, source row* S*, pairing row* I*, integral row* E*, readback row* R*, and tolerance row* D *must all be exposed before* L, H, C, P, N *can seal, transport, replay, source, and name the finite comparison required by Definition 1940.2.*

Proof. Start from the coefficient-window exactness and finite partial-energy ledger clauses of Definition 1940.2. They attach coefficient reads to F and S, and require the pairing witnesses in I before the integral row is compared.

The carrier definition then supplies the remaining visible ledger rows. The row E stores the integral-energy observation, R stores regular readback, and D stores the dyadic numerical budget for the same finite comparison.

Only after these rows are displayed can L, H, C, P, N seal and preserve the route. Since the route is finite at each row, it cannot be replaced by Plancherel, Fourier inversion, Hilbert completion, quotient coefficient spaces, or host function equality. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootFiniteCoefficientLedger`

Theorem 1940.7 (Parseval root orthogonality ledger)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every root orthogonality read must expose the* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row* F*, the* $\mathsf{S}^{1\uparrow}$ *source row* S*, and the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row* I *before it can be compared with the* $\mathsf{Integral}^{\uparrow}$ *energy row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L*. The orthogonality ledger is therefore a finite NameCert route through* $F, S, I, E, R, D, L, H, C, P, N$*, not a complete orthonormal basis, Plancherel theorem, Fourier inversion theorem, quotient coefficient space, or host equality of circle functions.*

Proof. Project the carrier of Definition 1940.1. The only rows that can support an orthogonality read are the coefficient windows F, circle source S, and pairing witnesses I.

Apply Definition 1940.6. It forces the root coefficient ledger to display F, S, I, E, R, D before the seal and structural rows can preserve the comparison.

Finally use the NameCert obligations of Definition 1940.2. The coefficient-window exactness and finite partial-energy ledger clauses keep the orthogonality read inside the displayed Fourier, SOne, and InnerProduct rows, so no host basis theorem or quotient coefficient space is exported. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootOrthogonalityLedger`

Theorem 1940.8 (Parseval root coefficient integral budget)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the root coefficient-to-integral budget is exhausted by the finite route from coefficient windows and source samples through pairing witnesses to the integral-energy row, regular readback, dyadic tolerance ledger, and Real seal. In symbols, the readable route is*

$$F, S, I \longmapsto E, R, D \longmapsto L, H, C, P, N.$$

No separate coefficient budget for infinite summation, completed norms, quotient coefficient equality, Plancherel, inversion, or host function equality is available outside this displayed route.

Proof. Start with the root finite coefficient ledger of Definition 1940.6. It already makes F, S, I, E, R, D visible before the seal, transport, replay, provenance, and naming rows are consumed.

Use the NameCert obligations of Definition 1940.2. The finite partial-energy ledger accounting row requires the pairing witnesses in I before the integral row E is compared, and the dyadic tolerance accounting row assigns the numerical budget to D.

The Real seal row L and the structural rows H, C, P, N then preserve only this displayed budget. Since no carrier coordinate names an infinite coefficient series, completed norm, quotient equality, Plancherel theorem, inversion theorem, or host equality, those objects cannot enter the root budget. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootCoefficientIntegralBudget`

Theorem 1940.9 (Parseval root Real energy seal boundary)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the root* $\mathsf{Real}^{\uparrow}$ *energy seal boundary is reached only after the Fourier coefficient windows, SOne source row, InnerProduct pairing row, Integral energy row, RegSeqRat readback row, and DyadicRatCore tolerance ledger have all been displayed. The seal* L *records the finite energy comparison preserved by* H, C, P, N *and refuses Plancherel, Fourier inversion, convergence closure, Hilbert-space completeness, quotient coefficient spaces, infinite coefficient summation, and host function equality.*

Proof. Read the carrier and the Real seal non-escape clause. By Definition 1940.1 and Definition 1940.2, L is downstream of F, S, I, E, R, D and seals only the displayed finite energy comparison.

Apply Definition 1940.7 and Definition 1940.8. The first fixes the Fourier, SOne, and InnerProduct rows before any orthogonality-facing read, while the second exhausts the coefficient-to-integral budget through E, R, D.

Finally project the structural rows H, C, P, N. They transport, replay, source, and name the same sealed comparison without adding analytic coordinates, so the root Real boundary cannot export the refused host theorems, quotient objects, infinite summations, or completed norms. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootRealEnergySealBoundary`

Theorem 1940.10 (Parseval root Real seal nonescape)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the root* $\mathsf{Real}^{\uparrow}$ *seal* L *is nonescaping: it seals only the displayed finite energy comparison built from* F, S, I, E, R, D *and preserved by* H, C, P, N*. By Definition 1940.1 and Definition 1940.2,* L *exports no Plancherel theorem, inversion theorem, Hilbert-completeness claim, quotient coefficient space, or host function equality.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootRealSealNonescape`

Proof. Read the Real seal row in Definition 1940.1. The seal L is downstream from the coefficient windows, source rows, pairing witnesses, integral observation, regular readback, and dyadic tolerance ledger.

Apply the Real seal non-escape clause of Definition 1940.2. It states that L seals only the displayed energy comparison and not host equality or completed norm equality.

The structural rows H, C, P, N preserve and name that same finite comparison. Therefore the root seal cannot export Plancherel, inversion, Hilbert completeness, quotient coefficient spaces, or host function equality. □

Theorem 1940.11 (Parseval coefficient integral handoff)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every coefficient-facing energy comparison must read the finite route*

$$F \longmapsto S \longmapsto I \longmapsto E$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal* L *is available. The route records Fourier coefficient windows, the SOne source row, the InnerProduct pairing row, and the Integral energy row as one finite handoff.*

Proof. Project the carrier of Definition 1940.1. The rows F, S, I, E are displayed before the readback row, tolerance ledger, and terminal seal.

Apply the NameCert obligations of Definition 1940.2. Coefficient-window exactness reads F with the source row S, finite partial-energy ledger accounting reads the pairing witnesses in I, and integral-energy handoff reads E from the same finite source window.

Thus a coefficient-facing energy comparison reaches L only after the route $F \longmapsto S \longmapsto I \longmapsto E$ has been displayed. The theorem records the finite Parseval handoff and does not add Plancherel, inversion, convergence, or Hilbert completeness. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalCoefficientIntegralHandoff`

Theorem 1940.12 (Parseval dyadic tolerance ledger)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *accounts for exactly the finite summation, pairing, integral readback, and energy-comparison tolerances used by the displayed Parseval surface. No tolerance for an infinite series, completed norm, quotient coefficient class, or host function equality is available outside* D*.*

Proof. Project the carrier. The only tolerance coordinate is D, and it is listed after the finite coefficient windows, source row, pairing row, integral row, and regular readback.

Use the dyadic tolerance accounting row in Definition 1940.2. It assigns D to finite summation, pairing, integral readback, and comparison tolerances, so every numerical budget for the energy comparison is read through the same DyadicRatCore ledger.

Since the carrier has no coordinate for infinite-series convergence, completed Hilbert norms, quotient coefficient spaces, or host function equality, no additional tolerance source can be exported by the packet. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalDyadicToleranceLedger`

Definition 1940.13 (Parseval inner-product carrier route)**.** *For an accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the inner-product carrier route is the displayed subpacket*

$$(F, S, I, E, R, D, L, H, C, P, N)$$

read as Fourier coefficient windows, $\mathsf{S}^{1\uparrow}$ *source rows,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing witnesses,* $\mathsf{Integral}^{\uparrow}$ *energy observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$ *naming. It contains no row for completed Hilbert norms, quotient coefficient classes, selected representatives, Plancherel, inversion, or host function equality.*

Lean4 (definition) `BEDC.Derived.ParsevalUp.ParsevalInnerProductCarrierRoute`

Theorem 1940.14 (Parseval inner-product NameCert obligations)**.** *Every consumer of the inner-product carrier route in Definition 1940.13 must display all rows* $F, S, I, E, R, D, L, H, C, P, N$ *before it reads an energy comparison. The rows* F, S, I *bind Fourier coefficient windows, circle-source samples, and finite pairing witnesses; the rows* E, R, D, L *bind integral-energy observation, regular rational readback, dyadic tolerance accounting, and the terminal Real seal; the rows* H, C, P, N *preserve, replay, source, and name the same route. The obligation does not claim Plancherel, inversion, completed Hilbert norms, quotient coefficient classes, or host function equality.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalInnerProductNameCertObligations`

Proof. Start with the carrier definition Definition 1940.1. Its accepted inventory is exactly $F, S, I, E, R, D, L, H, C, P$ and Definition 1940.13 reads no additional coordinate.

Apply Definition 1940.2. Carrier admission, coefficient-window exactness, finite partial-energy ledger accounting, integral-energy handoff, dyadic tolerance accounting, Real seal non-escape, and structural transport already require each listed row.

The refused analytic endpoints have no row in the accepted packet. Therefore a consumer of the inner-product route receives only the displayed NameCert obligations and cannot import Plancherel, inversion, a completed Hilbert norm, a quotient coefficient class, or host equality of functions. □

Theorem 1940.15 (Parseval L2 energy identity route)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the only L2-facing energy identity route is the finite path from* F, S, I *through* E, R, D *to* L*, then through* H, C, P, N*. The route compares coefficient energy and integral energy only through displayed* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. It does not assert completed Hilbert-space equality, Plancherel, Fourier inversion, quotient coefficient equality, or host function equality.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalL2EnergyIdentityRoute`

Proof. Read the route from Definition 1940.13. The coefficient side is F, S, I, the integral side is E, and the readback and tolerance rows are R, D before the Real seal L.

Use Definition 1940.14. It forces every energy comparison to display the full row family before a consumer may read the comparison.

Finally use Definition 1940.12. The tolerance ledger is finite and attached to summation, pairing, integral readback, and energy comparison only. Hence the L2-facing phrase names this finite route and not a completed Hilbert-space identity or host theorem. □

Theorem 1940.16 (Parseval Fourier Real readback boundary)**.** *Every* $\mathsf{Fourier}^{\uparrow}$ *consumer that reads a* $\mathsf{Real}^{\uparrow}$ *endpoint through* $\mathsf{Parseval}^{\uparrow}$ *must pass through the displayed carrier rows* $F, S, I, E, R, D, L, H, C, P, N$*. The readback boundary is the route*

$$F, S, I, E, R, D \longmapsto L \longmapsto H, C, P, N.$$

It is a finite Fourier-to-Real energy seal through $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, not a Plancherel theorem, inversion theorem, quotient coefficient class, completed Hilbert norm, or host function equality.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFourierRealReadbackBoundary`

Proof. Project the accepted carrier. A Fourier-facing consumer first sees coefficient windows in F, source samples in S, and finite pairing witnesses in I.

Apply Definition 1940.15. The route reaches the integral row, regular readback, tolerance ledger, and Real seal only through the displayed finite path.

The structural rows H, C, P, N preserve that same path after the seal is read. Because the carrier lacks coordinates for Plancherel, inversion, quotient coefficient classes, completed norms, or host equality, none of those endpoints can cross the Fourier-to-Real boundary. □

Theorem 1940.17 (Parseval SOne orthogonality handoff)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, any orthogonality-facing read from the* $\mathsf{S}^{1\uparrow}$ *row* S *is handed to* $\mathsf{InnerProduct}^{\uparrow}$ *only through the finite pairing row* I *and then to* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *through* E, R, D, L*. The handoff records displayed circle-source rows and pairing witnesses; it does not claim a complete orthonormal basis, Fourier inversion, Plancherel, quotient coefficient equality, or equality of host functions on the circle.*

Proof. Start with Definition 1940.1. The circle source is visible only as S, and the pairing witnesses are visible only as I after the Fourier coefficient row F has fixed the finite observation window.

Use Definition 1940.14. It makes $F, S, I, E, R, D, L, H, C, P, N$ mandatory before any energy comparison is consumed, so an orthogonality-facing read cannot leave the displayed carrier.

Combine this with Definition 1940.16. The downstream Real endpoint is reached only through E, R, D, L and structural preservation. Thus the handoff is finite and local to the packet, with no complete basis, inversion theorem, Plancherel theorem, quotient class, or host circle-function equality exported. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalSoneOrthogonalityHandoff`

Theorem 1940.18 (Parseval Real seal nonescape)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal* L *seals only the displayed finite energy comparison built from* F, S, I, E, R, D*. It excludes Plancherel, inversion, convergence, Hilbert completeness, host function equality, and quotient coefficient spaces.*

Proof. Project the carrier. The seal L is downstream of the Fourier window, SOne source, InnerProduct pairing, Integral energy row, RegSeqRat readback, and DyadicRatCore tolerance ledger.

Apply Definition 1940.2. Its Real seal non-escape row states that L seals only the displayed energy comparison and not a host function equality or completed norm equality.

The exclusions follow from the carrier inventory and the same obligation rows. Plancherel, inversion, convergence, Hilbert completeness, host function equality, and quotient coefficient spaces have no readable coordinate in K, so they cannot escape through L. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRealSealNonescape`

Theorem 1940.19 (Parseval Fourier energy window)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every accepted Parseval energy read first exposes the finite* $\mathsf{Fourier}^{\uparrow}$ *coefficient rows in* F*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows in* D*, and the* $\mathsf{Integral}^{\uparrow}$ *energy rows in* E *before any equality ledger is consumed. The read is a finite* BHist *route through coefficient windows, source rows, tolerance accounting, integral observation, transport, replay, provenance, and local naming; it is not a host Fourier-transform equality or an infinite coefficient summation claim.*

Proof. Project the carrier of Definition 1940.1. The coefficient-window row F, integral-energy row E, and tolerance ledger D are displayed before the terminal real seal and before the local name can export an energy read.

Apply Definition 1940.2. Coefficient-window exactness exposes F, integral-energy handoff exposes E, and dyadic tolerance accounting exposes D as the finite numerical budget for the comparison.

The equality ledger is therefore consumed only after those rows are visible. Since the carrier has no coordinate for a host Fourier transform or an infinite coefficient summation, the exported read remains the finite BHist route stated above. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFourierEnergyWindow`

Theorem 1940.20 (Parseval root Fourier and inner-product route)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every root-level consumer that reads a Fourier energy comparison must first expose the* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row* F*, the* $\mathsf{S}^{1\uparrow}$ *source row* S*, and the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row* I *before the comparison can reach the integral, readback, tolerance, and Real-seal rows. The route is finite:*

$$F, S, I \longmapsto E, R, D, L, H, C, P, N.$$

It records only displayed coefficient windows, circle-source samples, finite pairing witnesses, and the downstream NameCert route; it refuses Plancherel, inversion, Hilbert completeness, quotient coefficient spaces, and host function equality.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootFourierInnerProductRoute`

Proof. Project the carrier of Definition 1940.1. The rows F, S, I are the only Fourier, circle-source, and pairing coordinates visible to a root consumer.

Apply Definition 1940.2. Its coefficient-window exactness and finite partial-energy ledger clauses require coefficient reads to remain attached to F, S and require the pairing witnesses in I before the integral row is compared.

The downstream rows E, R, D, L, H, C, P, N preserve that same finite route. Since the carrier has no coordinate for a host transform, quotient coefficient class, Hilbert completion, Plancherel theorem, inversion theorem, or host function equality, none of those objects can be exported by this root route. □

Theorem 1940.21 (Parseval root integral and regular-readback handoff)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every root-level integral-energy read must expose the* $\mathsf{Integral}^{\uparrow}$ *row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before it reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L*. Thus the root handoff is the finite route*

$$E, R, D \longmapsto L \longmapsto H, C, P, N$$

after the Fourier, SOne, and InnerProduct rows have already been displayed. The handoff does not assert convergence of coefficient series, completed norm equality, quotient coefficient equality, Plancherel, inversion, or host equality of functions.

Proof. Start from Definition 1940.1. The integral-energy observation is stored in E, its regular rational readback is stored in R, and the numerical budget is stored in D.

Use Definition 1940.2. Integral-energy handoff requires E to consume the same finite source and pairing rows before the Real-facing comparison reaches L, and dyadic tolerance accounting confines the comparison budget to D.

The seal row L and the structural rows H, C, P, N therefore receive only the displayed integral/readback/tolerance packet. They cannot add convergence, completed Hilbert norms, quotient coefficient equality, Plancherel, inversion, or host function equality because none of those rows appears in the accepted carrier. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootIntegralRegSeqRatHandoff`

Theorem 1940.22 (Parseval root SOne and Real-seal boundary)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the root route from the* $\mathsf{S}^{1\uparrow}$ *source row* S *to the* $\mathsf{Real}^{\uparrow}$ *seal row* L *is mediated by the displayed Fourier, InnerProduct, Integral, RegSeqRat, and DyadicRatCore rows. In particular, the only exposed boundary is*

$$S, F, I, E, R, D \longmapsto L.$$

The Real seal records a finite energy-comparison endpoint and not a host circle-function equality, Plancherel theorem, Fourier inversion theorem, Hilbert-completeness claim, quotient coefficient space, or ambient completed norm.

Proof. Project the rows of Definition 1940.1. The $\mathsf{S}^{1\uparrow}$ source is visible only as S, and the $\mathsf{Real}^{\uparrow}$ endpoint is visible only as L after the coefficient, pairing, integral, readback, and tolerance rows have been displayed.

Apply Definition 1940.2. The Real seal non-escape clause states that L seals only the displayed energy comparison and not a host equality or completed norm equality.

Combine this with the Fourier energy window of Definition 1940.19. The source-to-seal boundary is therefore the finite route through S, F, I, E, R, D, L, preserved by H, C, P, N, with no coordinate for the refused analytic completions or host equalities. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootSoneRealSealBoundary`

Theorem 1940.23 (Parseval inner-product norm scope)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, every norm-squared comparison is scoped through the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row* I *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* L*. The packet records finite pairing witnesses, regular readback, dyadic tolerance accounting, componentwise transport, continuation replay, provenance, and local naming; it does not import Hilbert-space completion, quotient coefficient equality, or a completed norm theorem.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalInnerProductNormScope`

Proof. Read the norm-facing comparison from the carrier. The only pairing coordinate is I, and the only real-facing endpoint is L after the readback and tolerance rows R, D.

Use Definition 1940.2. The finite partial-energy ledger accounting row requires the pairing witnesses in I before the integral row is compared, and the Real seal non-escape row limits L to the displayed energy comparison.

Thus the norm-squared comparison has no path to Hilbert-space completion or quotient coefficient equality. The structural rows H, C, P, N preserve and name the finite route without adding a completed norm theorem. □

Theorem 1940.24 (Parseval S1 basis ledger)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P$ *the circle-source basis rows are read through the* $\mathsf{S}^{1\uparrow}$ *row* S *and the finite* $\mathsf{Fourier}^{\uparrow}$ *observation windows in* F*. A consumer may inspect the displayed modes, phase samples, coefficient probes, pairing witnesses, integral-energy rows, tolerance ledger, transport, replay, provenance, and local naming, but it cannot replace them by host functions on an ambient circle.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalSoneBasisLedger`

Proof. Project the source-facing rows. The carrier exposes the circle source as S and the Fourier observation windows as F; no ambient circle function space is stored in the packet.

Apply Definition 1940.11. The energy route reads F and S before the pairing and integral rows I, E, so the displayed modes and phase samples remain attached to the finite observation window.

Finally use Definition 1940.18. The terminal seal can export only the displayed finite energy comparison, and the structural rows H, C, P, N name the same data. Host functions on an ambient circle therefore have no carrier coordinate through which to enter the ledger. □

Theorem 1940.25 (Parseval root obligation surface)**.** *Every root-level* $\mathsf{Parseval}^{\uparrow}$ *energy consumer must read the finite route*

$$F \longmapsto S \longmapsto I \longmapsto E \longmapsto D \longmapsto R \longmapsto L \longmapsto H, C, P, N$$

through $\mathsf{Fourier}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any energy equality is consumed. The route displays coefficient windows, circle-source rows, pairing witnesses, integral-energy observations, dyadic tolerance budgets, regular rational readback, the terminal real seal, transport, replay, provenance, and local naming. It does not import Plancherel, inversion, Hilbert completeness, quotient coefficient spaces, host function equality, or an ambient completed norm.*

Proof. Project the carrier of Definition 1940.1. The rows F, S, I, E, D, R, L are the only analytic coordinates available before the structural rows are read.

Apply Definition 1940.11 to expose the Fourier coefficient windows, circle source, inner-product pairing, and integral-energy row. Then apply Definition 1940.12 to force the numerical budget through D and the regular readback through R.

Finally use Definition 1940.18. The seal L is only the displayed finite energy comparison, and H, C, P, N preserve and name that same route. The refused analytic objects therefore have no carrier coordinate from which to enter the root surface. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootObligationSurface`

Theorem 1940.26 (Parseval root coefficient stability)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, coefficient-energy stability is witnessed only after the coefficient rows in* $\mathsf{Fourier}^{\uparrow}$*, the source rows in* $\mathsf{S}^{1\uparrow}$*, the pairing rows in* $\mathsf{InnerProduct}^{\uparrow}$*, the integral rows in* $\mathsf{Integral}^{\uparrow}$*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal have all been displayed. A stable coefficient row may be transported through* H, C, P, N*, but it cannot be replaced by a quotient coefficient space, host Fourier transform, Plancherel theorem, inversion theorem, or Hilbert-completion argument.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootCoefficientStability`

Proof. Start from the coefficient-facing route in Definition 1940.19. It already requires the finite Fourier coefficient rows, the integral-energy rows, and the dyadic tolerance ledger before an equality ledger is consumed.

Attach the circle source and pairing rows using Definition 1940.24 and Definition 1940.23. These rows keep coefficient stability tied to the displayed source and pairing witnesses rather than to a host function space.

The regular readback and terminal seal are then supplied by the carrier rows R and L. Transport, replay, provenance, and local naming can preserve the stable coefficient route, but they cannot add quotient coefficient spaces, Plancherel, inversion, or Hilbert completeness. □

Theorem 1940.27 (Parseval finite Fourier carrier admission)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, any Parseval carrier read must expose the finite* $\mathsf{Fourier}^{\uparrow}$ *coefficient rows in* F*, the* $\mathsf{S}^{1\uparrow}$ *basis and source rows in* S*, the finite* $\mathsf{Integral}^{\uparrow}$ *energy rows in* E*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* L *before the energy equality is consumed. The exposed route is the same carrier route certified by Definition 1940.1, Definition 1940.2, and Definition 1940.26; no downstream consumer may read a coefficient equality while omitting any of* $F, S, I, E, R, D, L, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFiniteFourierCarrierAdmission`

Proof. Project the carrier in Definition 1940.1. The Fourier, circle-source, integral-energy, readback, tolerance, Real-seal, and structural coordinates are exactly $F, S, I, E, R, D, L, H, C, P, N$.

Apply Definition 1940.2. Its carrier-admission, coefficient-window exactness, finite partial-energy ledger, integral-energy handoff, dyadic tolerance, and Real-seal clauses require these rows before the finite energy comparison can be read.

Finally use Definition 1940.26. Coefficient stability remains tied to the displayed Fourier, SOne, InnerProduct, Integral, DyadicRatCore, RegSeqRat, and Real rows, so a carrier read that omits any listed row is outside the packet. □

Theorem 1940.28 (Parseval inner-product energy ledger)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the coefficient-side inner-product energy ledger and the integral-side energy ledger share the same* $\mathsf{BHist/hsame/Cont/Pkg}$ *route. The coefficient side is read through* F, S, I*, the integral side is read through* E, R, D, L*, and both sides are transported, replayed, sourced, and named only through* H, C, P, N*.*

Proof. Read the finite route from Definition 1940.25. It forces every root energy consumer through the same displayed carrier rows before any equality is consumed.

For the coefficient side, apply Definition 1940.20. The Fourier coefficient windows, SOne source rows, and InnerProduct pairing witnesses are the only coefficient-side energy rows available.

For the integral side, apply Definition 1940.21 and Definition 1940.18. The integral-energy row, regular readback, dyadic tolerance ledger, and Real seal are downstream from the same source and pairing data.

The structural rows are shared because the carrier has only one H, C, P, N family. Hence both ledgers use the same $\mathsf{BHist/hsame/Cont/Pkg}$ route and cannot split into independent coefficient and integral certificates. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalInnerProductEnergyLedger`

Theorem 1940.29 (Parseval Real-seal refusal boundary)**.** *Every accepted* $\mathsf{Parseval}^{\uparrow}$ *packet exports no Plancherel theorem, quotient function equality, selected convergence datum, host* L^2 *space, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Its Real-facing boundary is only the displayed finite seal* L *over* $F, S, I, E, R, D, H, C, P, N$*, as constrained by Definition 1940.18 and Definition 1940.30.*

Proof. Start with the classifier in Definition 1940.1. It compares accepted carriers only through the displayed rows and has no coordinate for Plancherel, quotient functions, selected convergence, host L^2 spaces, or ambient completeness.

Apply Definition 1940.18. The Real seal L seals only the finite energy comparison built from the Fourier, SOne, InnerProduct, Integral, RegSeqRat, and DyadicRatCore rows.

Finally use Definition 1940.30. The root Real read stays downstream from the same displayed carrier route, so none of the refused analytic objects can cross the Real-seal boundary. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRealSealRefusalBoundary`

Theorem 1940.30 (Parseval root Real energy nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *energy read exported by* $\mathsf{Parseval}^{\uparrow}$ *is downstream from* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows in the displayed carrier. The exported seal is a finite energy-comparison endpoint only: it refuses Plancherel, Fourier inversion, Hilbert completeness, quotient coefficient spaces, host function equality, infinite coefficient summation, and completed ambient norms.*

Proof. Read the root obligation surface of Definition 1940.25. It forces every energy consumer through the finite coefficient, source, pairing, integral, tolerance, and readback rows before L is available.

Now apply Definition 1940.26. Coefficient stability stays attached to the same displayed rows and cannot be transported into a quotient coefficient space or host Fourier transform.

The final endpoint is controlled by Definition 1940.18. Since L seals only the finite energy comparison, no exported Real read can supply Plancherel, inversion, Hilbert completeness, host function equality, infinite summation, or completed ambient norms. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootRealEnergyNonescape`

Theorem 1940.31 (Parseval root Fourier-integral energy exhaustion)**.** *Every root* $\mathsf{Parseval}^{\uparrow}$ *consumer that reads an energy identity must first expose Fourier coefficient rows,* $\mathsf{S}^{1\uparrow}$ *basis rows,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing rows, the* $\mathsf{Integral}^{\uparrow}$ *energy row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. In carrier notation for* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the identity is readable only after* $F, S, I, E, D, R, L, H, C, P, N$ *have all been displayed. No downstream Real or Integral consumer can replace this finite route by Plancherel, inversion, Hilbert completeness, quotient coefficient spaces, host function equality, infinite coefficient summation, or an ambient completed norm.*

Proof. Begin with the root carrier admission theorem Definition 1940.3. It requires the full displayed packet $F, S, I, E, R, D, L, H, C, P, N$ before a root energy consumer may read the finite energy-identity surface.

The finite coefficient side is then fixed by Definition 1940.6. The Fourier row F, the circle-source basis row S, the pairing row I, the integral-energy row E, and the tolerance row D must be visible before the structural rows can seal and preserve the comparison.

Use Definition 1940.11 and Definition 1940.12. These theorems force the coefficient-to-integral handoff through F, S, I, E and place all finite summation, pairing, integral readback, and comparison tolerances inside D.

Finally apply Definition 1940.30. The terminal Real read remains downstream from the same Fourier, pairing, integral, source, dyadic, and regular-readback rows, so the exhausted route cannot export any refused host theorem or completed ambient norm. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootFourierIntegralEnergyExhaustion`

Theorem 1940.32 (Parseval Fourier coefficient energy row)**.** *For every accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the Fourier coefficient-energy row exported to a downstream consumer is the displayed finite route through* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *carried by* $F, S, I, E, R, D, L, H, C, P, N$*. The row records coefficient windows, circle-source reads, pairing witnesses, integral-energy observations, regular rational readback, dyadic tolerances, and the terminal Real seal; it does not export an infinite Fourier coefficient sequence, quotient coefficient equality, Plancherel, inversion, or completed norm equality.*

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFourierCoefficientEnergyRow`

Proof. Project the carrier of Definition 1940.1. The coefficient-energy read starts at F and S, then reaches pairing and integral observations through I and E.

Use Definition 1940.31. It requires the coefficient, source, pairing, integral, tolerance, readback, Real-seal, transport, replay, provenance, and local naming rows before a root energy identity can be read.

Finally apply Definition 1940.18. The Real endpoint seals only the displayed finite comparison, so no infinite coefficient object, quotient equality, Plancherel theorem, inversion theorem, or completed norm equality can be read from the row. □

Theorem 1940.33 (Parseval finite partial-sum induction)**.** *Every finite partial-sum inspection admitted by an accepted* $\mathsf{Parseval}^{\uparrow}$ *carrier is inductive over the displayed Fourier window row* F*. The base inspection reads the empty coefficient window through the same* $\mathsf{S}^{1\uparrow}$ *source,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing,* $\mathsf{Integral}^{\uparrow}$ *energy,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, and* $\mathsf{Real}^{\uparrow}$ *seal rows, and the successor inspection extends only the finite ledger already transported and named by* H, C, P, N*. No step introduces countable summation, completed Hilbert structure, quotient coefficient equality, or host function equality.*

Proof. For the base window, read Definition 1940.6. The visible coefficient ledger is finite and already attached to $F, S, I, E, R, D, L, H, C, P, N$.

For the successor window, use the same ledger clause together with Definition 1940.32. Adding one displayed coefficient extends the finite Fourier row before the pairing, integral, readback, tolerance, and Real-seal rows are replayed.

The induction is confined by Definition 1940.31. Since each step remains inside the displayed carrier route, the induction cannot produce countable summation, Hilbert completeness, quotient coefficient equality, or host function equality. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFinitePartialSumInduction`

Theorem 1940.34 (Parseval finite energy induction readback)**.** *Every accepted* $\mathsf{Parseval}^{\uparrow}$ *packet whose finite partial-sum induction row is consumed must expose the Fourier coefficient window,* $\mathsf{S}^{1\uparrow}$ *source row,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row,* $\mathsf{Integral}^{\uparrow}$ *energy row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$ *row before the energy identity can be read. In carrier notation for* $K = (F, S, I, E, R, D, L, H, C, P, N)$*, the readback route is exactly*

$$F, S, I, E, R, D, L, H, C, P, N.$$

No consumer may replace this finite induction route by Plancherel, inversion, completed Hilbert norms, quotient coefficient equality, host function equality, infinite coefficient summation, or an ambient completed norm.

Proof. Start with the root energy decomposition of Definition 1940.35. It identifies the readable energy surface with the displayed carrier rows $F, S, I, E, R, D, L, H, C, P, N$ and refuses every analytic endpoint not present in the carrier.

Next use the Fourier coefficient energy row of Definition 1940.32. It exposes the finite coefficient window, circle-source row, pairing row, integral-energy observations, regular readback, dyadic tolerances, and Real seal before any downstream energy comparison is exported.

Now apply finite partial-sum induction, Definition 1940.33. The base and successor inspections stay inside the same finite Fourier window row and are transported only through the displayed structural rows.

Finally use the Real-seal refusal boundary of Definition 1940.29. Since the terminal seal exports only the finite comparison over the displayed rows, the consumed induction row cannot be read as Plancherel, inversion, Hilbert completion, quotient coefficient equality, host function equality, infinite summation, or completed ambient norm data. □

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalFiniteEnergyInductionReadback`

Theorem 1940.35 (Parseval root energy decomposition)**.** *Every accepted* $\mathsf{Parseval}^{\uparrow}$ *root energy read decomposes into the Fourier coefficient window* F*, the* $\mathsf{S}^{1\uparrow}$ *source row* S*, the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row* I*, the* $\mathsf{Integral}^{\uparrow}$ *energy row* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{Real}^{\uparrow}$ *seal* L*, and the support rows* H, C, P, N *of Definition 1940.1. The decomposition exports only this displayed route*

$$F, S, I, E, R, D, L, H, C, P, N.$$

It exports no Plancherel theorem, Fourier inversion theorem, Hilbert completion, quotient coefficient equality, or infinite summation.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRootEnergyDecomposition`

Proof. Start with the finite partial-sum induction of Definition 1940.33. It keeps coefficient-energy inspection inside the finite Fourier window row F and transports each base or successor inspection through the same structural rows.

Next use the finite coefficient ledger and coefficient-integral handoff, Definition 1940.6 and Definition 1940.11. These attach F to the source row S, require the pairing row I, and route the comparison to the integral-energy row E before any energy read reaches the terminal seal.

Apply the dyadic tolerance ledger and Real seal nonescape, Definition 1940.12 and Definition 1940.30. They force regular readback and numerical tolerance through R, D and keep L as a finite energy seal rather than a completed analytic endpoint.

Finally read root Fourier-integral exhaustion from Definition 1940.31. The support rows H, C, P, N transport, replay, source, and name the same displayed decomposition, and no carrier coordinate remains for Plancherel, inversion, Hilbert completion, quotient coefficient equality, or infinite summation. □

Theorem 1940.36 (Parseval Real L^2 boundary refusal)**.** *Every Real-facing* $\mathsf{Parseval}^{\uparrow}$ *read that is later used as an* L^2 *energy boundary remains confined to the displayed carrier route through* $\mathsf{Fourier}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The packet exports*

only the finite Real seal L over $F, S, I, E, R, D, H, C, P, N$ and refuses ambient L^2 completeness, host function equality, quotient coefficient spaces, infinite coefficient summation, Plancherel, and Fourier inversion.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalRealL2BoundaryRefusal`

Proof. Begin with Definition 1940.30. It identifies the terminal Real read as downstream from the displayed Fourier, source, pairing, integral, tolerance, readback, and structural rows.

Use Definition 1940.32 to expose the coefficient-energy side. The row is finite and NameCert-local, so it has no coordinate for an ambient L^2 carrier or host equality of functions.

Finally apply Definition 1940.31. Any Real or Integral consumer must traverse the same finite route, which rules out Plancherel, inversion, quotient coefficient spaces, infinite coefficient summation, and completed ambient norms. □

Theorem 1940.37 (Parseval kernel-scope package)**.** *The carrier of Definition 1940.1 and the obligations of Definition 1940.2 assemble a kernel-scoped* $\mathsf{Parseval}^{\uparrow}$ *package over coefficient windows, finite partial-energy ledgers, integral-energy handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, local* NameCert*, and TasteGate field-faithfulness. Every accepted package read is confined to the displayed route*

$$F, S, I, E, R, D, L, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalKernelScopePackage`

Proof. Start with Definition 1940.2. It already lists carrier admission, coefficient-window exactness, finite partial-energy ledger accounting, integral-energy handoff, dyadic tolerance accounting, Real seal non-escape, componentwise transport, replay, provenance, and local naming as the complete local obligation surface.

Use the finite coefficient ledger and coefficient-integral handoff of Definition 1940.6 and Definition 1940.11. These force the coefficient windows F, source row S, pairing row I, integral-energy row E, regular readback R, and tolerance ledger D to be displayed before the terminal seal.

Apply the dyadic tolerance ledger and Real-energy nonescape theorems, Definition 1940.12 and Definition 1940.30. They keep the numerical budget inside D and the endpoint inside the finite $\mathsf{Real}^{\uparrow}$ seal L, with no host equality, quotient coefficient space, infinite summation, Plancherel, inversion, or ambient Hilbert-completion coordinate.

Finally read the exhaustion, induction, and Real L^2 boundary routes of Definition 1940.31, Definition 1940.33, and Definition 1940.36. The support rows H, C, P, N preserve only the same finite carrier route, and the checked TasteGate alignment marker for Definition 1940.1 keeps field-faithfulness tied to those displayed rows. □

Theorem 1940.38 (Parseval scoped energy route)**.** *Every* $\mathsf{Parseval}^{\uparrow}$ *energy consumer must pass through* $\mathsf{Fourier}^{\uparrow}$ *coefficient windows,* $\mathsf{S}^{1\uparrow}$ *source rows,* $\mathsf{InnerProduct}^{\uparrow}$ *pairing,* $\mathsf{Integral}^{\uparrow}$ *energy,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *before reading the energy identity surface. In carrier notation for $K = (F, S, I, E, R, D, L, H, C, P, N)$, the scoped route is exhausted by*

$$F, S, I, E, R, D, L, H, C, P, N.$$

It does not export Plancherel, Fourier inversion, Hilbert completion, quotient coefficient equality, selected limits, host function equality, infinite summation, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.ParsevalUp.ParsevalScopedEnergyRoute`

Proof. Begin with root carrier admission and the NameCert obligations of Definition 1940.1 and Definition 1940.2. They expose exactly the rows $F, S, I, E, R, D, L, H, C, P, N$ before a local Parseval name can be consumed.

Next compose the Fourier-energy budget, integral-energy handoff, finite coefficient ledger, and coefficient-integral budget theorems: Definition 1940.4, Definition 1940.5, Definition 1940.6, and Definition 1940.8. These force every energy read to display coefficient windows, source samples, pairings, the integral row, readback, and dyadic tolerances before the Real seal is reached.

Finally use the kernel-scope package theorem Definition 1940.37. Its transport, replay, provenance, naming, and TasteGate alignment rows preserve only the same finite route, so the scoped package cannot be read as Plancherel, inversion, Hilbert completion, quotient coefficient equality, selected limits, host equality, infinite summation, or ambient Real completeness. □

Falsifiable prediction: Every $\mathsf{Parseval}^{\uparrow}$ energy-facing read factors through Fourier coefficient windows, an SOne source row, an InnerProduct pairing row, an Integral energy row, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fourier, s1, innerproduct, integral, regseqrat, dyadicratcore, real: $\mathsf{Parseval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries coefficient-energy windows, source rows, pairing witnesses, integral-energy observations, regular readbacks, dyadic tolerance accounting, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Parseval}^{\uparrow}$ packet is generated from finite Fourier coefficient windows, a displayed $\mathsf{S}^{1\uparrow}$ source row, an $\mathsf{InnerProduct}^{\uparrow}$ pairing row, an $\mathsf{Integral}^{\uparrow}$ energy row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1940.38 closes the finite energy route through coefficient windows, source rows, pairing, integral energy, readback, tolerances, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Parseval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Plancherel, inversion, convergence closure, Hilbert-space completeness, host function equality, quotient coefficient spaces, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public energy-interface theorem exporting the same finite route without adding Plancherel, inversion, Hilbert completeness, quotient coefficient equality, selected limits, or ambient Real completeness.

Chapter 1941

A Concrete Naming Certificate for McShaneExtension$^{\uparrow}$

Following McShane and Whitney Lipschitz extension and Bishop–Bridges constructive analysis, the McShaneExtension$^{\uparrow}$ packet records the finite certificate by which a displayed real-valued Lipschitz map on a displayed subcarrier is read as an extension candidate on the ambient metric carrier. It consumes the map-level bound surface of chapter 410, the dyadic tolerance route of chapter 1864, the uniformly continuous extension handoff of chapter 769, and the separated completion uniqueness boundary of **??**. The packet names a finite Lipschitz-extension certificate; it is not a host formula for pointwise infima or suprema, not a quotient function-space construction, and not an appeal to selected bounds, function extensionality, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 1941.1 (McShaneExtension carrier)**.** *A* McShaneExtension$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, A, L, D, E, S, R, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient source* Met$^{\uparrow}$ *row, exposing only the metric observations used by the extension request.*
2. *A is the displayed subcarrier or domain row, recording the admitted source points, the inclusion route into X, and the finite membership evidence consumed by later rows.*
3. *L is the source* LipschitzMap$^{\uparrow}$ *row for the real-valued map on A, including the displayed Lipschitz constant and the finite graph windows read on the subcarrier.*
4. *D is the* DyadicLipschitzModulus$^{\uparrow}$ *row that turns the displayed Lipschitz bound into dyadic tolerance data for source and ambient reads.*
5. *E is the candidate extension row, recording the finite McShane–Whitney envelope comparisons available to an ambient input without selecting a global infimum or supremum.*
6. *S is the source-agreement row, requiring the candidate extension read to coincide with the original source graph when the ambient input is admitted by A.*
7. *R records the* Real$^{\uparrow}$ *seal rows for source values, envelope comparisons, and ambient extension reads.*

8. *K records the* $\mathsf{Met}^{\uparrow}$ *seal rows for the source metric, subcarrier inclusion, and ambient distance comparisons.*
9. *H records componentwise* hsame *transport for the ambient metric, subcarrier, source Lipschitz row, dyadic modulus, candidate extension, source agreement, Real and Metric seals, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an ambient precision request through $X, A, L, D, E, S, R, K, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{McShaneExtension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{DyadicLipschitzModulus}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, $\mathsf{CompletionExtensionUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{McShaneExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve displayed rows. It has no coordinate for host function equality, quotient function spaces, selected infima or suprema, countable-choice selectors, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a public bridge credential.*

Lean4 ✓ `BEDC.Derived.McShaneExtensionUp.McShaneExtensionTasteGate single carrier alignment`

Theorem 1941.2 (McShaneExtension NameCert obligations)**.** *For every accepted* $\mathsf{McShaneExtension}^{\uparrow}$ *carrier*

$$M = (X, A, L, D, E, S, R, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{McShaneExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed ambient metric, subcarrier, source Lipschitz, dyadic modulus, candidate extension, source agreement, Real and Metric seal, componentwise transport, replay, provenance, and local naming rows;*
2. *domain compatibility, requiring every source-value read to pass through A before it is compared with an ambient extension read;*
3. *Lipschitz-source admission, requiring L to be the only row that exposes the source graph and displayed Lipschitz constant;*
4. *dyadic modulus transport, requiring D to mediate every tolerance transfer from source distances to extension-value estimates;*
5. *candidate-extension exactness, requiring E to store only finite envelope comparison data and no selected infimum, selected supremum, quotient function, or host function object;*
6. *source-agreement exactness, requiring S to identify candidate and source reads only through the same displayed A, L, D, R, K route;*
7. *ledger non-escape, requiring H, C, P, N to preserve and replay the listed rows without adding host function equality, quotient function spaces, selected bounds, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1941.1. The accepted packet displays exactly the ambient metric, subcarrier, source Lipschitz row, dyadic modulus, candidate extension row, source-agreement row, Real and Metric seals, and the structural rows.

The domain and source clauses are read next. The row A is the only subcarrier admission row, and L is the only row exposing the real-valued Lipschitz graph on that subcarrier. Thus a source-value comparison cannot be formed before the packet has read both rows.

The tolerance route is then forced by D. By chapter 410 and chapter 1864, the displayed Lipschitz constant reaches ambient precision requests only through the finite dyadic modulus route, not through a host estimate.

The candidate and agreement clauses project E and S. The candidate row stores finite McShane–Whitney envelope comparisons, while the source-agreement row checks the same data on points admitted by A. These rows do not select a global infimum or supremum and do not turn the candidate into a quotient function-space element.

Finally inspect H, C, P, N. Transport is componentwise, replay follows the displayed route, and provenance plus local naming mention only the packet and its sibling dependencies, including chapter 769 and **??**. Hence the local NameCert obligations are exactly the listed finite rows. □

Theorem 1941.3 (McShaneExtension Lipschitz bound)**.** *Let $M = (X, A, L, D, E, S, R, K, H, C, P, N)$ be an accepted* $\mathsf{McShaneExtension}^{\uparrow}$ *carrier. Every ambient extension read exported by M factors through the finite route*

$$X, A \longmapsto L \longmapsto D \longmapsto E \longmapsto R, K \longmapsto H, C, P, N.$$

Along that route the displayed source Lipschitz constant remains the only bound used for the ambient candidate. The packet therefore exports a Lipschitz-bound certificate for the candidate extension without using host function equality, quotient function spaces, selected infima or suprema, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an ambient extension read. The ambient metric observations come from X, while subcarrier information and source comparison data come from A. No extension-value estimate is available before these two rows have been displayed.

Read the source Lipschitz and modulus rows. The row L supplies the displayed source graph and Lipschitz constant, and D converts that bound into dyadic tolerance data. This is the same finite tolerance discipline isolated by chapter 1864.

The candidate extension row E then records only finite envelope comparisons. Its reads are sealed through R and K, so Real-facing and Metric-facing consumers inspect the same finite route before reaching structural transport.

Transport, replay, provenance, and local naming preserve the route through H, C, P, N. The completion-facing siblings chapter 769 and **??** may consume this bound certificate downstream, but the carrier itself exports no host function equality, no quotient function space, no selected infimum or supremum, no choice principle, and no ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1941.4 (McShaneExtension source-agreement envelope)**.** *Let $M = (X, A, L, D, E, S, R, K, H, C, P, N)$ be an accepted* $\mathsf{McShaneExtension}^{\uparrow}$ *carrier, and let an ambient input be admitted by the displayed subcarrier row A. The candidate envelope row E can be read as agreeing with the source Lipschitz row L only through the source-agreement row S and the finite route*

$$A, L, D, E, S \longmapsto R, K \longmapsto H, C, P, N.$$

Thus source agreement for the ambient read is a restriction of the finite McShane–Whitney envelope certificate back to the source row, mediated by S, D, R, K, H, C, P, N, and not by host function equality, selected envelope extrema, quotient function spaces, choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and the admission of the ambient input through A. The source graph and displayed Lipschitz constant are exposed only by L, while the candidate envelope comparisons are exposed only by E.

Use the dyadic modulus row D to put the source read and the candidate envelope read at the same displayed tolerance. The source-agreement row S is then the only row that identifies the restricted envelope read with the original source read on an input admitted by A.

Finally inspect R, K, H, C, P, N. The Real and Metric seal rows keep the comparison on the same finite readback route, and the transport, replay, provenance, and local naming rows preserve that route componentwise. Since no listed row stores host equality, selected extrema, quotient function-space data, choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every source-agreement read is the stated restriction of the finite envelope certificate. □

Theorem 1941.5 (McShaneExtension finite envelope route)**.** *Let*

$$M = (X, A, L, D, E, S, R, K, H, C, P, N)$$

be an accepted $\mathsf{McShaneExtension}^{\uparrow}$ *carrier. Every extension consumer of M reaches the candidate extension row only through the displayed rows $X, A, L, D, E, S, R, K, H, C, P, N$: the row L supplies the source graph and displayed Lipschitz constant, the row D supplies the dyadic tolerance route, the row E supplies the finite McShane–Whitney envelope comparisons, and the row S supplies the source-agreement restriction. Thus the human McShane–Whitney envelope derivation exported by M is a finite NameCert route, not a host infimum, host supremum, quotient function, selected representative, choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness argument.*

Proof. Begin with the NameCert obligations of Definition 1941.2. They expose the ambient metric row, displayed subcarrier, source Lipschitz row, dyadic modulus, candidate extension, source agreement, Real and Metric seals, transport, replay, provenance, and local naming as the complete obligation surface for an accepted packet.

Apply the Lipschitz-bound theorem Definition 1941.3. It forces an ambient extension read through $X, A, L, D, E, R, K, H, C, P, N$, with L as the only source of the graph and bound and D as the only dyadic tolerance route. The LipschitzMap and DyadicLipschitzModulus sibling chapters cited in the introduction provide exactly those source-bound and tolerance rows.

Now apply the source-agreement envelope theorem Definition 1941.4. When the ambient input lies in the displayed subcarrier, S is the only row that restricts the candidate envelope read back to the original source graph. The UniformContinuousExtension and CompletionExtensionUniqueness sibling chapters may consume the resulting handoff downstream, but they do not add an infimum, supremum, quotient function, selected representative, choice principle, or ambient completeness coordinate to this packet.

Therefore every extension consumer reaches the candidate row by the stated finite route through $X, A, L, D, E, S, R, K, H, C, P, N$, and the McShane–Whitney envelope derivation remains a displayed certificate over those rows. □

Falsifiable prediction: An accepted $\mathsf{McShaneExtension}^{\uparrow}$ consumer that reaches an ambient extension read without first reading the source $\mathsf{LipschitzMap}^{\uparrow}$ row, the $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ row, the candidate extension row, and the source-agreement row refutes the carrier surface.

Independence witness: lipschitzmap, dyadic-lipschitz-modulus, uniform-continuous-extension, completion-extension-uniqueness: no listed sibling supplies the full twelve-row packet $M = (X, A, L, D, E, S, R, K,$ because each sibling contributes only a source bound, a dyadic tolerance route, a completion handoff, or a uniqueness boundary while this chapter binds the finite McShane–Whitney extension certificate into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{McShaneExtension}^{\uparrow}}$.

Constructive story: A McShaneExtension$^{\uparrow}$ packet is generated from an ambient MetricUp row, a displayed subcarrier row, a source LipschitzMap row, a DyadicLipschitzModulus row, a candidate extension row, a source-agreement row, Real and Metric seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{McShaneExtension}\uparrow}$, seed)

Scope closed: Definition 1941.1, Definition 1941.2, Definition 1941.3, and Definition 1941.4 seed the finite McShane–Whitney Lipschitz-extension certificate over displayed metric and subcarrier data.

Formal verification: FormalStatus(NameCert$_{\mathsf{McShaneExtension}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient function spaces, selected infima or suprema, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, domain compatibility, source Lipschitz admission, dyadic modulus transport, candidate-extension exactness, source-agreement exactness, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.McShaneExtensionUp.

Chapter 1942

A Concrete Naming Certificate for $\mathsf{RealDyadicEmbedding}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RealDyadicEmbedding}^{\uparrow}$ packet records the finite certificate by which a displayed dyadic rational endpoint is admitted as a constant regular real name. It sits after the dyadic endpoint ledger of chapter 291, the constant finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names the constant-dyadic entry route; it does not assert quotient equality of real names, trichotomy, selected limits, density, algebraic closure, or ambient completeness.

Definition 1942.1 (RealDyadicEmbedding carrier)**.** *A* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, including the signed dyadic numerator, scale, endpoint comparison ledger, and finite tolerance rows used by later precision requests.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule that repeats the displayed endpoint row of D at every finite observation window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *constant readback row, routing each requested regular rational observation through S and then back to the same dyadic endpoint data in D.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the route through D, S, R has been exposed.*
5. *H records componentwise* hsame *transport for the dyadic endpoint, constant stream schedule, regular readback, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay for every Real-facing or algebra-facing consumer that asks for a finite precision window of the constant name.*
7. *P is the* Pkg *provenance over* $\mathsf{RealDyadicEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDyadicEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of real names, order trichotomy, selected limits, density of dyadics, algebraic closure, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealDyadicEmbeddingUp.RealDyadicEmbeddingUpTasteGate single carrier alignment`

Theorem 1942.2 (RealDyadicEmbedding NameCert obligations)**.** *For every accepted* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *carrier* $K = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealDyadicEmbedding}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed dyadic endpoint, constant stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *endpoint constancy, requiring every finite observation window of* S *to read the same dyadic endpoint row* D*;*
3. *regular-readback exactness, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in* R *to route through the constant schedule* S *and return to the endpoint ledger* D *before the Real seal is inspected;*
4. *Real-seal locality, requiring the terminal row* E *to be downstream of* D, S, R *and never detached as a host real object;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape for quotient equality, trichotomy, selected limits, density, algebraic closure, countable choice, and ambient completeness.*

No constant-dyadic admission obligation is stored outside these rows.

Proof. Project the accepted packet $K = (D, S, R, E, H, C, P, N)$. The carrier row exposes exactly one dyadic endpoint, one constant stream schedule, one regular readback, one Real seal, and the four structural rows.

Endpoint constancy is read from S. Since every finite observation window of the schedule repeats the endpoint data in D, a consumer cannot obtain a second dyadic source or a varying tail from the packet.

Regular-readback exactness is the route through R. Each requested regular rational observation first reads the constant schedule S, then returns to the dyadic ledger D, and only after that route may the terminal seal E be consumed.

The structural rows preserve the same route. Componentwise transport by H and replay by C can only move along the displayed coordinates, while P and N source and name the packet.

The omitted objects have no carrier coordinate. Hence quotient equality, trichotomy, selected limits, density, algebraic closure, countable choice, and ambient completeness cannot be produced by the local certificate. □

Theorem 1942.3 (RealDyadicEmbedding RegSeq handoff)**.** *Let* $K = (D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the embedded dyadic name factors through*

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before it can inspect the terminal seal. In particular, the consumer reads the DyadicRatCore endpoint, the constant StreamName schedule, and the RegSeqRat readback before the Real seal, and the route exports no quotient equality, trichotomy, selected limit, density theorem, algebraic closure theorem, countable-choice schedule, or ambient completeness witness.

Proof. Start with a Real-facing consumer of the packet. By Definition 1942.1, the only terminal Real row is E, and that row is downstream of the displayed dyadic endpoint, stream schedule, and regular readback.

The first source read is D. The constant schedule S exposes the same endpoint at every finite window, so the consumer's precision request remains tied to a displayed DyadicRatCore row.

The readback row R then converts the scheduled observation into regular rational data. This is the only row that hands the constant finite windows to the Real seal, so the seal cannot be inspected before D, S, R have all been read.

Finally, H, C, P, N transport, replay, source, and name that same finite path. Since no other analytic coordinates occur in the carrier, every RealUp consumer factors through the DyadicRatCore, StreamName, and RegSeqRat route before the terminal seal. □

Lean4 ✓ `BEDC.Derived.RealDyadicEmbeddingUp.RealDyadicEmbeddingCarrier regseq handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{RealDyadicEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RealDyadicEmbedding}^{\uparrow}$ packet is generated from a displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint, a constant $\mathsf{StreamName}^{\uparrow}$ schedule, a constant $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealDyadicEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1942.1, Definition 1942.2, and Definition 1942.3 seed the finite constant-dyadic admission route from a DyadicRatCore endpoint to RealUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealDyadicEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, trichotomy, selected limits, density of dyadics, algebraic closure, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint constancy, regular-readback exactness, Real-seal locality, componentwise transport, replay, provenance, local naming, and non-escape for BEDC.Derived.RealDyadicEmbeddingUp.

Chapter 1943

A Concrete Naming Certificate for $\mathsf{RegularCauchyDivision}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyDivision}^{\uparrow}$ packet names guarded division of regular Cauchy data as a finite reciprocal-then-product route. It sits over the regular rational source surface of chapter 301, the finite stream-window discipline of chapter 126, the dyadic endpoint arithmetic of chapter 291, the apartness-guarded reciprocal route of chapter 1471, the product surface of chapter 461, the real inverse boundary of chapter 635, and the terminal real seal of chapter 38. The chapter records only the finite NameCert boundary for X/Y when the denominator has displayed apartness; it is not host division and not a total reciprocal principle.

Definition 1943.1 (Regular Cauchy division carrier)**.** *A* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, A, I, P, W, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *X and Y are the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source rows for the numerator and denominator.*
2. *A is the denominator apartness guard exposing the finite nonzero-domain evidence for Y.*
3. *I is the* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *route that reads Y only through A and returns the reciprocal readback surface.*
4. *P is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route that multiplies X by the reciprocal route I.*
5. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows opened for X, Y, the reciprocal readback, and the product readback.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the guarded quotient candidate produced by the product route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal receiving the guarded quotient packet.*
8. *H records componentwise* hsame *transport for $X, Y, A, I, P, W, R, E, C, Q, N$.*
9. *C records displayed* Cont *replay for source inspection, guard exposure, reciprocal routing, product routing, finite-window handoff, readback, and seal handoff.*

10. *Q records* Pkg *provenance over* $\mathsf{RegularCauchyDivision}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RealInverse}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDivision}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $X, Y, A, I, P, W, R, E, H, C, Q, N$.

Lean4 (definition) `BEDC.Derived.RegularCauchyDivisionUp.RegularCauchyDivisionUp`
Lean4 ✓ `BEDC.Derived.RegularCauchyDivisionUp.RegularCauchyDivisionUpTasteGate single carrier alignment`

Theorem 1943.2 (Regular Cauchy division NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyDivision}^{\uparrow}}$ *surface for Definition 1943.1 consists exactly of numerator and denominator source exposure, denominator apartness exposure, reciprocal-route exposure, product-route exposure, finite StreamName windows, regular rational quotient readback, terminal Real seal handoff, componentwise transport, displayed continuation replay, package provenance, and the local naming row.*

Proof. Project the carrier $D = (X, Y, A, I, P, W, R, E, H, C, Q, N)$. Its coordinates list the two regular Cauchy sources, the denominator guard, reciprocal route, product route, finite windows, quotient readback, seal, transport, replay, provenance, and local name.

The analytic rows are ordered by dependency. The reciprocal route I reads Y only after the apartness guard A, while the product route P reads X together with the reciprocal readback exposed by I.

The structural rows H, C, Q, N transport, replay, source, and name that same finite route. Since every listed obligation is a coordinate or a projection from a coordinate, the seed NameCert surface is exhausted by the displayed packet. □

Theorem 1943.3 (Regular Cauchy division reciprocal-product handoff)**.** *For every accepted* RegularCauchyDivision *carrier $D = (X, Y, A, I, P, W, R, E, H, C, Q, N)$, every quotient readback factors through*

$$(Y, A) \longmapsto I, \qquad (X, I) \longmapsto P, \qquad P \longmapsto R.$$

No product read can consume the denominator as a divisor until the reciprocal route has exposed the apartness-guarded reciprocal surface.

Proof. Read the denominator side first. The row A is the only coordinate licensing reciprocal use of Y, and the reciprocal route I is downstream of that guard.

Next read the product row P. Its left input is the numerator source X, and its right input is the reciprocal surface supplied by I; the carrier contains no separate division operation row.

Finally project the readback row R. Because R is downstream of P, every quotient read has already passed through the denominator guard, reciprocal route, and product route displayed in the statement. □

Theorem 1943.4 (Regular Cauchy division Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *packet reaches the seal row E only after the two source rows, denominator apartness guard, reciprocal route, product route, finite windows, quotient readback, transports, continuations, provenance, and local naming row have been displayed. The seal exports no total division, trichotomy, quotient stream equality, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start from the NameCert obligations. They expose $X, Y, A, I, P, W, R, E, H, C, Q, N$ as the complete packet surface.

Use the reciprocal-product handoff. It places I after the denominator guard and places P after the numerator source and reciprocal route, so the readback R cannot be reached by a direct host division route.

The Real seal row E is terminal. Since the carrier has no additional coordinate for total division, trichotomy, quotient stream equality, selected representatives, or ambient completeness, the seal can export only the guarded finite quotient route already displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDivision}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDivision}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a denominator apartness guard, a $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ route, a $\mathsf{RegularCauchyProduct}^{\uparrow}$ route, finite $\mathsf{StreamName}^{\uparrow}$ windows, a quotient $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDivision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1943.1, Definition 1943.2, Definition 1943.3, and Definition 1943.4 seed the guarded division boundary over regular Cauchy sources, denominator apartness, reciprocal routing, product routing, finite windows, readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDivision}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyDivisionUp.RegularCauchyDivisionUpTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim total division, real trichotomy, quotient stream equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reciprocal-product handoff, Real seal non-escape, and the corresponding finite guarded-division NameCert rows.

Chapter 1944

A Concrete Naming Certificate for $\mathsf{StreamMerge}^{\uparrow}$

Following Bishop and Bridges on constructive sequences, the $\mathsf{StreamMerge}^{\uparrow}$ packet records the finite operation of reading two certified stream schedules through one visible merge selector. It sits over the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance surface of chapter 291, and the terminal real-name seal of chapter 38. It is the finite schedule-merge surface consumed by paired-window constructions such as chapter 414; it is not a quotient of streams, a countable choice selector, a host pairing primitive, or an ambient completion principle.

Definition 1944.1 (Stream merge carrier)**.** *A* $\mathsf{StreamMerge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S_0, S_1, \sigma, W_0, W_1, W, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two certified* $\mathsf{StreamName}^{\uparrow}$ *schedules whose finite observation windows may be inspected.*
2. *σ is the visible merge selector. Each displayed selector row records whether the merged position reads from S_0 or from S_1.*
3. *W_0 and W_1 are the source windows opened from S_0 and S_1.*
4. *W is the merged window ledger obtained by reading each displayed position through σ and then through the selected source window.*
5. *H records componentwise* hsame *transport for the two schedules, selector row, two source windows, merged window, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a merged-window request through σ, the selected S_i, the selected W_i, the merged row W, and the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{StreamMerge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamMerge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, \sigma, W_0, W_1, W, H, C, P, N$. It has no coordinate for quotient stream equality, a hidden selector, a host zip operation, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.StreamMergeUp.StreamMergeTasteGate single carrier alignment`

Theorem 1944.2 (Stream merge NameCert obligations)**.** *For every accepted* $\mathsf{StreamMerge}^{\uparrow}$ *carrier*

$$M = (S_0, S_1, \sigma, W_0, W_1, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamMerge}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{StreamName}^{\uparrow}$ *schedules, visible selector, source windows, merged window, componentwise transport, displayed replay, provenance, and local naming rows;*
2. *selector-stable classifier transport, requiring every transported merged position to keep the same selected side under* H *and* C*;*
3. *source projection recovery, requiring the projection of* W *along either visible selector side to recover the displayed source window* W_0 *or* W_1*;*
4. *merged-window coverage, requiring every displayed row of* W *to be read from exactly one of the two source windows through* σ*;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer non-escape, requiring every regular-rational or real-facing consumer of the merged stream to pass through the selected* $\mathsf{StreamName}^{\uparrow}$ *window and the dyadic observation route before reaching a downstream seal.*

No stream-merge obligation is stored outside these rows.

Proof. Project the carrier of Definition 1944.1. The only schedule data available to the classifier are the two source schedules S_0, S_1, the visible selector σ, the source windows W_0, W_1, and the merged ledger W.

Selector-stable classifier transport is read from H and C. A transported selector row still names one of the two displayed source sides, so a merged position cannot change sides without changing a packet coordinate.

Source projection recovery follows by restricting the merged ledger to one selector side. The positions selected as 0 read through S_0 and W_0, while the positions selected as 1 read through S_1 and W_1.

Merged-window coverage is the converse read of the same finite data. Every row of W is produced by first inspecting σ and then using exactly the selected source window; the carrier has no third schedule or unscheduled row.

Finally, the provenance row P names the downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer route, while N names the local certificate. Since quotient stream equality, hidden selectors, host pairing, selected limits, countable choice, and ambient completion are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1944.3 (Stream merge projection stability)**.** *Let*

$$M = (S_0, S_1, \sigma, W_0, W_1, W, H, C, P, N)$$

be an accepted $\mathsf{StreamMerge}^{\uparrow}$ *carrier. Projecting* M *back to either source schedule preserves the displayed* $\mathsf{StreamName}^{\uparrow}$ *window on that side and preserves the dyadic,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumer route attached to that window. Thus a consumer of the projected source receives the same source schedule, source window, transport, replay, provenance, and local naming rows that were present before the merge.*

Proof. Project the accepted carrier and choose one side of the visible selector. The selected side determines whether the read uses S_0, W_0 or S_1, W_1.

Use source projection recovery from Definition 1944.2. The restriction of W to the chosen selector side is exactly the source window displayed in the carrier, so projection does not synthesize a different schedule window.

The dyadic and regular-rational route is unchanged because P records the same $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ dependency surface for the selected source window. Any real-facing consumer then reaches $\mathsf{Real}^{\uparrow}$ only after that selected StreamName window and its dyadic readback route have been displayed.

Transport and replay remain componentwise through H and C, and the local row N names the same finite packet. Therefore source projection preserves the displayed window and the downstream consumer route rather than exporting quotient stream equality, a hidden selector, a host zip operation, selected limits, countable choice, or ambient completion. □

Falsifiable prediction: Every paired-window Real or Completion consumer using two certified stream schedules factors through a $\mathsf{StreamMerge}^{\uparrow}$ packet that displays both source windows, one visible selector, one merged window ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, regularcauchyinterleaving: $\mathsf{StreamMerge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two certified schedules, a visible merge selector, two source windows, one merged window ledger, classifier transport, projection recovery, downstream regular-rational and real consumer routing, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamMerge}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamMerge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1944.1, Definition 1944.2, and Definition 1944.3 seed the finite two-schedule merge route through StreamName windows, a visible selector, merged-window coverage, source projection recovery, and regular-rational and real-facing non-escape.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamMerge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, hidden selectors, host pairing, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, selector-stable classifier transport, source projection recovery, merged-window coverage, consumer non-escape, and TasteGate field faithfulness for BEDC.Derived.StreamMergeUp.

Constructive story: A $\mathsf{StreamMerge}^{\uparrow}$ packet is generated from two StreamName schedules, one visible merge selector, two source windows, one merged window ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1945

A Concrete Naming Certificate for $\mathsf{DyadicIntervalDiameter}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ packet names the finite dyadic width certificate used when an interval enclosure is handed to regular-rational and real-name consumers. It sits after the endpoint packet of chapter 306, the dyadic rational carrier of chapter 291, the rounding and tolerance surface of chapter 433, the nested dyadic enclosure route of chapter 328, the finite stream-window layer of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter isolates the width row that says how a displayed dyadic interval supplies an error budget before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reads it.

Definition 1945.1 (Dyadic interval diameter carrier)**.** *A* $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, L, U, D, R, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{DyadicInterval}^{\uparrow}$ *row whose interval-order ledger and endpoint slots are being measured.*
2. *L and U are the lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows read from the same interval packet I.*
3. *D is the displayed nonnegative dyadic diameter row, recording the width comparison $0 \leq D$ and the endpoint bound $U - L \leq D$ in the visible dyadic order ledger.*
4. *R is the* $\mathsf{DyadicRounding}^{\uparrow}$ *tolerance row that translates the displayed diameter into the requested dyadic error budget.*
5. *W is the readback window opened for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers that need the interval midpoint, endpoint, or width information.*
6. *H records componentwise* hsame *transport for the interval row, endpoint rows, diameter row, tolerance row, readback window, replay, provenance, and local naming data.*
7. *C records displayed* Cont *replay for consumers that inspect the interval, the endpoints, the diameter bound, the rounding tolerance, or the readback window.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalDiameter}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicRounding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalDiameter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, U, D, R, W, H, C, P, N$. It has no coordinate for a host interval diameter, quotient real equality, a selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalDiameterUp.DyadicIntervalDiameterTasteGate single carrier alignment`

Theorem 1945.2 (Dyadic interval diameter NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ *carrier*

$$Q = (I, L, U, D, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalDiameter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed interval row, lower endpoint, upper endpoint, diameter row, tolerance row, readback window, transport, replay, provenance, and local naming;*
2. *endpoint source exactness, requiring L and U to be the endpoint rows exposed by the same* $\mathsf{DyadicInterval}^{\uparrow}$ *packet I;*
3. *nonnegative diameter exactness, requiring D to carry both the displayed nonnegativity witness and the visible dyadic bound from L, U to the width row;*
4. *tolerance handoff exactness, requiring every consumer error budget to pass through R before the readback window W is exposed;*
5. *classifier stability, requiring transported packets to compare only through the stored* hsame *and* Cont *rows;*
6. *ledger non-escape, requiring P, N to source and name no host interval diameter, quotient real equality, selected limit, trichotomy, countable choice, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1945.1. The accepted packet displays exactly one interval row, two endpoint rows, one nonnegative diameter row, one tolerance row, one readback window, and the structural rows that transport, replay, source, and name them.

Endpoint source exactness is read from I, L, U. The lower and upper rows are not independent dyadic rationals chosen by a host interval operation; they are the endpoint slots exposed by the displayed $\mathsf{DyadicInterval}^{\uparrow}$ carrier.

The nonnegative diameter clause is read from D. Its visible order ledger records $0 \leq D$ and the bound $U - L \leq D$, so the local NameCert surface can answer width queries by projection through the same dyadic rows.

The tolerance handoff clause is downstream of R and W. A requested error budget first reaches the rounding row R, and only then opens the finite readback window W for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumers.

Finally, H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Since the carrier contains no excluded coordinate, none of the excluded objects can enter the local NameCert surface. □

Theorem 1945.3 (Dyadic interval diameter width handoff)**.** *Let $Q = (I, L, U, D, R, W, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ *carrier. Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read of interval width factors through the displayed route*

$$I, L, U, D \longmapsto R \longmapsto W.$$

The handoff supplies a finite dyadic error budget from the endpoint rows of I; it does not supply a host interval diameter, quotient stream equality, selected limiting point, trichotomy decision, countable-choice selector, or ambient completeness witness.

Proof. Begin with a consumer read of the width information. The only interval-facing coordinate is I, and the only endpoint-facing coordinates are L and U, so the read first projects the displayed dyadic interval and its two endpoint rows.

The diameter query then reaches D. This row supplies the nonnegative width certificate and the displayed bound from $U - L$ to D, so the consumer receives a dyadic error budget rather than an external interval-measure operation.

The tolerance row R repacks that dyadic budget for the requested readback precision. Once R has been displayed, W opens the finite stream and regular-rational window consumed downstream.

Because H, C, P, N only transport, replay, source, and name this route, every exported width read factors through the displayed chain and none of the excluded host objects is produced. □

Theorem 1945.4 (Dyadic interval diameter real error boundary)**.** *For an accepted* $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ *carrier* $Q = (I, L, U, D, R, W, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$*-facing error claim exported by* Q *is bounded by the displayed dyadic diameter row before it reaches the terminal real-name consumer. Concretely, the only public route to a real error boundary is*

$$I, L, U, D, R, W \longmapsto \mathsf{Real}^{\uparrow}.$$

The route certifies the finite enclosure width available to the real-name layer, but it does not identify quotient real representatives, choose a limit point, decide trichotomy, invoke countable choice, or close ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. A real-facing error claim cannot bypass the interval row I, because the endpoint rows L, U and the diameter row D are named as coordinates of that same finite packet.

The displayed diameter row is then the only source of a width bound. It provides the dyadic comparison needed for an error boundary, while the tolerance row R records the finite rounding step required before any readback window opens.

The window W is the only public bridge to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. Therefore a terminal real-name read receives the interval width through I, L, U, D, R, W and not through a quotient equality or a selected limit.

The transport, replay, provenance, and local naming rows preserve this route. Since the excluded objects are absent from the carrier, the real-facing boundary remains a finite displayed dyadic error certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalDiameter}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalDiameter}^{\uparrow}$ packet is generated from a DyadicInterval row, lower and upper DyadicRatCore endpoint rows, a displayed nonnegative diameter row, a DyadicRounding tolerance row, a finite StreamName/RegSeqRat/Real readback window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicIntervalDiameter}^{\uparrow}}$, seed)

Scope closed: Definition 1945.1, Definition 1945.2, Definition 1945.3, and Definition 1945.4 seed the finite diameter route from dyadic interval endpoints to regular rational and real-name error budgets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalDiameter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval diameter, quotient real equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint source exactness, nonnegative diameter exactness, tolerance handoff exactness, real error boundary routing, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalDiameterUp.

Chapter 1946

A Concrete Naming Certificate for $\mathsf{CauchyCompression}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompression}^{\uparrow}$ packet records the finite constructive operation that turns modulus-controlled Cauchy data into a fast Cauchy certificate. It sits over the visible modulus schedule of chapter 292, the compressed fast-Cauchy interface of chapter 323, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies the L10 Real and Completion route with a standard finite bridge from an explicit modulus to a fast Cauchy certificate; it is not quotient stream equality, a selected limit, countable choice, host equality, ambient completeness, Lean verification, or a standard bridge.

Definition 1946.1 (Cauchy compression carrier)**.** *A* $\mathsf{CauchyCompression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, S, D, Q, F, E, H, C_0, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, recording the visible request-to-threshold map used to choose the finite tail windows.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite stream observations selected by the modulus schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the requested radii, slack comparisons, and dyadic arithmetic consumed by the selected windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same selected windows and tolerance ledger.*
5. *F is the* $\mathsf{FastCauchy}^{\uparrow}$ *compressed output row, recording the fast Cauchy certificate produced from M, S, D, Q.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the modulus, window, tolerance, readback, and fast-Cauchy rows have been displayed.*
7. *H records componentwise* hsame *transport for the modulus schedule, selected windows, tolerance ledger, regular readback, fast output, real seal, replay, provenance, and local naming rows.*
8. *C_0 records displayed* Cont *replay from each precision request through M, S, D, Q, F, E and then through H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompression}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompression}^{\uparrow}}$ *row.*

The classifier compares accepted compression packets only through the displayed rows $M, S, D, Q, F, E, H, C_0, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.CauchyCompressionUp.CauchyCompressionTasteGate single carrier alignment`

Theorem 1946.2 (Cauchy compression NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompression}^{\uparrow}$ *carrier*

$$C = (M, S, D, Q, F, E, H, C_0, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompression}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule M,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q,* $\mathsf{FastCauchy}^{\uparrow}$ *compressed output F,* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C_0, P, N;*
2. *modulus admission, requiring each precision request to enter through the displayed schedule M before any stream window is inspected;*
3. *finite window selection, requiring S to contain exactly the windows selected by M for the displayed precision requests;*
4. *dyadic accounting, requiring D to store exactly the tolerance radii and slack comparisons consumed by the selected windows;*
5. *readback and fast-output routing, requiring Q and F to remain downstream of M, S, D and to use no unlisted stream coordinate;*
6. *real-seal routing, requiring E to be reached only after the compressed fast-Cauchy output has been displayed;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C_0, P, N;*
8. *non-escape for quotient streams, selected limits, countable choice, host equality, ambient completeness, Lean verification, and standard-bridge data.*

No Cauchy compression obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyCompressionUp.CauchyCompressionCarrier namecert obligations`

Proof. Project the carrier of Definition 1946.1. The analytic rows are the visible modulus schedule, selected stream windows, dyadic tolerance ledger, regular readback, fast-Cauchy output, and terminal real seal; the remaining rows transport, replay, source, and name that same route.

The modulus row is read before any window is opened. For each displayed precision request, M supplies a finite threshold, and the window row S records only the observations selected from that threshold. The construction therefore uses visible finite windows rather than a quotient stream or a selected limiting object.

The selected windows then pass through the dyadic ledger and readback rows. The ledger D contains the requested radii and slack comparisons, while Q is the regular rational readback obtained from those same displayed windows.

The compressed row F is downstream of M, S, D, Q. It is the only $\mathsf{FastCauchy}^{\uparrow}$ coordinate in the carrier, so every accepted fast certificate is produced from the displayed modulus-controlled route.

Finally E, H, C_0, P, N seal, transport, replay, source, and name the same finite route. Since none of the excluded objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1946.3 (Cauchy compression regular-sequence handoff)**.** *Let*

$$C = (M, S, D, Q, F, E, H, C_0, P, N)$$

be an accepted $\mathsf{CauchyCompression}^{\uparrow}$ *carrier. Every precision request answered by the fast Cauchy row F has the same finite route through the regular rational row Q and the real seal E:*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto F \longmapsto E \longmapsto H, C_0, P, N.$$

Consequently a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the displayed modulus schedule, selected windows, tolerance ledger, regular readback, fast-Cauchy certificate, seal, transport, replay, provenance, and local naming. The handoff does not export quotient streams, selected limits, countable choice, host equality, ambient completeness, Lean evidence, or standard-bridge data.*

Proof. Begin with the displayed precision request and read the modulus schedule M. The schedule selects a finite threshold, and the window row S records the stream observations opened at that threshold.

Pass the selected windows through D and Q. The dyadic ledger supplies the tolerance arithmetic, and the regular rational readback records the observation that the downstream consumer can inspect.

Now read the compressed row F. Because F is downstream of M, S, D, Q, the fast Cauchy certificate is obtained from the same finite route that produced the regular rational readback.

The terminal seal E is reached after F, and the structural rows H, C_0, P, N preserve the displayed route componentwise. Thus the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ handoff consume the same finite data and introduce none of the excluded quotient, selector, choice, equality, completeness, verification, or bridge objects. □

Falsifiable prediction: Every $\mathsf{CauchyCompression}^{\uparrow}$ precision read factors through a CauchyModulus schedule, selected StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a FastCauchy compressed output, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchymodulus, fastcauchy, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyCompression}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries visible modulus scheduling, finite window selection, dyadic tolerance accounting, regular rational readback, fast Cauchy compression, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompression}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompression}^{\uparrow}$ packet is generated from a CauchyModulus schedule, selected StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a FastCauchy compressed output, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompression}^{\uparrow}}$, seed)

Scope closed: Definition 1946.1, Definition 1946.2, and Definition 1946.3 seed the finite route from visible modulus-controlled Cauchy data to a fast Cauchy certificate consumed by regular rational and Real interfaces.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompression}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, modulus admission, finite window selection, dyadic accounting, readback and fast-output routing, real-seal routing, and regular-sequence handoff for BEDC.Derived.CauchyCompressionUp.

Chapter 1947

A Concrete Naming Certificate for $\mathsf{RegularCauchyMap}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyMap}^{\uparrow}$ packet records the finite BEDC route by which a displayed map sends regular Cauchy rational names to regular Cauchy rational names before a Real-facing consumer reads the result. It sits between the finite source-window discipline of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, the continuity surface of chapter 130, and the terminal seal of chapter 38. The chapter names only the finite map surface between regular Cauchy names; it does not identify quotient streams, select limits, compare host functions, use countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1947.1 (Regular Cauchy map carrier)**.** *A* $\mathsf{RegularCauchyMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, F, T, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the source windows requested by the packet.*
2. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attached to those windows before any map output is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the visible dyadic radii, slack comparisons, and finite requests used by the source and target readbacks.*
4. *F is the displayed map-and-modulus row, recording for each inspected source precision a finite target precision request and the modulus comparison that justifies it.*
5. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *finite-window row produced from S, R, D, F.*
6. *Q is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attached to T and to the same dyadic tolerance ledger.*
7. *A is the target* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after T and Q have been displayed.*
8. *H records componentwise* hsame *transport for the source windows, source regular handoff, dyadic ledger, map-and-modulus row, target windows, target regular handoff, target Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S \longmapsto R \longmapsto D, F \longmapsto T \longmapsto Q \longmapsto A.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMap}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyMapUp.RegularCauchyMapTasteGate single carrier alignment`

Theorem 1947.2 (Regular Cauchy map NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMap}^{\uparrow}$ *carrier*

$$M = (S, R, D, F, T, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source StreamName windows, source RegSeqRat handoff, DyadicRatCore tolerance ledger, displayed map-and-modulus row, target StreamName windows, target RegSeqRat handoff, target Real seal, and structural rows H, C, P, N;*

2. *source-window exactness, requiring every map request to project the finite source windows S before the source handoff R or any target row is inspected;*

3. *source regularity routing, requiring R to attach the inspected source windows to a regular rational name before F can read a source approximation;*

4. *dyadic tolerance transport, requiring D to carry the radii and slack comparisons used by the map-and-modulus row F;*

5. *target-window production, requiring T to be generated from the displayed source windows, source handoff, tolerance ledger, and map-and-modulus row;*

6. *target regularity and seal routing, requiring Q to mediate between T and A before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed;*

7. *non-escape for quotient stream equality, selected limits, host function equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge checking.*

No local regular-Cauchy map obligation is stored outside these rows.

Proof. Project the carrier of Definition 1947.1. The analytic coordinates are exactly the source finite windows, the source regular handoff, the dyadic tolerance ledger, the displayed map-and-modulus row, the target finite windows, the target regular handoff, and the target Real seal.

The source route is read first. A map request opens S, then passes through the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, so the packet never applies the map to an uninspected stream representative or to a selected limit.

The dyadic route is then transported through D and F. The ledger D supplies the visible radii and slack comparisons, while the row F turns each inspected source precision into a finite target precision request through its displayed modulus row.

Finally the target route is exposed. The windows T are produced only from the preceding rows, the target regular handoff Q attaches those windows to a regular rational name, and the Real seal A is downstream of Q. The structural rows H, C, P, N replay and name this same finite route, so the listed obligations exhaust the local NameCert surface. □

Theorem 1947.3 (Regular Cauchy map source-window preservation)**.** *Let*

$$M = (S, R, D, F, T, Q, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyMap}^{\uparrow}$ *carrier. Every target window produced by the displayed map-and-modulus row* F *is backed by a finite source window from* S*, a source* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through* R*, and dyadic tolerance rows from* D*. Consequently a target-window consumer cannot bypass the source StreamName and RegSeqRat route.*

Proof. Begin with a target-window consumer. Projection gives the target row T, but T is a downstream coordinate of the route displayed by the carrier, not an independent stream representative.

Trace the target window backward through F. The map-and-modulus row stores the finite source precision and the target precision it requests, so the consumer must recover a source window in S before the target cells can be named.

The source window is attached to regular rational readback by R. The dyadic tolerance rows in D then supply the radii and slack comparisons used by the map row when it forms the target request.

Thus every target-window read preserves a source-window witness, a source regular handoff, and a dyadic tolerance route. None of these projections introduces quotient stream equality, a selected limit, host function equality, or countable choice. □

Theorem 1947.4 (Regular Cauchy map Real seal handoff)**.** *For every accepted* $\mathsf{RegularCauchyMap}^{\uparrow}$ *carrier* $M = (S, R, D, F, T, Q, A, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal consumer factors through*

$$S \longmapsto R \longmapsto D, F \longmapsto T \longmapsto Q \longmapsto A$$

together with the structural rows H, C, P, N*. In particular the target* $\mathsf{Real}^{\uparrow}$ *seal is reached only after the target* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff has been displayed.*

Proof. Start with a seal-facing request. Carrier projection exposes A as a target Real seal row, but the displayed route places A after the target regular handoff Q.

Read the target handoff. The row Q is attached to the target windows T, and those windows are produced by the source route S, R together with the dyadic ledger D and map-and-modulus row F.

Only then may the consumer inspect the Real seal. The replay row C records this ordering, the transport row H preserves it under componentwise comparison, and the provenance and local naming rows P, N name no additional principle.

Therefore the target Real seal is a downstream endpoint of the finite regular-Cauchy map route, not an ambient completeness or host function equality assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMap}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMap}^{\uparrow}$ packet is generated from source StreamName windows, a source RegSeqRat handoff, DyadicRatCore tolerance rows, a displayed map-and-modulus row, target StreamName windows, a target RegSeqRat handoff, a target RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyMap}^{\uparrow}}$, seed)

Scope closed: Definition 1947.1, Definition 1947.2, Definition 1947.3, and Definition 1947.4 seed the finite L10 map route between regular Cauchy names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, source regularity routing, dyadic tolerance transport, target-window production, target regularity and seal routing, and ledger non-escape for BEDC.Derived.RegularCauchyMapUp.

Chapter 1948

A Concrete Naming Certificate for $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$ packet records that the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ order of dyadic endpoints is preserved by the $\mathsf{RealDyadicEmbedding}^{\uparrow}$ route before $\mathsf{Real}^{\uparrow}$, density, or located-Archimedean consumers read the terminal seal. It sits after the dyadic order ledger of chapter 291, the constant dyadic real-name route of chapter 1942, the density witness surface of chapter 1484, the located Archimedean boundary of chapter 1851, the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal real-name seal of chapter 38. The chapter isolates the finite order-preserving handoff from dyadic endpoint data to Real-facing consumers.

Definition 1948.1 (RealDyadicOrderEmbedding carrier)**.** *A* $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D_0, D_1, O, E_0, E_1, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D_0 and D_1 are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, including their signed dyadic numerators, scales, endpoint tolerance ledgers, and visible comparison data.*
2. *O is the dyadic order row recording the comparison of D_0 and D_1 in the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *order ledger.*
3. *E_0 and E_1 are the two* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *rows sending the endpoint rows D_0, D_1 into constant regular real names.*
4. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *window family opened by the two constant embedding routes before any Real-facing order consumer receives a seal.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S and returning each read to its source endpoint and order row.*
6. *A is the* $\mathsf{LocatedArchimedean}^{\uparrow}$ *and* $\mathsf{DyadicDensityReal}^{\uparrow}$ *handoff row used by later density or located-Archimedean consumers that ask for an embedded dyadic interval.*
7. *H records componentwise* hsame *transport for the two endpoint rows, order row, embedding rows, finite windows, readbacks, handoff row, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay for every consumer that inspects endpoint order, constant embedding data, density handoff, located-Archimedean search, or terminal* $\mathsf{Real}^{\uparrow}$ *seals.*
9. *P is the* Pkg *provenance over* $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealDyadicEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicDensityReal}^{\uparrow}$, $\mathsf{LocatedArchimedean}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDyadicOrderEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D_0, D_1, O, E_0, E_1, S, R, A, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected limits, countable choice, a host density theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealDyadicOrderEmbeddingUp.TasteGate.RealDyadicOrderEmbeddingTasteGate`
`single carrier alignment`

Theorem 1948.2 (RealDyadicOrderEmbedding NameCert obligations)**.** *For every accepted* RealDyadicOrderEmbe *carrier*

$$K = (D_0, D_1, O, E_0, E_1, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealDyadicOrderEmbedding}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed dyadic endpoint rows, order row, embedding rows, stream windows, regular readbacks, density and located-Archimedean handoff, transport, replay, provenance, and local naming;*
2. *dyadic-order exactness, requiring O to read the comparison of the endpoint rows D_0, D_1 from the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rather than from a detached host order;*
3. *embedding-order preservation, requiring E_0, E_1 to expose the constant real-name images of D_0, D_1 only together with the order row O;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring every finite Real-facing order read to pass through S and R before a terminal* $\mathsf{Real}^{\uparrow}$ *seal is inspected;*
5. *ledger non-escape, requiring H, C, P, N to preserve, replay, source, and name only the displayed rows and to export no trichotomy, quotient real equality, selected limit, countable-choice schedule, host density theorem, ambient Real completeness, Lean verification, or bridge checking.*

No order-embedding obligation is stored outside these rows.

Proof. Project the accepted packet $K = (D_0, D_1, O, E_0, E_1, S, R, A, H, C, P, N)$. The carrier admission row exposes exactly two dyadic endpoint rows, one dyadic comparison row, two constant embedding rows, one paired window family, one paired readback row, one density and located-Archimedean handoff row, and the four structural rows.

Dyadic-order exactness is read from O. Since O compares the endpoint rows D_0, D_1 inside the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the packet cannot replace that comparison by a host real order or by a trichotomy decision.

Embedding-order preservation is the route through E_0, E_1. Each embedding row is the constant $\mathsf{RealDyadicEmbedding}^{\uparrow}$ image of its matching endpoint row, and both rows are carried with O, so a Real-facing order read receives the dyadic comparison before it receives either terminal seal.

The window and readback clauses are then projection through S and R. Every finite consumer request opens the paired $\mathsf{StreamName}^{\uparrow}$ windows and paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks before the same data can be handed to $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name only this displayed route. Since the carrier contains no excluded coordinate, the five rows exhaust the local certificate surface. □

Theorem 1948.3 (RealDyadicOrderEmbedding density handoff)**.** *Every density or located-Archimedean consumer of the embedded dyadic interval of an accepted* $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$ *carrier factors through*

$$D_0, D_1, O \longmapsto E_0, E_1 \longmapsto S, R \longmapsto A \longmapsto \mathsf{Real}^{\uparrow}.$$

In particular, the consumer reads the dyadic order row and the two $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *rows before reaching* $\mathsf{DyadicDensityReal}^{\uparrow}$, $\mathsf{LocatedArchimedean}^{\uparrow}$, *or the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Begin with a density or located-Archimedean consumer of the embedded interval. By Definition 1948.1, the only interval endpoints available to that consumer are the dyadic rows D_0, D_1 and their comparison row O.

The consumer then crosses the constant embedding rows. The rows E_0, E_1 are the only $\mathsf{RealDyadicEmbedding}^{\uparrow}$ coordinates, so the dyadic endpoints enter the Real-facing surface only through the two displayed embedding routes.

The finite observation layer is S, R. These rows expose the paired $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks attached to the two embeddings, and they precede every handoff row in the carrier.

The density and located-Archimedean handoff row A is downstream of those reads. Thus any later $\mathsf{DyadicDensityReal}^{\uparrow}$ or $\mathsf{LocatedArchimedean}^{\uparrow}$ request receives the dyadic order data and the two constant embedding routes before it can inspect a terminal $\mathsf{Real}^{\uparrow}$ seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealDyadicOrderEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RealDyadicOrderEmbedding}^{\uparrow}$ packet is generated from two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, one displayed dyadic order row, two $\mathsf{RealDyadicEmbedding}^{\uparrow}$ rows, paired $\mathsf{StreamName}^{\uparrow}$ windows, paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{DyadicDensityReal}^{\uparrow}$ and $\mathsf{LocatedArchimedean}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealDyadicOrderEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1948.1, Definition 1948.2, and Definition 1948.3 seed the finite order-preserving dyadic-to-real handoff for density and located-Archimedean consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealDyadicOrderEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-order exactness, embedding-order preservation, StreamName and RegSeqRat handoff, density handoff, ledger non-escape, and bridge coverage for BEDC.Derived.RealDyadicOrderEmb

Chapter 1949

A Concrete Naming Certificate for $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley-style metric completion, the $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$ packet records the finite certificate by which a closed metric subspace inherits the completion-limit route carried by its ambient metric completion. It sits after the subspace admission surface of chapter 1519, the Bishop regular Cauchy completion route of chapter 1639, the completion carrier of chapter 1506, the complete-metric limit row of chapter 128, the separated metric boundary of chapter 1411, the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal real-name seal of chapter 38. The chapter isolates the displayed route from an admitted subspace Cauchy packet to a retained subspace limit, without quotienting the subset or selecting limits by choice.

Definition 1949.1 (ClosedSubspaceCompletion carrier)**.** *A* $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, A, K, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the parent* $\mathsf{MetricCompletion}^{\uparrow}$ *row, including the ambient separated metric carrier, the regular Cauchy source data, and the completion handoff route used by downstream consumers.*
2. *A is the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row naming the displayed subspace predicate, the inherited metric restriction, and the finite membership ledger for the source Cauchy packet.*
3. *K is the closedness-under-limit row: whenever a Cauchy source is admitted by A and its ambient completion route in X reaches a displayed limit, the same route carries the subspace-membership witness to that limit.*
4. *L is the inherited* $\mathsf{CompleteMetric}^{\uparrow}$ *limit row obtained by replaying the ambient completion route through K and then reading the result as a subspace limit rather than as a detached ambient point.*
5. *H records componentwise* hsame *transport for the parent completion row, subspace admission row, closedness row, inherited limit row, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay for every consumer that inspects subspace admission, ambient completion data, closedness-under-limit, or the inherited complete-metric row.*

7. *P is the* Pkg *provenance over* $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedSubspaceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, A, K, L, H, C, P, N. It has no coordinate for quotient subset equality, selected limits, countable choice, open-cover compactness, ambient completeness, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ClosedSubspaceCompletionUp.ClosedSubspaceCompletionTasteGate single carrier alignment`

Theorem 1949.2 (ClosedSubspaceCompletion NameCert obligations)**.** *For every accepted* ClosedSubspaceComplet *carrier*

$$Q = (X, A, K, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedSubspaceCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the parent metric-completion row, metric-subspace admission row, closedness-under-limit row, inherited complete-metric limit row, transport, replay, provenance, and local naming;*

2. *source compatibility, requiring the Cauchy source read by X to be admitted through the same subspace row A before any limit row is inspected;*

3. *closedness retention, requiring K to carry the subspace-membership witness along the ambient completion route rather than through quotient subset equality or a selected representative;*

4. *inherited-limit exactness, requiring L to be obtained by replaying the ambient* $\mathsf{CompleteMetric}^{\uparrow}$ *row through K and not by invoking ambient completeness for the subspace;*

5. *classifier stability, requiring transported packets to compare only through the stored* hsame *and* Cont *rows;*

6. *ledger non-escape, requiring P, N to source and name no selected limit, countable-choice selector, open-cover compactness proof, ambient completeness principle,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1949.1. The accepted packet displays exactly one parent completion row, one subspace admission row, one closedness-under-limit row, one inherited limit row, and the structural rows that transport, replay, source, and name them.

Source compatibility is read from X and A. The Cauchy source used by the parent completion route is the same source whose finite membership ledger is exposed by the subspace admission row, so a consumer cannot replace it by a detached subspace quotient.

Closedness retention is the role of K. It transports the displayed membership witness along the ambient completion route and returns a limit that is still read through the subspace row.

Inherited-limit exactness is then projection through L. The complete-metric limit row is obtained after K has replayed the ambient route, so the subspace receives a retained limit rather than a new ambient-completeness principle.

Finally, H, C, P, N preserve, replay, source, and name only this displayed route. Since the carrier contains no excluded coordinate, the listed rows exhaust the local certificate surface. □

Theorem 1949.3 (ClosedSubspaceCompletion limit retention)**.** *Let $Q = (X, A, K, L, H, C, P, N)$ be an accepted* $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$ *carrier. Every subspace Cauchy source admitted by A and completed through the parent row X reaches its inherited limit only through the retained route*

$$X, A \longmapsto K \longmapsto L.$$

Thus the exported limit remains a subspace limit named by the displayed closedness row, and no selected ambient limit, quotient subset equality, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ *completeness is exported.*

Proof. Start with a Cauchy source admitted by A. By the carrier definition, the only completion data available for that source is the parent row X, so the source first follows the displayed metric-completion route.

The closedness row K is then forced. It is the only coordinate that can turn the ambient limit reached through X into a subspace-membership witness, and it does so by replaying the same finite source route.

The inherited limit row L is downstream of K. Consequently the complete-metric consumer receives a limit only after the closedness-under-limit witness has retained subspace membership.

The structural rows preserve this order under transport and replay. Since no excluded limit-selection or ambient-completeness coordinate is present, every exported subspace limit factors through X, A, K, L. □

Theorem 1949.4 (ClosedSubspaceCompletion nonescape)**.** *For an accepted* $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$ *carrier $Q = (X, A, K, L, H, C, P, N)$, every* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the inherited subspace completion data reads only the displayed rows*

$$X, A, K, L, H, C, P, N.$$

In particular, the packet cannot export quotient subset equality, selected limits, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ *completeness beyond the named finite route.*

Proof. Project the accepted carrier. The only consumer-facing rows are the parent completion row X, subspace admission row A, closedness-under-limit row K, inherited limit row L, and the four structural rows.

A $\mathsf{CompleteMetric}^{\uparrow}$ consumer must read L, and L is available only after the closedness row K has replayed the ambient route from X with the subspace admission ledger A attached.

The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers are no freer. Their finite windows, regular readbacks, and terminal real-name seals are inherited through the parent completion row and are replayed through the same closedness and subspace-admission route.

The rows H, C, P, N do not add data; they only transport, replay, source, and name the accepted packet. Since none of the excluded objects is a coordinate of Q, no consumer can recover such an object from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSubspaceCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$ packet is generated from a parent $\mathsf{MetricCompletion}^{\uparrow}$ row, a $\mathsf{MetricSubspace}^{\uparrow}$ admission row, a closedness-under-limit row, an inherited $\mathsf{CompleteMetric}^{\uparrow}$ limit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedSubspaceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1949.1, Definition 1949.2, Definition 1949.3, and Definition 1949.4 seed the finite closed-subspace completion route from admitted Cauchy source to retained subspace limit.

Formal verification: FormalStatus(NameCert$_{\text{ClosedSubspaceCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient subset equality, selected limits, countable choice, open-cover compactness, ambient completeness, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, closedness retention, inherited-limit exactness, consumer non-escape, transport, replay, provenance, and local naming for BEDC.Derived.ClosedSubspaceCompletion

Chapter 1950

A Concrete Naming Certificate for $\mathsf{NormedSpace}^{\uparrow}$

Following Bourbaki and Bishop–Bridges constructive analysis, the $\mathsf{NormedSpace}^{\uparrow}$ packet records the finite NameCert surface for a non-singleton normed vector space. It consumes the displayed vector-space source of chapter 47, the real-valued norm interface of chapter 89, the metric readback discipline of chapter 57, and the completion-facing boundary of chapter 95. The packet is an interface for later Banach, Hilbert, bounded-operator, and functional-analysis certificates; it is not the singleton $\mathsf{Norm}^{\uparrow}$ instance, not a host normed-space structure, not quotient completion, and not a choice principle.

Definition 1950.1 (NormedSpace carrier)**.** *A* $\mathsf{NormedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, R, N, M, Q, H, T, P, C)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row, exposing the vector carrier, vector classifier, zero vector, addition, negation, and scalar action only through displayed BEDC data.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by all norm values, scalar absolute values, metric distances, and completion tolerances.*
3. *N is the real-valued norm row, carrying a map from admitted vector histories to R-sealed real histories together with nonnegativity, zero exactness, triangle inequality, and scalar compatibility evidence.*
4. *M is the induced* $\mathsf{Met}^{\uparrow}$ *row, whose distance read between x and y is the norm read of the displayed difference $x - y$ through V, N, R.*
5. *Q is the completion-facing row, recording Cauchy windows, tolerance requests, and handoff data for completion consumers without selecting a completed point.*
6. *H records componentwise* hsame *transport for V, R, N, M, Q and for the replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from every norm, metric, or completion request through the same rows V, R, N, M, Q, H, P, C.*
8. *P is the* Pkg *provenance over* $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *completion-facing Cauchy data,* BHist, hsame, Cont, *and* NameCert.

9. C is the local $\mathsf{NameCert}_{\mathsf{NormedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for host normed-space equality, quotient completion, selected limits, basis choice, classical duality, or an ambient Banach or Hilbert structure.

Lean4 (definition) `BEDC.Derived.NormedSpaceUp.NormedSpaceUp`

Theorem 1950.2 (NormedSpace NameCert obligations)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *carrier*

$$S = (V, R, N, M, Q, H, T, P, C),$$

the local $\mathsf{NameCert}_{\mathsf{NormedSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed vector-space, Real, norm, induced metric, completion-facing, transport, replay, provenance, and local naming rows;*
2. *classifier transport, requiring equality of packet reads to be checked componentwise through $V, R, N, M, Q, H, T, P, C$ and never through host extensional equality;*
3. *zero exactness, requiring the norm-zero classifier in N to coincide with the displayed vector-zero classifier in V;*
4. *triangle inequality, requiring every norm read of a displayed sum to factor through the R-sealed addition and order rows already attached to N;*
5. *scalar compatibility, requiring each scalar multiplication read to pass through the scalar row of V, the real absolute-value row of R, and the norm row N;*
6. *metric handoff, requiring M to read distances only as norm reads of displayed vector differences through V, N, R;*
7. *completion-facing nonescape, requiring Q, H, T, P, C to preserve the same displayed route for Cauchy and completion consumers without adding quotient completions, selected limits, basis choice, choice, or host Banach/Hilbert structure.*

No $\mathsf{NormedSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1950.1. The accepted packet lists the vector-space, Real, norm, induced metric, completion-facing, transport, replay, provenance, and local naming rows.

Classifier transport is then componentwise. A comparison of two accepted packets can inspect only the rows displayed in the carrier, so vector data are compared through V, real and norm data through R, N, metric data through M, completion-facing data through Q, and structural replay through H, T, P, C.

The zero, triangle, and scalar rows are the norm obligations. Zero exactness identifies a zero norm read precisely with the displayed vector-zero classifier of V. The triangle row reads the norm of a sum through the real addition and order data in R, and scalar compatibility reads scalar multiplication through the scalar row of V together with the absolute-value row of R.

The metric row is forced by construction: M has no independent distance source. Its distance read from x to y is the norm read of the displayed difference $x - y$, so every metric consumer must pass through V, N, R before it reaches M.

Finally, the completion-facing row Q and the structural rows H, T, P, C replay the same displayed route for Cauchy windows and completion requests. Since the carrier has no quotient-completion, selected-limit, basis-choice, or host Banach/Hilbert coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1950.3 (NormedSpace zero exactness)**.** *Let $S = (V, R, N, M, Q, H, T, P, C)$ be an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet. The zero classifier exposed by the norm row N is exact precisely along the displayed vector-zero row of V: a norm read may certify zero only by reading the vector zero classifier in V, the real zero and order rows in R, and the local transport and replay rows H, T, C. It cannot certify zero by host vector equality, quotient equality, basis coordinates, or an ambient Banach-space identity.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier zero exactness`

Proof. Project the carrier of Definition 1950.1. The only vector zero datum is in V, and the only real zero and order data available to a norm read are in R.

Apply the zero-exactness clause of Definition 1950.2. It identifies a zero norm read with the displayed vector-zero classifier rather than with a host equality relation.

The structural rows H, T, C preserve this route under transport and replay, while P and the local naming row keep it inside the same packet. Since no quotient equality, basis coordinate, or ambient Banach identity is a carrier row, the zero read is exact along V, R, N. □

Theorem 1950.4 (NormedSpace triangle and scalar compatibility)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet $S = (V, R, N, M, Q, H, T, P, C)$, the triangle and scalar-compatibility obligations are routed through the same displayed rows. A norm read of a sum must first expose vector addition in V, then the norm row N, and then the real addition and order rows in R. A norm read of a scalar multiple must first expose scalar action in V, then the scalar absolute-value read in R, and then the norm row N. Neither read may use host linearity, an external ordered field, basis expansion, quotient vectors, or a hidden continuity principle.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion request budget`

Proof. Start with the triangle request. The sum is not a host vector expression; it is the displayed addition operation in V. Once the sum row is read, the norm row N supplies the norm observation and the Real row R supplies the addition and order comparison.

Now consider scalar compatibility. The scalar action is again a displayed operation in V, while the absolute-value and real multiplication reads come from R. The norm row N relates those two displayed sources.

Finally transport and replay the two routes through H, T, C with provenance in P. Because the carrier contains no host linearity, external ordered field, basis expansion, quotient-vector coordinate, or hidden continuity row, the triangle and scalar obligations stay inside V, R, N. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier triangle scalar compatibility`

Theorem 1950.5 (NormedSpace metric nonescape)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet, the metric row M can read a distance between displayed vectors only as the norm read of their displayed difference through V, N, R. The metric consumer may then pass through Q, H, T, P, C for completion-facing handoff, transport, replay, provenance, and local naming, but it cannot export an independent host metric, quotient completion, selected limit, or Banach/Hilbert structure.*

Proof. Read M from Definition 1950.1. Its distance data are induced data, and the carrier names no distance source except the norm row N applied to a displayed vector difference from V.

Apply the metric handoff clause of Definition 1950.2. It forces each distance request through V, N, R before M can be read by a downstream consumer.

The completion-facing row Q and the structural rows H, T, P, C preserve the same displayed route. Since no independent host metric, quotient completion, selected limit, or Banach/Hilbert coordinate is present, metric reads cannot escape the induced norm route. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier metric nonescape`

Theorem 1950.6 (NormedSpace completion handoff)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet reads the packet through the displayed route*

$$V, R, N, M, Q \longmapsto H, T, P, C.$$

In particular, the consumer obtains its vector operations from V, its real-valued norm and scalar absolute-value reads from R, N, its metric comparisons from M, and its Cauchy or completion-facing requests from Q. It does not obtain a host normed-space object, quotient completion, selected limit, basis choice, choice principle, or ambient Banach/Hilbert structure from the packet.

Proof. Start with a downstream consumer request. A vector operation can be answered only by projecting the displayed vector-space row V, while a norm or scalar-size request must read R and N before any real-valued comparison is available.

Metric requests are not separate host data. By Definition 1950.2, the metric row M reads distance as the norm of a displayed vector difference, so the route necessarily passes through V, N, R before a metric comparison is exported.

Completion-facing requests then pass through Q. This row stores only Cauchy windows, tolerance requests, and handoff data, so a Banach or Hilbert chapter may consume readiness for completion without receiving a selected completed point or a quotient object.

The structural rows H, T, P, C preserve the same route under transport, replay, provenance, and local naming. Thus every listed consumer sees exactly the displayed VecSpace, Real, Metric, and Completion rows, and no host normed-space structure or choice-based completion datum is introduced. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion handoff`

Theorem 1950.7 (NormedSpace root-unblock source triad)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet*

$$S = (V, R, N, M, Q, H, T, P, C),$$

the root-unblock handoff to Banach, Hilbert, bounded-operator, and functional-analysis consumers is exhausted by the following three displayed source obligations:

1. *the* $\mathsf{VecSpace}^{\uparrow}$ *carrier is transported through the* $\mathsf{Norm}^{\uparrow}$ *row N by the same* BHist, hsame, Cont, Pkg, *and* NameCert *rows that name S;*
2. *the* $\mathsf{Met}^{\uparrow}$ *identity-of-indiscernibles read is routed through the zero norm row, the* $\mathsf{Real}^{\uparrow}$ *zero and order cells in R, and the displayed vector-zero classifier in V;*
3. *the* $\mathsf{Completion}^{\uparrow}$ *handoff is a nonescape handoff through Q, H, T, P, C, carrying only Cauchy windows and tolerance requests derived from V, R, N, M.*

No source obligation quantifies over abstract source-equivalence pairs, and no consumer receives host vector equality, quotient completion, selected limits, basis choice, classical duality, or an ambient Banach or Hilbert structure.

Proof. Project the carrier S. The vector-space source is the row V, and the norm row N is the only row that can expose a real-valued norm read over vectors from V.

For the carrier-transport obligation, read V through N and then through H, T, P, C. This keeps the $\mathsf{VecSpace}^{\uparrow}$ source inside the same BHist packet and makes the local $\mathsf{NameCert}$ row the only naming boundary.

For identity of indiscernibles, use Definition 1950.3. The zero norm row reads the $\mathsf{Real}^{\uparrow}$ zero and order cells in R and then returns to the displayed vector-zero classifier in V, so the induced $\mathsf{Met}^{\uparrow}$ row M has no independent equality source.

For completion handoff, use Definition 1950.6. The row Q stores Cauchy windows and tolerance requests only after the vector, Real, norm, and metric rows have been displayed, while H, T, P, C preserve the same route for downstream consumers.

Thus the three obligations are finite source rows of the packet itself. Since no abstract source-equivalence pair, host vector equality, quotient completion, selected limit, basis choice, classical duality, or ambient Banach or Hilbert coordinate occurs in S, the root-unblock surface is exactly the displayed triad. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier root unblock source triad`

Theorem 1950.8 (NormedSpace completion-facing obligation triad)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet*

$$S = (V, R, N, M, Q, H, T, P, C),$$

the completion-facing surface is exhausted by the displayed $\mathsf{VecSpace}^{\uparrow}$ *row* V*, the* $\mathsf{Real}^{\uparrow}$ *row* R*, the norm row* N*, the induced* $\mathsf{Met}^{\uparrow}$ *row* M*, and the Cauchy-window handoff row* Q *transported and replayed through* H, T, P, C*. No completion-facing obligation is stored outside the VecSpace, Real, Norm, Metric, and Cauchy-window rows.*

Proof. Project the carrier S. The rows V, R, N, M, Q are the only coordinates that a completion consumer can inspect before structural transport and replay.

Apply Definition 1950.3 to pin zero reads to V, R, N. Apply Definition 1950.5 to pin distance reads to the induced metric row M through the same vector, norm, and Real rows.

Use Definition 1950.6 and Definition 1950.7. The handoff theorem identifies Q as the only Cauchy-window and tolerance-request boundary, while the triad theorem shows that downstream consumers receive the displayed route rather than an abstract source-equivalence surface.

Therefore the completion-facing obligations are exactly the VecSpace, Real, Norm, Metric, and Cauchy-window rows, preserved by H, T, P, C. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion facing obligation triad`

Theorem 1950.9 (NormedSpace completion-facing nonescape)**.** *Let* $S = (V, R, N, M, Q, H, T, P, C)$ *be an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet. No quotient completion, selected limit, basis choice, host vector equality, ambient Banach structure, or ambient Hilbert structure can be read from* Q, H, T, P, C*. These rows transport, replay, source, and locally name only the displayed completion-facing route already determined by* V, R, N, M*.*

Proof. Read the completion-facing row Q. By Definition 1950.6, this row stores Cauchy windows and tolerance requests only after the vector, Real, norm, and metric rows have been displayed.

Apply Definition 1950.5. The metric row feeding Q is induced from V, N, R, so Q cannot import an independent host metric or quotient equality.

Finally use Definition 1950.7. The rows H, T, P, C preserve the same finite route for downstream consumers. Since quotient completions, selected limits, basis choices, host vector equality, and ambient Banach or Hilbert structures are absent from the carrier, none can be read from the completion-facing surface. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion facing nonescape`

Theorem 1950.10 (NormedSpace consumer exhaustion)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet must factor through the displayed route*

$$V, R, N, M, Q, H, T, P, C.$$

The consumer obtains vector operations from V, real scalar and norm comparisons from R, N, metric comparisons from M, completion-facing windows from Q, and structural transport, replay, provenance, and local naming from H, T, P, C; no additional host analysis structure is exported by the packet.

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier consumer exhaustion`

Proof. Start with a downstream analysis request. By Definition 1950.8, the only completion-facing surface available to the request is the displayed VecSpace, Real, Norm, Metric, and Cauchy-window route.

Use Definition 1950.9. The structural rows do not add quotient completion, selected limits, basis choice, host vector equality, or ambient Banach/Hilbert structure.

Apply Definition 1950.6. Banach, Hilbert, bounded-operator, and functional-analysis consumers all receive their data from the same displayed route $V, R, N, M, Q, H, T, P, C$.

Thus every such consumer factors through the named finite packet, and the consumer surface is exhausted by that route. □

Theorem 1950.11 (NormedSpace Banach-completion nonescape)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet*

$$S = (V, R, N, M, Q, H, T, P, C)$$

must read the displayed route $V, R, N, M, Q, H, T, P, C$ before any completion-facing handoff is available. The packet exposes vector operations only through $\mathsf{VecSpace}^{\uparrow}$ *row V, real-valued norm and scalar-size data only through R, N, metric comparisons only through the induced metric row M, and completion requests only through Q, H, T, P, C.*

It cannot supply quotient completion, selected limits, basis choice, host vector equality, classical duality, or ambient Banach/Hilbert structure.

Proof. Apply Definition 1950.3 for the vector-zero boundary. A zero norm read returns to the displayed vector-zero classifier in V after passing through the $\mathsf{Real}^{\uparrow}$ zero and order cells in R, so no host vector equality or quotient equality can enter through the norm row.

Use Definition 1950.5 for metric consumers. The metric row M reads distance as a norm of a displayed vector difference through V, N, R, and therefore has no independent host metric or ambient Banach coordinate.

Next apply Definition 1950.6. Completion-facing reads pass through Q only after the vector, Real, norm, and metric rows have been displayed, and Q stores Cauchy windows and tolerance requests rather than a quotient completion or selected completed point.

Finally use Definition 1950.7. The structural rows H, T, P, C transport, replay, source, and name the same route for downstream Banach, Hilbert, bounded-operator, and functional-analysis consumers, so the displayed packet admits no basis choice, classical duality, host equality, selected limit, or ambient Banach/Hilbert datum. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier banach completion nonescape`

Theorem 1950.12 (NormedSpace vector transport obligation)**.** *Let*

$$S = (V, R, N, M, Q, H, T, P, C)$$

be an accepted $\mathsf{NormedSpace}^{\uparrow}$ *packet. Every vector-space read exported to Banach, Hilbert, bounded-operator, or functional-analysis consumers must transport the displayed row V through the same* BHist, hsame, Cont, Pkg, *and local* NameCert *rows H, T, P, C that name S, while keeping the norm row N, the real row R, the induced metric row M, and the completion-facing row Q in scope. The transport cannot be replaced by host vector equality, quotient completion, selected limits, basis choice, or host normed-space equality.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier vector transport obligation`

Proof. Project the carrier of Definition 1950.1. The row V is the only vector-space source, and H, T, P, C are the only componentwise transport, replay, provenance, and local naming rows available to a consumer.

Apply Definition 1950.2. Its classifier-transport row compares packet reads through $V, R, N, M, Q, H, T, P, C$ and never through host extensional equality.

Finally use Definition 1950.7. The vector-space source is transported through the norm row and the same structural rows before any downstream consumer can read it. Since the carrier has no quotient-completion, selected-limit, basis-choice, or host normed-space equality coordinate, the displayed transport route is forced. □

Definition 1950.13 (NormedSpace completion-window carrier)**.** *For an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet $S = (V, R, N, M, Q, H, T, P, C)$, the completion-window carrier is the finite subroute*

$$W_S = (V, R, N, M, Q, H, T, P, C)$$

read with Q as the Cauchy-window row and with V, R, N, M already displayed as the vector-space source, Real seal, norm row, and induced metric row. A Banach, Hilbert, bounded-operator, or functional-analysis completion request may inspect W_S only through BHist, hsame, Cont, Pkg, *and local* NameCert *transport; it is not a quotient completion, selected limit, ambient Banach carrier, Hilbert inner-product surface, or host normed-space equality.*

Lean4 (definition) `BEDC.Derived.NormedSpaceUp.NormedSpaceCompletionWindowCarrier`

Theorem 1950.14 (NormedSpace Cauchy-window handoff)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis completion request over an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet must first read the completion-window carrier of Definition 1950.13. The request receives the displayed* $\mathsf{VecSpace}^{\uparrow}$ *row V, terminal* $\mathsf{Real}^{\uparrow}$ *row R,* $\mathsf{Norm}^{\uparrow}$ *row N, induced* $\mathsf{Met}^{\uparrow}$ *row M, and Cauchy-window row Q through H, T, P, C before any completion-facing conclusion is available.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier cauchy window handoff`

Proof. Start with the source triad of Definition 1950.7. It requires vector-source reads, metric identity reads, and completion handoff reads to pass through the displayed rows $V, R, N, M, Q, H, T, P, C$.

Use the zero exactness and metric nonescape theorems, Definition 1950.3 and Definition 1950.5. They force the induced metric row to read through the vector zero classifier, Real zero and order cells, and real-valued norm row rather than through host equality.

Finally apply the completion handoff and vector transport obligation theorems, Definition 1950.6 and Definition 1950.12. The completion request can reach Q only after those rows have been transported and replayed through H, T, P, C, which is exactly the carrier W_S. □

Theorem 1950.15 (NormedSpace completion-window nonescape)**.** *For every accepted* NormedSpace$^{\uparrow}$ *packet, the completion-window carrier W_S is the whole completion-facing surface exported to Banach, Hilbert, bounded-operator, and functional-analysis consumers. No consumer can extract a quotient completion, selected completed point, host vector equality, basis choice, classical dual object, ambient Banach object, or Hilbert-space structure from W_S.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion window nonescape`

Proof. Read the handoff theorem Definition 1950.14. It places every completion request on W_S after the VecSpace, Real, Norm, induced Metric, and Cauchy-window rows have been displayed.

The existing nonescape boundaries then close the excluded routes. Metric nonescape blocks an independent metric source, completion handoff blocks a selected completed point or quotient object, and the root-unblock source triad blocks abstract source-equivalence replacement.

The vector transport obligation preserves the same finite route under BHist, hsame, Cont, Pkg, and local NameCert rows. Since none of the excluded host objects is a coordinate of the carrier, every listed downstream consumer remains inside W_S. □

Theorem 1950.16 (NormedSpace real-norm metric factorization)**.** *For every accepted* NormedSpace$^{\uparrow}$ *packet*

$$S = (V, R, N, M, Q, H, T, P, C),$$

each metric comparison exported by M factors through the real-valued norm route V, R, N before it reaches the structural rows H, T, P, C and the completion-facing row Q. Thus the identity, triangle, and scalar-size reads seen by a downstream consumer are BHist*-anchored* hsame *and* Cont *reads through the displayed rows, not host metric equality, quotient completion, selected limits, basis choice, or host normed-space equality.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier real norm metric factorization`

Proof. Begin with Definition 1950.5. The induced metric row M can read a distance only as the norm of a displayed vector difference through V, N, R.

The zero, triangle, and scalar rows then come from the established norm obligations. By Definition 1950.3, zero distance returns to the displayed vector-zero classifier in V after reading the real zero and order data in R. By Definition 1950.4, triangle and scalar-size reads pass through V, R, N.

Transport the resulting metric read through H, T, P, C, with completion-facing requests held in Q. The carrier contains no host metric equality, quotient completion, selected limit, basis choice, or host normed-space equality row, so the real-norm factorization is the only exported metric route. □

Theorem 1950.17 (NormedSpace completion request budget)**.** *Let*

$$S = (V, R, N, M, Q, H, T, P, C)$$

be an accepted NormedSpace$^{\uparrow}$ *packet. Every completion request exported by Q is budgeted by the already displayed vector, real, norm, and metric rows V, R, N, M and is transported through the same* BHist, hsame, Cont, Pkg, *and local* NameCert *rows H, T, P, C. The request may carry Cauchy windows and tolerance data only; it may not add quotient completion, selected limits, basis choice, host vector equality, host normed-space equality, or an ambient Banach/Hilbert object.*

Proof. Read the completion-facing row in Definition 1950.1. The row Q records Cauchy windows, tolerance requests, and handoff data, and it is attached to the rows V, R, N, M, H, T, P, C of the same packet.

Apply Definition 1950.6. Banach, Hilbert, bounded-operator, and functional-analysis consumers must read the displayed route V, R, N, M, Q before the structural rows H, T, P, C can export the handoff.

Use Definition 1950.11 to close the boundary. Because the packet has no quotient-completion, selected-limit, basis-choice, host vector equality, host normed-space equality, or ambient Banach/Hilbert coordinate, Q supplies only the finite request budget for later completion work. □

Theorem 1950.18 (NormedSpace completion budget envelope)**.** *Let $S = (V, R, N, M, Q, H, T, P, C)$ be an accepted* NormedSpace$^{\uparrow}$ *packet. Every completion request read by a downstream consumer is a* BHist*-anchored envelope over the displayed rows $V, R, N, M, Q, H, T, P, C$: the vector source, real-valued norm, induced metric, and completion-facing budget must be read before the request reaches any Banach, Hilbert, bounded-operator, or functional-analysis consumer. The envelope is exactly the route isolated by Definition 1950.16, Definition 1950.17, and Definition 1950.11; it cannot add quotient completion, selected limits, basis choice, host normed-space equality, or an ambient complete object.*

Proof. Start with Definition 1950.17. It places every completion-facing request in the row Q and keeps that request attached to V, R, N, M, H, T, P, C.

Use Definition 1950.16 to expose the source of the budget. The metric read is already downstream of the real-valued norm route through V, R, N, M, so Q cannot read a completion request independently of those rows.

Finally apply Definition 1950.11. Banach and Hilbert consumers receive only the displayed completion request, transported by the same history, replay, provenance, and local naming rows. Since the excluded host objects are absent from the carrier, the displayed rows form the whole envelope. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedspaceCompletionBudgetEnvelope`

Theorem 1950.19 (NormedSpace metric completion source)**.** *For every accepted* NormedSpace$^{\uparrow}$ *packet $S = (V, R, N, M, Q, H, T, P, C)$, each induced metric read that supplies a completion source factors through the real-norm route V, R, N, M and then through the completion-facing row Q. The metric source is therefore a* BHist*-anchored read through $V, R, N, M, Q, H, T, P, C$, with the same structural transport required by Definition 1950.16 and the same completion budget required by Definition 1950.17. It is not host metric equality, quotient vector equality, a selected Cauchy limit, or an ambient Banach/Hilbert metric.*

Proof. Read the induced metric row through Definition 1950.16. A distance exported by M is the norm of a displayed vector difference, so the source rows are V, R, N, M.

Attach the completion-facing row by Definition 1950.17. The request in Q can carry Cauchy windows and tolerance data only after the metric read has passed through those source rows.

The nonescape boundary of Definition 1950.11 then rules out an alternate metric source for Banach or Hilbert consumers. Transport and replay through H, T, P, C preserve the same finite route, so every metric completion source is read through the displayed packet. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedspaceMetricCompletionSource`

Theorem 1950.20 (NormedSpace functional-analysis handoff)**.** *Every functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$ *must receive the handoff through the displayed rows* $V, R, N, M, Q, H, T, P, C$*. The handoff first reads the vector carrier and real-valued norm, then the induced metric, then the completion-facing budget, and finally the* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The route is the common downstream surface of Definition 1950.16, Definition 1950.17, and Definition 1950.11; it exports no host duality theorem, basis choice, quotient completion, selected limit, or ambient complete normed space.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier functional analysis handoff`

Proof. Project the carrier of Definition 1950.1. The only available rows for a general functional-analysis consumer are $V, R, N, M, Q, H, T, P, C$.

The metric and completion parts of the handoff are already fixed. Apply Definition 1950.16 for the path from vector data to induced metric reads, then apply Definition 1950.17 for the completion-facing request budget.

Use Definition 1950.11 for the downstream boundary. It prevents Banach and Hilbert consumers from receiving a completed host object or selected limit. Since bounded-operator and functional-analysis consumers depend on the same displayed normed-space packet, their handoff is forced through the same rows. □

Theorem 1950.21 (NormedSpace carrier transport completion service)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$*, carrier transport through the componentwise* hsame *rows preserves the common* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{Completion}^{\uparrow}$ *service rows. A completion-facing consumer transported along* H *therefore receives the same vector carrier, real-valued norm, induced metric, completion request budget, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *route, not a host equivalence of normed spaces or a selected completed object.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrierTransportCompletionService`

Proof. Project the accepted carrier. The rows V, R, N, M, Q are the displayed analytic service rows, while H, T, P, C transport, replay, source, and name them.

Use the componentwise clauses in H. They move the vector carrier, real row, norm row, metric row, and completion budget to a common finite comparison surface without changing which rows are exposed.

The completion service is then read through Q together with T, P, C. Since the carrier has no coordinate for a host equivalence or selected completion, transport preserves the displayed service route and nothing else. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier transport completion service`

Theorem 1950.22 (NormedSpace Real norm metric route)**.** *Every metric read induced by the norm of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$ *factors through the* $\mathsf{Real}^{\uparrow}$ *norm row* R, N*, the triangle ledger, the scalar compatibility row, the induced metric row* M*, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The metric route is therefore the finite norm route of the carrier, not host metric equality, quotient vector equality, basis coordinates, or an external ordered-field theorem.*

Proof. Begin with the normed-space carrier. The norm is not a detached metric; it is stored as the real-valued norm row N over the real row R and vector source V.

Apply the triangle and scalar compatibility obligations already displayed in the packet. They are the finite ledgers that allow a norm read to become a metric read through M.

The structural rows T, P, C replay, source, and name this route, while H keeps it stable under componentwise transport. Hence every induced metric read factors through the displayed Real norm route. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedspaceRealNormMetricRoute`

Theorem 1950.23 (NormedSpace functional-analysis root package)**.** *The displayed norm, induced metric, vector-space carrier, completion request budget, replay, provenance, and naming rows of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$ *form the root package consumed by Banach, Hilbert, bounded-operator, and functional-analysis chapters. Downstream chapters receive the finite rows* $V, R, N, M, Q, H, T, P, C$ *and their local* NameCert *surface; they do not receive a completed host normed space, a basis choice, a quotient completion, selected limits, or a classical duality theorem.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedspaceFunctionalAnalysisRootPackage`

Proof. Read the functional-analysis handoff of Definition 1950.20. It already places every downstream consumer behind the displayed rows $V, R, N, M, Q, H, T, P, C$.

The carrier transport service and Real norm metric route identify the two root interfaces needed by those consumers: completion-facing transport through Q, H, T, P, C and metric-facing norm reads through V, R, N, M.

Package the two interfaces with the local naming row. Banach, Hilbert, bounded-operator, and functional-analysis chapters may depend on that finite root package, but the excluded host objects are not exported by the carrier. □

Theorem 1950.24 (NormedSpace L10 completion obligation)**.** *Every L10-facing completion request exported by an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$ *must read the norm-to-metric route before it reads the completion-facing row* Q*. The request is therefore a finite dependency chain through* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{Completion}^{\uparrow}$*, with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It does not introduce abstract carrier-equivalence transport, selected completion points, quotient limits, or an ambient Banach carrier.*

Proof. Project the accepted packet. The vector row V, real row R, norm row N, and metric row M are already displayed before the completion request Q is available to a downstream consumer.

Use the Real norm metric route to bind M to the visible norm data. The L10 request then reads Q only as a completion-facing budget over that displayed metric route, with H, T, P, C providing transport, replay, provenance, and local naming.

Since no row of S contains carrier-equivalence transport, selected completion points, quotient limits, or a Banach carrier, the completion obligation remains the finite NameCert route through the displayed rows. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier l10 completion obligation`

Theorem 1950.25 (NormedSpace completion triad)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet* $S = (V, R, N, M, Q, H, T, P, C)$*, the displayed* $\mathsf{VecSpace}^{\uparrow}$ *row* V*,* $\mathsf{Norm}^{\uparrow}$ *row* N*, and induced* $\mathsf{Met}^{\uparrow}$ *row* M *jointly determine the completion-facing NormedSpace packet. The completion row* Q *may be consumed only after the vector operations, zero classifier, Real-valued norm, triangle ledger, scalar-compatibility ledger, and norm-induced metric route have been read through* V, R, N, M, H, T, P, C*.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion triad`

Proof. Project the carrier of Definition 1950.1. The vector row V, Real row R, norm row N, induced metric row M, and completion row Q are displayed coordinates of the same finite packet.

Use the zero exactness and compatibility routes already established above. The zero classifier is read through V, R, N, while the triangle and scalar-compatibility ledgers attach addition, scalar action, Real order, and norm reads to the same carrier.

Finally apply Definition 1950.24. The completion row Q is available only after the norm-to-metric route has been exposed, and H, T, P, C transport, replay, source, and name the resulting NormedSpace packet. □

Theorem 1950.26 (NormedSpace metric completion unblock)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet must read the norm-induced metric row* M *before it reads the completion-facing row* Q*. The consumer therefore receives a metric completion source through* $V, R, N, M, Q, H, T, P, C$*, not through an independent host metric, quotient vector equality, selected completion point, or ambient Banach carrier.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedspaceMetricCompletionUnblock`

Proof. Read the induced metric route of Definition 1950.22. It makes M a metric row generated from the Real-valued norm over the displayed vector source, rather than an independent metric coordinate.

The completion-facing handoff is then forced by Definition 1950.24. A completion request in Q is downstream of the metric row and remains attached to the same transport, replay, provenance, and local naming rows.

The nonescape boundary follows from Definition 1950.30. Since no row supplies a host metric, quotient equality, selected limit, or ambient Banach carrier, a MetricCompletion consumer can only use the displayed metric-completion route. □

Theorem 1950.27 (NormedSpace Banach and Hilbert consumer route)**.** *Every Banach or Hilbert consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet receives only the displayed VecSpace, Real, Norm, Metric, Completion, transport, replay, provenance, and local naming rows*

$$V, R, N, M, Q, H, T, P, C.$$

In particular, the consumer may request completion data through Q *and metric data through* M*, but it receives no completed host normed space, Hilbert inner product, quotient completion, selected limit, basis choice, or classical dual object.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier banach hilbert consumer route`

Proof. Start with Definition 1950.25. It identifies the VecSpace, Norm, and Metric rows that determine the completion-facing NormedSpace packet.

Use Definition 1950.26 for the completion entrance. Banach and Hilbert consumers must pass through the induced metric row M before reaching Q, and the same H, T, P, C rows preserve the route.

Finally apply Definition 1950.30. The carrier contains no host Banach object, Hilbert inner product, quotient completion, selected limit, basis choice, or dual object, so the displayed rows are the entire consumer surface. □

Theorem 1950.28 (NormedSpace Real metric transport)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet, a metric read transported along the Real-valued norm row must pass through* R, N, M, H, T, P, C*. The transported metric surface is the same displayed norm-induced metric route: it preserves the zero-row, triangle, scalar-compatibility, replay, provenance, and naming ledgers, and it does not pass through host metric equality, quotient vector identity, basis coordinates, or abstract carrier equivalence.*

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier real metric transport`

Proof. Start with the metric row M of the carrier. By construction it is induced from the Real-valued norm row N over R, rather than supplied as an independent host metric.

Transport the rows componentwise through H. The zero, triangle, and scalar compatibility ledgers remain attached to the same Real norm data, while T, P, C replay, source, and name the transported metric read.

The carrier contains no coordinate for host metric equality, quotient vector identity, basis coordinates, or carrier-equivalence transport. Thus the transported metric surface is exactly the displayed Real norm route. □

Theorem 1950.29 (NormedSpace completion-metric root unblock)**.** *For every accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet*

$$S = (V, R, N, M, Q, H, T, P, C),$$

each $\mathsf{MetricCompletion}^{\uparrow}$*, Banach, Hilbert, or bounded-operator consumer of* S *must read first through the displayed VecSpace row* V*, Real row* R*, norm row* N*, induced metric row* M*, and completion window row* Q*, and only then through* H, T, P, C*. The packet exports no quotient completion, selected limit, basis choice, host metric, or ambient Banach or Hilbert carrier.*

Proof. Project the carrier S. The vector source, Real-valued norm, induced metric, and completion-facing window are exactly the rows V, R, N, M, Q, while H, T, P, C supply transport, replay, provenance, and local naming.

Use zero exactness and metric nonescape first. The zero row is exact only along V, R, N, and the metric row M reads distances only as norm reads of displayed differences through the same source rows.

Next apply the completion handoff and the L10 completion obligation. They place every completion-facing request behind the route V, R, N, M, Q and prevent the request from selecting a completed point or quotient limit.

Finally use the Real metric transport theorem above. Transport preserves the Real norm route through R, N, M, H, T, P, C, so downstream MetricCompletion, Banach, Hilbert, and bounded-operator consumers receive only the displayed completion-metric root surface and none of the excluded host data. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier completion metric root unblock`

Theorem 1950.30 (NormedSpace Banach consumer nonescape)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet can read only the rows*

$$V, R, N, M, Q, H, T, P, C.$$

Such a consumer may request completion-facing data through Q *and metric data through* M*, but it cannot extract a completed host normed space, selected limit, quotient completion, basis choice, dual object, or Hilbert-space structure from the* $\mathsf{NormedSpace}^{\uparrow}$ *certificate alone.*

Proof. Use Definition 1950.23. It identifies the root package consumed by Banach, Hilbert, bounded-operator, and functional-analysis chapters as the displayed rows $V, R, N, M, Q, H, T, P, C$.

Separate the two consumer routes. Completion-facing reads pass through Q together with transport, replay, provenance, and naming; metric-facing reads pass through M together with the Real norm route.

No additional row remains for a completed host normed space, selected limit, quotient completion, basis choice, dual object, or Hilbert structure. Hence each listed consumer is bounded by the finite $\mathsf{NormedSpace}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.NormedSpaceUp.NormedSpaceCarrier banach consumer nonescape`

VecSpace carrier transport obligation. Every $\mathsf{NormedSpace}^{\uparrow}$ consumer that needs the vector-space source must read the $\mathsf{VecSpace}^{\uparrow}$ carrier row V through the $\mathsf{Norm}^{\uparrow}$ row N and the structural rows H, T, P, C. The transported carrier is therefore a finite BHist route with hsame stability, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming; it is not a host vector-space equality or an abstract source-equivalence comparison.

Metric zero-row identity obligation. Every $\mathsf{Met}^{\uparrow}$ identity-of-indiscernibles read exported by M must pass through the zero norm row in N, the $\mathsf{Real}^{\uparrow}$ zero and order cells in R, and the displayed vector-zero classifier in V. The packet supplies metric identity only through this zero-norm route, not through quotient vector equality, host metric equality, basis coordinates, or an external ordered-field argument.

Completion handoff nonescape obligation. Every $\mathsf{Completion}^{\uparrow}$ request exported by Q is a handoff over the already displayed V, R, N, M rows. The completion-facing consumer receives Cauchy windows and tolerance requests transported by H, replayed by T, sourced by P, and named by C, but receives no quotient completion, selected completed point, choice principle, ambient Banach object, or Hilbert-space structure.

Theorem 1950.31 (NormedSpace public NameCert export)**.** *Every Banach, Hilbert, bounded-operator, or functional-analysis consumer of an accepted* $\mathsf{NormedSpace}^{\uparrow}$ *packet receives the public* $\mathsf{NormedSpace}^{\uparrow}$ *interface only through the displayed route*

$$V, R, N, M, Q, H, T, P, C.$$

The public export consists of the vector source, Real-valued norm, induced metric, completion-facing handoff, componentwise transport, displayed replay, provenance, and local $\mathsf{NameCert}$ *rows. It exports no completed host normed space, quotient completion, selected limit, basis choice, dual object, or Hilbert-space structure.*

Proof. Start from the Banach consumer nonescape theorem. Definition 1950.30 already fixes the only route available to Banach, Hilbert, bounded-operator, and functional-analysis consumers as $V, R, N, M, Q, H, T, P, C$.

Next project the three local obligations above. VecSpace carrier transport keeps V behind N, H, T, P, C, metric zero-row identity keeps M behind the Real norm route, and completion handoff nonescape keeps every completion-facing request behind Q and the same structural rows.

Therefore the exported public interface is exactly the displayed finite NameCert route. Since no additional carrier coordinate names a host completion, selected limit, basis, dual object, or Hilbert structure, every listed consumer receives $\mathsf{NormedSpace}^{\uparrow}$ only through the public rows stated above. □

Falsifiable prediction: An accepted $\mathsf{NormedSpace}^{\uparrow}$ consumer that reaches a Banach, Hilbert, bounded-operator, or functional-analysis read without first reading the displayed rows $V, R, N, M, Q, H, T, P, C$ refutes the carrier surface.

Independence witness: norm, normed-real-line, metricspace, cauchycompletion: no listed sibling supplies the full non-singleton packet $S = (V, R, N, M, Q, H, T, P, C)$, because each sibling contributes only a singleton norm instance, a one-dimensional real-line normed surface, a metric readback, or a completion handoff while this chapter binds the general normed-vector-space NameCert interface into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{NormedSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{NormedSpace}^{\uparrow}$ packet is generated from a displayed VecSpace row, a Real-valued norm row, an induced Metric row, a completion-facing Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NormedSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1950.1, Definition 1950.2, Definition 1950.6, and Definition 1950.31 bind the displayed VecSpace, Real norm, induced Metric, completion-facing Cauchy handoff, hsame, Cont, Pkg, and NameCert route for Banach, Hilbert, bounded-operator, and functional-analysis consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NormedSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host normed-space equality, quotient completion, selected limits, basis choice, classical duality, Lean verification, or bridge checking.

Upgrade path: Lean verification and bridge checking of the mature VecSpace, Real norm, induced Metric, completion-facing Cauchy handoff, hsame, Cont, Pkg, and NameCert route remain the next obligations.

Chapter 1951

A Concrete Naming Certificate for $\mathsf{CauchyModulusPullback}^{\uparrow}$

Following Bishop and Bridges on explicit moduli and cofinal subsequences, the $\mathsf{CauchyModulusPullback}^{\uparrow}$ packet records the finite certificate by which a displayed Cauchy modulus is read along a cofinal reindexing route before any regular rational or real-name consumer may use its threshold. It sits between the source and target schedule discipline of chapter 1568, the explicit threshold surface of chapter 292, the finite observation rows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal boundary of chapter 38. The packet names only the finite pullback route; it is not a quotient of streams, not a selected subsequence limit, not countable choice, not host real equality, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1951.1 (Cauchy modulus pullback carrier)**.** *A* $\mathsf{CauchyModulusPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, I, K, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *schedule whose original explicit Cauchy modulus is already displayed.*
2. *I is the reindexed* $\mathsf{StreamName}^{\uparrow}$ *schedule obtained by reading S along the cofinal route.*
3. *K is the* $\mathsf{CauchyReindexing}^{\uparrow}$ *route row, containing the monotone and cofinal unary index data that connect I back to S.*
4. *M is the original* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row on S, read only after K has turned a target tolerance request into a source-window request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the target request, the source threshold selected by M, and the slack introduced by the route K.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row showing that the reindexed schedule remains a regular rational name after K, M, D have been consumed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the reindexing, modulus, dyadic tolerance, and regular readback rows have been displayed.*

8. *H records componentwise* hsame *transport for the source schedule, target schedule, reindexing route, modulus threshold, dyadic tolerance, regular readback, Real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route from a target precision request through $I, K, S, M, D, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusPullback}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusPullback}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, countable-choice selectors, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusPullbackUp.TasteGate.CauchyModulusPullbackTasteGate single carrier alignment`

Theorem 1951.2 (Cauchy modulus pullback NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusPullback}^{\uparrow}$ *carrier*

$$B = (S, I, K, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusPullback}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source schedule S, reindexed schedule I, reindexing route K, original modulus row M, dyadic tolerance row D, regular readback row R, Real seal row E, and structural rows H, C, P, N;*
2. *route-before-threshold discipline, requiring each target precision request to replay through I and K before it can consult the original modulus row M on S;*
3. *cofinal threshold pullback, requiring the threshold selected by M to be converted into a target-window bound only by the monotone and cofinal rows inside K;*
4. *dyadic tolerance compatibility, requiring D to record the source tolerance, target tolerance, and route slack used by the pulled-back threshold;*
5. *regular rational transport, requiring R to consume K, M, D before it exports any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
6. *terminal seal routing, requiring E to remain downstream of I, K, S, M, D, R and the structural replay rows;*
7. *ledger refusal for quotient streams, selected limits, countable choice, host real equality, trichotomy, and ambient Real completeness.*

No local pullback obligation is stored outside these rows.

Proof. Project the carrier of Definition 1951.1. The analytic coordinates are exactly the source schedule, target schedule, reindexing route, original modulus threshold, dyadic tolerance ledger, regular readback, and terminal seal.

Read the request in dependency order. A target precision request first exposes I, then the route K back to S, and only then the original modulus row M can be consulted.

The cofinal and monotone data inside K convert the source threshold into a target-window bound. The dyadic row D stores the tolerance comparison used during that conversion, and the row R consumes the converted window before any regular rational readback is exported.

Finally the seal row E is downstream of R. The transport, continuation, provenance, and naming rows replay and package the same finite route, so no excluded analytic coordinate remains available. □

Lean4 ✓ `BEDC.Derived.CauchyModulusPullbackUp.CauchyModulusPullbackCarrier namecert obligations`

Theorem 1951.3 (Cauchy modulus pullback reindex threshold)**.** *Let $B = (S, I, K, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusPullback}^{\uparrow}$ *carrier. Every pulled-back threshold consumed by the reindexed schedule I is read only after the* $\mathsf{CauchyReindexing}^{\uparrow}$ *route K has displayed the monotone and cofinal connection from I to S. Thus the original modulus row M cannot be used as a target-schedule threshold before the reindexing route has been replayed through C.*

Proof. Start with a target-schedule threshold request. The carrier projection gives the target schedule row I, but the threshold row M is a modulus row for the source schedule S.

Replay the continuation row C. The request must pass from I through K before it reaches S; the monotone row inside K controls the direction of target-window reads, while the cofinal row supplies the source-window reach needed for the requested tolerance.

Only after that route is displayed can M choose a source threshold. The dyadic row D then records the comparison that turns the source threshold into a target-window bound, and R, E, H, P, N consume only the resulting pulled-back row. □

Theorem 1951.4 (Cauchy modulus pullback Real seal nonescape)**.** *For every accepted* $\mathsf{CauchyModulusPullback}^{\uparrow}$ *carrier $B = (S, I, K, M, D, R, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing read factors through the finite route*

$$I \longmapsto K \longmapsto S \longmapsto M \longmapsto D \longmapsto R \longmapsto E$$

together with the structural rows H, C, P, N. The exported route contains no quotient stream, selected limit, countable-choice row, host real equality, trichotomy row, or ambient Real completeness principle.

Proof. Begin with a Real-facing consumer. Carrier admission exposes E only as a terminal row downstream of the regular readback row R.

Trace R backward through the packet. The regular readback consumes the dyadic tolerance row D, which in turn records the comparison between the reindexed request and the source threshold obtained from M.

The modulus row M is attached to the source schedule S, so the target schedule I reaches it only through the reindexing route K. This gives the displayed route from I to K, then to S, M, D, R, E.

The structural rows H, C, P, N preserve and name that route without adding an analytic source. Since the carrier of Definition 1951.1 has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness, none of those objects can be exported by the Real-facing read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusPullback}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusPullback}^{\uparrow}$ packet is generated from a source StreamName schedule, a reindexed StreamName schedule, a CauchyReindexing route, an original CauchyModulus threshold row, DyadicRatCore tolerance rows, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1951.1, Definition 1951.2, Definition 1951.3, and Definition 1951.4 seed the finite certificate for moving explicit Cauchy modulus schedules across cofinal reindexing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusPullback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold pullback, transport, replay, and ledger non-escape for the finite Cauchy modulus pullback surface.

Chapter 1952

A Concrete Naming Certificate for $\mathsf{CompactOperator}^{\uparrow}$

Following Riesz and Schauder, the $\mathsf{CompactOperator}^{\uparrow}$ packet records the finite BEDC surface by which a bounded linear operator between Banach carriers is witnessed through finite image-net schedules and tail moduli. It reads the bounded-operator row of chapter 1644, the Banach endpoint rows of chapter 90, the compact-witness rows already consumed by chapter 94, the operator-ideal dependency of chapter 213, and the compact-prefix consumer route of chapter 215. The chapter names only the reusable compact-operator certificate; it does not assert spectral theory, trace-class theory, choice-selected compactness, or host equality of operators.

Definition 1952.1 (Compact operator carrier)**.** *A* $\mathsf{CompactOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, B, N, M, H, C, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{Banach}^{\uparrow}$ *source row, including the carried source endpoints, source classifier, norm-induced metric rows, and visible completion ledger.*
2. *T is the* $\mathsf{Banach}^{\uparrow}$ *target row, including the carried target endpoints, target classifier, norm-induced metric rows, and visible completion ledger.*
3. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row recording the displayed operator action, linearity ledger, norm-bound endpoint, and bounded-operator provenance over S and T.*
4. *N is the finite image-net schedule: for each displayed precision request it records a finite family of target endpoints and the source-unit-bound rows whose images are covered by those endpoints.*
5. *M is the tail/modulus row binding the finite schedules in N to the target Banach metric and recording the precision transitions used by downstream consumers.*
6. *H records componentwise* hsame *transport for S, T, B, N, M and the structural rows.*
7. *C records displayed* Cont *replay of the route*

$$S, T, B \longmapsto N \longmapsto M.$$

8. *P is the* Pkg *provenance over* $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{CompactOperator}^\uparrow}$ *row.*

The classifier of the carrier compares accepted packets only through the displayed Banach endpoints, bounded-operator row, finite image-net schedules, tail/modulus rows, componentwise transport, continuation replay, provenance, and local naming row.

Lean4 ✓ `BEDC.Derived.CompactOperatorUp.CompactOperatorTasteGate single carrier alignment`

Theorem 1952.2 (Compact operator NameCert obligations)**.** *For every accepted* $\mathsf{CompactOperator}^\uparrow$ *carrier*

$$K = (S, T, B, N, M, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOperator}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Banach row, target Banach row, bounded-linear-operator row, finite image-net schedule, tail/modulus row, transport row, replay row, provenance row, and local naming row;*
2. *finite-image-net stability, requiring every transported precision request to replay through the same finite schedule row N and the same target metric coverage rows;*
3. *classifier transport, requiring componentwise* hsame *transport of the source endpoint, target endpoint, bounded-operator endpoint, image-net endpoints, and tail/modulus ledger;*
4. *ledger non-escape, requiring P and L to source no spectral row, trace-class row, choice-selected compactness row, host operator equality, or external compactness principle;*
5. *bounded-operator compatibility, requiring every compactness read to enter through the bounded-linear-operator row B before any finite image-net or tail/modulus row can be consumed.*

No compact-operator obligation is stored outside these rows.

Proof. Project the carrier of Definition 1952.1. The visible analytic coordinates are exactly the two Banach endpoint rows, the bounded-linear-operator row, the finite image-net schedule, and the tail/modulus ledger.

Finite-image-net stability is componentwise. A transported precision request keeps the same source-unit-bound row and target metric row after hsame transport, so replay through C reaches the same schedule coordinate N and the same tail/modulus coordinate M.

The classifier clauses are inherited row by row from the Banach and bounded-linear-operator surfaces. The source and target classifiers move endpoints, the bounded-operator classifier moves the operator and norm-bound ledger, and the compact schedule moves only through the displayed image-net endpoints and moduli.

Finally inspect P and L. Their source list is finite and contains no spectral, trace-class, choice, host-equality, or external compactness coordinate. Since every compactness read is downstream of B, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier namecert obligations`

Theorem 1952.3 (Compact operator functional-analysis route)**.** *Every compact-operator witness exposed by* $\mathsf{FunctionalAnalysis}^\uparrow$ *factors through an accepted* $\mathsf{CompactOperator}^\uparrow$ *carrier before it can be consumed by* $\mathsf{Nuclear}^\uparrow$ *or* $\mathsf{OperatorIdeal}^\uparrow$*. Equivalently, a downstream compact read must pass through the finite route*

$$\mathsf{Banach}^\uparrow, \mathsf{BoundedLinearOperator}^\uparrow \longmapsto \mathsf{CompactOperator}^\uparrow \longmapsto \mathsf{OperatorIdeal}^\uparrow, \mathsf{Nuclear}^\uparrow$$

where the middle packet supplies the image-net schedules, tail/modulus rows, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route is a certificate-level factorization, not host equality between operators.*

Proof. Begin with a compact witness from the $\mathsf{FunctionalAnalysis}^{\uparrow}$ surface. Its bounded-operator part is already a displayed $\mathsf{BoundedLinearOperator}^{\uparrow}$ row over Banach source and target endpoints, and its compactness evidence is a finite probe ledger for images of carried source-unit-bound rows.

Package those rows as in Definition 1952.1. The Banach endpoints supply S and T, the bounded-operator row supplies B, and the compact probe ledger supplies the finite schedule N together with its tail/modulus row M.

The downstream handoff is then forced by Definition 1952.2. $\mathsf{OperatorIdeal}^{\uparrow}$ may read the compact row only through the bounded-operator-compatible carrier, and $\mathsf{Nuclear}^{\uparrow}$ may read compact prefixes only after the same carrier has supplied its finite image-net and tail/modulus rows. No host operator equality is introduced in either handoff. □

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier functional analysis route`

Definition 1952.4 (Compact operator approximation scheme)**.** *A compact operator approximation scheme is a finite* BHist *packet*

$$A = (S, T, B, N, M, H, C, P, L)$$

whose rows display a source $\mathsf{Banach}^{\uparrow}$ *row S, a target* $\mathsf{Banach}^{\uparrow}$ *row T, a* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row B, a finite image-net schedule N, a tail/modulus ledger M, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and a local* $\mathsf{NameCert}_{\mathsf{CompactOperator}^{\uparrow}}$ *row L. The scheme is accepted only when N and M are read after B, so compactness is exposed by finite image-net and tail data rather than by host equality of operators or a choice-selected compactness witness.*

Lean4 (definition) `BEDC.Derived.CompactOperatorUp.CompactOperatorApproximationScheme`

Theorem 1952.5 (Compact operator bounded-image precompactness)**.** *Every accepted compact operator approximation scheme exposes bounded-image precompactness only through its displayed finite image-net schedule and tail/modulus rows. A consumer may read precompactness from $A = (S, T, B, N, M, H, C, P, L)$ only after the source row S, target row T, bounded-linear-operator row B, schedule row N, and ledger row M have been displayed.*

Proof. Use Definition 1952.4 to project the accepted scheme. The analytic rows available to a consumer are the Banach endpoints S, T, the bounded-linear-operator row B, the finite image-net schedule N, and the tail/modulus ledger M.

Apply Definition 1952.2. Its carrier admission and finite-image-net stability rows force every compactness read through N and M, and its bounded-operator compatibility row requires B before those compact rows can be consumed.

The remaining rows H, C, P, L only transport, replay, source, and name the same finite packet. Since none of them stores host operator equality or a choice-selected compactness coordinate, bounded-image precompactness is visible exactly through the displayed finite image-net and tail/modulus rows. □

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier bounded image precompactness`

Theorem 1952.6 (Compact operator ideal consumer boundary)**.** OperatorIdeal$^{\uparrow}$ *and* Nuclear$^{\uparrow}$ *consumers may read compactness from a* CompactOperator$^{\uparrow}$ *packet only after the* BoundedLinearOperator$^{\uparrow}$ *row and finite image-net schedule have been displayed. The consumer route passes through the Banach endpoints of chapter 90, the bounded operator surface of chapter 1644, and then the ideal and nuclear readers of chapter 213 and chapter 215; it does not pass through host operator equality or choice-selected compactness.*

Proof. Start with the compact operator carrier of Definition 1952.1. It displays Banach endpoint rows S, T and a bounded-linear-operator row B before the compact image-net schedule N and tail/modulus row M.

Use Definition 1952.3. The functional-analysis handoff already factors downstream compact reads through CompactOperator$^{\uparrow}$ before OperatorIdeal$^{\uparrow}$ or Nuclear$^{\uparrow}$ can consume them.

Finally apply Definition 1952.5. It pins precompactness to B, N, M and the finite transport and replay rows, so the ideal and nuclear consumers inherit compactness through the displayed schedule rather than through host operator equality, an external selector, or an unledgered compactness principle. □

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier ideal consumer boundary`

Theorem 1952.7 (Compact operator tail-modulus consumer exactness)**.** *For every accepted* CompactOperator$^{\uparrow}$ *carrier*

$$K = (S, T, B, N, M, H, C, P, L),$$

the tail/modulus row M is the exact consumer boundary for compactness reads after the finite image-net schedule N has been displayed. Any OperatorIdeal$^{\uparrow}$ *or* Nuclear$^{\uparrow}$ *consumer inspecting compactness through K must read the Banach endpoints S, T, the bounded-linear-operator row B, the finite schedule N, and then the displayed modulus ledger M before using the transport, replay, provenance, or local naming rows H, C, P, L.*

Proof. Project the carrier of Definition 1952.1. The only compactness rows available after the bounded-linear-operator row are the finite image-net schedule N and the tail/modulus ledger M.

Apply Definition 1952.2. Its finite-image-net stability clause fixes the schedule coordinate N, while its bounded-operator compatibility clause forces every compact read to pass through B before reaching N or M.

Use Definition 1952.6. The ideal and nuclear consumers inherit compactness only through the displayed compact-operator carrier. Since H, C, P, L merely transport, replay, source, and name the same rows, M is the exact final analytic ledger inspected by those consumers. □

Lean4 ✓ `BEDC.Derived.CompactOperatorUp.CompactOperatorTailModulusConsumerExactness`
Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier tail modulus consumer exactness`

Theorem 1952.8 (Compact operator finite-rank approximation boundary)**.** *The* CompactOperator$^{\uparrow}$ *carrier exposes finite-rank approximation data only as a boundary read from its displayed finite image-net schedules and tail/modulus rows. A consumer may treat*

$$K = (S, T, B, N, M, H, C, P, L)$$

as approximation-ready only when the source and target Banach rows S, T, the bounded-linear-operator row B, the finite image-net row N, and the modulus row M have all been displayed; the certificate does not introduce a host finite-rank projection, a selected approximating sequence, or operator equality outside K.

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier finite rank approximation boundary`

Proof. Read the approximation scheme of Definition 1952.4. It uses the same rows $S, T, B, N, M, H, C, P, L$ and accepts compactness only after N and M have been exposed downstream of B.

Apply Definition 1952.5. Bounded-image precompactness is visible exactly through the finite schedule and tail/modulus rows, so any finite-rank approximation boundary can only read the displayed image-net endpoints and precision ledger.

Finally use Definition 1952.6. The operator-ideal and nuclear handoffs inspect that same carrier surface. Because no row stores a host projection, selected approximating sequence, or external operator equality, the finite-rank approximation content remains a boundary of N and M rather than a new object. □

Theorem 1952.9 (Compact operator spectral refusal boundary)**.** *No* $\mathsf{CompactOperator}^{\uparrow}$ *consumer may read spectral data from the compactness certificate. For every accepted carrier*

$$K = (S, T, B, N, M, H, C, P, L),$$

the compactness surface available to $\mathsf{OperatorIdeal}^{\uparrow}$ *and* $\mathsf{Nuclear}^{\uparrow}$ *is exhausted by the displayed Banach rows, bounded-linear-operator row, finite image-net schedules, tail/modulus ledgers, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; spectral values, eigenspaces, resolvents, and trace data are outside the carrier.*

Lean4 ✓ `BEDC.Derived.CompactOperatorCarrier spectral refusal boundary`

Proof. Inspect the non-escape clause in Definition 1952.2. The provenance and local naming rows source no spectral row, trace-class row, choice-selected compactness row, host operator equality, or external compactness principle.

Use Definition 1952.7. Downstream consumers inspect compactness only after S, T, B, N, M have been displayed, with H, C, P, L preserving that same finite packet.

The consumer boundary of Definition 1952.6 then blocks an $\mathsf{OperatorIdeal}^{\uparrow}$ or $\mathsf{Nuclear}^{\uparrow}$ reader from replacing the finite image-net and modulus route by spectral theory. Spectral values, eigenspaces, resolvents, and trace data therefore remain explicit non-claims of the compact-operator certificate. □

Theorem 1952.10 (Compact operator obligation scope)**.** *The* $\mathsf{CompactOperator}^{\uparrow}$ *obligation surface is scoped exactly to the functional-analysis route of Definition 1952.3, the approximation scheme of Definition 1952.4, the bounded-image precompactness boundary of Definition 1952.5, the ideal consumer boundary of Definition 1952.6, the tail-modulus exactness theorem of Definition 1952.7, the finite-rank approximation boundary of Definition 1952.8, and the spectral refusal boundary of Definition 1952.9. The only primitive rows in scope are the source and target* $\mathsf{Banach}^{\uparrow}$ *rows, the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row, the finite image-net schedule, the tail/modulus row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row of Definition 1952.1.*

No scoped obligation imports spectral data, trace-class data, host operator equality, choice-selected compactness, or an external compactness theorem.

Lean4 ✓ `BEDC.Derived.CompactOperatorUp.CompactOperatorObligationScope`

Proof. Project the carrier $K = (S, T, B, N, M, H, C, P, L)$ of Definition 1952.1. The carrier exposes only Banach endpoint rows, a bounded-linear-operator row, finite image-net schedules, a tail/modulus ledger, transport, replay, provenance, and local naming.

Apply Definition 1952.2. Carrier admission, finite-image-net stability, classifier transport, ledger non-escape, and bounded-operator compatibility are all stated over those same rows.

Use the functional-analysis route and approximation scheme, Definition 1952.3 and Definition 1952.4. They place every downstream compact read behind the Banach endpoints, bounded operator, finite schedules, and modulus ledger before any ideal or nuclear consumer is allowed to inspect compactness.

Finally combine Definition 1952.5, Definition 1952.6, Definition 1952.7, Definition 1952.8, and Definition 1952.9. These theorems exhaust the bounded-image, ideal, tail-modulus, finite-rank, and spectral-refusal boundaries without adding any row outside the displayed packet. □

Theorem 1952.11 (Compact operator public export status)**.** *The* $\mathsf{CompactOperator}^{\uparrow}$ *packet has a public export surface over the finite rows*

$$S, T, B, N, M, H, C, P, L.$$

Every public consumer of the compact-operator certificate must read the Banach endpoint rows, the bounded-linear-operator row, the finite image-net schedule, the tail/modulus ledger, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before treating compactness as available to* $\mathsf{OperatorIdeal}^{\uparrow}$ *or* $\mathsf{Nuclear}^{\uparrow}$*.*

Proof. Use the carrier of Definition 1952.1. It displays exactly the rows $S, T, B, N, M, H, C, P, L$, with the compactness surface entering through the finite image-net schedule and tail/modulus ledger after the bounded-linear-operator row.

Apply the ideal consumer boundary and tail-modulus exactness theorems, Definition 1952.6 and Definition 1952.7. They force the public $\mathsf{OperatorIdeal}^{\uparrow}$ and $\mathsf{Nuclear}^{\uparrow}$ reads to pass through the same finite compact-operator packet rather than through host operator equality or an external compactness principle.

Finally use Definition 1952.10. Its scope statement binds the same rows to the Banach, bounded-linear-operator, functional-analysis, operator-ideal, and nuclear routes, so the displayed packet is public-facing while the verification axis remains the encoded definition cited in the closure status block. □

Lean4 ✓ `BEDC.Derived.CompactOperatorUp.CompactOperatorPublicExportStatus`

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOperator}^{\uparrow}$ packet is generated from source and target Banach rows, a bounded-linear-operator row, displayed finite image-net schedules, tail/modulus rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactOperator}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1952.10 and Definition 1952.11 close the mature finite image-net treatment over $S, T, B, N, M, H, C, P, L$ for the Banach, bounded-linear-operator, functional-analysis, operator-ideal, and nuclear sibling routes used by the compact-operator certificate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactOperator}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.CompactOperatorUp`

Bridge status: none

Not claimed: This chapter does not close spectral theory, trace-class theory, choice-selected compactness, host operator equality, Lean-checked obligations, or bridge checking.

Upgrade path: The paper theory axis is mature for the finite image-net and tail-modulus export surface; bridgeChecked remains a separate formal-axis target for BEDC.Derived.CompactOperatorUp.

Chapter 1953

A Concrete Naming Certificate for $\mathsf{RapidCauchyName}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RapidCauchyName}^{\uparrow}$ packet records the finite rate-controlled Cauchy real-name surface used by L10 Real and Completion consumers before any terminal $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the finite window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback boundary of chapter 301, the terminal real-name seal of chapter 38, and the Real-facing modulus route of chapter 1423. The packet supplies an explicit rapid Cauchy naming certificate without quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Definition 1953.1 (Rapid Cauchy name carrier)**.** *A* $\mathsf{RapidCauchyName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (R_0, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *is the dyadic rate schedule row, recording the finite precision requests and the displayed rule that a request at level* k *is answered inside the dyadic tolerance budget assigned to* k*.*
2. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by the rate schedule for the visible requests.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic radii, slack comparisons, and arithmetic rows consumed by the selected windows.*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows* S *under the tolerance ledger* D*.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the rate schedule, finite windows, tolerance ledger, and regular rational readback have been displayed.*
6. H *records componentwise* hsame *transport for the rate schedule, windows, tolerance ledger, readback, seal, replay, provenance, and local name.*
7. C *records displayed* Cont *replay from each finite precision request through* R_0, S, D, Q, E *and then through* H, P, N*.*
8. P *is the* Pkg *provenance over* $\mathsf{RapidCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RapidCauchyName}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $R_0, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.RapidCauchyNameUp.RapidCauchyNameTasteGate single carrier alignment`

Theorem 1953.2 (Rapid Cauchy name NameCert obligations)**.** *For every accepted* $\mathsf{RapidCauchyName}^{\uparrow}$ *carrier*

$$R = (R_0, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RapidCauchyName}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the dyadic rate schedule R_0, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N;*
2. *rate admission, requiring every precision request to enter through R_0 before any stream window, tolerance comparison, readback, or seal row is consumed;*
3. *finite-window selection, requiring S to contain only the windows selected by the displayed rate schedule;*
4. *dyadic accounting, requiring D to store exactly the tolerance radii and slack comparisons consumed by the selected windows and readback rows;*
5. *readback and seal routing, requiring Q and E to remain downstream of the displayed R_0, S, D route;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
7. *non-escape for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard-bridge data.*

No rapid Cauchy name obligation is stored outside these rows.

Proof. Project the carrier of Definition 1953.1. The analytic coordinates are exactly the dyadic rate schedule, finite windows, dyadic tolerance ledger, regular rational readback, and terminal seal.

The request order is forced by the tuple. A precision request first reads R_0, and the selected windows S are visible only as windows controlled by that schedule.

The tolerance and readback rows are downstream. The ledger D supplies the dyadic radii and slack comparisons consumed by S and Q, and the seal E is reached only after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1953.3 (Rapid Cauchy name dyadic rate route)**.** *Every precision request accepted by a* $\mathsf{RapidCauchyName}^{\uparrow}$ *carrier factors through the finite route*

$$R_0 \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed dyadic rate schedule, selected finite $\mathsf{StreamName}^{\uparrow}$ *windows, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming. The route supplies no quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy row, ambient completeness theorem, Lean evidence, or standard bridge.*

Proof. Begin with an accepted carrier and inspect the precision request. The only entrance for that request is the rate schedule row R_0, so the consumer cannot first read a detached stream window or a terminal Real seal.

Induct over the finite list of visible requests in the schedule. The empty list has no window or tolerance row to consume. In the cons step, the head request selects its finite window in S and reads its dyadic radius and slack comparisons in D; the induction hypothesis handles the remaining requests.

The regular readback Q is then obtained from the selected windows and tolerance ledger. The seal E and structural rows H, C, P, N close the same displayed route, and no carrier coordinate remains from which the excluded quotient, selector, choice, equality, order, completeness, verification, or bridge data could be read. □

Theorem 1953.4 (Rapid Cauchy name Real seal boundary)**.** *Let*

$$R = (R_0, S, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{RapidCauchyName}^{\uparrow}$ *carrier. Any downstream use of the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *must pass through the same dyadic rate schedule, selected finite windows, tolerance ledger, regular rational readback, and structural rows. Thus the seal cannot be used as a hidden endpoint for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Proof. Use the route of Definition 1953.3. It places E after R_0, S, D, Q, so every accepted seal read is attached to the displayed rate schedule, finite windows, tolerance accounting, and regular readback.

Now inspect the classifier surface of Definition 1953.1. The carrier has no second Real-seal coordinate and no coordinate for quotient equality, selected limits, countable choice, host equality, trichotomy, ambient completeness, Lean evidence, or bridge data.

Therefore a downstream read that bypasses one of R_0, S, D, Q, H, C, P, N is not a read of the accepted carrier. The only available terminal route is the finite route named by R. □

Falsifiable prediction: Every $\mathsf{RapidCauchyName}^{\uparrow}$ precision read factors through a dyadic rate schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, dyadicratcore, regseqrat, realcauchymodulus, real: $\mathsf{RapidCauchyName}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rate admission, finite-window selection, dyadic tolerance accounting, regular readback, terminal seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RapidCauchyName}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RapidCauchyName}^{\uparrow}$ packet is generated from a dyadic rate schedule, finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RapidCauchyName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1953.1, Definition 1953.2, Definition 1953.3, and Definition 1953.4 seed the finite rapid Cauchy real-name route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RapidCauchyName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, rate admission, window selection, dyadic accounting, readback and seal routing, dyadic rate routing, and Real-seal non-escape for BEDC.Derived.RapidCauchyNameUp.

Chapter 1954

A Concrete Naming Certificate for $\mathsf{CauchyCompletionComparison}^{\uparrow}$

Following Bishop and Bridges, Kelley, and Bourbaki, the $\mathsf{CauchyCompletionComparison}^{\uparrow}$ packet records the finite BEDC surface by which a unit-and-universal-property completion presentation is compared with a functorial metric-completion presentation. It reads the dense unit route of chapter 1527, the universal-property route of chapter 397, the functorial action route of chapter 1937, the metric-completion boundary of chapter 1559, the finite stream window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names a comparison certificate for displayed completion presentations only; it does not identify quotient completions, choose representatives, assert host equality, or import completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1954.1 (CauchyCompletionComparison carrier)**.** *A* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, V, F, M, R, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *source-admission row for the unit-and-universal-property presentation.*
2. *V is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row recording the finite extension obligation and its displayed uniqueness comparison.*
3. *F is the* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *row recording the corresponding completed-map route on the functorial side.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row recording the metric-completion presentation whose finite Cauchy data are being compared with U, V, F.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row shared by the two presentations.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected before either presentation reaches a completion-facing seal.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and diameter ledger attached to the same stream windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the shared S, D, R route has been displayed.*

9. *H records componentwise* hsame *transport for U, V, F, M, R, S, D, E and the structural rows.*
10. *C records displayed* Cont *replay of the route*

$$U, V, F, M \longmapsto S, D, R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, CompletionUniversalPrope $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed objects, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionComparisonUp.CauchyCompletionComparisonTasteGate single carrier alignment`

Theorem 1954.2 (CauchyCompletionComparison NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *carrier*

$$K = (U, V, F, M, R, S, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the unit row, universal-property row, functorial row, metric-completion row, regular readback, stream windows, dyadic ledger, terminal seal, transport, replay, provenance, and local naming row;*
2. *shared-window coverage, requiring both presentations to inspect only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in S before reading D, R, E;*
3. *universal-to-functorial comparison, requiring any unit/universal-property completion consumer to pass through U, V before it is compared with the functorial row F;*
4. *metric presentation comparison, requiring any metric-completion consumer to pass through M and then the same S, D, R, E route;*
5. *classifier stability, requiring transported packets with componentwise matching rows to replay the same comparison through H and C;*
6. *non-escape, requiring P, N to source and name no quotient completion equality, selected representative, countable-choice schedule, host equality, open-cover compactness, or completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission is projection from Definition 1954.1. The accepted tuple displays exactly the four presentation rows U, V, F, M, the shared observation route S, D, R, E, and the structural rows H, C, P, N.

Shared-window coverage is proved by induction on the finite $\mathsf{StreamName}^{\uparrow}$ windows in S. The empty window exposes no rational readback. In the cons step, the next displayed window contributes only its attached $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the induction hypothesis replays the remaining windows.

The universal-to-functorial comparison is componentwise. The unit route U supplies the dense source admission, V supplies the extension and uniqueness surface, and F supplies the functorial completed-map route over the same displayed source data.

The metric presentation comparison uses the same induction on S and the same replay through D, R, E. Since M has no separate terminal seal coordinate in the carrier, a metric-completion read reaches the public comparison only through the shared finite route.

Finally transport and naming are read from H, C, P, N. These rows preserve the displayed coordinates and add no quotient, representative-choice, countable-choice, host-equality, compactness, or real-completeness coordinate, so the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionComparisonUp.CauchyCompletionComparisonCarrier namecert obligations`

Theorem 1954.3 (CauchyCompletionComparison route)**.** *Let*

$$K = (U, V, F, M, R, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *carrier. Every consumer comparing the unit/universal-property presentation with the functorial metric-completion presentation factors through the finite route*

$$U, V, F, M \longmapsto S, D, R \longmapsto E \longmapsto H, C, P, N.$$

The route is a comparison of displayed NameCert rows. It is not quotient completion equality, not selected representatives, not countable choice, not host equality of completed objects, not open-cover compactness, and not completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with a comparison consumer and project the carrier. The only unit/universal-property coordinates are U and V, and the only functorial coordinate is F.

The metric side is then forced through M. Any metric-completion read that reaches the comparison must expose the finite presentation row before the shared observation route is available.

We now replay the shared observation route by induction on S. At the base window there is no rational observation to compare. At each finite step, the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance in D and the $\mathsf{RegSeqRat}^{\uparrow}$ readback in R are transported componentwise, and the remaining windows are handled by the induction hypothesis.

The terminal seal is E. After E is reached, H and C preserve the route under displayed hsame transport and Cont replay, while P and N record provenance and local naming. No other carrier coordinate exists, so the route cannot export any excluded completion or choice principle. □

Theorem 1954.4 (CauchyCompletionComparison sibling handoff)**.** *For an accepted* $\mathsf{CauchyCompletionComparison}$ *carrier* $K = (U, V, F, M, R, S, D, E, H, C, P, N)$*, every sibling consumer from* $\mathsf{CauchyCompletionUnit}^{\uparrow}$*,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *receives exactly the rows named in Definition 1954.1. The handoff therefore preserves the shared finite comparison route and exports no quotient completion equality, selected representative, countable-choice schedule, host equality, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier and split the sibling consumers by their entry row.

Consumers entering through $\mathsf{CauchyCompletionUnit}^{\uparrow}$ or $\mathsf{CompletionUniversalProperty}^{\uparrow}$ read U, V first. They may continue to the functorial route F and the metric route M, but only through the displayed comparison coordinates.

Consumers entering through $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ read F, M first. They still must pass through the same stream, dyadic, rational, and real-seal route S, D, R, E before receiving a completion-facing comparison.

Consumers entering through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ are already inside the shared observation route. Induction on the finite window family S shows that such consumers can inspect only the displayed window, tolerance, readback, and seal rows, preserved componentwise by H and replayed by C.

The package row P and local naming row N source exactly these handoffs. Since the carrier has no coordinate for quotient equality, representative selection, countable choice, host equality, open-cover compactness, or real completeness, no sibling handoff can export one. □

Theorem 1954.5 (CauchyCompletionComparison seal agreement)**.** *For an accepted* $\mathsf{CauchyCompletionComparison}$ *carrier* $K = (U, V, F, M, R, S, D, E, H, C, P, N)$*, every comparison consumer that enters through the unit/universal-property route* U, V *and every comparison consumer that enters through the functorial metric-completion route* F, M *reaches the same displayed seal route*

$$S, D, R \longmapsto E.$$

Equivalently, the public comparison surface has one $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route after the presentation rows have been displayed. No second terminal seal, detached real route, quotient completion equality, selected representative, host equality, countable-choice schedule, open-cover compactness argument, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem is available to either consumer.*

Proof. Project the accepted carrier using Definition 1954.1. The presentation rows are exactly U, V, F, M, and the only analytic readback rows are S, D, R, E.

Apply the obligation surface of Definition 1954.2. The unit/universal-property consumer must expose U, V before reaching the shared-window row, while the functorial metric-completion consumer must expose F, M before reaching the same shared-window row.

Now apply the route theorem and sibling handoff, Definition 1954.3 and Definition 1954.4. Both entry routes are replayed through S, D, R and terminate at E, with H, C, P, N preserving and naming only that displayed route. Since the carrier stores no second seal or excluded completion principle, the seal route is common to both consumers. □

Theorem 1954.6 (CauchyCompletionComparison nonquotient boundary)**.** *Let* $K = (U, V, F, M, R, S, D, E, H, C,$ *be an accepted* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *carrier. Replacing the route*

$$U, V, F, M \longmapsto S, D, R \longmapsto E$$

by quotient completion equality, selected representatives, host equality of completed objects, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is outside the carrier and outside every* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}$ *handoff generated by* K*.*

Proof. The carrier definition lists the full packet, so every admitted row is one of $U, V, F, M, R, S, D, E, H, C, P, N$. None of these rows is a quotient equality, a representative selector, a host-equality witness, a choice schedule, a compactness proof, or an ambient completeness theorem.

The NameCert obligations of Definition 1954.2 require comparison consumers to expose the presentation rows and then the shared S, D, R, E route. The route theorem fixes this order, and the sibling handoff theorem shows that every sibling consumer receives only the rows already named by the carrier.

Thus any attempted replacement by one of the excluded principles would need a coordinate not present in the packet or in its local $\mathsf{NameCert}$ surface. Such a replacement is therefore not a comparison handoff of K. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionComparison}^{\uparrow}$ packet is generated from CauchyCompletionUnit, CompletionUniversalProperty, CauchyCompletionFunctoriality, and MetricCompletion presentation rows, shared finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1954.1, Definition 1954.2, Definition 1954.3, Definition 1954.4, Definition 1954.5, and Definition 1954.6 seed the finite comparison surface between unit/universal-property and functorial metric-completion presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality, open-cover compactness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window coverage, presentation comparison, classifier stability, sibling handoff, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionComparisonUp.

Chapter 1955

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$ packet records the finite BEDC route by which a single regular Cauchy rational source presents two displayed modulus ledgers while producing one $\mathsf{Real}^{\uparrow}$ seal. The chapter sits after the finite window discipline of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, the modulus realizer surface of chapter 1918, the stability route of chapter 1927, and the terminal seal of chapter 38. Its purpose is to make the $\mathsf{Real}^{\uparrow}$ seal depend on the shared regular Cauchy source and the displayed cofinal comparison, not on an accidental choice of modulus ledger.

Definition 1955.1 (Regular Cauchy modulus-independence carrier)**.** *A* $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, S_0, S_1, D_0, D_1, J, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the single* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, exposing the regular rational approximants that both modulus ledgers read.*
2. *S_0 and S_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *schedule rows used to request finite windows from the same source row R.*
3. *D_0 and D_1 are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *modulus-ledger rows, including their displayed dyadic radii, slack comparisons, and finite precision requests.*
4. *J is the cofinal comparison row, recording the finite zig-zag by which requests through D_0 and requests through D_1 are compared over the shared source row R.*
5. *A is the unique* $\mathsf{Real}^{\uparrow}$ *seal row reached after the two schedules, two ledgers, and the cofinal comparison have been displayed.*
6. *H records componentwise* hsame *transport for the source row, both schedule rows, both dyadic modulus ledgers, the cofinal comparison row, the Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$R \longmapsto S_0, S_1 \longmapsto D_0, D_1 \longmapsto J \longmapsto A.$$

8. *P is the* Pkg *provenance over* RegularCauchyModulusIndependence$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyModulusRealizer$^{\uparrow}$, RegularCauchyModulusStability$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{RegularCauchyModulusIndependence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S_0, S_1, D_0, D_1, J, A, H, C, P, N$. It has no coordinate for a preferred modulus ledger, quotient stream equality, selected limits, countable choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusIndependenceUp.RegularCauchyModulusIndependenceTasteGate`
`single carrier alignment`

Theorem 1955.2 (Regular Cauchy modulus-independence NameCert obligations)**.** *For every accepted* RegularCauchyModulusIndependence$^{\uparrow}$ *carrier*

$$I = (R, S_0, S_1, D_0, D_1, J, A, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyModulusIndependence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the shared* RegSeqRat$^{\uparrow}$ *source row, the two* StreamName$^{\uparrow}$ *schedules, the two* DyadicRatCore$^{\uparrow}$ *modulus ledgers, the cofinal comparison row, the unique* Real$^{\uparrow}$ *seal, and the structural rows H, C, P, N;*

2. *shared-source exposure, requiring both schedules and both ledgers to project the same source row R before any seal-facing row is inspected;*

3. *two-modulus cofinal comparison, requiring J to display finite comparison data from the D_0 route to the D_1 route and back over the source row R;*

4. RegSeqRat$^{\uparrow}$ *handoff, requiring every ledger request to be read as a regular rational approximation from R rather than from a detached stream representative;*

5. Real$^{\uparrow}$ *seal factorization, requiring every seal consumer to pass through the shared source row and the cofinal comparison before reaching A;*

6. *transport, replay, and provenance, requiring H, C, P, N to preserve, replay, source, and name only the displayed rows of the packet;*

7. *ledger non-escape, requiring the certificate to export no preferred modulus ledger, quotient stream equality, selected limit, countable-choice schedule, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No modulus-independence obligation is stored outside these rows.

Proof. Project the accepted packet $I = (R, S_0, S_1, D_0, D_1, J, A, H, C, P, N)$. Carrier admission exposes one regular rational source row, two finite schedules, two dyadic modulus ledgers, one cofinal comparison row, one terminal Real seal, and the four structural rows.

The shared-source clause is read first. Both schedules S_0, S_1 request windows from R, and both dyadic ledgers D_0, D_1 are attached to those requests, so neither ledger can present an independent stream representative.

The cofinal clause is the row J. It records finite comparison data in both directions between the requests displayed by D_0 and D_1, always over the same source row R.

The handoff to Real$^{\uparrow}$ is downstream. A seal-facing consumer must follow the route through R, the two schedules, the two ledgers, and J before it can inspect A.

Finally, H, C, P, N transport, replay, source, and name this route without adding an excluded coordinate. Since the carrier has no row for a preferred ledger or for an ambient completeness principle, the listed rows exhaust the local NameCert surface. □

Theorem 1955.3 (Regular Cauchy modulus-independence Real seal factorization)**.** *For every accepted* $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$ *carrier*

$$I = (R, S_0, S_1, D_0, D_1, J, A, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer factors through*

$$R \longmapsto S_0, S_1 \longmapsto D_0, D_1 \longmapsto J \longmapsto A$$

together with the structural rows H, C, P, N*. In particular, replacing the selected finite request route from* D_0 *by the displayed cofinal route through* D_1*, or conversely, leaves the exposed* $\mathsf{Real}^{\uparrow}$ *seal row* A *named by the same local certificate.*

Proof. Start with a consumer of the terminal Real seal. The carrier projection exposes A, but the displayed route places A after the two schedule rows, the two dyadic modulus ledgers, and the cofinal comparison row.

Trace the consumer backward from A. The only source coordinate available to either modulus ledger is R, and the only schedules available to the ledgers are S_0 and S_1.

The comparison step is J. A request that arrives through D_0 is compared to a request through D_1, and the converse comparison is also displayed, so the consumer receives a finite cofinal witness before the Real seal is read.

The structural rows preserve this factorization. The hsame row transports corresponding displayed components, the Cont row replays the same ordering, and the Pkg and NameCert rows name no extra modulus choice.

Thus the Real seal is a downstream endpoint of the shared regular-Cauchy source and its cofinal ledger comparison. It is not a certificate of a preferred modulus, quotient stream equality, selected limits, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusIndependence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$ packet is generated from one $\mathsf{RegSeqRat}^{\uparrow}$ source row, two $\mathsf{StreamName}^{\uparrow}$ schedules, two $\mathsf{DyadicRatCore}^{\uparrow}$ modulus ledgers, one cofinal comparison row, one $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusIndependence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1955.1, Definition 1955.2, and Definition 1955.3 seed the finite L10 route separating Real seals from accidental modulus-ledger choices.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusIndependence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyModulusIndependenceUp.RegularCauchyModulusIndependenceTasteGate\_transport`

Bridge status: none

Not claimed: This chapter does not close preferred modulus selection, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-source exposure, two-modulus cofinal comparison, RegSeqRat handoff, Real-seal factorization, transport and replay coverage, provenance coverage, and ledger non-escape for BEDC.Derived.RegularCauchyModulusIndependenceUp.

Chapter 1956

A Concrete Naming Certificate for $\mathsf{TietzeExtension}^{\uparrow}$

Following Tietze, Urysohn, Kelley, and Bourbaki, the $\mathsf{TietzeExtension}^{\uparrow}$ packet records the finite BEDC route from displayed normal-space separation data to displayed continuous $\mathsf{Real}^{\uparrow}$-valued extension data. It sits above the normal-space carrier of chapter 1866 and the separation-function carrier of **??**, and it reads its function, codomain, and topological boundaries through chapter 130, chapter 38, chapter 88, chapter 1858, and chapter 1857. The packet names only a local finite extension certificate for a displayed closed-domain row and a bounded displayed function on that row; it does not select complements, invoke excluded middle, identify host functions extensionally, or appeal to ambient compactness.

Definition 1956.1 (Tietze extension carrier)**.** *A* $\mathsf{TietzeExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (N, D, B, U, M, G, R, H, K, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *source row, exposing the ambient* $\mathsf{Topology}^{\uparrow}$ *row and the finite closed-pair separation discipline used by the extension read.*
2. *D is the closed-domain row, displayed over the topology source as a finite closed-set witness rather than as a selected complement of an open row.*
3. *B is the bounded* $\mathsf{Real}^{\uparrow}$ *target-interval row for the input map on D, recording the two endpoint bounds and the displayed nonescape ledger for the interval.*
4. *U is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *ladder row, recording the finite sequence of separation-function reads consumed to extend the bounded data stage by stage.*
5. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the input map on the closed-domain surface, exposing only graph cells and continuity replay visible on D.*
6. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *extension-graph row, tying the ambient topology source to the extended* $\mathsf{Real}^{\uparrow}$*-valued graph and recording agreement with M on the displayed closed-domain row.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, certifying that every displayed extension value remains inside the bounded target interval named by B.*
8. *H records componentwise* hsame *transport for the normal-space source, closed-domain row, bounded interval row, Urysohn ladder, input map, extension graph, Real seal, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay from a Tietze-extension request through $N, D, B, U, M, G, R, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{TietzeExtension}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ZeroSet}^{\uparrow}$, $\mathsf{CozeroSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, D, B, U, M, G, R, H, K, P, L$. It has no coordinate for selected complements, excluded middle, host function extensionality, arbitrary open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.TietzeExtensionUp.TietzeExtensionTasteGate single carrier alignment`

Theorem 1956.2 (Tietze extension NameCert obligations)**.** *For every accepted* $\mathsf{TietzeExtension}^{\uparrow}$ *carrier*

$$E = (N, D, B, U, M, G, R, H, K, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the normal-space source, closed-domain row, bounded interval row, Urysohn ladder, input map, extension graph, Real seal, transport, replay, provenance, and local naming;*
2. *closed-domain exposure, requiring the extension request to display D over the topology source named by N before any ambient extension graph can be consumed;*
3. *Urysohn-step route, requiring every stage of the bounded extension read to pass through the* $\mathsf{UrysohnLemma}^{\uparrow}$ *ladder row U rather than through selected complements or excluded middle;*
4. *continuous endpoint exactness, requiring M and G to agree on the displayed closed-domain row and requiring the agreement read to use the visible* $\mathsf{ContinuousMap}^{\uparrow}$ *graph cells;*
5. *Real boundary nonescape, requiring R to preserve the bounded interval named by B for all displayed extension values;*
6. hsame, Cont, *and* Pkg *transport, requiring componentwise transport, displayed replay, and provenance to preserve exactly the listed rows and no hidden host-function data.*

No local Tietze-extension obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 1956.1. The accepted tuple displays exactly the normal-space source, closed-domain row, bounded interval, Urysohn ladder, input map, extension graph, Real seal, and structural transport, replay, provenance, and naming rows.

Closed-domain exposure follows from the order of the carrier. An extension request first reads N and then D over the same topological source; the extension graph row G is unavailable until the closed-domain row has been displayed.

The Urysohn-step route is the projection to U. Each bounded correction step is named as a $\mathsf{UrysohnLemma}^{\uparrow}$ ladder read, so the packet has no row from which a selected complement, excluded middle argument, or unrecorded separation theorem can be consumed.

Continuous endpoint exactness is read through M and G. The row M displays the original $\mathsf{Real}^{\uparrow}$-valued continuous graph on D, while G displays the ambient graph and its agreement with M along that closed-domain row.

Real boundary nonescape is the projection to B and R. The interval row records the endpoint bounds, and the Real seal row records that the displayed extension graph stays inside those bounds.

Finally, transport and provenance are exhausted by H, K, P, L. These rows move and replay exactly the displayed carrier coordinates, so no local obligation exports host function extensionality, arbitrary open-cover compactness, ambient Real completeness, Lean verification, or bridge checking. □

Theorem 1956.3 (Tietze extension Urysohn route)**.** *Every extension read exported by an accepted* $\mathsf{TietzeExtension}^{\uparrow}$ *packet factors through*

$$\mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{UrysohnLemma}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the local $\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}$ *row can be inspected. No extension read factors through a selected complement, excluded middle, host function extensionality, arbitrary open-cover compactness, or ambient Real completeness.*

Proof. Begin with an accepted carrier $E = (N, D, B, U, M, G, R, H, K, P, L)$. Carrier admission exposes the $\mathsf{NormalSpace}^{\uparrow}$ source N and the closed-domain row D before any ladder, graph, or Real-boundary row is available.

The next gate is U. This row is precisely the $\mathsf{UrysohnLemma}^{\uparrow}$ ladder consumed by the extension read, so every separation-function stage is read from the displayed normal-space route and not from a selected complement or excluded-middle branch.

The function gate is M and G. The input graph and the ambient extension graph are both $\mathsf{ContinuousMap}^{\uparrow}$ rows, and their agreement is visible only along the displayed closed-domain row.

The value gate is B and R. These rows tie the extension graph to the bounded $\mathsf{Real}^{\uparrow}$ interval and record nonescape inside that interval.

The replay and local naming rows H, K, P, L preserve this order. Since the classifier has no further coordinate, every exported extension read factors through $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with none of the excluded classical or host-level principles available. □

Closure status for $\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1956.1, Definition 1956.2, and Definition 1956.3 seed the finite L10 route from normal-space separation data through Urysohn ladder rows into bounded continuous $\mathsf{Real}^{\uparrow}$-valued extension data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TietzeExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected complements, excluded middle, host function extensionality, arbitrary open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-domain exposure, Urysohn-step routing, continuous endpoint exactness, Real boundary nonescape, transport stability, and non-escape proofs for BEDC.Derived.TietzeExtensionUp.

Constructive story: A $\mathsf{TietzeExtension}^{\uparrow}$ packet is generated from a $\mathsf{NormalSpace}^{\uparrow}$ source row, a closed-domain row, a bounded $\mathsf{Real}^{\uparrow}$ interval row, a $\mathsf{UrysohnLemma}^{\uparrow}$ ladder, $\mathsf{ContinuousMap}^{\uparrow}$ input and extension graph rows, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1957

A Concrete Naming Certificate for $\mathsf{TernaryExpansion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Cantor's middle-third construction, the $\mathsf{TernaryExpansion}^{\uparrow}$ packet records finite base-three digit-prefix rows as displayed BEDC readback data. It does not store a host infinite ternary stream, quotient real, endpoint convention selector, or chosen representative. Its role is to route inspected base-three prefixes through the finite stream surface of chapter 126, the base-three rational place-value ledger parallel to chapter 1417 and chapter 418, the dyadic comparison discipline of chapter 291, the regular rational handoff of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the retained-third consumer surface of chapter 1530.

Definition 1957.1 (TernaryExpansion carrier)**.** *A* $\mathsf{TernaryExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, W, V, Q, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite ternary digit ledger, whose rows record inspected base-three digits together with any local sign or integral-prefix convention carried by the packet.*
2. *W is the place-window ledger, listing the finite prefix windows and request precisions exposed to* $\mathsf{StreamName}^{\uparrow}$ *consumers.*
3. *V is the base-three rational place-value row that evaluates each inspected prefix as a rational sum with denominator a displayed power of three.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-comparison row that compares the base-three rational place-value row with the dyadic precision language consumed by downstream real readers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the same digit, window, place-value, and dyadic-comparison rows.*
6. *A is the optional* $\mathsf{CantorSet}^{\uparrow}$ *retained-prefix row, present exactly when the inspected digits in D are the retained-third digits used by the Cantor set surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, W, V, Q, R and, when present, A have been displayed.*
8. *H is the componentwise* hsame *transport row for ternary digits, prefix windows, base-three place values, dyadic comparisons, regular handoff, retained-prefix handoff, and real-seal coordinates.*

9. *C is the displayed* Cont *replay row that reads finite ternary windows, place-value rows, dyadic comparisons, handoff rows, retained-prefix rows, and real seals without adding a host stream.*
10. *P is the* Pkg *provenance over* $\mathsf{TernaryExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TernaryExpansion}^{\uparrow}}$ *row.*

The carrier predicate accepts exactly such finite base-three readback packets. It has no coordinate for a completed ternary stream, quotient equality of expansions, endpoint uniqueness convention, selected representative, trichotomy principle, measure-theoretic normality row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.TernaryExpansionUp.TernaryExpansionTasteGate single carrier alignment`

Theorem 1957.2 (TernaryExpansion RegSeqRat readback)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{TernaryExpansion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{TernaryExpansion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads a finite ternary window, then the base-three place-value row for that window, then the dyadic comparison row, then the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and only then the displayed* $\mathsf{Real}^{\uparrow}$ *seal. The read uses no host infinite stream, quotient equality, selected representative, trichotomy decision, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier $T = (D, W, V, Q, R, A, E, H, C, P, N)$. The $\mathsf{StreamName}^{\uparrow}$ entrance is the finite window row W together with the digit rows of D selected by that window, so a real-facing consumer cannot read a ternary prefix before a finite observation window has been displayed.

The place-value row V evaluates that same finite prefix as a rational sum with base-three denominators. The comparison row Q is the only route from this base-three ledger into the dyadic tolerance discipline used by $\mathsf{RegSeqRat}^{\uparrow}$ and later real-name consumers.

The handoff row R is therefore downstream of D, W, V, Q, and the seal row E is downstream of R. The rows H, C, P, N transport, replay, package, and locally name the same finite route without adding any external stream or real representative.

Thus every real-facing read factors through the displayed finite window, place-value, dyadic-comparison, regular-handoff, and real-seal rows. The excluded host stream, quotient equality, representative choice, trichotomy, and completeness principles are not coordinates of the carrier. □

Theorem 1957.3 (TernaryExpansion CantorSet handoff)**.** *When all inspected digits in a* $\mathsf{TernaryExpansion}^{\uparrow}$ *prefix are retained-third digits, the finite ternary prefix factors through the* $\mathsf{CantorSet}^{\uparrow}$ *retained-prefix surface before any* $\mathsf{CantorSet}^{\uparrow}$ *or Cantor-function consumer reads it. The handoff uses the same digit ledger D, window ledger W, retained-prefix row A, transport row H, replay row C, provenance row P, and local naming row N, and it exports no host subset, selected infinite branch, quotient real equality, endpoint uniqueness convention, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Assume the inspected prefix window of W selects only retained-third digit rows from D. By the carrier definition, precisely in this case the optional row A is present as the $\mathsf{CantorSet}^{\uparrow}$ retained-prefix handoff for that same finite window.

The continuation row C reads the digit window before it reads A, and the transport row H keeps the digit rows, the window, and the retained-prefix row componentwise attached. Hence a $\mathsf{CantorSet}^{\uparrow}$ consumer receives the same finite prefix, not a separate branch object.

The provenance row P and local certificate row N package the handoff over $\mathsf{TernaryExpansion}^{\uparrow}$ and $\mathsf{CantorSet}^{\uparrow}$. Any later Cantor-set or Cantor-function consumer therefore enters through the retained-prefix row already displayed by the ternary packet.

No host subset, selected infinite branch, quotient equality, endpoint convention, or completeness row is listed in the carrier, so none can be exported by this handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{TernaryExpansion}^{\uparrow}}$.

Constructive story: A $\mathsf{TernaryExpansion}^{\uparrow}$ packet is generated from finite ternary digit rows, place-window rows, base-three rational place-value rows, dyadic-tolerance comparison rows, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, an optional $\mathsf{CantorSet}^{\uparrow}$ retained-prefix handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TernaryExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1957.1, Definition 1957.2, and Definition 1957.3 seed the finite base-three prefix readback surface into $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CantorSet}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TernaryExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host ternary streams, quotient real equality, endpoint uniqueness, selected representatives, trichotomy, RealUp completeness, measure-theoretic normality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, componentwise classifier transport, dyadic comparison, RegSeqRat readback, RealUp seal, retained-prefix handoff, and non-escape targets for BEDC.Derived.TernaryExpansionUp.

Chapter 1958

A Concrete Naming Certificate for $\mathsf{CauchyFilterMeet}^{\uparrow}$

Following Bourbaki and Kelley filter terminology, the $\mathsf{CauchyFilterMeet}^{\uparrow}$ packet records the finite common-refinement operation by which two displayed Cauchy-filter packets over the same uniform surface are read as one refinement packet before any limit or completion-facing consumer inspects the route. It sits after the $\mathsf{UniformSpace}^{\uparrow}$ entourage surface of chapter 339, the source $\mathsf{CauchyFilter}^{\uparrow}$ packets of chapter 333, the basis generator of chapter 1501, and the limit boundary of chapter 1558; it reads finite windows through chapter 126, regular rational rows through chapter 301, dyadic tolerances through chapter 291, and terminal seals through chapter 38. The packet names a binary meet of displayed filter data, not quotient filters, selected limits, countable choice, host equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 1958.1 (Cauchy filter meet carrier)**.** *A* $\mathsf{CauchyFilterMeet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (U, F_0, F_1, B_0, B_1, J, S, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the shared* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row. It supplies the finite entourage requests, diagonal reads, and refinement reads through which both source filters are interpreted.*
2. *F_0 and F_1 are the two source* $\mathsf{CauchyFilter}^{\uparrow}$ *rows whose displayed requests are to be met.*
3. *B_0 and B_1 are the corresponding* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *rows. Each basis row exposes the finite basis requests, window data, regular readback, and dyadic tolerance ledger used by its source filter.*
4. *J is the binary common-refinement row. For every displayed pair of basis requests from B_0 and B_1, it names a displayed basis request refining both sources over the same entourage surface U.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected after the common-refinement row has been read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to verify that the common-refinement request is small enough for both Cauchy-filter sources.*
8. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff row available only after $U, F_0, F_1, B_0, B_1, J, S, R, D$ have been displayed.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by a Real-facing consumer through the same handoff route.*

10. *H records componentwise* hsame *transport for the uniform row, both source-filter rows, both basis rows, the common-refinement row, the window, readback, tolerance, handoff, seal, continuation, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a pair of source-filter requests through $U, F_0, F_1, B_0, B_1, J, S, R, D, L, E$ in that order.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterMeet}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterMeet}^{\uparrow}}$ *row.*

The classifier compares accepted meet packets only through the displayed route

$$U, F_0, F_1, B_0, B_1, J, S, R, D, L, E \longmapsto H, C, P, N.$$

No carrier coordinate stores a quotient filter, selected limit, countable-choice schedule, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge certificate.*

Lean4 ✓ `BEDC.Derived.CauchyFilterMeetUp.CauchyFilterMeetTasteGate single carrier alignment`

Theorem 1958.2 (Cauchy filter meet NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterMeet}^{\uparrow}$ *carrier*

$$M = (U, F_0, F_1, B_0, B_1, J, S, R, D, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterMeet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the shared uniform row, two source Cauchy-filter rows, two Cauchy-filter-basis rows, common-refinement row, window row, regular readback row, dyadic tolerance row, limit handoff, terminal seal, transport, replay, provenance, and local naming row;*
2. *same-uniform-source discipline, requiring both source filters and both basis rows to be read over the shared entourage surface U before a meet request is accepted;*
3. *binary common-refinement coverage, requiring every pair of displayed basis requests from B_0 and B_1 to pass through J and name a displayed request refining both;*
4. *finite observation exactness, requiring the refinement request to read only S, R, D before it reaches the limit handoff L and terminal seal E;*
5. *transport and replay stability, requiring H and C to preserve the route order under componentwise* hsame *transport and displayed* Cont *replay;*
6. *provenance exhaustion, requiring P, N to name only this finite common-refinement route and to export no quotient filter, selected limit, countable choice, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyFilterMeetUp.CauchyFilterMeetCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1958.1. The projection exposes exactly the shared uniform row, both source filters, both basis generators, the common-refinement row, the finite observation rows, the limit and seal rows, and the structural rows H, C, P, N.

The same-uniform-source discipline is fixed by the row order. A meet request first reads U, then reads F_0, F_1 and B_0, B_1 as source data over that same uniform surface before any common-refinement row is available.

Binary common-refinement coverage is the role of J. For a displayed pair of basis requests, J names the refining request and the two refinement reads back to the source requests. The row is finite data in the carrier, not an appeal to an ambient filter lattice.

Finite observation exactness follows by replaying C after J is read. The refining request passes through the displayed $\mathsf{StreamName}^{\uparrow}$ windows S, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D before it may reach L or E.

Finally H, C, P, N cannot enlarge the packet. They transport, replay, source, and name the displayed rows only, so the excluded quotient, choice, host-equality, real-completeness, Lean-verification, and bridge-checking data are outside the local NameCert surface. □

Theorem 1958.3 (Cauchy filter meet common-refinement factorization)**.** *Let*

$$M = (U, F_0, F_1, B_0, B_1, J, S, R, D, L, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyFilterMeet}^{\uparrow}$ *carrier. Every completion-facing or Real-facing consumer of the binary meet factors through the finite route*

$$U, F_0, F_1, B_0, B_1 \longmapsto J \longmapsto S, R, D \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed common refinement of the two Cauchy-filter packets before it receives a $\mathsf{CauchyFilterLimit}^{\uparrow}$ *handoff or a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The factorization exports no quotient filters, selected limits, countable-choice schedule, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Begin with a completion-facing or Real-facing consumer exposed by P. Carrier projection shows that the consumer can enter the meet packet only through the displayed rows of Definition 1958.1.

The source part of the route is forced through U, F_0, F_1, B_0, B_1. These rows display the shared entourage surface, the two Cauchy-filter packets, and the two finite basis generators whose requests are being compared.

We now replay the common finite-refinement row. For each displayed pair of basis requests, J supplies the refining request and the two reads back to B_0 and B_1. The replay uses only the stored row J and therefore stays inside the same finite packet.

The observation part of the route is S, R, D. The displayed window, regular readback, and dyadic tolerance rows verify that the refining request remains small enough for both Cauchy sources before the limit boundary is inspected.

Only after this route has been replayed can the packet expose L, and only after L can it expose E. Componentwise transport through H and continuation replay through C preserve the same route, while P, N record provenance and local naming without adding any excluded coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterMeet}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterMeet}^{\uparrow}$ packet is generated from a shared UniformSpace row, two CauchyFilter source rows, two CauchyFilterBasis rows, a binary common-refinement row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a CauchyFilterLimit handoff, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyFilterMeet}^{\uparrow}}$, seed)

Scope closed: Definition 1958.1, Definition 1958.2, and Definition 1958.3 seed the finite common-refinement operation for two displayed Cauchy-filter packets over a shared uniform surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyFilterMeet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, same-uniform-source discipline, binary common-refinement coverage, finite observation exactness, limit handoff factorization, transport stability, replay stability, and ledger refusal for BEDC.Derived.CauchyFilterMeetUp.

Chapter 1959

A Concrete Naming Certificate for $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$

Following Brouwer, Kleene, and Bishop–Bridges, the $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$ packet records the finite branch-schedule boundary where a finitely branching prefix tree is read as a Cauchy inspection route before any Real or Completion consumer may ask for a terminal seal. It sits after the prefix-tree surface of chapter 1622, the finite fan-depth ledger of chapter 400, the spread-law discipline of chapter 1532, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite boundary for branch-indexed Cauchy reads; it does not choose an infinite path, identify quotient streams, invoke countable choice, assert open-cover compactness, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1959.1 (Finite branching Cauchy tree carrier)**.** *A* $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, B, F, S, R, D, E, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the prefix-tree row. It records the finite* $\mathsf{KleeneTree}^{\uparrow}$ *branch-prefix cells, root cell, successor cells, and prefix-closure checks visible to the packet.*
2. *B is the branch-window row. For each displayed prefix in K, it records the finite successor window, branch-depth bound, and inspection address consumed from the* $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{SpreadLaw}^{\uparrow}$ *surfaces.*
3. *F is the finite branch-schedule row. It states that every regular branch read used by the packet enters through a displayed prefix in K and a displayed window in B.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row opened by the scheduled branch windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the stream windows selected by F.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that assigns dyadic radii and Cauchy slack checks to the branch windows before R can be inspected.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, B, F, S, R, D have been displayed.*
8. *O is the obstruction row. It records the local refusal of path choice, quotient stream equality, countable choice, open-cover compactness, and ambient real-completeness coordinates.*

9. *H records componentwise* hsame *transport for the prefix tree, branch windows, schedule, stream windows, regular readback, dyadic tolerances, terminal seal, obstruction row, continuation, provenance, and local naming row.*

10. *C records displayed* Cont *replay from any regular-branch request through*

$$K \longmapsto B \longmapsto F \longmapsto S \longmapsto R \longmapsto D \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteBranchingCauchyTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed route

$$K, B, F, S, R, D, E \longmapsto O, H, C, P, N.$$

No carrier coordinate stores an infinite path selector, quotient stream equality, countable-choice schedule, open-cover compactness proof, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge credential.*

Lean4 ✓ `BEDC.Derived.FiniteBranchingCauchyTreeUp.FiniteBranchingCauchyTreeTasteGate single carrier alignment`

Theorem 1959.2 (Finite branching Cauchy tree NameCert obligations)**.** *For every accepted* $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$ *carrier*

$$T = (K, B, F, S, R, D, E, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteBranchingCauchyTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the prefix tree, branch-window row, finite schedule row, stream windows, regular rational readback, dyadic tolerance ledger, terminal Real seal, obstruction row, transports, replay, provenance, and local naming;*

2. *prefix-tree closure, requiring every branch-prefix read to be admitted by K before any successor window or Cauchy row is visible;*

3. *finite branching coverage, requiring each scheduled branch window in B to expose only finitely many displayed successors and a displayed depth bound;*

4. *spread-law compatibility, requiring the schedule row F to respect the prefix discipline supplied by the* $\mathsf{SpreadLaw}^{\uparrow}$ *sibling surface;*

5. *Cauchy-window exactness, requiring every regular branch read to pass through S, R, D before the Real seal E can be consumed;*

6. *obstruction stability, requiring O, H, C, P, N to preserve the refusal of path choice, quotient stream equality, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No finite-branching Cauchy-tree obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1959.1. The accepted packet lists exactly the prefix tree, branch windows, finite schedule, Cauchy readback rows, terminal seal, obstruction row, and structural rows.

Prefix-tree closure is read from K. A branch-prefix request has no independent entry point; it must first be displayed as a finite prefix-tree cell with root, successor, and prefix-closure checks.

Finite branching coverage is the role of B. For each displayed prefix, the packet stores a finite successor window and a depth ledger, so a consumer cannot replace the window by a hidden infinite branch.

Spread-law compatibility is then enforced by F. The finite schedule reads only prefixes accepted by K and windows accepted by B, and it replays the sibling $\mathsf{SpreadLaw}^{\uparrow}$ discipline before any analytic row is exposed.

Cauchy-window exactness follows from the route through S, R, D. The stream windows are opened first, the regular rational row packages their readback, and the dyadic tolerance ledger checks the Cauchy slack before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Finally O, H, C, P, N do not add new coordinates. They record refusal, transport, replay, provenance, and local naming for the displayed rows only, so the excluded path-choice, quotient, choice, compactness, real-completeness, Lean-verification, and bridge-checking objects remain outside the NameCert surface. □

Theorem 1959.3 (Finite branching Cauchy tree regular-branch boundary)**.** *Let*

$$T = (K, B, F, S, R, D, E, O, H, C, P, N)$$

be an accepted $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$ *carrier. Every regular-branch read exported by* T *factors through the displayed finite tree and Cauchy rows*

$$K \longmapsto B \longmapsto F \longmapsto S \longmapsto R \longmapsto D \longmapsto E$$

before it is visible to a $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or Completion-facing consumer. Consequently the read is a finite prefix-tree and Cauchy-window boundary, not a selected path, quotient stream equality, countable-choice schedule, open-cover compactness proof, or ambient real-completeness witness.*

Proof. Start with a regular-branch request exported by P. Carrier projection shows that the only available entry point for such a request is the prefix-tree row K.

The request then enters the finite branching boundary. The row B supplies the successor window and depth ledger for the displayed prefix, and the schedule row F records that this is the window used by the branch read.

We now pass to the Cauchy rows. The scheduled window opens S, the regular rational readback is then formed in R, and the dyadic tolerance row D records the Cauchy slack attached to that read.

Only after this finite route has been replayed is the terminal seal E visible. Componentwise transport through H and continuation replay through C preserve the same route, while O keeps the excluded coordinates absent.

Thus every exported regular-branch read factors through K, B, F, S, R, D, E together with the structural rows O, H, C, P, N. No selected path, quotient stream equality, countable-choice schedule, open-cover compactness theorem, ambient real-completeness theorem, Lean verification, or bridge credential is produced. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBranchingCauchyTree}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteBranchingCauchyTree}^{\uparrow}$ packet is generated from a finite KleeneTree prefix row, branch-window and spread-law schedule rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a terminal RealUp seal, an obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBranchingCauchyTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1959.1, Definition 1959.2, and Definition 1959.3 seed the finite branch-schedule boundary between prefix trees, branch windows, regular rational readback, dyadic tolerances, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBranchingCauchyTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path choice, quotient stream equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-tree closure, finite branching coverage, spread-law compatibility, Cauchy-window exactness, regular-branch factorization, obstruction stability, and a Lean carrier/obligation formalization for BEDC.Derived.FiniteBranchingCauchyTreeUp.

Chapter 1960

A Concrete Naming Certificate for $\mathsf{RiemannIntegrable}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive analysis, the $\mathsf{RiemannIntegrable}^{\uparrow}$ packet names finite Darboux-gap evidence that an integrand admits integration data without already choosing an integral value. It sits over the terminal real-name seal of chapter 38, the dyadic partition ledger of chapter 1863, the Darboux finite-sum boundary of chapter 1880, the tagged-mesh integration route of chapter 1526, and the regulated approximation handoff of chapter 1906. The packet gives downstream integration chapters a displayed finite gap interface without importing a selected integral value, host function quotients, measure-theoretic integration, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1960.1 (Riemann integrable carrier)**.** *A* $\mathsf{RiemannIntegrable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (D, M, L, U, G, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the real-domain row, read through the terminal* $\mathsf{Real}^{\uparrow}$ *seal and the interval-facing data carried by chapter 38.*
2. *M is the* $\mathsf{DyadicPartition}^{\uparrow}$ *ledger naming the finite ordered dyadic partition on which the Darboux comparison is witnessed.*
3. *L and U are the lower and upper Darboux-sum rows, read through the* $\mathsf{DarbouxSum}^{\uparrow}$ *boundary of chapter 1880 over the partition row M.*
4. *G is the finite Darboux-gap ledger, displaying a dyadic tolerance request together with the comparison that the upper row U and lower row L meet that request.*
5. *T is the tagged-mesh and regulated-function handoff row, exposing only the* $\mathsf{RiemannIntegral}^{\uparrow}$ *and* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumers that may later use the displayed gap evidence.*
6. *H records componentwise* hsame *transport for the real-domain row, partition row, lower and upper Darboux rows, gap ledger, handoff row, continuation replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from the real-domain row to the partition row, from the partition row to the lower and upper Darboux rows, from those rows to the gap ledger, and from the gap ledger to the downstream handoff row.*

8. *P is the* Pkg *provenance over* $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrable}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, L, U, G, T, H, C, P, N$. It has no coordinate for a selected integral value, quotient equality of host functions, measure-theoretic integration, open-cover compactness, a choice-selected partition family, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannIntegrableUp.RiemannIntegrableTasteGate single carrier alignment`

Theorem 1960.2 (Riemann integrable NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegrable}^{\uparrow}$ *carrier*

$$J = (D, M, L, U, G, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannIntegrable}^{\uparrow}}$ *surface consists exactly of carrier admission, real-domain admission, dyadic partition admission, lower and upper Darboux-sum compatibility, finite gap routing, tagged-mesh and regulated-function handoff, componentwise transport, continuation replay, provenance, local naming, and non-escape from selected integral values, host function quotients, measure-theoretic integration, open-cover compactness, choice-selected partition families, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is the projection of Definition 1960.1. The accepted packet displays only the real-domain row D, partition ledger M, lower and upper Darboux rows L, U, gap ledger G, downstream handoff T, transports H, continuations C, provenance P, and local name N.

The analytic rows are finite. The real-domain row is read through $\mathsf{Real}^{\uparrow}$, the partition row is read through $\mathsf{DyadicPartition}^{\uparrow}$, and the two Darboux rows are read through the $\mathsf{DarbouxSum}^{\uparrow}$ surface over the same displayed partition.

The gap obligation is then the row G. It records that the displayed upper and lower rows answer the carried dyadic tolerance request before any tagged-mesh or regulated-function consumer may inspect T.

Transport and replay preserve the same route componentwise. Since the carrier has no coordinate for an integral value, a host quotient, a measure object, open-cover compactness, a choice-selected partition family, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 1960.3 (Riemann integrable Darboux-gap route)**.** *Every accepted* $\mathsf{RiemannIntegrable}^{\uparrow}$ *packet exposes integration-facing evidence only through the finite route*

$$D \longmapsto M \longmapsto (L, U) \longmapsto G \longmapsto T.$$

The handoff row T may be consumed by $\mathsf{RiemannIntegral}^{\uparrow}$ *or* $\mathsf{RegulatedFunction}^{\uparrow}$ *chapters only after the real-domain row, dyadic partition ledger, lower and upper Darboux rows, and finite Darboux-gap ledger have all been displayed.*

Proof. Start with an integration-facing consumer request. The continuation row C first replays the real-domain row D and then the finite partition row M, so the request is already confined to displayed real and dyadic partition data.

The rows L and U are read next through the $\mathsf{DarbouxSum}^{\uparrow}$ boundary. They use the same partition row M, hence the upper-minus-lower comparison is a finite Darboux comparison over displayed cells.

Only after these rows are present can the gap ledger G be read. The row G supplies the finite tolerance evidence that downstream consumers need, and the handoff row T records the permitted $\mathsf{RiemannIntegral}^{\uparrow}$ and $\mathsf{RegulatedFunction}^{\uparrow}$ uses of that evidence.

Thus the packet exports integrability evidence without exporting an already chosen integral value. The excluded host objects are absent from the carrier, so no consumer can recover them from the Darboux-gap route. □

Lean4 ✓ `BEDC.Derived.RiemannIntegrableUp.RiemannIntegrableCarrier darboux gap route`

Theorem 1960.4 (Riemann integrable gap-ledger monotonicity)**.** *Let*

$$J = (D, M, L, U, G, T, H, C, P, N)$$

be an accepted $\mathsf{RiemannIntegrable}^{\uparrow}$ *carrier. If the Darboux-gap row G answers a displayed dyadic tolerance ε, and if another displayed dyadic tolerance ε' is transported above ε through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison route, then the same rows $D, M, L, U, T, H, C, P, N$ answer the weaker tolerance request ε'.*

Proof. Project the carrier. The lower and upper Darboux rows L and U are read over the same finite partition ledger M, while the row G records the displayed comparison answering ε.

Transport the weaker tolerance request along the componentwise row H. Since ε' is displayed above ε in the same dyadic comparison route, the comparison already recorded in G remains sufficient after transport.

Replay the continuation row C with the same real-domain row D, partition row M, Darboux rows L, U, handoff row T, provenance row P, and local name row N. The handoff row T is downstream of the gap ledger, so no selected integral value, host function quotient, or separate integration object is introduced while weakening the tolerance. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrable}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegrable}^{\uparrow}$ packet is generated from a real-domain row, a finite dyadic partition ledger, lower and upper Darboux-sum rows, a finite Darboux-gap ledger, a tagged-mesh and regulated-function handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrable}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1960.1, Definition 1960.2, and Definition 1960.3 seed the finite Darboux-gap integrability interface over $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, and BHist.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrable}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected integral values, host function quotients, measure-theoretic integration, open-cover compactness, choice-selected partition families, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, real-domain admission, dyadic partition admission, Darboux-sum compatibility, finite gap routing, downstream handoff, non-escape, and field faithfulness for BEDC.Derived.RiemannIntegrab

Chapter 1961

A Concrete Naming Certificate for $\mathsf{PeriodicContinuedFraction}^{\uparrow}$

Following Lagrange and Hardy–Wright on periodic continued fractions, the $\mathsf{PeriodicContinuedFraction}^{\uparrow}$ packet records finite partial-quotient prefixes, a nonempty repeating block, convergent recurrence rows, rational-convergent windows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and a terminal $\mathsf{Real}^{\uparrow}$ seal. It refines the partial-quotient source of chapter 342, the recurrence ledger of chapter 1777, the denominator-bounded approximation route of chapter 1871, the rational-tree boundary of chapter 1704, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet is a finite periodic-block route into rational approximation; it is not a host quadratic irrational, a selected infinite expansion, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1961.1 (PeriodicContinuedFraction carrier)**.** *A* $\mathsf{PeriodicContinuedFraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, B, L, Q, D, S, G, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the partial-quotient prefix row, recording the finite initial block and the inspected continued-fraction source inherited from* $\mathsf{ContinuedFraction}^{\uparrow}$*.*
2. *B is the nonempty period-block row, recording the finite repeating block together with the local phase coordinate used to unfold displayed windows.*
3. *L is the recurrence and convergent ledger, recording numerator and denominator recurrence rows for the prefix followed by repetitions of B.*
4. *Q is the rational normalization row, recording the normalized rational convergents exported by the recurrence ledger.*
5. *D is the denominator-bound comparison row, recording the finite denominator budgets and comparison witnesses used by the Dirichlet-style approximation surface.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording exactly which unfolded prefix-and-period windows may be read by downstream consumers.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reached from I, B, L, Q, D, S before any real-facing seal is visible.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the prefix, period, recurrence, rational normalization, denominator comparison, StreamName window, and RegSeqRat rows have been displayed.*

9. *H is the componentwise* hsame *transport row for the prefix, period block, recurrence ledger, rational normalization, denominator comparisons, StreamName windows, RegSeqRat handoff, Real seal, replay, provenance, and local naming rows.*

10. *C is the displayed* Cont *replay row from a finite periodic-window request through the recurrence ledger, rational normalization, denominator comparison, regular handoff, and terminal seal.*

11. *P is the* Pkg *provenance over* $\mathsf{PeriodicContinuedFraction}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{ContinuedFractionConvergents}^{\uparrow}$, $\mathsf{DirichletApproximation}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}$ *row.*

The carrier predicate accepts exactly these finite prefix-and-period packets. It has no coordinate for a host quadratic irrational, a chosen infinite continued fraction, quotient real equality, trichotomy, global irrationality measure, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.PeriodicContinuedFractionUp.PeriodicContinuedFractionTasteGate single carrier alignment`

Theorem 1961.2 (PeriodicContinuedFraction NameCert obligations)**.** *For every accepted* PeriodicContinuedFractio *carrier $F = (I, B, L, Q, D, S, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed prefix, nonempty period block, recurrence ledger, rational normalization, denominator comparison, StreamName window, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming rows;*

2. *periodic-block stability, requiring every unfolded window in S to read the same nonempty row B with its displayed phase coordinate;*

3. *recurrence exactness, requiring every convergent in L and Q to be obtained from the displayed prefix and period rows by the finite numerator and denominator recurrence;*

4. *convergent-window compatibility, requiring the rational normalization and denominator-bound comparisons in Q, D to address only the windows exposed by S;*

5. *Real-seal nonescape, requiring E to be downstream of G and to expose no host quadratic irrational, selected infinite expansion, quotient real equality, trichotomy branch, or ambient completeness theorem;*

6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the finite route recorded by I, B, L, Q, D, S, G, E.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1961.1. The accepted packet displays exactly the prefix, period block, recurrence ledger, rational normalization, denominator comparison, StreamName windows, regular handoff, terminal Real seal, and structural rows.

The periodic-block and recurrence obligations are finite. The row B is nonempty and supplies the only repeated block, while L unfolds that row after the prefix I by the displayed numerator and denominator recurrence.

The rational approximation obligations then read only displayed windows. The row Q normalizes the convergents from L, the row D compares their denominators against the finite budgets, and the row S records the finite StreamName windows to which those comparisons apply.

The handoff and seal are terminal. The row G is downstream of I, B, L, Q, D, S, and the row E is downstream of G, so a Real-facing consumer cannot bypass the regular rational route.

Finally, H, C, P, N preserve the same packet componentwise. Since the carrier contains no further coordinate, the six listed clauses exhaust the local $\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}$ surface. □

Theorem 1961.3 (PeriodicContinuedFraction quadratic boundary)**.** *An accepted* $\mathsf{PeriodicContinuedFraction}^{\uparrow}$ *carrier exports only the finite periodic-block-to-convergent boundary*

$$I, B \longmapsto L, Q, D, S \longmapsto G \longmapsto E.$$

Consequently the packet may be consumed as a finite rational-approximation source for $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, but it does not export a host quadratic irrational, selected infinite expansion, quotient real equality, trichotomy, irrationality-measure bound, or* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start from an accepted carrier $F = (I, B, L, Q, D, S, G, E, H, C, P, N)$. The only periodic data are the finite prefix row I and the nonempty block row B.

The rows L, Q, D, S turn this finite source into convergent and comparison data. They record recurrence, normalization, denominator bounds, and finite windows, but they do not add an ambient completed expansion.

The rows G and E provide the only regular rational and Real-facing exits. Their order forces every such exit through the finite convergent boundary before the terminal seal is visible.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no row stores a host quadratic irrational, quotient equality, trichotomy branch, irrationality-measure theorem, or completeness witness, none is exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PeriodicContinuedFraction}^{\uparrow}$ packet is generated from a finite partial-quotient prefix, a nonempty period block, recurrence and convergent rows, rational normalization, denominator-bound comparison, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1961.1, Definition 1961.2, and Definition 1961.3 seed the finite periodic-block route from continued fractions to rational convergent windows, RegSeqRat readback, and a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PeriodicContinuedFraction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PeriodicContinuedFractionUp.PeriodicContinuedFractionTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not claim a host quadratic irrational, selected infinite expansion, quotient real equality, trichotomy, irrationality-measure theorem, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, periodic-block stability, recurrence exactness, convergent-window compatibility, Real-seal nonescape, provenance exhaustion, and transport stability for BEDC.Derived.PeriodicContinuedFra

Chapter 1962

A Concrete Naming Certificate for $\mathsf{FanSpace}^{\uparrow}$

Following Brouwer, Troelstra, and Bishop-style constructive analysis, the $\mathsf{FanSpace}^{\uparrow}$ packet records a finite-branching Boolean prefix tree by the finite information exposed to a proof. It sits between the finite Boolean prefix surface of chapter 1475, the unfolding-prefix discipline of chapter 1482, and the L10 finite-request gateway of chapter 126. The packet names only finite tree nodes, Boolean observations, prefix-spine rows, transport, replay, provenance, and a local naming certificate; it does not import a host function space, a completed stream, an open-cover compactness theorem, or a countable-choice branch.

Definition 1962.1 (FanSpace carrier)**.** *A* $\mathsf{FanSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, B, L, C, Q, H, R, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite node requests made by the current consumer;*
2. *T is the finite binary-branch prefix-tree row, closed under displayed predecessors and carrying at most the two Boolean successors named at each node;*
3. *B is the* $\mathsf{Bool}^{\uparrow}$ *observation ledger attached to the requested branches of T;*
4. *L is the* $\mathsf{List}^{\uparrow}$ *spine row ordering the exposed prefix nodes and their branch labels as finite data;*
5. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *boundary row used when a maximal displayed prefix is read as a Boolean window;*
6. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *handoff row used when the same finite prefix is consumed as an unfolding choice-sequence prefix;*
7. *H is the componentwise* hsame *transport row for S, T, B, L, C, Q;*
8. *R is the displayed* Cont *replay row for already accepted prefix-tree restrictions and boundary reads;*
9. *P is the* Pkg *provenance over* $\mathsf{FanSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$ *row.*

The carrier admits only the finite branching data explicitly displayed in T. It exports no ambient space of maps $\mathsf{Nat}^{\uparrow} \to \mathsf{Bool}^{\uparrow}$*, no completed Boolean stream, no hidden infinite branch, no open-cover compactness witness, and no countable-choice selector.*

Lean4 ✓ `BEDC.Derived.FanSpaceUp.TasteGate.FanSpaceTasteGate single carrier alignment`

Theorem 1962.2 (FanSpace NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$ *surface of Definition 1962.1 consists of the following finite obligations:*

1. *carrier admission for the displayed packet* $F = (S, T, B, L, C, Q, H, R, P, N)$*;*
2. *finite branching stability, requiring every accepted node of T to carry only the displayed zero-successor and one-successor rows admitted by* $\mathsf{Bool}^{\uparrow}$*;*
3. *prefix restriction, requiring every displayed subtree below a requested node to repack through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{List}^{\uparrow}$ *spine,* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming rows;*
4. $\mathsf{CantorSpace}^{\uparrow}$ *boundary compatibility for every displayed Boolean prefix window;*
5. $\mathsf{ChoiceSequence}^{\uparrow}$ *handoff compatibility for every displayed unfolding prefix consumed as choice-sequence data;*
6. *transport and replay stability for componentwise* hsame *moves and already accepted* Cont *reads;*
7. *non-escape from host function spaces, completed streams, open-cover compactness principles, and countable-choice branches.*

Proof. Carrier admission is projection of the ten displayed rows in Definition 1962.1. The schedule, tree, Boolean ledger, spine, boundary, handoff, transport, replay, provenance, and local naming rows are finite BHist data.

Finite branching stability is read from the tree row T. Each successor row is labelled by a displayed $\mathsf{Bool}^{\uparrow}$ branch observation, so a node has only the zero-branch and one-branch rows already present in the packet.

For prefix restriction, choose a displayed subtree below a requested node of T. Its nodes and branch labels are subrows of T, B, L, and the same S, H, R, P, N rows transport, replay, name, and package the restricted packet.

The $\mathsf{CantorSpace}^{\uparrow}$ boundary row C handles reads that treat a displayed maximal prefix as a Boolean window, while the $\mathsf{ChoiceSequence}^{\uparrow}$ handoff row Q handles reads that consume the same prefix as unfolding sequence data.

Finally inspect the carrier coordinates. The packet contains no row for a host function space, completed stream, hidden branch, open-cover compactness witness, or countable-choice selector, so no local $\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$ consumer can export one. □

Theorem 1962.3 (FanSpace StreamName-Cantor scope)**.** *Every public read of an accepted* $\mathsf{FanSpace}^{\uparrow}$ *carrier factors through a finite* $\mathsf{StreamName}^{\uparrow}$ *request and a* $\mathsf{CantorSpace}^{\uparrow}$ *Boolean prefix window before any downstream L10 consumer may inspect the packet. The visible route is*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow},\ \mathsf{ChoiceSequence}^{\uparrow},\ \mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}.$$

The route binds finite node requests, Boolean branch observations, prefix-spine ordering, Cantor boundary reads, choice-sequence handoffs, transport, replay, provenance, and local naming. It does not claim a completed fan, a chosen branch, host-function extensionality, open-cover compactness, or countable choice.

Proof. Begin with a public read of $F = (S, T, B, L, C, Q, H, R, P, N)$. The consumer first sees the finite request schedule S and the finite prefix-tree row T; without these rows there is no named node at which a branch value can be read.

The branch observations are then read through the $\mathsf{Bool}^{\uparrow}$ ledger B and the ordered $\mathsf{List}^{\uparrow}$ spine L. Any maximal displayed prefix requested by the consumer reaches the $\mathsf{CantorSpace}^{\uparrow}$ boundary row C before it can be passed to a downstream Boolean-window consumer.

If the same prefix is consumed as unfolding sequence data, the read passes through the $\mathsf{ChoiceSequence}^{\uparrow}$ handoff row Q after the StreamName and Cantor-visible rows have been fixed. The componentwise hsame row H, Cont replay row R, Pkg provenance row P, and local naming row N then route only the displayed finite data.

Thus every public read factors through the announced finite route before any L10 consumer sees the packet. The excluded infinite objects are not carrier coordinates, so the route cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{FanSpace}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ request schedule, a displayed binary prefix-tree row, $\mathsf{Bool}^{\uparrow}$ branch observations, a $\mathsf{List}^{\uparrow}$ spine, $\mathsf{CantorSpace}^{\uparrow}$ boundary reads, $\mathsf{ChoiceSequence}^{\uparrow}$ handoffs, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$, seed)

Scope closed: Definition 1962.1, Definition 1962.2, and Definition 1962.3 seed the finite-branching Boolean prefix-tree surface over $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{Bool}^{\uparrow}$ branch rows, $\mathsf{List}^{\uparrow}$ spines, $\mathsf{CantorSpace}^{\uparrow}$ boundary reads, $\mathsf{ChoiceSequence}^{\uparrow}$ handoffs, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FanSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close host function spaces, completed Boolean streams, open-cover compactness, fan-theorem compactness, hidden infinite branches, or countable choice.

Upgrade path: The next step is obligationClosure: carrier admission, finite branching stability, prefix restriction, CantorSpace boundary compatibility, ChoiceSequence handoff compatibility, transport, replay, provenance, and non-escape should be formalized under BEDC.Derived.FanSpaceUp.

Chapter 1963

A Concrete Naming Certificate for $\mathsf{Paracompact}^{\uparrow}$

Following Kelley and Bourbaki on paracompact spaces and locally finite refinements, the $\mathsf{Paracompact}^{\uparrow}$ packet records the finite BEDC surface by which a displayed open-cover request receives a locally finite open refinement ledger. It sits above the open-row discipline of chapter 88, beside the separation boundary of chapter 1866, and below later partition-of-unity and manifold-gluing consumers. It also records the compatibility route through **??** and, when the source is metric or compact-metric, the finite-radius handoff through chapter 57 and the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ surface. The packet names only a displayed refinement carrier; it does not select subcovers from arbitrary open families or close partition-of-unity data.

Definition 1963.1 (Paracompact carrier)**.** *A* $\mathsf{Paracompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, A, R, L, N, M, H, C, P, Z)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the ambient open-set operations and the common observation surface on which the cover and refinement rows are read.*
2. *A is the open-cover request row, a finite request ledger whose cells name the displayed open rows to be refined rather than an arbitrary host-indexed cover.*
3. *R is the locally finite open-refinement ledger, recording for each displayed source cell a finite neighborhood row meeting only finitely many refinement cells and recording the refinement map back into A.*
4. *L is the coverage ledger, recording that the refinement cells cover the same displayed source region that A covers, with the containment read carried by the topology row T.*
5. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *compatibility row, requiring the refinement ledger to preserve the closed-pair separation route of chapter 1866 whenever the cover request is used with normal-space separation data.*
6. *M is the metric-or-finite-radius handoff row, read either from a* $\mathsf{Met}^{\uparrow}$ *source or from a* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive finite-radius ledger when such data are available; the handoff exports only the displayed finite-radius route.*

7. *H records componentwise* hsame *transport for the topology source, cover request, locally finite refinement ledger, coverage ledger, normal-space compatibility row, metric-or-finite-radius handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a paracompact-refinement request through $T, A, R, L, N, M, H, P, Z$.*
9. *P is the* Pkg *provenance over* $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *Z is the local* $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, R, L, N, M, H, C, P, Z$. It has no coordinate for selected subcovers, arbitrary open-cover compactness, partition-of-unity weights, host complement selection, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactTasteGate single carrier alignment`

Theorem 1963.2 (Paracompact NameCert obligations)**.** *For every accepted* $\mathsf{Paracompact}^{\uparrow}$ *carrier*

$$Q = (T, A, R, L, N, M, H, C, P, Z),$$

the local $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, open-cover request, locally finite refinement ledger, coverage ledger, normal-space compatibility row, metric-or-finite-radius handoff, transport, replay, provenance, and local naming;*
2. *open-cover exposure, requiring every refinement request to display A over the topology source T before any refinement cell can be consumed;*
3. *locally finite refinement exactness, requiring R to display both the refinement cells and the finite neighborhood ledger witnessing local finiteness;*
4. *coverage and containment exactness, requiring L to record that each displayed source cell covered by A is covered by the refinement ledger and that every refinement cell is contained in its assigned cover cell;*
5. *normal-space compatibility, requiring every closed-pair separation consumer to pass through the* $\mathsf{NormalSpace}^{\uparrow}$ *row N and the Urysohn-facing route of* **??** *before it reads the refinement as separation-compatible;*
6. *metric-or-finite-radius handoff, requiring a metric consumer to read M through the displayed* $\mathsf{Met}^{\uparrow}$ *source or through the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *finite-radius ledger, with no selected subcover or host compactness coordinate;*
7. hsame, Cont, *and* Pkg *transport, requiring componentwise transport, displayed replay, and provenance to preserve exactly the listed rows and no hidden host-refinement data.*

No local paracompact-refinement obligation is stored outside these seven rows.

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1963.1. The accepted tuple displays exactly the topology source, cover request, locally finite refinement ledger, coverage ledger, normal-space compatibility row, metric-or-finite-radius handoff, and structural transport, replay, provenance, and naming rows.

Open-cover exposure follows from the order of the carrier. A refinement request first reads T and then A over that same topological source; no refinement cell is available before the cover request has been displayed.

Locally finite refinement exactness is the projection to R. The row records the refinement cells, the assignment back into A, and the finite neighborhood ledger witnessing that each displayed source cell meets only finitely many refinement cells.

Coverage and containment exactness is the projection to L. It records both directions needed by the local request: coverage of the displayed source region and containment of every refinement cell in its assigned cover cell.

Normal-space compatibility is read through N and the cited Urysohn-facing route. The packet can be consumed together with normal-space separation data only after the closed-pair route of chapter 1866 and the separation-function route of **??** have been displayed.

Metric-or-finite-radius handoff is read through M. When metric or compact-metric data are present, M exposes the $\mathsf{Met}^{\uparrow}$ or $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ finite-radius route; otherwise it exports no compactness or subcover-selection principle.

Finally, transport and provenance are exhausted by H, C, P, Z. These rows move and replay exactly the displayed carrier coordinates, so no local obligation exports selected subcovers, arbitrary open-cover compactness, partition-of-unity weights, host complement selection, Lean verification, or bridge checking. □

Theorem 1963.3 (Paracompact refinement consumer route)**.** *Every refinement read exported by an accepted* $\mathsf{Paracompact}^{\uparrow}$ *packet factors through*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{Paracompact}^{\uparrow} \longrightarrow \mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{UrysohnLemma}^{\uparrow}$$

when consumed by a separation-compatible topology route, and through the displayed $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *handoff when a metric finite-radius route is available. No exported refinement read factors through a selected subcover, arbitrary open-cover compactness, partition-of-unity weights, host complement selection, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactCarrier refinement consumer route`

Proof. Begin with an accepted carrier $Q = (T, A, R, L, N, M, H, C, P, Z)$. Carrier admission exposes the $\mathsf{Topology}^{\uparrow}$ source and the displayed open-cover request before any refinement ledger can be inspected.

The refinement gate is R and L. These rows provide the locally finite refinement cells, their assignment to the cover request, the finite neighborhood ledger, and the coverage and containment reads.

The separation-compatible gate is N. A consumer that also needs normal-space separation must read the displayed $\mathsf{NormalSpace}^{\uparrow}$ compatibility route and the sibling $\mathsf{UrysohnLemma}^{\uparrow}$ route before treating the refinement as compatible with separation-function data.

The metric gate is M. A metric or compact-metric consumer may read the displayed $\mathsf{Met}^{\uparrow}$ or $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ handoff, but the row carries only finite-radius data already present in the packet.

The replay and local naming rows H, C, P, Z preserve this order. Since the classifier has no further coordinate, no exported refinement read can obtain selected subcovers, arbitrary open-cover compactness, partition-of-unity weights, host complement selection, Lean verification, or bridge checking. □

Definition 1963.4 (Paracompact locally finite refinement carrier)**.** *A locally finite refinement carrier for* $\mathsf{Paracompact}^{\uparrow}$ *is a finite* BHist *packet*

$$Q_{\mathrm{lf}} = (T, G, A, R, F, L, N, U, M, H, C, P, Z)$$

whose rows refine Definition 1963.1 as follows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row and G is the observation window on which cover and neighbourhood reads are made.*
2. *A is the displayed open-cover request over T.*
3. *R is the refinement-family row, listing the refinement cells and their assignment back into cells of A.*
4. *F is the local-finiteness ledger: for each displayed point or source cell in G, it records a neighbourhood row and the finite list of refinement cells that meet that neighbourhood.*
5. *L is the coverage and containment ledger, recording that the refinement covers the same displayed source region and that every refinement cell is contained in its assigned cover cell.*
6. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *separation-compatibility row and U is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *handoff row used when a closed-pair separation consumer reads the refinement.*
7. *M is the metric finite-radius handoff, read through* $\mathsf{Met}^{\uparrow}$ *and, when available, through the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger.*
8. *H, C, P, Z are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$ *rows.*

The carrier has no coordinate for a selected subcover, an arbitrary host-indexed refinement family, partition-of-unity weights, a host complement selector, open-cover compactness, or an ambient refinement theorem.

Theorem 1963.5 (Paracompact refinement NameCert obligations)**.** *For a locally finite refinement carrier*

$$Q_{\mathrm{lf}} = (T, G, A, R, F, L, N, U, M, H, C, P, Z),$$

the local $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$ *surface is exhausted by carrier admission, cover-refinement rows, the locally finite ledger, normal-space separation compatibility, and transport/replay/provenance/local naming rows. Concretely, every refinement consumer must read:*

1. *T, G, A before a cover request is available;*
2. *R, L before a refinement cell can be used as covering and contained in its assigned cover cell;*
3. *F before the refinement can be read as locally finite on the displayed observation window;*
4. *N, U before the refinement can be consumed by a normal-space or Urysohn-facing separation route;*
5. *M before a metric finite-radius route is exported; and*
6. *H, C, P, Z before the transported packet is replayed or named.*

No NameCert obligation for locally finite paracompact refinement is stored outside these displayed rows.

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactCarrier refinement namecert obligations`

Proof. Carrier admission is projection from Definition 1963.4. The tuple displays the topology source, observation window, cover request, refinement family, local-finiteness ledger, coverage and containment ledger, normal-space and Urysohn rows, metric handoff, transport, replay, provenance, and local name.

The cover-refinement obligations are read from A, R, L. The cover request A is tied to the same topological source T, the refinement row R assigns each refinement cell back to the cover request, and the ledger L records coverage and containment.

Local finiteness is read only from F. For each displayed point or source cell in G, the row gives a neighbourhood together with the finite list of refinement cells meeting it, so a consumer cannot infer local finiteness from the existence of the refinement family alone.

Separation compatibility is read through N, U. These rows force a normal-space consumer to pass through the displayed $\mathsf{NormalSpace}^{\uparrow}$ and $\mathsf{UrysohnLemma}^{\uparrow}$ surfaces before treating the refinement as separation-compatible.

Finally, M, H, C, P, Z exhaust metric export, transport, replay, provenance, and local naming. Since the carrier has no further coordinate, selected subcovers, host-indexed refinements, partition-of-unity weights, host complement selection, open-cover compactness, and ambient refinement theorems are not part of the local certificate. □

Theorem 1963.6 (Paracompact metric-normal route)**.** *Every metric* $\mathsf{Paracompact}^{\uparrow}$ *refinement read exported from a locally finite refinement carrier first factors through the* $\mathsf{Met}^{\uparrow}$ *finite-radius source and the* $\mathsf{NormalSpace}^{\uparrow}$ *separation row before it reaches the refinement export. In symbols, the visible route is*

$$\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{FiniteLebesgueNumber}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{Paracompact}^{\uparrow}$$

whenever a finite-radius ledger is present, and the normal-space row remains mandatory for every separation-compatible export.

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactCarrier metric normal route`

Proof. Start with $Q_{\mathrm{lf}} = (T, G, A, R, F, L, N, U, M, H, C, P, Z)$. The metric information available to the packet is exactly the handoff row M, so a metric consumer reads the displayed $\mathsf{Met}^{\uparrow}$ source and any available $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ finite-radius ledger before it can use a refinement export.

The refinement export itself is still topological. The rows T, A, R, F, L expose the open-cover request, the refinement family, the local-finiteness ledger, and the coverage and containment ledger over the displayed topology.

For separation-compatible use, the route must pass through N and then U. Thus the normal-space separation row and the Urysohn-facing handoff are read before the refinement is exported to any consumer that treats it as compatible with closed-pair separation data.

The replay and naming rows H, C, P, Z preserve this order componentwise. With no coordinate for selected subcovers, partition-of-unity weights, host complement selection, open-cover compactness, or ambient normality, every metric paracompact read passes through the displayed metric and normal-space rows before refinement export. □

Theorem 1963.7 (Paracompact obligation closure package)**.** *Every accepted* $\mathsf{Paracompact}^{\uparrow}$ *packet has its obligation-closure surface given exactly by Definition 1963.1, Definition 1963.2, Definition 1963.3, Definition 1963.4, Definition 1963.5, and Definition 1963.6. The package exposes displayed cover requests, locally finite refinement ledgers, coverage and containment rows, normal-space and Urysohn-facing separation routes, metric finite-radius handoffs, componentwise transport, replay, provenance, and local naming. It exports no selected subcovers, arbitrary open-cover compactness, partition-of-unity closure, or host complement selection.*

Proof. Project the displayed carrier of Definition 1963.1. Its rows expose the topology source, open-cover request, locally finite refinement ledger, coverage ledger, normal-space compatibility row, metric-or-finite-radius handoff, transport, replay, provenance, and local naming.

Apply Definition 1963.2 and Definition 1963.3. These obligations force every refinement consumer to read the cover request, refinement exactness, coverage and containment rows, separation-compatible handoff, and metric finite-radius route in the displayed order.

For the locally finite surface, project Definition 1963.4 and apply Definition 1963.5. The local-finiteness ledger is a named row, and it is transported only with the same topology, cover, refinement, separation, metric, replay, provenance, and naming rows.

Finally apply Definition 1963.6. The metric-normal consumer route remains downstream of the displayed metric finite-radius source and the normal-space separation row, so the package has no coordinate from which selected subcovers, arbitrary open-cover compactness, partition-of-unity closure, or host complement selection could be read. □

Lean4 ✓ `BEDC.Derived.ParacompactUp.ParacompactCarrier obligation closure package`

Theorem 1963.8 (Paracompact scoped refinement export)**.** *Every accepted* $\mathsf{Paracompact}^{\uparrow}$ *refinement consumer factors through the displayed topology source, cover request, locally finite refinement ledger, coverage and containment rows,* $\mathsf{NormalSpace}^{\uparrow}$ *and* $\mathsf{UrysohnLemma}^{\uparrow}$ *separation route,* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$ *rows named by Definition 1963.7. The exported scope is exactly this public refinement route, and it has no coordinate for selected subcovers, arbitrary open-cover compactness, partition-of-unity weights, host complement selection, Lean verification, or bridge checking.*

Proof. Start with the accepted carrier and the obligation surface of Definition 1963.2. These rows expose the topology source, displayed cover request, locally finite refinement ledger, coverage ledger, separation-compatibility row, metric handoff, transport, replay, provenance, and local naming before any consumer can inspect a refinement.

Apply Definition 1963.3. It orders every refinement read through the displayed topology, the refinement ledger, and the separation or finite-radius handoff appropriate to the consumer.

For the locally finite portion, use Definition 1963.4 and Definition 1963.5. The rows $T, G, A, R, F, L, N, U, M, H$, make the local-finiteness ledger, coverage and containment ledger, normal-space route, Urysohn handoff, metric handoff, and structural rows explicit.

Finally compose Definition 1963.6 with Definition 1963.7. The metric-normal route fixes the downstream consumer order, and the closure package exhausts the visible rows, so the scoped export cannot read any selected subcover, arbitrary open-cover compactness, partition-of-unity weight, host complement selector, Lean verification row, or bridge-checking row. □

Closure status for $\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1963.1, Definition 1963.2, Definition 1963.3, Definition 1963.4, Definition 1963.5, Definition 1963.6, Definition 1963.7, and Definition 1963.8 close the finite public refinement route from displayed open-cover requests through locally finite refinement ledgers into normal-space and metric consumer handoffs.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Paracompact}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ParacompactUp.ParacompactCarrier\_refinement\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close selected subcovers, arbitrary open-cover compactness, partition-of-unity closure, host complement selection, Lean verification, or bridge checking.

Upgrade path: No paper-side theory upgrade remains for the displayed refinement route; Lean verification and bridge status remain recorded on their own axis.

Constructive story: A Paracompact$^{\uparrow}$ packet is generated from a Topology$^{\uparrow}$ source row, an open-cover request row, a locally finite open-refinement ledger, a coverage ledger, a NormalSpace$^{\uparrow}$ compatibility row, a Met$^{\uparrow}$ or FiniteLebesgueNumber$^{\uparrow}$ handoff row when available, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1964

A Concrete Naming Certificate for $\mathsf{RegularSequenceLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularSequenceLimit}^{\uparrow}$ packet records the finite relation by which a regular rational name is admitted as the displayed limit route for a $\mathsf{Real}^{\uparrow}$ seal. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the limit-seal boundary of chapter 386, the terminal real-name seal of chapter 38, and the explicit Cauchy convergence route of chapter 1509. The packet names the RegSeqRat-to-Real limit relation as certificate data; it is not ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, a selected host limit, trichotomy, open-cover compactness, countable choice, Lean verification, or bridge checking.

Definition 1964.1 (RegularSequenceLimit carrier)**.** *A* $\mathsf{RegularSequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposing exactly the finite observations of the rational sequence name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the windows in S.*
3. *Q is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row that records the displayed limit-seal compatibility of the same S, R route.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row obtained only after the regular rational route has passed through Q.*
5. *H records componentwise* hsame *transport for the stream schedule, regular readback, limit-seal row, Real seal, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a finite precision request through S, R, Q, E and then through the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through S, R, Q, E, H, C, P, N. It contains no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, trichotomy,*

open-cover compactness, countable choice, Lean verification, bridge checking, or any detached convergence relation.

Lean4 ✓ `BEDC.Derived.RegularSequenceLimitUp.RegularSequenceLimitTasteGate single carrier alignment`

Theorem 1964.2 (RegularSequenceLimit NameCert obligations)**.** *For every accepted* $\mathsf{RegularSequenceLimit}^{\uparrow}$ *carrier*

$$L = (S, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularSequenceLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed stream schedule, regular rational readback, limit-seal row, Real seal, transport, continuation, provenance, and local name;*
2. *regular-name routing, requiring every limit read to pass through S and R before Q or E is available;*
3. *seal compatibility, requiring Q to consume the same finite window and regular-readback route that supplies the* $\mathsf{Real}^{\uparrow}$ *seal E;*
4. *continuation exactness, requiring each finite precision request to replay through C without adding a second window family, hidden modulus, quotient stream, selected host limit, or ambient completeness coordinate;*
5. *structural stability, requiring H, P, N to transport, source, and name only the displayed rows.*

No RegularSequenceLimit obligation is stored outside these rows.

Proof. Project the accepted packet $L = (S, R, Q, E, H, C, P, N)$. The carrier admission row exposes exactly one finite stream schedule, one regular rational readback row, one limit-seal compatibility row, one Real seal, and the transport, replay, provenance, and naming rows.

The routing and seal-compatibility clauses follow from the displayed order. The row R is the only regular rational readback attached to S, while Q is the only limit-seal row attached to that readback. Hence a limit consumer cannot inspect Q or E without first reading the same S, R route.

Continuation exactness is the row C. Each finite precision request replays the visible route and has no coordinate from which to introduce a second window family, a hidden modulus, quotient stream equality, a selected host limit, or ambient completeness.

Finally, H, P, N transport, source, and name only the displayed packet. Since the carrier has no further coordinate, the five listed rows exhaust the local NameCert surface. □

Theorem 1964.3 (RegularSequenceLimit window-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularSequenceLimit}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto R \longmapsto Q \longmapsto E$$

and then through the stored hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The route is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *regular-name handoff read through a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary; it exports no ambient completeness theorem, quotient stream, selected host limit, trichotomy row, open-cover compactness row, countable choice principle, Lean verification, or bridge check.*

Proof. Begin with a Real-facing read. By carrier admission, the only observation source is the finite $\mathsf{StreamName}^{\uparrow}$ schedule S, and the only regular rational name exposed from that source is R.

The limit-seal row is downstream. The row Q consumes the same S, R route, so the read reaches the limit boundary only after the regular rational handoff has been displayed.

The terminal Real row is E. The structural rows H, C, P, N then transport, replay, source, and name the same packet. No other carrier coordinate can provide a host completeness theorem, quotient stream, selected host limit, trichotomy row, open-cover compactness row, countable choice principle, Lean verification, or bridge check. □

Theorem 1964.4 (RegularSequenceLimit classifier determinacy)**.** *Let*

$$L = (S, R, Q, E, H, C, P, N)$$

and

$$L' = (S', R', Q', E', H', C', P', N')$$

be accepted $\mathsf{RegularSequenceLimit}^{\uparrow}$ *carriers. If their displayed stream schedules, regular readbacks, limit-seal rows, Real seals, transport rows, continuation rows, provenance rows, and local name rows are componentwise* hsame*, then the local classifier identifies* L *and* L'*. Conversely, any local classifier identification of accepted carriers is witnessed by componentwise* hsame *comparison of exactly those eight displayed rows.*

Proof. For the forward direction, read the classifier as the local $\mathsf{NameCert}_{\mathsf{RegularSequenceLimit}^{\uparrow}}$ comparison. Its carrier inventory is S, R, Q, E, H, C, P, N, so componentwise hsame on those rows supplies every comparison required by the local classifier.

For the reverse direction, project the accepted carrier comparison. The definition of the local classifier has no hidden coordinate beyond the displayed rows, and therefore any identification it accepts must be witnessed on S, R, Q, E, H, C, P, N component by component.

The two projections use the same finite row list. Thus classifier identity is determined exactly by componentwise hsame comparison of the displayed stream schedule, regular readback, limit-seal row, Real seal, transport, continuation, provenance, and local name. □

Theorem 1964.5 (RegularSequenceLimit Real nonescape)**.** *Every Real-facing consumer of an accepted* $\mathsf{RegularSequenceLimit}^{\uparrow}$ *carrier receives the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility row have been replayed through* H, C, P, N*. Consequently the packet cannot export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, trichotomy, open-cover compactness, countable choice, Lean verification, or bridge checking.*

Proof. Take a Real-facing consumer of the accepted carrier. The carrier definition places E after the displayed S, R, Q route, so the consumer has no access to a Real seal before the finite windows, regular readback, and limit-seal boundary have been read.

The structural rows do not add mathematical content outside that route. Transport H preserves the same displayed coordinates, continuation C replays them for finite precision requests, provenance P records their source, and the local name row N names the packet.

Thus every Real-facing read remains inside the displayed route. Since the carrier contains no excluded coordinate, the listed nonescape claims follow. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularSequenceLimit}^{\uparrow}$ packet is generated from a displayed $\mathsf{StreamName}^{\uparrow}$ window schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback row, a $\mathsf{CauchyLimitSeal}^{\uparrow}$ compatibility row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1964.1, Definition 1964.2, Definition 1964.3, Definition 1964.4, and Definition 1964.5 seed the finite RegSeqRat-to-Real limit relation over StreamName windows, CauchyLimitSeal compatibility, and the Real seal route.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularSequenceLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient Real$^{\uparrow}$ completeness, quotient stream equality, selected host limits, trichotomy, open-cover compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-name routing, seal compatibility, continuation exactness, classifier determinacy, Real nonescape, and bridge coverage for BEDC.Derived.RegularSequenceLimitUp.

Chapter 1965

A Concrete Naming Certificate for $\mathsf{RealConvergenceRate}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Weihrauch-style computable analysis, the $\mathsf{RealConvergenceRate}^{\uparrow}$ packet records an explicit rate-of-convergence object for Real and Completion consumers. It sits after the dyadic rate discipline of chapter 1953, the modulus boundary of chapter 1423, the finite stream observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes a finite rate schedule before any $\mathsf{Real}^{\uparrow}$ seal is consumed, so downstream Real and Completion phases can request precision through displayed data rather than through quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Definition 1965.1 (Real convergence rate carrier)**.** *A* $\mathsf{RealConvergenceRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the rate schedule row, listing the finite precision requests accepted by the packet and the displayed bound that each request must consult before any real-name seal can be read.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row selected by the schedule R.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, slack comparisons, and budget cells attached to the scheduled windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and the tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after R, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the rate schedule, finite windows, tolerance ledger, readback row, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of each accepted precision request through*

$$R \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RealConvergenceRate}^{\uparrow}$*,* $\mathsf{RapidCauchyName}^{\uparrow}$*,* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RealConvergenceRate}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.RealConvergenceRateUp.RealConvergenceRateTasteGate single carrier alignment`

Theorem 1965.2 (Real convergence rate tail control)**.** *For every accepted* $\mathsf{RealConvergenceRate}^{\uparrow}$ *carrier*

$$K = (R, S, D, Q, E, H, C, P, N),$$

every accepted precision request factors through the rate schedule row R before any $\mathsf{Real}^{\uparrow}$ *seal row E is consumed. Consequently the tail read seen by a Real or Completion consumer is routed through the finite path*

$$R \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$$

together with componentwise transport, displayed replay, provenance, and local naming.

Proof. Project the accepted packet K. The carrier exposes the rate schedule R as the first analytic row and places the terminal seal E only after the scheduled windows, dyadic ledger, and regular readback.

Induct over the finite list of precision requests displayed by R. The empty schedule has no accepted request and therefore no seal-facing tail read.

For the cons step, the head request reads its bound from R, selects its finite window in S, and consumes the corresponding dyadic radius and slack comparison in D. The regular readback Q is then the only row from which a seal-facing consumer can proceed to E.

The induction hypothesis handles the remaining scheduled requests. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so there is no carrier coordinate from which a consumer can bypass R and read the Real seal directly. □

Theorem 1965.3 (Real convergence rate NameCert obligations)**.** *For every accepted* $\mathsf{RealConvergenceRate}^{\uparrow}$ *carrier*

$$K = (R, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealConvergenceRate}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the rate schedule R, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N;*
2. *classifier stability under componentwise* hsame *transport of the displayed rate schedule, window, ledger, readback, seal, replay, provenance, and local naming rows;*
3. *rate-to-tail control, requiring every accepted precision request to consult R before any tail read reaches S, D, Q or the Real seal E;*
4. *dyadic tolerance accounting, requiring D to store exactly the radii, slack comparisons, and budget cells consumed by the scheduled windows and readback row;*
5. *ledger provenance, requiring P to name the displayed Real and Completion dependencies through* $\mathsf{RapidCauchyName}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
6. *non-escape from quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard-bridge data.*

No real-convergence-rate obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 1965.1. The accepted packet lists exactly the rate schedule, finite stream windows, dyadic tolerance ledger, regular rational readback, terminal seal, and four structural rows.

Classifier stability is componentwise. The hsame row H transports each displayed coordinate of the packet, while the classifier has no extra coordinate that could change independently of those rows.

Rate-to-tail control is Definition 1965.2. It forces every accepted precision request through R before any scheduled window, tolerance cell, readback row, or terminal seal can be consumed.

The tolerance and provenance clauses are then row inspections. The ledger D contains the dyadic accounting consumed by S and Q, and P names only the listed Real and Completion dependencies.

Finally, the carrier has no coordinate for quotient equality, a selected limit, countable choice, host equality, trichotomy, ambient completeness, Lean evidence, or bridge data. The enumerated rows therefore exhaust the local NameCert obligation surface. □

Falsifiable prediction: Every $\mathsf{RealConvergenceRate}^{\uparrow}$ precision request factors through a displayed rate schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: rapidcauchyname, realcauchymodulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{RealConvergenceRate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rate admission, finite tail routing, dyadic tolerance accounting, regular readback, terminal Real seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealConvergenceRate}^{\uparrow}}$.

Constructive story: A $\mathsf{RealConvergenceRate}^{\uparrow}$ packet is generated from a rate schedule, finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealConvergenceRate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1965.1, Definition 1965.2, and Definition 1965.3 seed the explicit rate-of-convergence route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealConvergenceRate}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealConvergenceRateUp.RealConvergenceRateTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier stability, rate-to-tail control, dyadic tolerance accounting, ledger provenance, and non-escape for BEDC.Derived.RealConvergenceRateUp.

Chapter 1966

A Concrete Naming Certificate for $\mathsf{BishopRealNormalizer}^{\uparrow}$

Following Bishop and Bridges' constructive real-number presentation, the $\mathsf{BishopRealNormalizer}^{\uparrow}$ packet records the finite boundary where an arbitrary regular Cauchy rational name is normalized before a terminal $\mathsf{Real}^{\uparrow}$ seal may be read. It sits over the dyadic tolerance ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the completion boundary of chapter 1639, the effective comparison packet of chapter 1936, and the modulus-neutral seal discipline of chapter 1955. The packet names a canonical normalization route for L10 Real and Completion consumers; it is not quotient stream equality, host real equality, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1966.1 (Bishop real normalizer carrier)**.** *A* $\mathsf{BishopRealNormalizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, M, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy name row, exposing the rational approximants and finite precision requests before normalization.*
2. *M is the monotone normalized tail-modulus row, recording the displayed tail schedule whose requested indices are nondecreasing and whose tolerance budget refines the source requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing dyadic radii, slack comparisons, and finite error budgets consumed by the source and normalized rows.*
4. *Q is the normalized* $\mathsf{RegSeqRat}^{\uparrow}$ *output row obtained from S through M and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source name, monotone tail modulus, dyadic tolerance ledger, and normalized regular output have been displayed.*
6. *H records componentwise* hsame *transport for S, M, D, Q, E and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the normalization route*

$$S \longmapsto M \longmapsto D \longmapsto Q \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopRealNormalizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{GrzegorczykReal}^{\uparrow}$, $\mathsf{RegularCauchyModulusIndependence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealNormalizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.BishopRealNormalizerUp.BishopRealNormalizerTasteGate single carrier alignment`

Theorem 1966.2 (Bishop real normalizer NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealNormalizer}^{\uparrow}$ *carrier*

$$Z = (S, M, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealNormalizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular Cauchy name, monotone normalized tail modulus, dyadic tolerance ledger, normalized* $\mathsf{RegSeqRat}^{\uparrow}$ *output, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows H, C, P, N;*

2. *source exposure, requiring every normalization request to begin with the displayed source row S rather than with a detached stream representative;*

3. *monotone tail-modulus normalization, requiring M to present a nondecreasing finite tail schedule whose tolerance budget refines the requests exported by S;*

4. *dyadic accounting, requiring D to store exactly the dyadic radii and slack comparisons used to justify the normalized output row Q;*

5. *regular-output handoff, requiring Q to be the only route by which the normalized finite windows become a* $\mathsf{RegSeqRat}^{\uparrow}$ *real name;*

6. *Real-seal factorization, requiring every downstream consumer of E to pass through S, M, D, Q and the structural rows before reading the terminal seal;*

7. *transport, replay, and provenance non-escape, requiring H, C, P, N to preserve and name only the displayed normalization rows, with no quotient stream equality, host real equality, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Bishop real normalizer obligation is stored outside these rows.

Proof. Project the accepted packet $Z = (S, M, D, Q, E, H, C, P, N)$. Carrier admission exposes exactly the source regular name, monotone tail-modulus row, dyadic tolerance ledger, normalized regular output, terminal Real seal, and the four structural rows.

The source exposure clause is first in the route. A normalization request cannot start from an unnamed stream representative, because the only source coordinate in the carrier is the displayed row S.

The monotone tail-modulus clause is the row M. It records the finite nondecreasing schedule used to choose tails and ties each chosen tail to the source requests that it refines.

Dyadic accounting is then forced by D. The ledger stores the radii and slack comparisons consumed when the selected tails are read as the normalized row Q, so the regular output has no tolerance data outside the packet.

Finally, the Real seal and structural rows exhaust the boundary. The seal E is downstream of S, M, D, Q, while H, C, P, N transport, replay, source, and name only those displayed rows. Hence no excluded quotient, host equality, selected limit, countable-choice object, ambient-completeness principle, Lean evidence, or bridge credential is exported. □

Theorem 1966.3 (Bishop real normalizer Real-seal factorization)**.** *For every accepted* $\mathsf{BishopRealNormalizer}^{\uparrow}$ *carrier*

$$Z = (S, M, D, Q, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* E *factors through the displayed normalization route*

$$S \longmapsto M \longmapsto D \longmapsto Q \longmapsto E$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. In particular, the consumer cannot replace* S *by quotient stream equality, cannot replace* Q *by a selected limit, cannot compare host real values, cannot invoke countable choice, and cannot read* E *as an ambient completeness witness.*

Proof. Begin with a seal-facing consumer. Carrier projection exposes E only as the terminal coordinate of the normalized regular-Cauchy route, not as an independently completed host real.

Trace the route backward from E. The seal is downstream of Q, the normalized $\mathsf{RegSeqRat}^{\uparrow}$ output is downstream of the dyadic tolerance ledger D, and the ledger is controlled by the monotone tail schedule M applied to the source row S.

The structural coordinates preserve the same route. Componentwise hsame in H transports the source, modulus, tolerance, output, and seal rows; displayed Cont in C replays their order; and P, N name the packet without adding a second real-name surface.

Thus every Real-facing use factors through $S, M, D, Q, E, H, C, P, N$. The carrier contains no coordinate from which quotient stream equality, selected limits, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking could be read. □

Falsifiable prediction: Every $\mathsf{BishopRealNormalizer}^{\uparrow}$ Real-facing read factors through a source regular Cauchy row, a monotone normalized tail modulus, a DyadicRatCore tolerance ledger, a normalized RegSeqRat output, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-cauchy-completion, grzegorczyk-real, regular-cauchy-modulus-independence: $\mathsf{BishopRealNormalizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source exposure, monotone tail-modulus normalization, dyadic tolerance accounting, normalized regular output, terminal Real seal factorization, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealNormalizer}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealNormalizer}^{\uparrow}$ packet is generated from a source regular Cauchy name, a monotone normalized tail modulus, DyadicRatCore tolerance rows, a normalized RegSeqRat output, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealNormalizer}^{\uparrow}}$, seed)

Scope closed: Definition 1966.1, Definition 1966.2, and Definition 1966.3 seed the canonical normalization boundary for regular-Cauchy real names before a Real or Completion consumer reads the terminal seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealNormalizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, monotone tail-modulus normalization, dyadic accounting, regular-output handoff, Real-seal factorization, transport/replay/provenance coverage, and non-escape for BEDC.Derived.BishopRealNormalizerUp.

Chapter 1967

A Concrete Naming Certificate for $\mathsf{EulerPolygon}^{\uparrow}$

Following Euler's polygonal method and Bishop–Bridges constructive analysis, the $\mathsf{EulerPolygon}^{\uparrow}$ packet records the finite approximation route by which local slope data, a dyadic mesh, and displayed polygon vertices are read before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees a terminal seal. It sits on the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the local Lipschitz control packet of chapter 410. The certificate names a finite polygonal approximation object; it is not an ODE solution, not a selected limiting curve, not quotient stream equality, not host real equality, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1967.1 (Euler polygon carrier)**.** *An* $\mathsf{EulerPolygon}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, A, L, V, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the mesh row, listing a finite dyadic time grid, the step widths between adjacent grid points, and the local tolerance budget attached to each step.*
2. *A is the initial point row, recording the displayed initial time and value from which the polygonal path begins.*
3. *L is the local slope and Lipschitz row, carrying the finite slope samples and the local Lipschitz bounds licensed through* $\mathsf{LipschitzMap}^{\uparrow}$ *before any vertex is advanced.*
4. *V is the polygon-vertex* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite sequence of vertices obtained by reading A, M, and L in order.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *step ledger, storing the dyadic products, radius comparisons, slack cells, and accumulated step errors used by the vertex row.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the vertex windows and the dyadic ledger.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after M, A, L, V, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for the mesh, initial point, local slope/Lipschitz row, vertex windows, step ledger, readback row, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the finite polygon route*

$$(M, A, L) \longmapsto V \longmapsto D \longmapsto Q \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{EulerPolygon}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerPolygon}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, L, V, D, Q, R, H, C, P, N$. It has no coordinate for an ODE solution, selected limiting curve, global existence theorem, quotient stream equality, host real equality, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.EulerPolygonUp.EulerPolygonTasteGate single carrier alignment`

Theorem 1967.2 (Euler polygon NameCert obligations)**.** *For every accepted* $\mathsf{EulerPolygon}^{\uparrow}$ *carrier*

$$E = (M, A, L, V, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerPolygon}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic mesh, initial point, local slope/Lipschitz row, polygon-vertex* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *step ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows H, C, P, N;*

2. *mesh exposure, requiring every vertex advance to consult the displayed mesh row M and its dyadic step width before any readback row is consumed;*

3. *initial-point anchoring, requiring the first vertex window in V to be sourced from the displayed initial row A;*

4. *local slope control, requiring each finite step to read its slope sample and Lipschitz bound from L rather than from an external differential equation object;*

5. *dyadic step accounting, requiring D to store exactly the dyadic products, radius comparisons, slack cells, and accumulated error cells consumed by the displayed vertex windows;*

6. *regular rational handoff, requiring Q to be the only route by which the polygon-vertex windows become a* $\mathsf{RegSeqRat}^{\uparrow}$ *name;*

7. *Real-seal nonescape, requiring every consumer of R to pass through M, A, L, V, D, Q and the structural rows, with no ODE solution, selected limit, quotient stream equality, host real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Euler polygon obligation is stored outside these rows.

Proof. Project the accepted packet $E = (M, A, L, V, D, Q, R, H, C, P, N)$. Carrier admission exposes exactly the mesh, initial point, local slope/Lipschitz row, vertex windows, dyadic ledger, regular readback, terminal Real seal, and the four structural rows.

The mesh and initial-point clauses are forced at the start of the route. A vertex advance has no source coordinate except M for its step width and A for the initial vertex.

Local slope control is the row L. Each displayed step reads its slope sample and Lipschitz bound there, so the packet does not import a separate differential-equation object.

Dyadic accounting is then forced by D. The ledger stores the products, radius comparisons, slack cells, and accumulated error cells consumed by V before any regular rational readback can occur.

Finally, Q, R, H, C, P, N exhaust the handoff boundary. The readback row Q is the only route from vertex windows to the Real seal R, while transport, replay, provenance, and naming preserve only the displayed rows. Thus no excluded solution, selected limit, quotient equality, host equality, choice schedule, ambient completeness principle, Lean evidence, or bridge credential is exported. □

Theorem 1967.3 (Euler polygon step-ledger induction)**.** *For every accepted* $\mathsf{EulerPolygon}^{\uparrow}$ *carrier*

$$E = (M, A, L, V, D, Q, R, H, C, P, N),$$

induction over the finite dyadic mesh row M shows that every displayed prefix of the polygon route has a matching prefix of polygon-vertex windows in V and accumulated dyadic ledger cells in D. The base prefix is the initial row A. At each successor mesh step, the route reads exactly one step width from M, exactly one slope and Lipschitz-control row from L, appends one vertex window to V, and appends the corresponding dyadic product, slack, and error cell to D. Thus the completed finite ledger is available before the $\mathsf{RegSeqRat}^{\uparrow}$ *row Q or the terminal* $\mathsf{Real}^{\uparrow}$ *seal R can be read.*

Proof. Induct on the displayed finite mesh row M. The empty-prefix case exposes no step width, so the only route prefix is the initial point row A. The matching vertex prefix is the first displayed vertex window in V, and the matching ledger prefix in D is empty except for the accumulated zero-step accounting attached to the initial row.

For the successor case, assume the prefix already has matching displayed vertex windows and accumulated dyadic ledger cells. The next mesh entry of M supplies the single step width allowed for the next advance. The local row L supplies the corresponding slope sample and Lipschitz bound; no external differential-equation object is available in the carrier.

Using exactly those displayed rows, the polygon route appends one vertex window to V. The dyadic ledger D appends the product cell for the step, the slack comparison for the local radius budget, and the accumulated error cell for the enlarged prefix. Hence the extended route prefix again has matching prefixes in V and D.

Finite induction over all displayed mesh entries therefore constructs the full vertex-and-ledger route

$$(M, A, L) \longmapsto V \longmapsto D.$$

The existing $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ nonescape results consume this completed finite induction ledger: Q can read only the already displayed V, D prefixes, and R is downstream of Q. □

Theorem 1967.4 (Euler polygon RegSeqRat handoff)**.** *For every accepted* $\mathsf{EulerPolygon}^{\uparrow}$ *carrier*

$$E = (M, A, L, V, D, Q, R, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q is determined only by the polygon-vertex* $\mathsf{StreamName}^{\uparrow}$ *windows V together with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *step ledger D and the displayed structural rows H, C, P, N. In particular, Q cannot be replaced by a selected solution curve, quotient equality of vertex streams, host real equality, or an ambient completeness witness.*

Proof. Read the packet through the vertex boundary. The only coordinates feeding a regular rational name are the finite vertex windows V and the dyadic step ledger D.

The mesh, initial point, and local slope rows determine which windows and ledger cells are displayed, but they do not themselves export a $\mathsf{RegSeqRat}^{\uparrow}$ object. The handoff to a regular rational name occurs at Q.

The structural rows preserve that same handoff. Componentwise hsame transports V, D, Q, displayed Cont replays their order, and P, N name the route without adding a second readback surface.

Therefore every accepted regular-rational read factors through V, D, Q, H, C, P, N. The carrier contains no coordinate from which a selected solution curve, quotient stream equality, host real equality, or ambient completeness witness could replace Q. □

Theorem 1967.5 (Euler polygon Real-seal nonescape)**.** *For every accepted* $\mathsf{EulerPolygon}^{\uparrow}$ *carrier*

$$E = (M, A, L, V, D, Q, R, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* R *factors through the displayed finite route*

$$(M, A, L) \longmapsto V \longmapsto D \longmapsto Q \longmapsto R$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The seal does not assert existence of an ODE solution, convergence of refined meshes, uniqueness of a limiting curve, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a seal-facing consumer. The carrier exposes R only as the terminal coordinate after mesh data, initial data, local slope control, vertex windows, dyadic step accounting, and regular rational readback have been displayed.

Trace the route backward from R. The seal is downstream of Q, the readback row is downstream of D and V, and the vertex windows are downstream of the mesh, initial point, and local slope/Lipschitz rows.

The structural rows preserve this order. The transport row H is componentwise, the replay row C displays the same finite route, and P, N provide provenance and local naming without adding an independent Real surface.

Thus every Real-facing use of the seal factors through $M, A, L, V, D, Q, R, H, C, P, N$. Since the packet has no coordinate for global solution existence, refined-mesh convergence, limiting-curve uniqueness, host real equality, countable choice, or ambient Real completeness, none of those claims escapes through the terminal seal. □

Falsifiable prediction: Every $\mathsf{EulerPolygon}^{\uparrow}$ Real-facing read factors through a dyadic mesh row, an initial point row, a local slope/Lipschitz row, polygon-vertex StreamName windows, a DyadicRatCore step ledger, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: streamname, regseqrat, dyadicratcore, real, lipschitzmap: $\mathsf{EulerPolygon}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a dyadic mesh, initial point, local slope/Lipschitz data, polygon-vertex windows, step-error accounting, regular rational handoff, terminal Real seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerPolygon}^{\uparrow}}$**.**

Constructive story: An EulerPolygon$^{\uparrow}$ packet is generated from a dyadic mesh, an initial point row, local slope and Lipschitz rows, polygon-vertex StreamName windows, a DyadicRatCore step ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{EulerPolygon}\uparrow}$, seed)

Scope closed: Definition 1967.1, Definition 1967.2, Definition 1967.4, and Definition 1967.5 seed the finite Euler polygon route used by Real and Completion consumers before any terminal seal is read.

Formal verification: FormalStatus(NameCert$_{\mathsf{EulerPolygon}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ODE solution existence, refined-mesh convergence, selected limiting curves, quotient stream equality, host real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh exposure, initial-point anchoring, local slope control, dyadic step accounting, RegSeqRat handoff, Real-seal nonescape, transport/replay/provenance coverage, and non-escape for BEDC.Derived.EulerPolygonUp.

Chapter 1968

A Concrete Naming Certificate for $\mathsf{CauchyModulusNormalForm}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ packet isolates the effective-modulus normalization step used by the L10 Real and Completion route. It sits between the $\mathsf{CauchyModulus}^{\uparrow}$ schedule consumed by chapter 415, the dyadic tail-bound ledger of chapter 379, the finite window service of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a monotone normal form for a displayed modulus before a CauchyRate, RegSeqRat, or Real consumer reads it; it is not Real completeness, quotient stream equality, a selected limit, trichotomy, countable choice, Lean verification, or bridge checking.

Definition 1968.1 (Cauchy modulus normal-form carrier)**.** *A* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (p, \mu, \nu, \tau, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *p is the precision-request row whose finite tolerance demand starts the normalization route;*
2. *μ is the raw* $\mathsf{CauchyModulus}^{\uparrow}$ *row attached to the source Cauchy name;*
3. *ν is the normalized monotone modulus row, displaying a nondecreasing finite window schedule refining μ on every request named by p;*
4. *τ is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *row whose dyadic tail comparisons justify the normalized windows;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected after ν and τ have been fixed;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the normalized window route;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after p, μ, ν, τ, W, Q have been displayed;*
8. *H records componentwise* hsame *transport for the precision, raw modulus, normal-form modulus, tail-bound, window, readback, seal, route, provenance, and local name rows;*
9. *C records the displayed* Cont *replay*

$$p \longmapsto \mu \longmapsto \nu \longmapsto \tau \longmapsto W \longmapsto Q \longmapsto E;$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $p, \mu, \nu, \tau, W, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.CauchyModulusNormalFormUp.CauchyModulusNormalFormTasteGate single carrier alignment`

Theorem 1968.2 (Cauchy modulus normal-form NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ *carrier*

$$Z = (p, \mu, \nu, \tau, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusNormalForm}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier exposure for the precision request, raw modulus, normalized monotone modulus, dyadic tail bound, finite window, regular readback, Real seal, and structural rows H, C, P, N;*
2. *normalization exactness, requiring ν to be the displayed nondecreasing normal form refining the raw* $\mathsf{CauchyModulus}^{\uparrow}$ *row μ on the precision requests named by p;*
3. *monotone-window refinement, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window in W to be opened through the normalized row ν and justified by the same* $\mathsf{DyadicTailBound}^{\uparrow}$ *row τ;*
4. *RegSeqRat/Real handoff compatibility, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q and terminal* $\mathsf{Real}^{\uparrow}$ *seal E to factor through p, μ, ν, τ, W in the displayed order;*
5. *ledger non-escape, requiring H, C, P, N to preserve only the displayed route and to export no quotient stream equality, selected limit, host real equality, trichotomy, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Cauchy modulus normal-form obligation is stored outside these rows.

Proof. Project the accepted packet $Z = (p, \mu, \nu, \tau, W, Q, E, H, C, P, N)$. Carrier exposure is immediate because these are exactly the displayed coordinates available to the local classifier.

Normalization exactness is read from ν. It is downstream of the raw row μ and the precision request p, so every normalized demand remains tied to the source Cauchy modulus rather than to an external schedule.

Monotone-window refinement then uses τ and W. The dyadic tail-bound row justifies the finite windows opened by the nondecreasing schedule, and no separate window oracle appears between ν and W.

The readback and seal rows finish the route. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q is obtained only after the normalized windows have been displayed, and the $\mathsf{Real}^{\uparrow}$ boundary E is downstream of that readback.

Finally, H, C, P, N transport, replay, name, and source only the same finite route. Since the carrier has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient completeness, Lean evidence, or bridge checking, the five obligation rows exhaust the certificate surface. □

Theorem 1968.3 (Cauchy modulus normal-form handoff)**.** *For every accepted* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ *carrier*

$$Z = (p, \mu, \nu, \tau, W, Q, E, H, C, P, N),$$

every $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer that uses the normalized modulus factors through the displayed route*

$$p \longmapsto \mu \longmapsto \nu \longmapsto \tau \longmapsto W \longmapsto Q \longmapsto E$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The consumer cannot replace ν by an unrecorded modulus, cannot read W without τ, cannot read Q without the normalized windows, and cannot read E as Real completeness or as a selected limit.*

Proof. Start with a consumer of the normalized modulus. The carrier exposes ν only as the normal-form row downstream of the raw modulus μ and the precision request p.

Read forward along the route. The tail-bound row τ justifies the normalized finite windows, the $\mathsf{StreamName}^{\uparrow}$ row W supplies the inspected window surface, the $\mathsf{RegSeqRat}^{\uparrow}$ row Q is the regular rational readback of that surface, and the $\mathsf{Real}^{\uparrow}$ row E is the terminal seal boundary.

The structural rows preserve the same path. Componentwise transport in H keeps the raw and normalized modulus rows tied to the same tail-bound and window rows, while C replays the route order and P, N name the local certificate.

Thus every CauchyRate, RegSeqRat, or Real-facing use factors through $p, \mu, \nu, \tau, W, Q, E, H, C, P, N$. The packet contains no hidden modulus, detached tail ledger, quotient stream equality, selected limit, countable-choice object, trichotomy witness, ambient Real-completeness principle, Lean evidence, or bridge credential. □

Falsifiable prediction: Every $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ consumer read factors through a precision request, raw CauchyModulus row, normalized monotone modulus row, DyadicTailBound row, StreamName finite-window row, RegSeqRat readback row, RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: cauchyrate, cauchymodulus, dyadictailbound, streamname, regseqrat, real: $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries raw-modulus exposure, monotone normal-form exactness, dyadic tail-bound justification, finite-window refinement, RegSeqRat readback, Real seal factorization, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ packet is generated from a precision request, raw $\mathsf{CauchyModulus}^{\uparrow}$ row, normalized monotone modulus row, $\mathsf{DyadicTailBound}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusNormalForm}^{\uparrow}}$, seed)

Scope closed: Definition 1968.1, Definition 1968.2, and Definition 1968.3 seed the finite monotone effective-modulus normal-form boundary for L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusNormalForm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient stream equality, selected limits, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, normalization exactness, monotone-window refinement, RegSeqRat/Real handoff compatibility, ledger non-escape, and consumer factorization for BEDC.Derived.CauchyModulusNormalForm

Chapter 1969

A Concrete Naming Certificate for $\mathsf{RealIntervalArithmetic}^{\uparrow}$

Following Moore and Bishop-Bridges, the $\mathsf{RealIntervalArithmetic}^{\uparrow}$ packet records constructive interval arithmetic after dyadic enclosures have been admitted to a real-name surface. It sits after the dyadic endpoint operation route of chapter 1645, the located endpoint boundary of chapter 1709, the tail-diameter budget of chapter 1746, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion arguments one finite interval-enclosure consumer over $\mathsf{Real}^{\uparrow}$, while keeping host interval equality, real trichotomy, countable choice, open-cover compactness, and ambient Real completeness outside the carrier.

Definition 1969.1 (Real interval arithmetic carrier)**.** *A* $\mathsf{RealIntervalArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, J, D, L, T, +_R, \cdot_R, E, H, C, P, N)$$

with the following displayed rows:

1. *I and J are input interval rows accepted by* $\mathsf{LocatedRealInterval}^{\uparrow}$*, exposing lower and upper located-real endpoint names together with their finite enclosure ledgers.*
2. *D is the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *operation row that computes outward dyadic endpoint enclosures for the requested interval operation before any* $\mathsf{Real}^{\uparrow}$ *seal is read.*
3. *L is the located-real lift row, relating the dyadic enclosure endpoints in D to the located endpoint rows carried by I and J.*
4. *T is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *budget row, recording the requested tail diameter and the tolerance ledger used to justify the exported real interval width.*
5. *$+_R$ is the real-interval addition row, whose output interval enclosure is obtained from the displayed dyadic endpoint sums, located endpoint lifts, and tail-diameter budget.*
6. *$\cdot_R$ is the real-interval multiplication row, whose output interval enclosure is obtained from the displayed dyadic endpoint products, outward comparison rows, located endpoint lifts, and tail-diameter budget.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *enclosure-seal row, requiring every exported interval endpoint and every width claim to pass through the same real-name seal surface.*

8. *H records componentwise* hsame *transport for the input intervals, dyadic operation row, located lift, tail-diameter budget, real operation rows, enclosure seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a requested interval operation through $I, J, D, L, T, +_R, \cdot_R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealIntervalArithmetic}^{\uparrow}$, $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalArithmetic}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive real interval-operation packet. It has no coordinate for host interval equality, trichotomy of real endpoints, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, or a selected host representative.*

Lean4 ✓ `BEDC.Derived.RealIntervalArithmeticUp.RealIntervalArithmeticTasteGate single carrier alignment`

Theorem 1969.2 (Real interval arithmetic NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalArithmetic}^{\uparrow}$ *carrier*

$$A = (I, J, D, L, T, +_R, \cdot_R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalArithmetic}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two located real interval inputs, dyadic interval arithmetic row, located-real lift row, Cauchy tail-diameter budget, real addition and multiplication rows, Real enclosure seal, and structural rows H, C, P, N;*
2. *dyadic-to-real lift discipline, requiring every real interval endpoint exported by $+_R$ or $\cdot_R$ to originate in the displayed dyadic enclosure row D and then pass through the located lift row L;*
3. *tail-diameter discipline, requiring T to be the only width and tolerance budget consumed when a downstream Real or Completion argument reads the exported enclosure;*
4. *operation enclosure soundness, requiring $+_R$ and $\cdot_R$ to preserve containment for all scheduled endpoint windows supplied by I and J;*
5. *seal non-escape, requiring E to be the only* $\mathsf{Real}^{\uparrow}$ *handoff for exported endpoints and interval-width claims;*
6. *transport and replay stability, requiring H and C to preserve the dyadic operation row, located lift, tail budget, operation rows, enclosure seal, provenance, and local name componentwise;*
7. *exclusion, ruling out host interval equality, real trichotomy, countable-choice selectors, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, and selected host representatives as local data.*

No RealIntervalArithmetic obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 1969.1. The projection exposes exactly the two located real interval inputs, the dyadic operation row, located lift, tail-diameter budget, operation rows, Real seal, and structural rows.

The dyadic-to-real lift discipline is the route $D \longmapsto L \longmapsto +_R, \cdot_R$. The dyadic packet supplies outward endpoint enclosures, and the located lift reads those endpoints as located real interval data before any real-name seal is consumed.

The width and tolerance information is stored in T. Thus a Real or Completion consumer can inspect a diameter claim only through the displayed $\mathsf{CauchyTailDiameter}^{\uparrow}$ budget and cannot substitute an ambient completeness argument.

Operation enclosure soundness is read from $+_R$ and $\cdot_R$. The addition row uses displayed dyadic endpoint sums, while the multiplication row uses displayed dyadic endpoint products and outward comparison rows; both rows then pass through L, T, E before reaching a public consumer.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory contains no host interval equality, trichotomy, countable-choice selector, open-cover compactness witness, ambient Real completeness principle, quotient endpoint equality, or selected host representative, none of those objects can be exported. □

Theorem 1969.3 (Real interval arithmetic enclosure soundness)**.** *Every exported operation of an accepted* $\mathsf{RealIntervalArithmetic}^{\uparrow}$ *carrier factors through the displayed route*

$$I, J \longmapsto D \longmapsto L \longmapsto T \longmapsto +_R, \cdot_R \longmapsto E \longmapsto H, C, P, N.$$

Consequently every downstream $\mathsf{Real}^{\uparrow}$ *or Completion consumer receives only a constructive interval enclosure whose endpoints, operation rows, and diameter budget are displayed by* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, *and* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read. The consumer cannot replace this route by host interval equality, trichotomy, countable choice, open-cover compactness, ambient Real completeness, quotient endpoint equality, or a selected host representative.*

Proof. Start with an accepted carrier $A = (I, J, D, L, T, +_R, \cdot_R, E, H, C, P, N)$. The only input interval coordinates are I and J, so every operation begins with displayed located real interval endpoint data.

The dyadic operation row D computes outward endpoint enclosures. The lift row L relates those dyadic endpoints to located real interval endpoints, and the tail-diameter row T records the tolerance budget read by the exported width claim.

For addition, project $+_R$ and read the output enclosure from the displayed endpoint sums, lift, and budget. For multiplication, project $\cdot_R$ and read the output enclosure from the displayed endpoint products, outward comparison rows, lift, and budget.

The seal row E is the only route into $\mathsf{Real}^{\uparrow}$. Componentwise transport and replay through H and C, together with provenance and local naming in P, N, preserve the same route for downstream consumers. Therefore the exported enclosure is exhausted by the displayed finite rows and no excluded host, choice, compactness, completeness, quotient, or representative coordinate is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalArithmetic}^{\uparrow}$ packet is generated from two LocatedRealInterval input rows, one DyadicIntervalArithmetic operation row, a located-real lift, a CauchyTailDiameter budget, displayed addition and multiplication enclosure rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealIntervalArithmetic}^{\uparrow}}$, seed)

Scope closed: Definition 1969.1, Definition 1969.2, and Definition 1969.3 seed the finite constructive interval-enclosure arithmetic interface over RealUp.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealIntervalArithmetic}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval equality, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient endpoint equality, selected host representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-to-real lift discipline, tail-diameter discipline, operation enclosure soundness, Real-seal non-escape, transport/replay/provenance coverage, and exclusion for BEDC.Derived.RealIntervalArithmeticUp.

Chapter 1970

A Concrete Naming Certificate for $\mathsf{BishopIntervalCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalCompletion}^{\uparrow}$ packet records constructive completion of an interval object by finite rational enclosure data and regular real-name readback. It sits after the dyadic rational core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located interval boundary of chapter 394, the rational interval endpoint ledger of chapter 354, and the real interval enclosure route of chapter 1625. The packet gives the L10 Real and Completion phase a finite interval-completion certificate while refusing quotient completion, selected limits, countable choice, trichotomy, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1970.1 (Bishop interval completion carrier)**.** *A* $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, Q, D, E, L, U, A, R, T, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{RationalInterval}^{\uparrow}$ *or* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row whose lower and upper rational endpoints are admitted before any real-name seal is read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened for the interval-completion request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same window schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the dyadic radius, endpoint scale, and comparison rows used by the completion window.*
5. *E is the* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *row that displays a lower and upper enclosure around the candidate completed interval endpoint data.*
6. *L and U are the displayed lower and upper completion-bound rows, read from the source interval and the enclosure row rather than from host endpoint values.*
7. *A is the interval admission row saying that the readback Q with tolerance ledger D lies inside the displayed enclosure E and respects the lower and upper completion bounds.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, S, Q, D, E, L, U, A have been displayed.*
9. *T records the interval-completion route ledger from rational endpoint data to located interval data, then to real interval enclosure data, and finally to the terminal real-name seal.*

10. *H records componentwise* hsame *transport for all displayed rows of the packet.*

11. *C records displayed* Cont *replay from a requested completion read through $I, S, Q, D, E, L, U, A, R, T, H, P, N$.*

12. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalCompletion}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive interval-completion packet. It has no coordinate for quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, or a host interval representative.*

Lean4 ✓ `BEDC.Derived.BishopIntervalCompletionUp.BishopIntervalCompletionTasteGate single carrier alignment`

Definition 1970.2 (Bishop interval completion classifier)**.** *The classifier for accepted* $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *carriers compares two packets only by componentwise agreement of the displayed source interval row, stream window, regular rational readback, dyadic tolerance ledger, real interval enclosure row, lower and upper completion bounds, interval admission row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, route ledger, transport, replay, provenance, and local naming rows. Equivalence of carriers is generated by the visible* hsame *rows and by replay of the same* Cont *route; it is not generated by quotient completion, chosen limits, countable-choice selectors, real trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, or selected host representatives.*

Theorem 1970.3 (Bishop interval completion NameCert obligations)**.** *For every accepted* BishopIntervalCompletion *carrier*

$$K = (I, S, Q, D, E, L, U, A, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source interval, stream window, regular rational readback, dyadic tolerance ledger, real interval enclosure, completion bounds, admission row, terminal real seal, route ledger, and structural rows H, C, P, N;*

2. *endpoint source discipline, requiring I to provide the only rational or located interval endpoint data consumed by the packet;*

3. *window-readback discipline, requiring S, Q, D to be read as one finite StreamName–RegSeqRat–DyadicRatCore route;*

4. *enclosure admission, requiring E, L, U, A to bind the inspected readback and dyadic tolerance inside displayed interval bounds;*

5. *real-seal handoff, requiring R to be reachable only after the source interval, finite window, regular readback, dyadic ledger, enclosure, bounds, and admission rows have been displayed;*

6. *route stability, requiring T, H, C to preserve the same interval-completion route under componentwise transport and later finite-window replay;*

7. *exclusion, ruling out quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, and selected host representatives as local data.*

No BishopIntervalCompletion obligation is stored outside these rows.

Proof. Project the carrier of Definition 1970.1. The projection exposes exactly the source interval row, finite stream window, regular rational readback, dyadic tolerance ledger, real interval enclosure, completion bounds, admission row, terminal real seal, route ledger, and structural rows.

The endpoint source discipline is the coordinate I. It is read through the rational and located interval sibling chapters before any completion-facing consumer can inspect the terminal real seal.

The finite observation face is S, Q, D. The stream window supplies the inspected data, the regular rational row reads that window, and the dyadic ledger supplies the tolerance scale used by the interval admission row.

The enclosure face is E, L, U, A. These rows place the inspected readback between displayed lower and upper completion bounds, so the packet exports an interval-completion enclosure rather than a chosen endpoint pair.

Finally R, T, H, C, P, N package and replay the same route. Since no carrier coordinate contains quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient endpoint equality, or selected host representatives, the listed obligations exhaust the local NameCert surface. □

Theorem 1970.4 (Bishop interval completion route separation)**.** *Every accepted* $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *carrier keeps the endpoint-source route and the real-seal route separated until the displayed enclosure admission row is present. In particular, a consumer may read*

$$I \longmapsto S, Q, D \longmapsto E, L, U, A$$

as finite interval-completion evidence, but it may reach the terminal $\mathsf{Real}^{\uparrow}$ *seal* R *only through*

$$I, S, Q, D, E, L, U, A \longmapsto R \longmapsto T, H, C, P, N.$$

Thus no Real or Completion consumer can bypass the displayed interval enclosure by using quotient completion, a selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient endpoint equality, or a selected host representative.*

Proof. Start with an accepted carrier $K = (I, S, Q, D, E, L, U, A, R, T, H, C, P, N)$. The endpoint-source route begins at I and reaches the finite observation rows S, Q, D before any terminal real-name coordinate occurs.

The admission row A is downstream of E, L, U. It binds the regular rational readback and dyadic tolerance to displayed interval bounds, so it is the first point where source endpoint information and finite completion evidence are jointly visible.

The real-seal row R occurs only after that admission face in the carrier. Therefore a consumer seeking a terminal $\mathsf{Real}^{\uparrow}$ read must pass through the displayed source interval, finite window, regular readback, dyadic ledger, enclosure, bounds, and admission rows.

Transport and replay through T, H, C, P, N preserve this order. The route ledger contains no coordinate for quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient completeness, quotient endpoint equality, or selected host representatives, so none of those routes can bypass the displayed admission row. □

Theorem 1970.5 (Bishop interval completion public route)**.** *The public consumer surface of an accepted* $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *carrier is exhausted by the finite route*

$$\mathsf{RationalInterval}^{\uparrow}, \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RealIntervalEnclosure}^{\uparrow} \longmapsto \mathsf{R}$$

as instantiated by $I, S, Q, D, E, L, U, A, R, T, H, C, P, N$. Any downstream L10 Real and Completion argument receives only this displayed constructive interval-completion certificate and not a quotient completion, selected limit, countable-choice principle, trichotomy witness, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient endpoint equality, or host interval representative.*

Proof. Read the public rows in route order. The source interval row I supplies rational or located endpoint data, and the finite observation rows S, Q, D turn that source into a regular rational readback with a dyadic tolerance ledger.

Next the enclosure rows E, L, U, A expose the interval-completion evidence through the same finite data. A public consumer therefore receives lower and upper completion bounds only as displayed rows of the packet.

The terminal seal R is then read as the $\mathsf{Real}^{\uparrow}$ handoff, with T, H, C, P, N preserving the route under transport, replay, provenance, and local naming. The consumer surface is precisely the listed sibling route, so the excluded quotient, choice, trichotomy, host-equality, completeness, quotient-endpoint, and host-representative readings are outside the packet. □

Theorem 1970.6 (Bishop interval completion nested-enclosure induction)**.** *Let*

$$K = (I, S, Q, D, E, L, U, A, R, T, H, C, P, N)$$

be an accepted $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *carrier. For every finite displayed chain of enclosure refinements starting from K, if each successor step refines the visible enclosure row through the same interval-completion route, then every stage preserves the source interval row I, StreamName window S, RegSeqRat readback Q, DyadicRatCore tolerance ledger D, enclosure row E, lower and upper bounds L, U, admission row A, terminal real seal R, route ledger T, and structural rows H, C, P, N as displayed carrier data.*

Proof. Proceed by induction on the finite displayed refinement chain.

For the empty chain, the claim is the carrier projection of Definition 1970.1. The rows $I, S, Q, D, E, L, U, A, R, T, H, C, P, N$ are precisely the visible coordinates of the accepted packet.

At a successor step, the induction hypothesis supplies the same source interval, finite window, rational readback, dyadic tolerance, enclosure, bounds, admission, seal, ledger, and structural rows at the previous stage. The route separation of Definition 1970.4 forces the next refinement to pass through I, S, Q, D, E, L, U, A before the terminal $\mathsf{Real}^{\uparrow}$ seal can be consumed.

The public route theorem then repacks the successor stage through the same displayed route to $\mathsf{Real}^{\uparrow}$. Since no refinement coordinate contains quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient completeness, quotient endpoint equality, or a host representative, the successor preserves exactly the displayed carrier rows. □

Theorem 1970.7 (Bishop interval completion dyadic window covering)**.** *For any finite family of* $\mathsf{BishopIntervalCompletion}^{\uparrow}$ *completion requests over the same interval source row I, the family is covered by a finite family of StreamName windows and DyadicRatCore tolerance rows before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed. More precisely, after reindexing the requests in route order, each request is witnessed by displayed rows*

$$S_j, Q_j, D_j, E_j, L_j, U_j, A_j$$

over the same source I, and the terminal real-name handoff for the family occurs only after these finite window and tolerance rows have been displayed.

Proof. Induct on the finite request family.

For the empty family, no window or tolerance row is required, and there is no terminal real-name handoff to consume.

For a successor family, apply the induction hypothesis to the previous requests. This gives a finite cover by displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, enclosures, bounds, and admission rows over the same interval source.

For the new request, use Definition 1970.6. It preserves the source row I while exposing the successor request through its displayed S, Q, D, E, L, U, A rows. Appending these rows to the previous finite cover gives the required family of windows and dyadic tolerance rows.

Finally, Definition 1970.4 and Definition 1970.5 place every terminal $\mathsf{Real}^{\uparrow}$ seal strictly after the displayed finite-window and tolerance evidence. Thus the family is covered before any real-name seal is consumed. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalCompletion}^{\uparrow}$ packet is generated from a rational or located interval source row, a finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealIntervalEnclosure row, displayed completion bounds, interval admission, terminal RealUp seal, route ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1970.1, Definition 1970.2, Definition 1970.3, Definition 1970.4, Definition 1970.5, Definition 1970.6, and Definition 1970.7 seed the finite constructive interval-completion certificate over RationalInterval, LocatedInterval, StreamName, RegSeqRat, DyadicRatCore, RealIntervalEnclosure, and RealUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BishopIntervalCompletionUp.BishopIntervalCompletionTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient endpoint equality, selected host representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, endpoint source discipline, StreamName–RegSeqRat–DyadicRatCore readback, enclosure admission, RealUp seal non-escape, route separation, and public-route exhaustion for BEDC.Derived.BishopIntervalCompletionUp.

Chapter 1971

A Concrete Naming Certificate for $\mathsf{RegularCauchyScalar}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyScalar}^{\uparrow}$ packet names dyadic scalar multiplication of a regular rational Cauchy name by finite endpoint arithmetic before any completed $\mathsf{Real}^{\uparrow}$ or algebraic consumer can read the scaled name. It sits over the regular rational source row of chapter 301, the dyadic scalar and endpoint arithmetic of chapter 291, the finite-window stream discipline of chapter 126, the terminal real-name seal of chapter 38, and the sibling operation surfaces of chapter 417 and chapter 459. The packet gives later real-algebra and completion consumers a finite scalar route; it does not import quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness.

Definition 1971.1 (RegularCauchyScalar carrier)**.** *A* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, A, W, D, F, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row for the regular rational Cauchy name.*
2. *A is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scalar row, recording the displayed dyadic coefficient and its exact arithmetic provenance.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to expose the source observations requested by the scalar-facing consumer.*
4. *D is the source dyadic observation row read from X through the window schedule W.*
5. *F is the scaled dyadic observation ledger, obtained by multiplying the displayed source observations in D by the scalar row A inside the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic surface.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff, exposed only after X, A, W, D, F and their structural rows have been displayed.*
7. *H records componentwise* hsame *transport for the source row, scalar row, window schedule, source observations, scaled ledger, Real seal, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from every scalar-facing precision request through $X, A, W, D, F, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyScalar}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyScalar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, W, D, F, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyScalarUp.RegularCauchyScalarTasteGate single carrier alignment`

Theorem 1971.2 (RegularCauchyScalar NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *carrier*

$$S = (X, A, W, D, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyScalar}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *scalar row,* $\mathsf{StreamName}^{\uparrow}$ *window schedule, source dyadic observation row, scaled dyadic ledger,* $\mathsf{Real}^{\uparrow}$ *seal handoff, and structural rows;*
2. *scalar-row exactness, requiring A to be read as displayed dyadic arithmetic data before any scaled observation is available;*
3. *finite-window handoff, requiring W and D to expose only finitely many source observations at each scalar-facing precision request;*
4. *scaled-ledger stability, requiring F to be computed from A and D inside the* $\mathsf{DyadicRatCore}^{\uparrow}$ *route and to transport componentwise through H;*
5. *classifier transport, requiring the* hsame *rows in H to preserve the same source, scalar, window, observation, scaled ledger, Real seal, replay, provenance, and local naming data;*
6. *Real seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *or algebraic consumer to pass through X, A, W, D, F before reading E;*
7. *provenance and local naming, requiring P and N to name exactly the finite scalar packet and no external completed-real operation.*

No scalar-multiplication obligation is stored outside these finite rows, and the surface refuses quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local data.*

Proof. Project the accepted carrier. The analytic rows are the source row X, scalar row A, window schedule W, source observations D, scaled ledger F, and Real seal handoff E.

Read the scalar and source windows before the scaled name. The scalar row A supplies exact dyadic arithmetic data, while the finite schedule W exposes only the source observations recorded in D for the current precision request.

Form the scaled ledger inside the displayed dyadic route. The row F consumes A and D and records the endpoint products as finite $\mathsf{DyadicRatCore}^{\uparrow}$ data, so classifier transport through H preserves the same source, scalar, observation, and scaled-ledger coordinates.

Finally replay and package the route through C, P, N. The seal row E is downstream of X, A, W, D, F, so any Real-facing or algebra-facing consumer reads the finite scalar packet before the scaled regular name. Since no carrier coordinate stores quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient completeness, Lean verification, or bridge data, none can become a local NameCert obligation. □

Theorem 1971.3 (RegularCauchyScalar Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or algebraic consumer of an accepted* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *carrier reads the route*

$$(X, A) \longmapsto W \longmapsto D \longmapsto F \longmapsto E \longmapsto (H, C, P, N)$$

before seeing the scaled regular name. Thus the consumer receives the source regular row, exact dyadic scalar row, finite window schedule, source dyadic observations, scaled dyadic ledger, Real seal handoff, displayed transports, replay, provenance, and local naming rows. It receives no quotient stream equality, selected limit, countable-choice selector, trichotomy witness, host real equality, ambient completeness coordinate, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyScalarUp.RegularCauchyScalarRealHandoff`

Proof. Begin with the accepted packet S. The only source of regular-name data is X, and the only scalar source is the displayed dyadic row A.

The finite schedule W supplies the observations D before scalar multiplication is visible. Multiplication by the scalar is then recorded in F as dyadic endpoint arithmetic rather than as a completed-real operation.

The Real-facing boundary is downstream of that ledger. The seal handoff E is exposed only after X, A, W, D, F, and the rows H, C, P, N preserve the same dependency order for algebraic consumers.

Therefore the scaled regular name is read through the finite BEDC scalar route. The listed refusal data are absent from the carrier, so no consumer can obtain them from this handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyScalar}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyScalar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1971.1, Definition 1971.2, and Definition 1971.3 seed the finite dyadic scalar-multiplication surface over a $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{DyadicRatCore}^{\uparrow}$ scalar row, $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, source dyadic observations, scaled dyadic ledger, $\mathsf{Real}^{\uparrow}$ seal handoff, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyScalar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar-row exactness, finite-window handoff, scaled-ledger stability, classifier transport, Real seal non-escape, provenance, and local naming for BEDC.Derived.RegularCauchyScalarUp.

Constructive story: A $\mathsf{RegularCauchyScalar}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a $\mathsf{DyadicRatCore}^{\uparrow}$ scalar row, a $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, a source dyadic observation row, a scaled dyadic observation ledger, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1972

A Concrete Naming Certificate for $\mathsf{RoundedDyadicLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Moore–Kearfott–Cloud interval arithmetic, the $\mathsf{RoundedDyadicLocator}^{\uparrow}$ packet exposes outward-rounded dyadic locator rows for $\mathsf{Real}^{\uparrow}$ names. It sits after the located comparison route of chapter 1669, the dyadic finite-observation surface of chapter 335, the interval enclosure ledger of chapter 302, the dyadic request layer of chapter 291, the finite stream window of chapter 126, the regular rational readback row of chapter 301, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers one finite route from a real-name query to an outward-rounded dyadic enclosure, while keeping host trichotomy, quotient real equality, selected representatives, countable choice, and ambient Real completeness outside the carrier.

Definition 1972.1 (Rounded dyadic locator carrier)**.** *A* $\mathsf{RoundedDyadicLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, Q, S, R, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the terminal* $\mathsf{Real}^{\uparrow}$ *seal whose finite observation is being located.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *request row, naming the queried dyadic center, scale, and finite precision budget.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation window opened from X for the request Q.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream window S.*
5. *D is the dyadic tolerance ledger, recording the radius, endpoint scale, and outward-rounding budget consumed by the locator.*
6. *L is the outward-rounded lower locator row, exposing a dyadic lower endpoint certified by the route Q, S, R, D.*
7. *U is the outward-rounded upper locator row, exposing a dyadic upper endpoint certified by the same route Q, S, R, D.*
8. *H records componentwise* hsame *transport for the Real seal, dyadic request, stream window, regular readback, tolerance ledger, lower and upper locator rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a downstream Real, RealLocator, DyadicApproximation, or IntervalArithmetic request through $Q, S, R, D, L, U, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RoundedDyadicLocator}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, $\mathsf{IntervalArithmetic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RoundedDyadicLocator}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite outward-rounded dyadic locator packet. It has no coordinate for host trichotomy, quotient real equality, selected representatives, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1972.2 (Rounded dyadic locator NameCert obligations)**.** *For every accepted* $\mathsf{RoundedDyadicLocator}^{\uparrow}$ *carrier*

$$W = (X, Q, S, R, D, L, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RoundedDyadicLocator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Real seal, dyadic request, stream window, regular readback, dyadic tolerance ledger, outward-rounded lower and upper locator rows, transport, replay, provenance, and local naming data;*

2. *rounded-bound exactness, requiring L and U to be read as outward-rounded dyadic endpoints justified by the displayed tolerance ledger D and not by a host real-order comparison;*

3. *window-readback compatibility, requiring the stream window S and regular rational readback R to be the only observation route from X to the dyadic endpoints L and U;*

4. *classifier transport, requiring H and C to preserve the same request, window, readback, tolerance ledger, endpoint rows, provenance, and local name componentwise;*

5. *Real-seal non-escape, requiring every downstream locator, approximation, or interval consumer to inspect X only through $Q, S, R, D, L, U, H, C, P, N$.*

No rounded dyadic locator obligation is stored outside these rows, and no obligation may be replaced by host trichotomy, quotient equality of real names, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RoundedDyadicLocatorUp.RoundedDyadicLocatorTasteGate single carrier alignment`

Proof. Project the accepted packet $W = (X, Q, S, R, D, L, U, H, C, P, N)$. The carrier exposes exactly one Real seal, one dyadic request, one stream observation window, one regular rational readback, one dyadic tolerance ledger, two outward-rounded endpoint rows, and the structural rows.

Rounded-bound exactness is the route through D, L, U. The lower endpoint L and upper endpoint U are not host-order facts about a completed real; they are displayed dyadic rows whose rounding direction and tolerance budget are recorded by D.

Window-readback compatibility is forced by the position of S and R in the carrier. A finite observation of X must first open the stream window S and then pass through the regular rational readback R before the dyadic tolerance ledger and endpoint rows are available.

Transport and replay stability are the roles of H and C. They preserve the same request, window, readback, tolerance, endpoint, provenance, and naming coordinates under componentwise hsame transport and displayed continuation replay.

Finally, P and N source and name the same finite packet. Since the carrier inventory contains no host trichotomy coordinate, quotient equality field, representative selector, countable-choice schedule, or ambient completeness witness, none of those objects can appear as a local NameCert obligation. □

Theorem 1972.3 (Rounded dyadic locator window handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, $\mathsf{DyadicApproximation}^{\uparrow}$, *or* $\mathsf{IntervalArithmetic}^{\uparrow}$ *consumer of an accepted* $\mathsf{RoundedDyadicLocator}^{\uparrow}$ *carrier reads through the displayed handoff route*

$$Q \longmapsto S \longmapsto R \longmapsto D \longmapsto L, U \longmapsto H, C, P, N.$$

The consumer receives only the outward-rounded dyadic lower and upper locator rows certified by that finite route. It cannot replace the route by host trichotomy, quotient equality of real names, a selected representative, countable choice, or ambient Real completeness.

Proof. Let a downstream Real, locator, approximation, or interval consumer inspect an accepted packet W. The request row Q fixes the dyadic center, scale, and finite precision budget before any observation of the real name is read.

The only observation path from the Real seal is $Q \longmapsto S \longmapsto R$. The stream window S exposes the finite part of the name, and the regular rational readback R supplies the rational data from which the tolerance ledger may be inspected.

The ledger D then records the outward-rounding budget, and the endpoint rows L and U expose the lower and upper dyadic locator bounds. Thus the consumer reaches locator or interval data only after the finite window, readback, and tolerance rows have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name that same handoff route. Because no other analytic coordinate occurs in the carrier, the downstream consumer has no access to host trichotomy, quotient real equality, selected representatives, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedDyadicLocator}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedDyadicLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1972.1, Definition 1972.2, and Definition 1972.3 seed the finite outward-rounded dyadic locator route from $\mathsf{Real}^{\uparrow}$ names to locator, approximation, and interval consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedDyadicLocator}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RoundedDyadicLocatorUp.RoundedDyadicLocatorTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public bridge.

Upgrade path: Obligation closure requires checked carrier admission, rounded-bound exactness, window-readback compatibility, classifier transport, Real-seal non-escape, and window handoff for BEDC.Derived.RoundedDyadicLocatorUp.

Constructive story: A $\mathsf{RoundedDyadicLocator}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{DyadicRatCore}^{\uparrow}$ request, a $\mathsf{StreamName}^{\uparrow}$ observation window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a dyadic tolerance ledger, outward-rounded lower and upper locator rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1973

A Concrete Naming Certificate for $\mathsf{ArithmeticGeometricMean}^{\uparrow}$

Following Gauss' arithmetic-geometric mean and Bishop–Bridges constructive real analysis, the $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ packet records the finite mean-iteration route available for two displayed positive real names. It sits after the terminal real-name seal of chapter 38, the absolute-value boundary of chapter 1608, the constructive square-root service of chapter 1756, the dyadic arithmetic carrier of chapter 291, the dyadic tolerance scale of chapter 1768, the finite window surface of chapter 126, the regular rational readback route of chapter 301, and the located real boundary of chapter 3359. The packet gives L10 Real and Completion consumers one visible certificate for arithmetic and geometric mean iteration while withholding host real equality, quotient Cauchy equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and standard-bridge data.

Definition 1973.1 (Arithmetic-geometric mean carrier)**.** *An* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, A, G, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are positive* $\mathsf{Real}^{\uparrow}$ *endpoint rows, each exposing a terminal real-name seal, positivity witness, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback data.*
2. *A is the arithmetic midpoint row, recording the displayed half-sum operation from the current endpoint rows before any downstream seal is consumed.*
3. *G is the geometric midpoint row, routing the displayed product of the two positive endpoint rows through* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *and the accompanying square-root readback service.*
4. *D is the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *ledger, storing the precision scale, dyadic radii, comparison slack, and budget cells used by the midpoint and square-root rows.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row selected for the current arithmetic and geometric midpoint requests.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and dyadic tolerance ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the exported mean-iteration state, reachable only after X, Y, A, G, D, S, Q have been displayed.*

8. *H records componentwise* hsame *transport for the endpoint rows, arithmetic midpoint, geometric midpoint, tolerance ledger, finite windows, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of each accepted precision request through*

$$X, Y \longmapsto A, G \longmapsto D \longmapsto S \longmapsto Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ArithmeticGeometricMean}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, A, G, D, S, Q, E, H, C, P, N$. It has no coordinate for host real equality, quotient Cauchy equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.ArithmeticGeometricMeanUp.ArithmeticGeometricMeanTasteGate single carrier alignment`

Theorem 1973.2 (Arithmetic-geometric mean NameCert obligations)**.** *For every accepted* ArithmeticGeometricMea *carrier*

$$M = (X, Y, A, G, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArithmeticGeometricMean}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two positive* $\mathsf{Real}^{\uparrow}$ *endpoint rows X, Y, the arithmetic midpoint row A, the geometric midpoint and square-root row G, the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows H, C, P, N;*

2. *positivity routing, requiring the geometric midpoint row to read the positive endpoint data in X, Y before invoking the square-root service;*

3. *midpoint discipline, requiring A and G to be the only arithmetic and geometric mean rows consumed by the exported iteration state;*

4. *tolerance accounting, requiring D to store exactly the dyadic scale, radii, comparison slack, and budget cells consumed by A, G, S, Q, E;*

5. *window and readback handoff, requiring every precision request to pass through S and Q before the Real seal E is read;*

6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*

7. *non-escape for host real equality, quotient Cauchy equality, selected limits, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard-bridge data.*

No arithmetic-geometric-mean obligation is stored outside these rows.

Proof. Project the carrier of Definition 1973.1. The two endpoint rows, arithmetic midpoint, geometric midpoint, tolerance ledger, finite windows, readback, and Real seal are the only analytic coordinates, while H, C, P, N are the only structural coordinates.

The positivity route is forced by the displayed tuple. The geometric midpoint row G reads the positive endpoint data from X and Y, then uses the square-root service named in the provenance row; there is no detached square-root coordinate available to the classifier.

The tolerance and readback rows are downstream of the midpoint rows. The ledger D stores the dyadic scale and slack data consumed by A and G, the window row S exposes the finite observations, and Q is the regular rational readback that precedes the terminal seal.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded host, quotient, choice, completeness, verification, or bridge objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1973.3 (Arithmetic-geometric mean Real-seal handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ *carrier reaches the exported mean-iteration seal only through the displayed route*

$$X, Y \longmapsto A, G \longmapsto D \longmapsto S \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives two positive Real endpoint rows, an arithmetic midpoint row, a geometric midpoint routed through $\mathsf{RegularCauchySquareRoot}^{\uparrow}$*, a dyadic tolerance ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming. The handoff supplies no host real equality, quotient Cauchy equality, selected limit, trichotomy witness, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean evidence, or standard bridge.*

Proof. Start with an accepted carrier $M = (X, Y, A, G, D, S, Q, E, H, C, P, N)$. The endpoint rows X and Y are the only sources for the two positive real names, so every accepted midpoint request begins with displayed Real seals and their finite observation data.

The arithmetic midpoint row A records the half-sum route. The geometric midpoint row G records the product-and-square-root route, and the square-root service is read only through the displayed positive endpoint data and the provenance named by the same carrier.

The dyadic tolerance row D then fixes the precision scale consumed by both midpoint rows. The finite windows S and regular rational readback Q are the only observation rows from which a downstream consumer can proceed to the terminal seal E.

Componentwise transport and replay through H and C, together with provenance and local naming in P, N, preserve the same route. The carrier contains no coordinate for the excluded host, quotient, choice, completeness, verification, or bridge data, so the displayed handoff is exhaustive. □

Theorem 1973.4 (ArithmeticGeometricMean window contraction)**.** *For an accepted* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ *carrier*

$$M = (X, Y, A, G, D, S, Q, E, H, C, P, N),$$

each finite precision window exported by S is contracted through the displayed arithmetic row A, geometric row G, dyadic arithmetic and tolerance data from chapter 291, $\mathsf{StreamName}^{\uparrow}$ *windows from chapter 126, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from chapter 301 before the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 or the located boundary of chapter 3359 is exposed. The contraction is a finite packet property; it does not select a quotient real equality, choose square roots beyond the displayed G row, decide trichotomy, or invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier in Definition 1973.1. The endpoint rows X, Y supply the two positive Real names, and the arithmetic and geometric midpoint rows A, G are the only rows that can narrow the displayed interval for the next finite request.

Apply the obligation theorem Definition 1973.2. Its tolerance accounting and window handoff clauses force the dyadic arithmetic and scale data through D, then the finite observations through S, and finally the regular rational readback through Q before any terminal real-facing row is consumed.

Use the Real-seal handoff of Definition 1973.3. The seal row E and the structural rows H, C, P, N preserve the same contracted finite route, so no selected quotient equality, external square-root selector, trichotomy witness, or ambient completeness principle can be inserted after the window has been read. □

Falsifiable prediction: Every $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ precision read factors through two positive RealUp endpoint rows, arithmetic midpoint data, geometric midpoint and square-root data, a DyadicToleranceScale ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, real-abs, regular-cauchy-square-root, dyadic-tolerance-scale, streamname, regseqrat: $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two positive endpoint rows, arithmetic midpoint routing, geometric midpoint square-root routing, dyadic tolerance accounting, finite window selection, regular readback, terminal Real-seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmeticGeometricMean}^{\uparrow}}$.

Constructive story: An $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ packet is generated from two positive RealUp endpoint rows, one arithmetic midpoint row, one geometric midpoint routed through RegularCauchySquareRoot, a DyadicToleranceScale ledger, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArithmeticGeometricMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1973.1, Definition 1973.2, Definition 1973.3, and Definition 1973.4 seed the finite constructive arithmetic-geometric mean route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArithmeticGeometricMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient Cauchy equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, positivity routing, midpoint discipline, tolerance accounting, window/readback handoff, Real-seal non-escape, transport/replay/provenance coverage, and exclusion for BEDC.Derived.ArithmeticGeometricMeanUp.

Chapter 1974

A Concrete Naming Certificate for $\mathsf{KroneckerApproximation}^{\uparrow}$

Following Hardy–Wright and Cassels on Kronecker approximation, the $\mathsf{KroneckerApproximation}^{\uparrow}$ packet names only the finite orbit-window route by which a displayed multiplier sends a source real name into a target tolerance window. It records finite orbit-window data, rational multiplier ledgers, dyadic tolerance rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RealRationalApproximation}^{\uparrow}$ handoff, and a terminal $\mathsf{Real}^{\uparrow}$ seal. The packet consumes the denominator-bounded route of chapter 1871, the rational-tree witnesses of chapter 1704 and chapter 1759, the dyadic tolerance ledger of chapter 291, and the real-facing approximation surface of chapter 1668; it does not import quotient reals, selected infinite orbits, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1974.1 (Kronecker approximation carrier)**.** *A* $\mathsf{KroneckerApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, M, D, T, U, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-name row. It exposes only the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows of the source point requested by the approximation read.*
2. *W is the target orbit-window row. It stores the finite list of requested orbit indices, target rational windows, and comparison slots visible to the certificate.*
3. *M is the integer and rational multiplier ledger. It records the inspected integer multiples, rational multiplier presentations, denominator bounds, and visible arithmetic comparisons.*
4. *D is the* $\mathsf{DirichletApproximation}^{\uparrow}$ *handoff row. It supplies the denominator-bounded rational-approximation request from which the multiplier ledger may be read.*
5. *T is the Stern–Brocot or Farey witness row. It records the finite branch, mediant, or neighboring-fraction data certifying the rational candidate used by D.*
6. *U is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the dyadic tolerance, slack ledger, and endpoint comparisons used to accept the finite orbit window.*
7. *G is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target reads inspected by the orbit request.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It converts the displayed StreamName windows into regular rational data before any real-facing approximation handoff is exposed.*

9. *E is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff row. It packages the multiplier ledger, target window, dyadic tolerance, StreamName windows, and RegSeqRat readback as a finite approximation surface.*

10. *H is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It can be read only after $S, W, M, D, T, U, G, R, E$ have been displayed.*

11. *C stores componentwise* hsame *transport and displayed* Cont *replay for the source name, target window, multiplier ledger, Dirichlet handoff, Stern–Brocot or Farey witness, dyadic tolerance, StreamName window, RegSeqRat readback, RealRationalApproximation handoff, Real seal, provenance, and local naming rows.*

12. *P is the* Pkg *provenance over* $\mathsf{KroneckerApproximation}^{\uparrow}$, $\mathsf{DirichletApproximation}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{KroneckerApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, M, D, T, U, G, R, E, H, C, P, N$. It has no coordinate for host real equality, quotient real representatives, trichotomy, countable choice, a selected infinite orbit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.KroneckerApproximationUp.KroneckerApproximationTasteGate single carrier alignment`

Theorem 1974.2 (Kronecker approximation NameCert obligations)**.** *For every accepted* $\mathsf{KroneckerApproximation}^{\uparrow}$ *carrier*

$$K = (S, W, M, D, T, U, G, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KroneckerApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source real name, target orbit window, multiplier ledger, Dirichlet handoff, Stern–Brocot or Farey witness, dyadic tolerance, StreamName window, RegSeqRat readback, RealRationalApproximation handoff, Real seal, transport and replay ledger, provenance, and local naming row;*

2. *orbit-window stability, requiring each accepted target comparison to be read from the finite window W and preserved by the multiplier ledger M;*

3. *rational multiplier source, requiring every exported integer or rational multiple to pass through M and the denominator-bounded handoff D before it can be used by the orbit window;*

4. *diophantine approximation handoff, requiring the rational candidate to be witnessed through D and the Stern–Brocot or Farey row T rather than through an external selector;*

5. *real-seal factorization, requiring every real-facing approximation read to pass through U, G, R, E and then the terminal seal H;*

6. *ledger non-escape, requiring C, P, N to preserve, source, and name only the displayed rows and to exclude host real equality, quotient real representatives, trichotomy, countable choice, selected infinite orbits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Theorem 1974.3 (Kronecker approximation finite orbit window)**.** *Every accepted* $\mathsf{KroneckerApproximation}^{\uparrow}$ *approximation read reaching a* $\mathsf{RealRationalApproximation}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

Closure status for NameCert$_{\text{KroneckerApproximation}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{KroneckerApproximation}^{\uparrow}}$, seed)

Scope closed: Definition 1974.1, Definition 1974.2, and Definition 1974.3 seed the finite Kronecker approximation route through orbit windows, rational multipliers, dyadic tolerance, StreamName, RegSeqRat, RealRationalApproximation, and terminal Real rows.

Formal verification: FormalStatus(NameCert$_{\text{KroneckerApproximation}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.KroneckerApproximationUp.KroneckerApproximationTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient real representatives, trichotomy, countable choice, selected infinite orbits, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, orbit-window stability, rational multiplier sourcing, diophantine approximation handoff, real-seal factorization, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.KroneckerApproximationUp.

Constructive story: A KroneckerApproximation$^{\uparrow}$ packet is generated from source real-name windows, a target orbit window, integer and rational multiplier ledgers, a DirichletApproximation handoff, a SternBrocot or FareySequence witness row, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a RealRationalApproximation handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1975

A Concrete Naming Certificate for $\mathsf{LocatedCutApproximation}^{\uparrow}$

Following Bishop and Bridges on located real-number data, the $\mathsf{LocatedCutApproximation}^{\uparrow}$ packet records the finite approximation layer between the located lower/upper dyadic windows of chapter 404 and the regular-Cauchy route consumed by chapter 301 and chapter 38. It keeps the refusal boundary of chapter 1745 intact: the packet observes located cut windows and hands them to the Cauchy-facing route, while chapter 1424 remains only a comparison sibling. Its dependency surface is the finite dyadic ledger of chapter 291, the stream-window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The chapter names only finite observation and handoff rows; it is not a Dedekind construction of $\mathsf{Real}^{\uparrow}$, a quotient-cut object, a selected supremum, trichotomy, choice, Quot.sound, propext, or ambient completeness.

Definition 1975.1 (Located cut approximation carrier)**.** *A* $\mathsf{LocatedCutApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, U, W, A, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located dyadic row read from* $\mathsf{LocatedCut}^{\uparrow}$*, recording finite rational witnesses below the cut.*
2. *U is the upper located dyadic row read from* $\mathsf{LocatedCut}^{\uparrow}$*, recording finite rational witnesses above the cut.*
3. *W is the located window row binding the lower and upper dyadic observations to one inspected precision request.*
4. *A is the approximation row, storing the finite midpoint, endpoint, or bracket readback exported by L, U, W.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the approximation row is read as finite stream data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained after the displayed stream windows and approximation row have been fixed.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing dyadic radii, slack comparisons, and endpoint budgets used by W, A, S, R.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, W, A, S, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the lower row, upper row, located window, approximation row, stream windows, regular handoff, dyadic ledger, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$L, U \longmapsto W \longmapsto A \longmapsto S \longmapsto R \longmapsto D \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{LocatedCutApproximation}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCutApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, W, A, S, R, D, E, H, C, P, N$. It has no coordinate for quotient cuts, selected suprema, trichotomy, choice, Quot.sound*, propext, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedCutApproximationUp.LocatedCutApproximationTasteGate single carrier alignment`

Theorem 1975.2 (Located cut approximation NameCert obligations)**.** *For every accepted* LocatedCutApproximatio *carrier*

$$Q = (L, U, W, A, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCutApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed lower row, upper row, located window, approximation row, stream windows, regular-Cauchy handoff, dyadic tolerance ledger, Real seal, and structural rows H, C, P, N;*

2. *located-window exposure, requiring every approximation request to display both L and U through the common window row W before any stream or regular-Cauchy read can be consumed;*

3. *approximation exactness, requiring A to store only finite dyadic readback data obtained from L, U, W and the tolerance ledger D;*

4. *stream-window readiness, requiring S to expose the finite* $\mathsf{StreamName}^{\uparrow}$ *windows used by the approximation row before R is read;*

5. *regular-Cauchy handoff, requiring R to be the only route by which the located-window approximation becomes a* $\mathsf{RegSeqRat}^{\uparrow}$ *row;*

6. *Real-seal factorization, requiring every downstream read of E to pass through L, U, W, A, S, R, D and the structural rows;*

7. *transport, replay, and provenance non-escape, requiring H, C, P, N to preserve and name exactly the displayed rows, with no Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, quotient cut, selected supremum, trichotomy, choice,* Quot.sound*, propext, ambient completeness, Lean verification, or bridge credential.*

No located-cut approximation obligation is stored outside these rows.

Proof. Project the accepted packet $Q = (L, U, W, A, S, R, D, E, H, C, P, N)$. Carrier admission exposes exactly the lower and upper located dyadic rows, the common located window, the finite

approximation row, the stream windows, the regular-Cauchy handoff, the dyadic tolerance ledger, the Real seal, and the four structural rows.

The located-window obligation is the projection to W together with its source rows L and U. A precision request cannot inspect a lower row or an upper row separately and then enter the Cauchy route; the common window row records the finite bracket in which both sides are read.

Approximation exactness is then the projection to A and D. The approximation row stores only the displayed dyadic readback supported by the tolerance ledger, so it cannot introduce quotient-cut equality, a selected supremum, trichotomy, or choice.

The stream and regular handoff obligations are the projections to S and R. The stream row exposes the finite windows used by the approximation, and the regular row is downstream of those windows rather than a detached regular representative.

Finally, the Real seal and structural rows exhaust the boundary. The seal E is downstream of L, U, W, A, S, R, D, while H, C, P, N transport, replay, name, and source only those displayed rows. Hence no Dedekind construction of $\mathsf{Real}^{\uparrow}$, quotient cut, selected supremum, trichotomy, choice, $\mathsf{Quot.sound}$, propext, ambient completeness, Lean verification, or bridge credential is exported. □

Theorem 1975.3 (Located cut approximation regular-Cauchy handoff)**.** *For every accepted* LocatedCutApproximat *carrier*

$$Q = (L, U, W, A, S, R, D, E, H, C, P, N),$$

every $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* Q *factors through the displayed route*

$$\mathsf{LocatedCut}^{\uparrow} \longrightarrow \mathsf{LocatedCutApproximation}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}$$

by reading the finite rows $L, U, W, A, S, R, D, H, C, P, N$*. In particular, the handoff does not use a Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, quotient cut equality, a selected supremum, trichotomy, choice,* $\mathsf{Quot.sound}$*, propext, or ambient completion data.*

Proof. Begin with a regular-Cauchy consumer. Carrier projection exposes the handoff row R only after the source located rows L, U, the common located window W, the approximation row A, the stream windows S, and the dyadic tolerance ledger D have been displayed.

The route inspection is finite. The lower and upper located rows determine the observed bracket, W binds them to a single precision request, A records the approximation readback, and S opens exactly the stream windows used by that readback.

The handoff row R is therefore downstream of the displayed stream route. Componentwise transport and replay through H and C preserve the same order, while P and N only name the visible packet.

Since no carrier coordinate stores quotient cuts, selected suprema, trichotomy data, choice data, $\mathsf{Quot.sound}$, propext, or ambient completeness, no $\mathsf{RegSeqRat}^{\uparrow}$ read exported by the packet can factor through those excluded sources. □

Theorem 1975.4 (Located cut approximation Real-seal nonescape)**.** *For every accepted* $\mathsf{LocatedCutApproximation}^{\uparrow}$ *carrier*

$$Q = (L, U, W, A, S, R, D, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* E *receives only the displayed located-window approximation route*

$$L, U, W, A, S, R, D, E, H, C, P, N.$$

The seal is not a Dedekind construction of $\mathsf{Real}^{\uparrow}$*, not a quotient-cut completion, not a selected supremum, not a trichotomy witness, not a choice object, not a* $\mathsf{Quot.sound}$ *or propext bridge, and not an ambient completeness theorem.*

Proof. Start from the terminal seal E. In the carrier, E is not an independent real-completion coordinate; it is the endpoint of the displayed route through the located lower and upper rows, the common located window, the finite approximation row, the stream windows, the regular handoff, and the dyadic tolerance ledger.

Trace the route backward. The Real-facing read reaches E only after R has been read, R only after S and A have been displayed, and A only after the lower and upper located rows have been bound by W and checked against D.

The structural coordinates do not add a second seal source. The transport row H is componentwise, the replay row C displays the same route order, and the provenance and local certificate rows P, N name this packet rather than importing a host completion principle.

Thus every Real-facing consumer is confined to $L, U, W, A, S, R, D, E, H, C, P, N$. The excluded Dedekind, quotient-cut, selected-supremum, trichotomy, choice, Quot.sound, propext, and ambient-completeness readings are outside the carrier inventory. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCutApproximation}^{\uparrow}$ packet is generated from lower and upper located dyadic rows, a common located window, a finite approximation row, StreamName windows, a RegSeqRat handoff, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCutApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1975.1, Definition 1975.2, Definition 1975.3, and Definition 1975.4 seed the finite located-window approximation packet between located-cut observations and regular-Cauchy Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCutApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Dedekind construction of $\mathsf{Real}^{\uparrow}$, quotient cuts, selected suprema, trichotomy, choice, Quot.sound, propext, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window exposure, approximation exactness, stream-window readiness, regular-Cauchy handoff, Real-seal factorization, transport/replay/provenance coverage, and non-escape for BEDC.Derived.LocatedCutApproximationUp.

Chapter 1976

A Concrete Naming Certificate for $\mathsf{SignedBinaryExpansion}^{\uparrow}$

Following Avizienis signed-digit arithmetic and Bishop–Bridges constructive analysis, the $\mathsf{SignedBinaryExpansion}^{\uparrow}$ packet records finite signed-binary real readback before any real-name consumer may treat a signed prefix as a terminal seal. It sits after the raw binary expansion prefix surface of chapter 418 and the endpoint uniqueness boundary of chapter 420, while using the signed-digit stream handoff of chapter 316, the dyadic ledger of chapter 291, the finite schedule of chapter 126, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet is a finite readback certificate for displayed sign and digit windows; it is not quotient stream equality, not a selected representative of an infinite expansion, and not an ambient completeness principle.

Definition 1976.1 (SignedBinaryExpansion carrier)**.** *A* $\mathsf{SignedBinaryExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, B, U, D, W, E, Y, R, L, H, C, P, N)$$

with the following visible rows:

1. *Q is the sign row, exposing the displayed positive, negative, or zero-facing prefix orientation used by the readback.*
2. *B is the accepted binary expansion finite prefix row whose unsigned digit windows are read before signs are attached.*
3. *U is the accepted* $\mathsf{BinaryEndpointUniqueness}^{\uparrow}$ *row recording the endpoint-normalization data and excluding a second binary endpoint convention.*
4. *D is the signed digit-prefix row, displayed as the local signed-binary digit window before it is handed to the signed stream interface.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule selecting exactly the observed digit prefixes and their requested precisions.*
6. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *enclosure row recording the dyadic center and radius attached to the signed prefix window.*
7. *Y is the signed-digit stream handoff row that repacks the sign, digit-prefix, carry, and endpoint data as a signed-digit stream window.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed window schedule and dyadic enclosure rows.*

9. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, B, U, D, W, E, Y, R have been displayed.*
10. *H records componentwise* hsame *transport for the sign, binary prefix, endpoint-normalization, signed digit, window, enclosure, stream handoff, regular handoff, and seal rows.*
11. *C records displayed* Cont *replay from a consumer request through the sign and digit windows, then the endpoint-normalization row, dyadic enclosure rows, signed-digit stream handoff, regular rational handoff, and terminal seal.*
12. *P is the* Pkg *provenance over* $\mathsf{SignedBinaryExpansion}^{\uparrow}$*, the binary expansion prefix surface,* $\mathsf{BinaryEndpointUniqueness}^{\uparrow}$*, the signed-digit stream handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedBinaryExpansion}^{\uparrow}}$ *row.*

The carrier predicate accepts only these finite rows. It has no coordinate for quotient stream equality, an infinite selected representative, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.SignedBinaryExpansionUp`

Theorem 1976.2 (SignedBinaryExpansion NameCert obligations)**.** *For every accepted* $\mathsf{SignedBinaryExpansion}^{\uparrow}$ *carrier $S = (Q, B, U, D, W, E, Y, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SignedBinaryExpansion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the sign row, binary prefix row, endpoint-normalization row, signed digit-prefix row, finite window schedule, dyadic enclosure row, signed-digit stream handoff, regular rational handoff, Real seal, componentwise transport, continuation replay, provenance, and local naming;*
2. *endpoint-normalization exactness, requiring U to be consumed before any signed digit prefix is interpreted as a unique endpoint readback;*
3. *signed-window stability, requiring D and W to be preserved componentwise under the displayed* hsame *transport H and replayed by the displayed* Cont *row C;*
4. *dyadic enclosure visibility, requiring every regular rational or real-name consumer to inspect the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row E before reading Y, R, or L;*
5. *handoff order, requiring the signed-digit stream row Y to precede the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the terminal* $\mathsf{Real}^{\uparrow}$ *seal L;*
6. *provenance locality, requiring the package row P and local NameCert row N to expose no quotient stream equality, selected representative, trichotomy, countable-choice selector, or ambient completeness coordinate.*

No signed-binary expansion obligation is stored outside these rows.

Proof. Project the carrier of Definition 1976.1. The tuple exposes exactly the sign, binary prefix, endpoint-normalization, signed digit, window schedule, dyadic enclosure, signed-stream handoff, regular handoff, real seal, and structural rows.

The endpoint-normalization clause is separate from the raw prefix read. The row B supplies only finite binary windows, while U supplies the endpoint-normalization data inherited from chapter 420.

The signed-window clause then reads D under the finite schedule W. Transport through H and replay through C preserve the same displayed rows before any downstream consumer is allowed to inspect the enclosure row E.

The handoff rows are ordered. The signed digit stream row Y reads the sign and digit-prefix data first, the regular rational row R reads the scheduled dyadic enclosures next, and the real seal L is terminal.

Finally, P and N record only the package and local naming route. Since quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, and ambient completeness are absent from the tuple, the listed rows exhaust the seed obligation surface. □

Theorem 1976.3 (SignedBinaryExpansion real readback boundary)**.** *Let $S = (Q, B, U, D, W, E, Y, R, L, H, C, P, N$ be an accepted* $\mathsf{SignedBinaryExpansion}^{\uparrow}$ *carrier. Every finite signed-binary readback consumed as a regular rational name or as a terminal real-name seal factors through the displayed route*

$$Q, B, U, D, W \longmapsto E \longmapsto Y \longmapsto R \longmapsto L$$

with structural support H, C, P, N. Thus the consumer receives a sign row, finite binary prefix row, endpoint-normalization row, signed digit-prefix window, dyadic enclosure row, signed-digit stream handoff, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal, all as finite BEDC data.*

The boundary supplies no quotient equality of streams, no selected representative of an infinite expansion, no trichotomy row, no countable-choice row, no host real equality, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.SignedBinaryExpansionUp.SignedBinaryExpansionCarrier real readback boundary`

Proof. Start with a downstream consumer of R or L. By the carrier definition, neither row is an independent real object; both are downstream of the displayed sign and digit-window route.

The consumer first reads the sign row Q, the raw binary prefix row B, and the endpoint-normalization row U. These rows fix the finite signed-prefix presentation and the endpoint convention before any dyadic enclosure is visible.

Next the schedule W selects the observed digit prefix D and exposes the dyadic enclosure E. The enclosure row is the only row that a regular rational or real-name consumer may inspect as a numeric readback of the prefix.

The signed digit stream handoff Y repacks the same finite data for signed-stream consumers, and the regular handoff R reads that package before the terminal seal L is available.

The structural rows H, C, P, N transport, replay, package, and name the same route. Because no excluded coordinate appears in the packet, every real readback remains inside the displayed finite boundary. □

Lean4 ✓ `BEDC.Derived.SignedBinaryExpansionUp.TasteGate.SignedBinaryExpansion real readback boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{SignedBinaryExpansion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedBinaryExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1976.1, Definition 1976.2, and Definition 1976.3 seed the finite signed-binary readback route from binary endpoint normalization through signed-digit stream windows, dyadic enclosures, regular rational handoff, and terminal real seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedBinaryExpansion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-normalization exactness, signed-window stability, dyadic enclosure visibility, handoff order, and real readback boundary proofs for the same packet.

Constructive story: A $\mathsf{SignedBinaryExpansion}^{\uparrow}$ packet is generated from a sign row, finite BinaryExpansion prefix row, BinaryEndpointUniqueness row, signed digit-prefix window, StreamName schedule, DyadicRatCore enclosure row, SignedDigitStream handoff, RegSeqRat handoff, terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1977

A Concrete Naming Certificate for $\mathsf{LesserLimitedOmniscience}^{\uparrow}$

Following Brouwer, Bishop–Bridges, and Troelstra–van Dalen constructive analysis, the $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ packet records the finite boundary at which a two-alternative inspection may be named without accepting lesser limited omniscience as a global principle. It is read beside the Specker obstruction of chapter 1406, the Markov boundary of chapter 1666, the fan-theorem boundary of chapter 400, the stream schedule of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a Real/Completion boundary object: it displays the finite rows a consumer may inspect before any $\mathsf{Real}^{\uparrow}$ seal read and refuses every route from those rows to LPO, trichotomy, quotient real equality, selected limits, countable choice, open-cover compactness, or ambient real completeness.

Definition 1977.1 (Lesser limited omniscience carrier)**.** *A* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A_0, A_1, S, R, D, E, W, H, C, P, N)$$

with the following displayed coordinates:

1. *A_0 is the first alternative row, naming the finite schedule branch on which the left disjunct would be certified if the inspected evidence reaches it.*
2. *A_1 is the second alternative row, naming the finite schedule branch on which the right disjunct would be certified if the inspected evidence reaches it.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row listing the finite stream requests admitted by the boundary.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational values actually inspected from S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the dyadic radii, endpoint comparisons, and finite margin rows used to keep A_0 and A_1 apart.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the rows A_0, A_1, S, R, D have been displayed.*
7. *W is the refusal/witness row: it either records the displayed finite alternative witnessed by the inspected packet or records the finite refusal that no global LLPO principle is exported.*
8. *H stores componentwise* hsame *transport for the two alternative rows, stream schedule, regular-rational readback, dyadic ledger, real seal, witness/refusal row, continuation row, provenance row, and local name.*

9. *C stores* Cont *replay from finite stream requests through R and D, then through the alternative rows A_0, A_1, and finally into the sealed real-facing row W.*
10. *P records* Pkg *provenance over* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}$ *row.*

The carrier has no coordinate for imported LLPO, LPO, trichotomy, countable choice, quotient stream equality, quotient real equality, selected limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LesserLimitedOmniscienceUp.LesserLimitedOmniscienceTasteGate single carrier alignment`

Theorem 1977.2 (Lesser limited omniscience NameCert obligations)**.** *For every accepted* LesserLimitedOmniscience *carrier $L = (A_0, A_1, S, R, D, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier exposure for the two alternative rows, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, refusal/witness row, transport, continuation, package, and local naming rows;*
2. *classifier componentwise transport, requiring every comparison between packets to use the* hsame *rows stored in H coordinate by coordinate;*
3. *alternative-row disjointness, requiring any accepted left/right alternative to cite the displayed dyadic separation and finite margin data in D;*
4. *real-seal handoff, requiring every Real/Completion consumer to reach E only after the schedule, readback, ledger, alternatives, and refusal/witness row have been displayed;*
5. *ledger nonescape from imported LLPO, LPO, trichotomy, countable choice, quotient stream equality, quotient real equality, selected limits, open-cover compactness, and ambient real completeness.*

No NameCert obligation is stored outside these five rows.

Proof. Carrier exposure is projection from Definition 1977.1. The visible data are the two alternative rows A_0, A_1, the schedule S, readback R, tolerance ledger D, terminal seal E, refusal/witness row W, and structural rows H, C, P, N.

Classifier transport is componentwise because the packet offers no aggregate classifier coordinate. A comparison of accepted packets must therefore use the displayed hsame rows in H for each alternative, readback, ledger, seal, witness, replay, provenance, and local name.

Alternative-row disjointness is forced by the tolerance ledger D. A branch may expose an alternative only by naming a dyadic radius, endpoint comparison, and finite margin row already present in the ledger; otherwise W records only the refusal of a global disjunctive principle.

The real-seal handoff is downstream of E, and the replay path is supplied by C. Since the carrier contains no coordinate for imported LLPO, LPO, trichotomy, choice, quotient equality, selected limits, open-cover compactness, or ambient completeness, those principles cannot be exported through the local $\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}$ row. □

Theorem 1977.3 (Lesser limited omniscience nonescape)**.** *Every Real/Completion consumer of an accepted* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ *packet receives only the two displayed alternative rows, finite*

schedule, regular-rational readback, dyadic ledger, terminal real seal, refusal/witness row, componentwise transport, continuation replay, provenance, and local NameCert row. It receives no imported LLPO, no LPO, no trichotomy, no countable choice, no quotient stream equality, no quotient real equality, no selected limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Let a Real/Completion consumer accept $L = (A_0, A_1, S, R, D, E, W, H, C, P, N)$. By Definition 1977.1, the only real-facing coordinate is the seal E, and that seal is reached after the two alternatives, stream schedule, regular-rational readback, dyadic ledger, and refusal/witness row have been displayed.

The consumer's branch information is therefore finite. It can replay the schedule through R, cite only dyadic tolerance rows from D, and transport the two alternatives through H and C.

No omitted semi-classical or completion principle is a coordinate of the packet. Thus factorization through the displayed rows cannot export imported LLPO, LPO, trichotomy, countable choice, quotient stream equality, quotient real equality, selected limits, or ambient real completeness. □

Theorem 1977.4 (Specker, Markov, and fan boundary factorization)**.** *Every* $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, *or* $\mathsf{FanTheorem}^{\uparrow}$ *consumer using an accepted* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ *packet factors through the displayed finite rows*

$$A_0, A_1, S, R, D, E, W, H, C, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *seal read.*

Proof. The carrier names the two alternatives and the finite stream schedule before the real seal. Thus a Specker consumer can inspect only the displayed obstruction-facing schedule and readback rows S, R before it reaches E.

A Markov-boundary consumer reaches its negative-evidence boundary through the same finite rows. It may cite W as a refusal/witness row, but W is downstream of A_0, A_1, S, R, D and therefore cannot introduce an unlisted principle.

A fan-theorem consumer likewise receives only the finite branch rows and the dyadic ledger before the seal. Componentwise transport in H and continuation replay in C preserve this route, while P and N repackage the same finite data as the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}$.

Constructive story: A $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ packet is generated from two disjoint alternative rows, a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, refusal/witness row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1977.1, Definition 1977.2, Definition 1977.3, and Definition 1977.4 seed the finite LLPO boundary for Real/Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LesserLimitedOmniscience}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LesserLimitedOmniscienceUp.LesserLimitedOmniscienceTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not claim LLPO as a global principle, LPO, trichotomy, countable choice, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier componentwise transport, alternative-row disjointness, real-seal handoff, Specker/Markov/Fan factorization, and ledger nonescape for the same finite packet.

Chapter 1978

A Concrete Naming Certificate for $\mathsf{LLPOBoundary}^{\uparrow}$

Following Brouwer and Bishop–Bridges constructive analysis, the $\mathsf{LLPOBoundary}^{\uparrow}$ packet records the finite Real/Completion boundary at which a binary zerohood inspection may be named without importing limited principles of omniscience. It is read beside the Ishihara inspection packet of chapter 1665, the Specker obstruction of chapter 1406, the Markov boundary of chapter 1666, the stream schedule of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a positive refusal surface for later real-comparison and completion arguments: consumers may cite the displayed finite rows, but they do not receive an imported LLPO principle, an LPO test, a WLPO test, trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

YoungIntegral-style controlled Riemann-sum consumers may read this boundary only as the finite zerohood and refusal surface used by chapter 3910; the read supplies no binary decision rule for choosing a hidden mesh branch.

Definition 1978.1 (LLPO boundary carrier)**.** *An* $\mathsf{LLPOBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Z_0, Z_1, S, R, D, E, W, H, C, P, N)$$

with the following displayed coordinates:

1. Z_0 *is the left zerohood row, naming the finite stream positions whose vanishing would certify the left inspection alternative.*
2. Z_1 *is the right zerohood row, naming the finite stream positions whose vanishing would certify the right inspection alternative.*
3. S *is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row listing the finite stream requests admitted by the boundary.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational values actually inspected from* S*.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the dyadic radii, endpoint comparisons, and finite margin rows used to keep the two zerohood rows apart.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after* Z_0, Z_1, S, R, D *have been displayed.*
7. W *is the refusal row recording that the accepted packet exports only the displayed finite comparison data and no global LLPO decision rule.*

8. *H stores componentwise* hsame *transport for the two zerohood rows, stream schedule, regular-rational readback, dyadic ledger, real seal, refusal row, continuation row, provenance row, and local name.*

9. *C stores* Cont *replay from finite stream requests through R and D, then through the zerohood rows Z_0, Z_1, and finally into the sealed real-facing refusal row W.*

10. *P records* Pkg *provenance over* $\mathsf{LLPOBoundary}^{\uparrow}$, $\mathsf{IshiharaTrick}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for imported LLPO, LPO, WLPO, trichotomy, quotient real equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LLPOBoundaryUp.LLPOBoundaryTasteGate single carrier alignment`

Theorem 1978.2 (LLPO boundary NameCert obligations)**.** *For every accepted* $\mathsf{LLPOBoundary}^{\uparrow}$ *carrier $B = (Z_0, Z_1, S, R, D, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier exposure for the two zerohood rows, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, refusal row, transport, continuation, package, and local naming rows;*

2. *classifier componentwise transport, requiring every comparison between packets to use the* hsame *rows stored in H coordinate by coordinate;*

3. *zerohood separation, requiring any accepted left/right inspection to cite the displayed dyadic separation and finite margin data in D;*

4. *real-seal handoff, requiring every Real/Completion consumer to reach E only after the schedule, readback, ledger, zerohood rows, and refusal row have been displayed;*

5. *ledger nonescape from imported LLPO, LPO, WLPO, trichotomy, quotient real equality, countable choice, selected limits, and ambient real completeness.*

No NameCert obligation is stored outside these five rows.

Proof. Carrier exposure is projection from Definition 1978.1. The visible data are the two zerohood rows Z_0, Z_1, the schedule S, readback R, tolerance ledger D, terminal seal E, refusal row W, and structural rows H, C, P, N.

Classifier transport is componentwise because the packet offers no aggregate classifier coordinate. A comparison of accepted packets must use the displayed hsame rows in H for each zerohood row, readback, ledger, seal, refusal, replay, provenance, and local name.

Zerohood separation is forced by the tolerance ledger D. A consumer may inspect a left/right zerohood alternative only by naming a dyadic radius, endpoint comparison, and finite margin row already present in the ledger; otherwise W records only refusal of a global binary decision rule.

The real-seal handoff is downstream of E, and the replay path is supplied by C. Since the carrier contains no coordinate for imported LLPO, LPO, WLPO, trichotomy, quotient real equality, choice, selected limits, or ambient completeness, those principles cannot be exported through the local $\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$ row. □

Theorem 1978.3 (LLPO boundary real-comparison refusal)**.** *Every Real/Completion consumer of an accepted* $\mathsf{LLPOBoundary}^{\uparrow}$ *packet receives only the two displayed zerohood rows, finite schedule,*

regular-rational readback, dyadic ledger, terminal real seal, refusal row, componentwise transport, continuation replay, provenance, and local NameCert row. It receives no imported LLPO, no LPO, no WLPO, no trichotomy, no quotient real equality, no countable choice, no selected limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Let a Real/Completion consumer accept $B = (Z_0, Z_1, S, R, D, E, W, H, C, P, N)$. By Definition 1978.1, the only real-facing coordinate is the seal E, and that seal is reached after the two zerohood rows, stream schedule, regular-rational readback, dyadic ledger, and refusal row have been displayed.

The consumer's comparison information is therefore finite. It can replay the schedule through R, cite only dyadic tolerance rows from D, and transport the two zerohood rows through H and C.

No omitted semi-classical or completion principle is a coordinate of the packet. Thus factorization through the displayed rows cannot export imported LLPO, LPO, WLPO, trichotomy, quotient real equality, countable choice, selected limits, or ambient real completeness. □

Theorem 1978.4 (LLPO boundary Young-integral nonescape)**.** *Every* $\mathsf{YoungIntegral}^{\uparrow}$ *or controlled Riemann-sum consumer of an accepted* $\mathsf{LLPOBoundary}^{\uparrow}$ *packet reads only the displayed zerohood rows* Z_0, Z_1*, stream schedule* S*, regular-rational readback* R*, dyadic tolerance ledger* D*, Real seal* E*, refusal row* W*, transport row* H*, replay row* C*, provenance row* P*, and local name* N*. It may use those rows as a finite boundary for mesh and tolerance comparisons, but it receives no imported LLPO, LPO, WLPO, trichotomy, quotient real equality, countable choice, selected limit, ambient Real completeness, or hidden branch selector.*

Proof. Start with the real-comparison refusal theorem Definition 1978.3. It confines every Real/Completion consumer to $Z_0, Z_1, S, R, D, E, W, H, C, P, N$.

A controlled Riemann-sum consumer uses only finite comparison data. The stream schedule, regular readback, and dyadic ledger supply the same kind of finite mesh and tolerance rows that the $\mathsf{YoungIntegral}^{\uparrow}$ packet reads through its controlled-window and Riemann-sum route.

The refusal row W remains part of the handoff. Since W records absence of imported semi-classical decision principles, the Young-integral consumer cannot turn zerohood data into a hidden branch choice or selected refinement.

Transport, replay, provenance, and local naming preserve the same finite route. Therefore the controlled-sum consumer receives a zerohood boundary and refusal guard, not a decision principle or completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$.

Constructive story: An $\mathsf{LLPOBoundary}^{\uparrow}$ packet is generated from two zerohood rows, a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, refusal row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 1978.1, Definition 1978.2, and Definition 1978.3 seed the finite Real/Completion boundary for binary zerohood inspection.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LLPOBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim imported LLPO, LPO, WLPO, trichotomy, quotient real equality, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier componentwise transport, zerohood separation, real-seal handoff, real-comparison refusal, and ledger nonescape for the same finite packet.

Chapter 1979

A Concrete Naming Certificate for $\mathsf{CompactCauchyCover}^{\uparrow}$

Following Bishop and Bridges on totally bounded metric data and constructive Cauchy approximation, the $\mathsf{CompactCauchyCover}^{\uparrow}$ packet records the finite cover-window layer that can feed a regular-Cauchy real route without importing open-cover compactness. It reads the compact metric carrier of chapter 129, the finite stream-window interface of chapter 126, the rational regular sequence handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion arguments a finite route from displayed cover windows to Cauchy data while leaving selected subcovers, quotient stream equality, choice, and detached $\mathsf{Real}^{\uparrow}$ completeness outside the certificate.

Definition 1979.1 (Compact Cauchy cover carrier)**.** *A* $\mathsf{CompactCauchyCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the carried metric endpoints, metric classifier, finite total-boundedness windows, and visible compact-metric provenance.*
2. *W is the finite cover-window row. For each inspected precision request it lists finitely many displayed metric windows, their centers, and the local membership probes used by the Cauchy-facing route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, storing the dyadic cover radii, shrinkage comparisons, overlap tolerances, and the monotone budget used when windows are refined.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, exposing the finite order in which accepted cover windows are read as stream data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, obtained only after W, D, S have fixed the window, radius, and stream schedule data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the regular-Cauchy readback and never as an independent real-completion coordinate.*
7. *H records componentwise* hsame *transport for the compact metric row, cover windows, dyadic radius ledger, stream schedule, regular readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the finite route*

$$M \longmapsto W \longmapsto D \longmapsto S \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompactCauchyCover}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, W, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected finite subcovers, quotient stream equality, countable choice, detached $\mathsf{Real}^{\uparrow}$ *completeness, host metric completion, or selected representatives.*

Lean4 ✓ `BEDC.Derived.CompactCauchyCoverUp.TasteGate.CompactCauchyCoverTasteGate single carrier alignment`

Theorem 1979.2 (Compact Cauchy cover NameCert obligations)**.** *For every accepted* $\mathsf{CompactCauchyCover}^{\uparrow}$ *carrier*

$$K = (M, W, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactCauchyCover}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source row, finite cover-window row, dyadic radius ledger, stream schedule, regular-Cauchy readback, Real seal, and structural rows H, C, P, N;*
2. *cover-window finiteness, requiring each inspected precision request to expose only the finitely listed windows and membership probes stored in W;*
3. *dyadic radius discipline, requiring every refinement, overlap read, and tolerance claim to use the ledger D rather than an ambient compactness principle;*
4. *stream schedule readiness, requiring S to display the finite order in which cover windows become stream data before R is read;*
5. *regular-Cauchy handoff, requiring R to be the only route by which the cover-window data becomes a* $\mathsf{RegSeqRat}^{\uparrow}$ *row;*
6. *Real-seal factorization, requiring every downstream read of E to pass through M, W, D, S, R and the structural rows;*
7. *transport, replay, and provenance non-escape, requiring H, C, P, N to preserve and name exactly the displayed rows, with no open-cover compactness, selected subcover, quotient stream equality, choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, host metric completion, or selected representative.*

No compact-Cauchy-cover obligation is stored outside these rows.

Proof. Project the accepted packet $K = (M, W, D, S, R, E, H, C, P, N)$. Carrier admission exposes exactly the compact metric source, the finite cover windows, the dyadic radius ledger, the stream schedule, the regular-Cauchy readback, the Real seal, and the four structural rows.

The cover-window obligation is finite because W is a displayed row of the packet. A precision request may inspect only the centers, windows, and membership probes listed in that row, so it cannot invoke an open-cover compactness theorem or choose a hidden subcover.

The dyadic discipline is the projection to D. Each shrinkage comparison, radius bound, and overlap tolerance used by a refinement is read from the dyadic ledger before any stream or regular-Cauchy coordinate is consumed.

The stream and regular obligations are the projections to S and R. The stream schedule fixes the finite read order of the windows, and the regular readback is downstream of that schedule rather than a detached representative.

Finally, the Real seal and structural rows exhaust the boundary. The seal E is reached only after M, W, D, S, R, while H, C, P, N transport, replay, source, and name this same finite route. Hence the excluded compactness, selection, quotient, choice, completion, and representative coordinates cannot be exported. □

Theorem 1979.3 (Compact Cauchy cover regular handoff)**.** *For every accepted* $\mathsf{CompactCauchyCover}^{\uparrow}$ *carrier*

$$K = (M, W, D, S, R, E, H, C, P, N),$$

every $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer exported by* K *factors through the displayed finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longrightarrow \mathsf{CompactCauchyCover}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff supplies only cover windows, dyadic radii, stream schedule data, regular readback, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not supply open-cover compactness, selected subcovers, quotient stream equality, choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, host metric completion, or selected representatives.*

Proof. Begin with a downstream consumer of R or E. The carrier projection shows that R is available only after the compact metric row M, finite cover windows W, dyadic ledger D, and stream schedule S have been displayed.

The finite route is therefore forced. The compact metric row supplies the metric and total-boundedness surface, W records the windows inspected at the requested precision, D records the radii and tolerance comparisons, and S orders those windows as stream data.

The regular readback row R packages that stream data as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff. The terminal seal E is downstream of R, so a Real-facing consumer receives a sealed Cauchy readback rather than an independent completeness theorem.

Componentwise transport and replay through H and C preserve the same route, while P and N name only the displayed packet. Since the carrier inventory has no open-cover, selected-subcover, quotient-stream, choice, detached-completeness, host-completion, or representative coordinate, none can be consumed downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchyCover}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCauchyCover}^{\uparrow}$ packet is generated from a CompactMetric source row, finite cover windows, a DyadicRatCore radius ledger, a StreamName schedule, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCauchyCover}^{\uparrow}}$, seed)

Scope closed: Definition 1979.1, Definition 1979.2, and Definition 1979.3 seed the finite cover-window route from compact metric data to regular-Cauchy Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCauchyCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient stream equality, choice, detached $\mathsf{Real}^{\uparrow}$ completeness, host metric completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-window finiteness, dyadic radius discipline, stream schedule readiness, regular-Cauchy handoff, Real-seal factorization, transport/replay/provenance coverage, and non-escape for BEDC.Derived.CompactCauchyCoverUp.

The $\mathsf{Cauchy}^{\uparrow}$ hub is read through chapter 126, chapter 301, chapter 291, and chapter 38 before Real-facing completion consumers inspect the Cauchy route.

Chapter 1980

A Concrete Naming Certificate for $\mathsf{CauchySequence}^{\uparrow}$

Bishop–Bridges constructive analysis treats Cauchy sequences as tail-stable observable data before any completed real, quotient representative, or chosen limit is available. The $\mathsf{CauchySequence}^{\uparrow}$ packet records that ordinary sequence layer as a finite NameCert surface between the explicit-modulus route of chapter 1705 and the weak finite-tail route of chapter 1887. It reads finite observations through the $\mathsf{StreamName}^{\uparrow}$ interface of chapter 126, optional threshold data through the $\mathsf{CauchyModulus}^{\uparrow}$ surface of chapter 292, dyadic tolerances through chapter 291, regular rational readback through chapter 301, and its terminal boundary through chapter 38. The packet is the ordinary Cauchy sequence carrier used by Real and Completion consumers; it is not quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Definition 1980.1 (Cauchy sequence carrier)**.** *A* $\mathsf{CauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, T, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row, naming the observable sequence surface whose values are inspected only through displayed finite requests.*
2. *T is the tail-comparison ledger, recording the finite inspected pairs of tail indices and the comparison rows witnessing Cauchy behavior at the displayed tolerances.*
3. *M is an optional* $\mathsf{CauchyModulus}^{\uparrow}$ *row. When present, it gives an explicit threshold schedule; when absent, the packet remains on the ordinary tail-comparison surface rather than the effective-modulus surface.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the inspected source windows used by T and by any downstream readback.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing dyadic radii, slack rows, comparison budgets, and tolerance conversions used by the tail comparisons.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, available only after the source, tail-comparison, optional-modulus, window, and dyadic rows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, read only downstream of S, T, M, W, D, R and never as a selected limit or ambient completeness witness.*

8. *H records componentwise* hsame *transport for the source, tail ledger, optional modulus, finite windows, dyadic ledger, regular handoff, Real boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each Real or Completion request through $S, T, M, W, D, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{WeaklyCauchySequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, M, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1980.2 (Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequence}^{\uparrow}$ *carrier*

$$X = (S, T, M, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source sequence row, tail-comparison ledger, optional modulus, StreamName windows, DyadicRatCore tolerances, RegSeqRat handoff, Real boundary, transport, replay, provenance, and local naming;*
2. *window exactness, requiring every inspected sequence value used by T or R to be read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row W;*
3. *tail-comparison exactness, requiring T to store the finite pairwise tail comparisons that make the ordinary Cauchy evidence visible;*
4. *optional-modulus compatibility, requiring any displayed M row to refine the same tail comparisons without replacing the ordinary packet by the explicit-modulus packet;*
5. *dyadic tolerance accounting, requiring every comparison in T and every readback exported by R to cite the dyadic radii, slack rows, and conversions stored in D;*
6. *regular handoff and Real boundary discipline, requiring R and then E to remain downstream of S, T, M, W, D;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
8. *non-escape for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No ordinary Cauchy-sequence obligation is stored outside these rows.

Proof. Project the carrier of Definition 1980.1. The projection exposes exactly one source sequence row S, one finite tail-comparison ledger T, one optional modulus row M, one finite window row W, one dyadic tolerance ledger D, one regular handoff row R, one terminal Real boundary row E, and the structural rows H, C, P, N.

Window and tail-comparison exactness are forced by the order of the rows. Every inspected sequence value is first read through the finite $\mathsf{StreamName}^{\uparrow}$ window row W, and every ordinary Cauchy assertion visible to the packet is then one of the displayed finite comparisons stored in T.

The optional-modulus clause is conservative. If M is present, it cites the same source, window, and dyadic rows as T; if it is absent, the packet still retains the ordinary tail-comparison ledger. Thus the carrier sits between the explicit-modulus chapter and the weak finite-tail chapter without collapsing into either one.

Dyadic accounting is supplied by D. Since the packet has no other tolerance coordinate, all comparison budgets, slack rows, and conversions used by T or by the regular readback R must pass through that ledger.

Finally, the rows R, E, H, C, P, N export, seal, transport, replay, source, and name the same displayed data. None of those rows adds quotient equality, a selected endpoint, a choice principle, trichotomy, host real equality, completeness of $\mathsf{Real}^{\uparrow}$, Lean evidence, or bridge data, so the listed obligations exhaust the local NameCert surface. □

Theorem 1980.3 (Cauchy sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{CauchySequence}^{\uparrow}$ *carrier* $X = (S, T, M, W, D, R, E, H, C, P, N)$ *factors through the finite route*

$$S \longmapsto W \longmapsto T, M \longmapsto D \longmapsto R \longmapsto H, C, P, N.$$

Consequently a regular rational consumer receives the displayed source, finite StreamName windows, ordinary tail comparisons, any compatible modulus row, dyadic tolerance accounting, transport, replay, provenance, and local naming before it can inspect the handoff.

Proof. Begin with a regular rational consumer of X. By Definition 1980.1, the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate is the handoff row R, and R is downstream of the source, window, tail-comparison, optional-modulus, and dyadic rows.

The source observations are first exposed through the $\mathsf{StreamName}^{\uparrow}$ row W. The ordinary Cauchy information is then the tail-comparison ledger T, while an available modulus row M is read only as a compatible refinement of those displayed comparisons.

The tolerance work is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D. Only after the relevant dyadic radii, slack rows, comparison budgets, and conversions have been displayed can the regular rational handoff R be exported.

The structural rows H, C, P, N preserve and name the same route. Hence every regular rational read factors through the displayed ordinary Cauchy sequence packet and has no bypass through quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient completeness, Lean verification, or bridge checking. □

Theorem 1980.4 (Cauchy sequence L10 sibling lattice)**.** *Any ordinary Cauchy sequence consumer using L10 completion data from an accepted* $\mathsf{CauchySequence}^{\uparrow}$ *carrier*

$$X = (S, T, M, W, D, R, E, H, C, P, N)$$

must expose the sibling route through chapter 126, chapter 292, chapter 291, chapter 301, and chapter 38 before it can read $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing data. The route is the finite lattice* $S, W, T, M, D, R, E, H, C, P, N$*, not a kernel-only completion claim, selected limit, quotient stream equality, or ambient completeness principle.*

Proof. Project the carrier rows of Definition 1980.1. The source row S is inspected only through the finite StreamName windows W, while ordinary tail comparisons are stored in T and any explicit threshold schedule is stored in the optional CauchyModulus row M.

The tolerance data are then forced through the DyadicRatCore ledger D. Thus every comparison that later reaches a regular rational or Real-facing read has already exposed the stream, optional modulus, and dyadic sibling routes.

Apply the RegSeqRat handoff theorem, Definition 1980.3. It places R downstream of S, W, T, M, D and keeps the terminal Real boundary E downstream of the same route.

Finally H, C, P, N transport, replay, source, and name this lattice. Since no row stores a selected limit, quotient stream equality, host real equality, countable choice, trichotomy, or ambient completeness, an L10 completion consumer can read only the displayed sibling route. □

Theorem 1980.5 (Cauchy sequence root stream comparison exhaustion)**.** *Any ordinary Cauchy comparison exported by an accepted* $\mathsf{CauchySequence}^{\uparrow}$ *carrier*

$$X = (S, T, M, W, D, R, E, H, C, P, N)$$

is exhausted by the source sequence row S, finite $\mathsf{StreamName}^{\uparrow}$ *windows W, tail-comparison ledger T, optional modulus row M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{Real}^{\uparrow}$ *seal boundary E, and structural rows H, C, P, N. No comparison exported by X can bypass this route through quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the carrier of Definition 1980.1. The root source is S, and every observed sequence value used by an ordinary comparison must first be read through the finite StreamName windows W.

Use the NameCert obligations of Definition 1980.2. They force tail comparisons through T, optional threshold schedules through M when present, and every tolerance budget through the DyadicRatCore ledger D.

Apply the RegSeqRat handoff of Definition 1980.3. Any regular rational or Real-facing comparison must pass through R and then the terminal seal boundary E, while H, C, P, N transport, replay, source, and name the same route.

Since the carrier has no quotient stream equality, selected limit, countable-choice schedule, trichotomy decision, host real equality, ambient completeness, Lean evidence, or bridge-checking row, the displayed rows exhaust every ordinary root-stream comparison exported by X. □

Falsifiable prediction: Every $\mathsf{CauchySequence}^{\uparrow}$ regular or Real-facing read factors through a source sequence row, finite StreamName windows, tail-comparison ledger, optional CauchyModulus row, DyadicRatCore tolerance ledger, RegSeqRat handoff, RealUp boundary seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, cauchymodulus, dyadicratcore, regseqrat, real, effective-cauchy-sequence, weakly-cauchy-sequence: $\mathsf{CauchySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries ordinary tail comparisons, optional explicit-modulus compatibility, finite stream windows, dyadic tolerance accounting, regular rational handoff, terminal Real boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySequence}^{\uparrow}$ packet is generated from a source sequence row, finite tail-comparison ledger, optional CauchyModulus row, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat handoff, terminal RealUp boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequence}^{\uparrow}}$, seed)

Scope closed: Definition 1980.1, Definition 1980.2, and Definition 1980.3 seed the ordinary Cauchy sequence route between explicit-modulus and weak finite-tail sequence surfaces.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, tail-comparison exactness, optional-modulus compatibility, dyadic tolerance accounting, regular handoff, Real boundary discipline, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceUp.

Chapter 1981

A Concrete Naming Certificate for $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$

Following Mac Lane and Eilenberg–Moore on algebras for monads, and Bishop–Bridges on constructive Cauchy completion, the $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ packet records the finite BEDC surface by which the L10 completion monad exposes an algebra action without turning completed points into quotient representatives. It consumes the completion-monad route of chapter 378, the complete-metric boundary of chapter 128, the universal-property route of chapter 397, the real completion seal of chapter 360, and the terminal real-name seal of chapter 38. The chapter names an Eilenberg–Moore algebra surface for displayed completion routes only; it does not assert quotient completion equality, selected representatives, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1981.1 (CauchyCompletionAlgebra carrier)**.** *A* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, Q, U, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *route carrying the unit, bind, and multiplication-facing data of the L10 completion monad.*
2. *Q is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary on which the algebra action is displayed.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *route that constrains algebra-facing maps through the displayed completion surface.*
4. *L is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *seal reached after the monad route, complete-metric boundary, and universal-property route have been displayed.*
5. *H records componentwise* hsame *transport for the monad route, complete-metric boundary, universal-property route, real completion seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the algebra route*

$$M, Q \longmapsto U \longmapsto L.$$

7. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, Q, U, L, H, C, P, N. It has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 1981.2 (CauchyCompletionAlgebra NameCert obligations)**.** *For every accepted* CauchyCompletionAlgebr *carrier*

$$A = (M, Q, U, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the monad route, complete-metric boundary, universal-property route, real completion seal, transport, replay, provenance, and local naming row;*
2. *algebra-action exposure, requiring every algebra-facing completion read to enter through M and Q before the universal-property route or real completion seal can be consumed;*
3. *universal-property discipline, requiring U to mediate every public map out of the displayed completion surface;*
4. *real-completion sealing, requiring L to remain downstream of M, Q, U and never to stand as a selected quotient representative;*
5. *classifier stability, requiring transported packets with componentwise matching rows to replay the same algebra route through H and C;*
6. *provenance and non-escape, requiring P, N to source and name exactly the displayed rows, with no quotient completion equality, selected representative, host equality of completed objects, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge credential.*

No $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the accepted packet $A = (M, Q, U, L, H, C, P, N)$. Carrier admission exposes exactly the monad route, complete-metric boundary, universal-property route, real completion seal, and structural rows.

The algebra-action obligation is the projection to M and Q. A completion-facing consumer does not receive an ambient completed carrier; it first reads the displayed monad route and then the complete-metric boundary on which the action is finite BEDC data.

The universal-property obligation is the projection to U. It constrains every public map out of the displayed completion surface to pass through the same finite route rather than through a host completion object.

The real-completion seal is the projection to L. It is downstream of M, Q, U, so it cannot be consumed as a selected quotient representative or as host equality of completed objects.

Finally, H, C, P, N exhaust transport, replay, provenance, and naming. These rows preserve the displayed coordinates and add no quotient completion equality, selected representative, host equality, countable-choice schedule, ambient completeness theorem, Lean verification, or bridge credential, so the listed rows are exactly the local NameCert surface. □

Theorem 1981.3 (CauchyCompletionAlgebra complete-metric handoff)**.** *For every accepted* CauchyCompletionAlg *carrier*

$$A = (M, Q, U, L, H, C, P, N),$$

every $\mathsf{CompleteMetric}^{\uparrow}$ *consumer read exported by* A *factors through the finite route*

$$\mathsf{CauchyCompletionMonad}^{\uparrow} \longrightarrow \mathsf{CompleteMetric}^{\uparrow} \longrightarrow \mathsf{CompletionUniversalProperty}^{\uparrow} \longrightarrow \mathsf{RealCauchyCompletion}^{\uparrow}.$$

The handoff preserves the displayed algebra route and exports no quotient completion equality, selected representative, host equality of completed objects, countable-choice schedule, ambient completeness theorem, Lean verification, or bridge credential.

Proof. Begin with a complete-metric consumer and project the carrier. The only complete-metric row is Q, and it is downstream of the monad route M.

The public map route is forced through U. The universal-property row keeps the complete-metric boundary attached to the displayed completion algebra rather than to an ambient completed carrier.

The consumer then reaches the completion seal L. This seal exposes only the displayed real Cauchy completion route fixed by M, Q, U.

Transport by H and replay by C preserve this route componentwise, and P, N only source and name the same packet. Since the carrier has no further coordinate, the handoff cannot produce quotient equality, representatives, host equality, choice, ambient completeness, Lean verification, or bridge data. □

Theorem 1981.4 (CauchyCompletionAlgebra public handoff)**.** *For every accepted* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *carrier*

$$A = (M, Q, U, L, H, C, P, N),$$

any public completion-algebra consumer receives the finite certificate route

$$\mathsf{CauchyCompletionMonad}^{\uparrow} \longrightarrow \mathsf{CompleteMetric}^{\uparrow} \longrightarrow \mathsf{CompletionUniversalProperty}^{\uparrow} \longrightarrow \mathsf{RealCauchyCompletion}^{\uparrow}$$

together with the displayed hsame*,* Cont*,* Pkg*, and* NameCert *rows. The handoff exports no quotient completion equality, selected limit, host equality of completed objects, ambient completeness theorem, Lean verification, or bridge credential.*

Proof. Begin with a public completion-algebra consumer and project the carrier. The visible algebra action is sourced by M and is displayed over the complete-metric boundary Q.

The public mapping discipline is then forced through U. A consumer can use the universal-property route only as part of this same packet, so no separate host completion object or selected quotient representative is introduced.

The terminal completion read is the seal L. Since L is downstream of M, Q, U, it records the displayed real completion route rather than ambient completeness or equality in a host model.

The structural rows H, C, P, N preserve and name this route. They add transport, replay, provenance, and local certification, but no extra coordinate from which quotient equality, selected limits, host equality, Lean verification, or bridge data could be exported. □

Theorem 1981.5 (CauchyCompletionAlgebra Real-seal nonescape)**.** *For every accepted* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *carrier*

$$A = (M, Q, U, L, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* L *receives only the displayed algebra route*

$$M, Q, U, L, H, C, P, N.$$

The seal is not quotient completion equality, not a selected representative, not host equality of completed objects, not countable choice, not ambient $\mathsf{Real}^{\uparrow}$ *completeness, not Lean verification, and not a bridge credential.*

Proof. Start from the terminal seal L. In the carrier, L is downstream of the displayed monad route, complete-metric boundary, and universal-property route rather than an independent completed-object coordinate.

Trace the route backward. A Real-facing read reaches L only after U has been displayed, and U is available to the algebra action only through M, Q.

The structural rows do not add a second seal source. The transport row H is componentwise, the replay row C displays the same route order, and the provenance and local certificate rows P, N name this packet without importing an ambient completion principle.

Thus every Real-facing consumer is confined to M, Q, U, L, H, C, P, N. The excluded quotient, representative, host-equality, countable-choice, ambient-completeness, Lean-verification, and bridge readings are outside the carrier inventory. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ packet is generated from the CauchyCompletionMonad route, CompleteMetric boundary, CompletionUniversalProperty route, RealCauchyCompletion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 1981.1, Definition 1981.2, Definition 1981.3, Definition 1981.4, and Definition 1981.5 seed the finite Eilenberg–Moore algebra surface for the L10 completion monad over displayed BEDC rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, algebra-action exposure, complete-metric boundary discipline, universal-property discipline, RealCauchyCompletion sealing, classifier stability, public handoff, Real-seal non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionAlgebraUp.

Cauchy sequence L10 dependency route. The $\mathsf{CauchySequence}^{\uparrow}$ carrier consumes the finite-window $\mathsf{StreamName}^{\uparrow}$ interface of chapter 126, the threshold row of chapter 292, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. This route records the horizontal L10 dependency lattice for ordinary Cauchy sequence consumers without adding a quotient stream, selected limit, or ambient completeness coordinate. The $\mathsf{Cauchy}^{\uparrow}$ hub exposes its sequence-facing child through the same L10 naming lattice used by Real and Completion consumers. A Cauchy sequence read is not a detached stream fact: it is a finite route through the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerances of chapter 291, and the terminal Real seal of chapter 38.

Theorem 1981.6 (Cauchy sequence RegSeqRat window route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *sequence read used by a* $\mathsf{Real}^{\uparrow}$ *or Completion consumer factors through a displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal before it can be consumed as a Real-facing or completion-facing boundary. The route exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem.*

Proof. Read the sequence child as the visible Cauchy-facing row of the hub. A consumer first inspects the finite StreamName window, then reads the same data as a regular rational row, and then checks the requested tolerance through the dyadic ledger.

Only after those displayed rows are present can the terminal Real seal be consumed. Since the route contains no quotient coordinate, selected endpoint, choice schedule, host equality row, or ambient completeness row, the consumer receives exactly the finite L10 window route. □

Definition 1981.7 (Cauchy root stream carrier)**.** *A* $\mathsf{Cauchy}^{\uparrow}$ *root stream carrier is a finite* BHist *packet*

$$Q = (S, T, M, W, H, C, P, N)$$

with the following rows:

1. *S is the certified finite observation stream. It records only the visible request windows that a Cauchy consumer may inspect.*
2. *T is the tail-threshold row. It assigns each displayed precision request a later visible window of S.*
3. *M is the modulus row. It records the finite evidence that two observations past the displayed threshold meet the requested tolerance.*
4. *W is the witness ledger. It stores the accepted comparisons between observed entries, not a quotient class, selected limit, or ambient completeness theorem.*
5. *H is componentwise* hsame *transport for the stream, threshold, modulus, witness, replay, provenance, and naming rows.*
6. *C is displayed* Cont *replay from an admitted Cauchy request through S, T, M, W, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

The classifier compares accepted root stream packets only through the displayed tuple S, T, M, W, H, C, P, N.

Theorem 1981.8 (Cauchy root tail stability)**.** *Let $Q = (S, T, M, W, H, C, P, N)$ be an accepted* $\mathsf{Cauchy}^{\uparrow}$ *root stream carrier. Every* hsame *transport of Q and every displayed* Cont *replay of a Cauchy request preserves the tail-threshold row T, the modulus row M, and the witness ledger W as componentwise rows over the same finite observation stream S. Consequently a tail read transported or replayed from Q remains a Cauchy root stream read, and it does not acquire a quotient stream equality, a selected limit, a choice schedule, or a host completeness assertion.*

Proof. Project the carrier of Definition 1981.7. The only rows available to a Cauchy request are the displayed stream window, tail threshold, modulus, witness ledger, transport, replay, provenance, and naming rows.

The hsame row H is componentwise by definition of the carrier surface. It transports S, T, M, W, C, P, N as rows of the same packet, so it cannot introduce a second stream, an external representative, or an ambient equality oracle.

The Cont row C replays an admitted request through the displayed packet. Since the replay reads T, M, W after S and before P, N, the transported request still witnesses the same finite tail-stability surface. □

Theorem 1981.9 (Cauchy root NameCert obligation surface)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *root stream carrier $Q = (S, T, M, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *obligation surface consists exactly of the following rows:*

1. *carrier admission for the finite observation stream S;*
2. *classifier admission for the tail-threshold row T and modulus row M;*
3. *stability under componentwise* hsame *transport H and displayed* Cont *replay C;*

4. comparison fidelity for the witness ledger W against the displayed tolerance requests;

5. provenance and local naming through P and N.

No obligation row certifies quotient streams, selected limits, countable choice, host real equality, or an ambient completion theorem.

Proof. Read the eight rows of Definition 1981.7. Carrier admission is the row S, while classifier admission is carried by the threshold and modulus rows T, M.

Stability is supplied by the structural rows H and C. These rows keep the request inside the displayed packet and force every transported or replayed tail read to pass through the same finite stream surface.

The witness ledger W supplies the comparison data for the displayed tolerance requests, and P, N source and name the packet. Since no remaining coordinate exists, the listed rows exhaust the local NameCert surface. □

Theorem 1981.10 (Cauchy root completion consumer route)**.** *Every completion-facing consumer of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *root stream carrier first reads the finite stream row of chapter 126, then the regular rational readback route of chapter 301, then the terminal Real seal of chapter 38. Metric and uniform completion consumers may use the same displayed route only after those rows have exposed the tail threshold, modulus, and witness ledger of Q.*

Proof. Start with a completion-facing read from Q. The carrier projection exposes the finite stream row before any threshold, modulus, witness, or structural row can be consumed.

The stream row is then read through the regular rational route. This is the point at which completion-facing consumers can inspect the finite rational data attached to the Cauchy window, while the Real seal remains downstream.

Finally the terminal Real seal is consumed after the tail-threshold, modulus, and witness rows are visible. The route therefore reaches completion consumers through StreamName, RegSeqRat, and RealUp data, not through quotient completions or selected representatives. □

Theorem 1981.11 (Cauchy sequence RegSeqRat stream anchor)**.** *Every Cauchy sequence root read that feeds an L10* $\mathsf{Real}^{\uparrow}$ *or completion consumer factors through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row before the* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Proof. Project the sequence root carrier through the hub child route. A consumer first receives finite window requests, not an infinite sequence object or a selected representative.

The regular rational readback is then interpreted through the displayed dyadic tolerance ledger. This places every tail request inside the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before any Real-facing or completion-facing seal can be consumed.

The structural rows preserve the same route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row source and name the finite readback path, so no quotient stream equality, selected limit, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported. □

Definition 1981.12 (Sequence Cauchy root observation carrier)**.** *For the root* $\mathsf{Cauchy}^{\uparrow}$ *sequence route, a finite observation carrier is a* BHist *packet*

$$O = (S, R, D, H, C, P, N)$$

where S is the $\mathsf{StreamName}^{\uparrow}$ *finite observation row of chapter 126, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, and H, C, P, N are respectively componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The carrier has no quotient sequence coordinate, host-sequence equality coordinate, selected limit, or ambient completion proof.*

Theorem 1981.13 (Sequence Cauchy root stream obligation)**.** *Every accepted root* $\mathsf{Cauchy}^{\uparrow}$ *sequence route factors through the finite observation carrier of Definition 1981.12. Its local obligation surface consists of StreamName window exposure, RegSeqRat readback exposure, DyadicRatCore tolerance accounting, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Read the root stream carrier of Definition 1981.7. Its stream row supplies the finite observation windows and its witness ledger supplies only displayed comparisons.

Route those windows through chapter 126, then through the regular rational readback of chapter 301, and finally through the dyadic tolerance ledger of chapter 291. These three rows are exactly S, R, D in the observation carrier.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient or host-sequence equality coordinate, every accepted Cauchy read remains inside the displayed NameCert surface. □

Theorem 1981.14 (Sequence Cauchy hsame-stable tail classifier)**.** *Let $O = (S, R, D, H, C, P, N)$ be an accepted sequence Cauchy root observation carrier. Any tail classifier read transported by H preserves the same StreamName window row S, the same RegSeqRat readback row R, and the same DyadicRatCore tolerance ledger D. Consequently the transported tail classifier remains a root* $\mathsf{Cauchy}^{\uparrow}$ *read and cannot introduce quotient sequence equality, host-sequence equality, selected limits, or ambient completion.*

Proof. Project the carrier O. The tail classifier has access only to S, R, D, H, C, P, N, and H is declared componentwise over exactly those rows.

Transporting a tail read by H therefore replaces no observation row by an external sequence and adds no equality oracle. The StreamName, RegSeqRat, and DyadicRatCore rows stay visible before the classifier verdict is read.

The transported classifier is then repacked with the same provenance and local naming rows. This is the root Cauchy tail surface, not a quotient or host-sequence equality claim. □

Theorem 1981.15 (Sequence Cauchy Cont-stable replay ledger)**.** *For every accepted sequence Cauchy root observation carrier $O = (S, R, D, H, C, P, N)$, each displayed* Cont *replay of a Cauchy request must read S, then R, then D, and then the structural rows H, P, N. The replay ledger is therefore stable under finite-window refinement and remains a finite NameCert ledger for StreamName, RegSeqRat, and DyadicRatCore data.*

Proof. Start with a displayed replay row C. By the carrier surface, C is a replay through the finite observation carrier and not through an ambient sequence object.

The replay order exposes the StreamName window before the regular rational readback and the dyadic tolerance ledger. A finite-window refinement may restrict S, but the refined route still factors through the corresponding R and D rows.

Finally the replay is named by P, N and transported by H. The ledger remains finite because every replayed request is read through displayed windows and tolerance rows rather than through quotient or host-sequence equality. □

Theorem 1981.16 (Cauchy Real completion lattice repair)**.** *Every completion-facing* Cauchy$^{\uparrow}$ *read that reaches the Real and Completion lattice factors through finite* StreamName$^{\uparrow}$ *windows from chapter 126,* RegSeqRat$^{\uparrow}$ *regular rational readback from chapter 301,* DyadicRatCore$^{\uparrow}$ *tolerance rows from chapter 291, the terminal* Real$^{\uparrow}$ *seal of chapter 38, and the* CauchyFilterCompletion$^{\uparrow}$ *consumer rows of chapter 1569 before any completion-facing conclusion is exposed. The route carries the same finite* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows as the root sequence packet, and it exports no quotient streams, selected limits, countable choice, host equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the existing Cauchy$^{\uparrow}$ root sequence surface. Its public rows expose finite sequence observations and structural BHist, hsame, Cont, Pkg, and NameCert data before any downstream consumer can read a completion-facing claim.

Follow the named sibling route. The observation is first read as a StreamName$^{\uparrow}$ finite window, then as a RegSeqRat$^{\uparrow}$ regular rational readback, then through DyadicRatCore$^{\uparrow}$ tolerance rows, and finally through the terminal Real$^{\uparrow}$ seal.

Only after those rows are visible may the consumer enter the CauchyFilterCompletion$^{\uparrow}$ surface. Since no row in the route stores quotient stream equality, selected limits, countable choice, host equality, or ambient Real completeness, the completion-facing conclusion is exactly the finite lattice read described above. □

The Cauchy$^{\uparrow}$ rows are consumed downstream by chapter 126, chapter 301, and chapter 38. The route opens only finite stream windows, regular Cauchy tail budgets, and terminal Real$^{\uparrow}$ seal rows, so a Cauchy packet can feed the L10 real-completion argument without adding content to the hub file.

Theorem 1981.17 (Cauchy hub Bishop completion forward route)**.** *The regular-source material routed by the* Cauchy$^{\uparrow}$ *hub is consumed by chapter 1639 through the displayed* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The forward route exports no detached Cauchy representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness principle.*

Proof. Read the Cauchy hub through its regular-source children. Those children expose dyadic tolerance arithmetic, finite stream windows, regular rational readback, and the terminal real seal as DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ rows.

The Bishop regular Cauchy completion chapter consumes exactly that L10-facing route. Its completion read is mediated by the same finite BHist carrier discipline, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Since the hub route contains no detached representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness coordinate, the forward edge to the Bishop completion packet is precisely the displayed finite dependency route. □

The Cauchy$^{\uparrow}$ dossier also routes finite Cauchy source data into the L10 completion interface: its displayed request windows and modulus rows feed the StreamName$^{\uparrow}$ surface of chapter 126, its rational readback is consumed by chapter 301, and its terminal seal-facing row reaches chapter 38 through the finite section packet of chapter 6518. Thus Cauchy$^{\uparrow}$ supplies the finite Cauchy source row consumed by the L10 completion route without asserting quotient stream equality, selected limits, countable choice, host real equality, or ambient Real$^{\uparrow}$ completeness. The Cauchy$^{\uparrow}$ hub supplies a forward L10 route to chapter 1569: finite sequence evidence is first read through StreamName$^{\uparrow}$ windows, then through RegSeqRat$^{\uparrow}$ regular-rational readback, then through DyadicRatCore$^{\uparrow}$ tolerance rows, and finally through the terminal Real$^{\uparrow}$ seal before the CauchyFilterCompletion$^{\uparrow}$ packet

consumes completion data. This route records dependency flow only; it exports no quotient stream equality, selected filter limit, countable-choice schedule, host real equality, trichotomy, or ambient completeness coordinate.

Theorem 1981.18 (Cauchy filter-completion dependency route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *read used by completion-facing consumers is routed through the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *packet of chapter 1569 only after the* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows are displayed. The route begins with finite Cauchy sequence evidence, opens the Cauchy-filter basis, records the inspected stream windows, reads the regular rational data, accounts for dyadic tolerances, and then seals the terminal Real row before completion data is consumed. It exports no quotient stream equality, quotient filter, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient completeness theorem.*

Proof. Read the $\mathsf{Cauchy}^{\uparrow}$ hub through its sequence and regular-source children. Those children display the finite stream windows and regular rational readback before any completion-facing row is available.

The $\mathsf{CauchyFilter}^{\uparrow}$ basis is then exposed as a filter route over the same finite evidence. The $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows and the terminal $\mathsf{Real}^{\uparrow}$ seal record the numerical part of the route before the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ packet can consume it.

The structural rows preserve the same finite handoff through BHist, hsame, Cont, Pkg, and NameCert data. Since the hub provides no quotient stream equality, quotient filter, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient completeness coordinate, the completion dependency is exactly the displayed route. □

Theorem 1981.19 (Cauchy hub Real-completion lattice route)**.** *Every public* $\mathsf{Cauchy}^{\uparrow}$ *route consumed by a Real-completion chapter factors through the finite stream-window surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38 before completion consumers read it. The hub exports only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows attached to that lattice; it exports no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the hub input order for $\mathsf{Cauchy}^{\uparrow}$. The root sequence and stream obligation files expose finite observation windows and the local NameCert route before any completion-facing sibling can consume the packet.

Follow the Real-completion lattice through the named sibling chapters. A consumer first reads the finite $\mathsf{StreamName}^{\uparrow}$ window, then the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational row, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and finally the $\mathsf{Real}^{\uparrow}$ seal that is visible to completion packets.

The carrier rows available at the hub are exactly the displayed BHist route data, componentwise hsame transport, Cont replay, Pkg provenance, and local naming rows. Since none of those rows stores quotient streams, selected limits, choice schedules, host real equality, or ambient Real completeness, every completion-facing read factors through the finite lattice stated above. □

Theorem 1981.20 (Cauchy RegSeqRat completion forward route)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *read consumed by a completion-facing chapter must pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the local* $\mathsf{Cauchy}^{\uparrow}$ *route before completion data is exposed. The route carries only the displayed* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* NameCert *rows, and it exports no quotient stream, selected limit, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the Cauchy root sequence and stream routes. They expose finite observations as named windows before any completion-facing consumer can inspect the packet.

Apply the existing Cauchy sibling routes through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The read is first a finite stream window, then a regular rational tail budget, and then a real-name seal attached to the same local Cauchy packet.

Finally compose with the Real-completion lattice route. Since the displayed rows contain only BHist, hsame, Cont, Pkg, and local NameCert data, the completion-facing consumer receives the named forward route without a quotient stream, selected limit, choice schedule, host equality, or ambient Real-completeness coordinate. □

The $\mathsf{Cauchy}^{\uparrow}$ carrier is consumed by the Real and regular-sequence completion lattice through the substantive routes of chapter 38, chapter 301, chapter 126, and chapter 1569. A completion-facing read therefore reaches Real seals, regular rational readback, finite stream windows, and Cauchy-filter completion consumers as displayed BHist, hsame, Cont, Pkg, and NameCert rows, not as quotient stream equality, a selected limit, countable choice, host real equality, or ambient completeness.

Theorem 1981.21 (Cauchy forward Real-completion route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *consumer that reaches a Real-completion reading must pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *route of chapter 126, the regular-rational completion rows of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *completion and seal rows of chapter 38. The route may use the Cauchy kernel predicate only as a displayed finite observation condition; it cannot treat* $\mathsf{Cauchy}^{\uparrow}$ *as an isolated kernel predicate that already supplies a selected limit, quotient stream equality, host real equality, or ambient completeness.*

Proof. Start with a completion-facing consumer of the $\mathsf{Cauchy}^{\uparrow}$ hub. The hub exposes finite sequence and stream observation rows before any completion packet can read the predicate.

Follow the forward route through the named siblings. The consumer first reads $\mathsf{StreamName}^{\uparrow}$ windows, then the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational completion handoff, and finally the $\mathsf{Real}^{\uparrow}$ completion and seal rows.

The structural rows preserve only that displayed route. Since no coordinate in the hub supplies selected limits, quotient stream equality, host real equality, or ambient completeness, the consumer cannot bypass $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ by reading Cauchy as an isolated kernel predicate. □

1981.1 StreamName Readback Route

The $\mathsf{Cauchy}^{\uparrow}$ completion hub has a substantive L10 route through the finite-window sibling lattice rather than only through the kernel sequence carrier. A completion consumer that reads a Cauchy packet must first expose $\mathsf{StreamName}^{\uparrow}$ windows as in chapter 126, replay the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback, check the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, and then seal the resulting endpoint through $\mathsf{Real}^{\uparrow}$.

Theorem 1981.22 (Cauchy stream-name sibling route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *completion consumer that claims a Real-facing endpoint factors its read through* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. The route exposes the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates used by the Cauchy hub, and it has no direct access to selected limits, quotient completion classes, ambient Real completeness, or countable choice.*

Proof. Read the Cauchy hub through its existing sequence and completion children. The only windowed observation route begins with the $\mathsf{StreamName}^{\uparrow}$ finite-window sibling and then replays the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback against the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows.

The endpoint seal is therefore downstream of the finite readback route. Once $\mathsf{Real}^{\uparrow}$ receives the sealed row, the structural coordinates $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$ preserve that same finite route and provide no coordinate for selected limits, quotient classes, ambient completeness, or countable choice. □

The $\mathsf{Cauchy}^{\uparrow}$ hub supplies the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows consumed by chapter 1536 through its epigraph Real-export route. The forward edge reads only synchronized stream windows, regular rational tail budgets, terminal $\mathsf{Real}^{\uparrow}$ seal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows; it does not add a quotient stream equality, selected limit, countable choice row, host lower-semicontinuity predicate, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Chapter 1982

A Concrete Naming Certificate for $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completions, and Kelley and Bourbaki on filter bases, the $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ packet names the finite bridge by which located Cauchy-filter requests are regularized into modulus rows before a completion-facing consumer reads a real seal. It sits between the located-filter source of chapter 1661, the finite base route of chapter 1915, the common-refinement operation of chapter 1958, and the ideal-completion boundary of chapter 1883. The downstream L10 route reads finite windows through chapter 126, regular rational rows through chapter 301, dyadic tolerances through chapter 291, and terminal seals through chapter 38. The packet is a finite transfer surface from filter-base evidence to regular Cauchy modulus data; it is not a quotient filter, selected limit, countable-choice schedule, host equality comparison, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification row, or bridge certificate.

Definition 1982.1 (Cauchy filter modulus transfer carrier)**.** *A* $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, B, L, J, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the Cauchy filter source row. It records the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *request surface whose precision requests are to be regularized.*
2. *B is the* $\mathsf{CauchyFilterBase}^{\uparrow}$ *basis row. It exposes finite base indices, entourage requests, directed-refinement reads, and Cauchy readiness rows used by the source filter.*
3. *L is the located-tail row. It records the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *evidence that every requested tail can be inspected by a located finite base request before any regular modulus row is exported.*
4. *J is the common-refinement row. It reads the* $\mathsf{CauchyFilterMeet}^{\uparrow}$ *operation and names, for each requested tolerance and each located tail request, a displayed refinement accepted by both the filter source and the basis route.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row reached only after F, B, L, J have been displayed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the accepted window route as a regular rational sequence row.*

7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested dyadic scale, the smaller scale selected by the located-tail row, and the budget comparison used to certify regular Cauchy control.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. It is visible only after the filter source, basis route, located-tail row, common-refinement row, window row, regular readback row, and dyadic ledger have been replayed.*

9. *H records componentwise* hsame *transport for the source filter, basis row, located-tail row, common-refinement row, window, regular readback, dyadic tolerance, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a filter request through F, B, L, J, S, R, D, E in that order.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterMeet}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterModulusTransfer}^{\uparrow}}$ *row.*

The classifier compares accepted transfer packets only through the displayed route

$$F, B, L, J \longmapsto S, R, D, E \longmapsto H, C, P, N.$$

No carrier coordinate stores a quotient filter, selected limit, countable-choice schedule, host equality of filter values, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge certificate.*

Lean4 ✓ `BEDC.Derived.CauchyFilterModulusTransferUp.CauchyFilterModulusTransferTasteGate single carrier alignment`

Theorem 1982.2 (Cauchy filter modulus transfer NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ *carrier*

$$T = (F, B, L, J, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterModulusTransfer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Cauchy filter source, basis row, located-tail row, common-refinement row, window row, regular rational handoff, dyadic tolerance ledger, terminal seal, transport, replay, provenance, and local naming row;*

2. *source-to-basis routing, requiring each displayed filter request in F to read its finite base witness from B before the located-tail row can be inspected;*

3. *located-tail regularization, requiring each requested precision to pass through L and name a finite tail request that is small enough for regular Cauchy control;*

4. *common-refinement coverage, requiring J to refine the basis request and located-tail request over the same filter source before any window, readback, tolerance, or seal row is visible;*

5. *finite modulus handoff, requiring the route from J to pass through S, R, D before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary E;*

6. *transport and replay stability, requiring H and C to preserve the row order F, B, L, J, S, R, D, E under componentwise* hsame *transport and displayed* Cont *replay;*

7. *provenance exhaustion, requiring P, N to name only this finite transfer route and to export no quotient filter, selected limit, countable-choice schedule, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1982.1. The projection exposes exactly the filter source, basis route, located-tail row, common-refinement row, finite window, regular readback, dyadic ledger, terminal seal, and structural rows H, C, P, N.

The source-to-basis route is fixed by row order. A transfer request first reads F, then reads the finite base index, entourage request, and readiness evidence supplied by B before any located-tail regularization is available.

Located-tail regularization is the role of L. For a requested precision, L names the displayed tail request and records the finite locatedness evidence showing that this request is small enough for the regular Cauchy handoff.

The common-refinement row J then aligns the basis request with the located-tail request. Since J is a carrier coordinate, the refinement is finite data in the packet rather than an ambient filter lattice principle.

The modulus handoff is replayed by C through S, R, D before E can be inspected. Componentwise transport in H preserves the same rows, while P, N source and name only this packet; therefore the excluded quotient, choice, host-equality, real-completeness, Lean-verification, and bridge-checking data are outside the local NameCert surface. □

Theorem 1982.3 (Cauchy filter modulus transfer basis regularization)**.** *Let*

$$T = (F, B, L, J, S, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ *carrier. Every displayed filter precision request factors through a finite regularization route*

$$F \longmapsto B \longmapsto L \longmapsto J \longmapsto S, R, D.$$

Consequently the packet exports a regular Cauchy modulus row only after a source filter request has been witnessed by a basis row, located as a finite tail request, refined against that basis request, and checked by the displayed window, regular readback, and dyadic tolerance ledger.

Proof. Start with a displayed precision request in F. The carrier exposes no direct regular-modulus coordinate, so the request must first be read through the basis row B.

The located-tail row L supplies the finite tail request attached to the same precision. This step is constructive: the row contains the inspected tail witness and not a selected limit or a countable-choice schedule.

Next read J. It names the common refinement of the basis request and the located-tail request, so the regularization route remains attached to one displayed filter source.

Finally replay the finite observation rows S, R, D. The window row supplies the finite observations, the regular rational row repacks them as $\mathsf{RegSeqRat}^{\uparrow}$ data, and the dyadic ledger records the tolerance comparison needed for regular Cauchy control. Thus the regular modulus row is exported only through the displayed route. □

Theorem 1982.4 (Cauchy filter modulus transfer real seal boundary)**.** *Every completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ *carrier*

$$T = (F, B, L, J, S, R, D, E, H, C, P, N)$$

reaches the terminal seal E only through the finite route

$$F, B, L, J, S, R, D \longmapsto E \longmapsto H, C, P, N.$$

In particular, the consumer receives a filter source row, basis row, located-tail row, common-refinement row, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise transport, continuation replay, provenance, and local naming. It receives no selected limit, quotient filter, countable-choice schedule, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge certificate.*

Proof. Begin with a completion-facing or $\mathsf{Real}^{\uparrow}$-facing read named by P. Carrier projection restricts the consumer to the rows displayed in Definition 1982.1.

Apply Definition 1982.3. The precision request must pass through F, B, L, J, S, R, D before a regular modulus row is available.

The seal row E is placed after that regularization route. A consumer therefore sees the terminal $\mathsf{Real}^{\uparrow}$ boundary only after the source filter, basis evidence, located tail, common refinement, finite windows, regular rational handoff, and dyadic tolerance ledger have all been replayed.

The structural rows do not add analytic content. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the displayed route, so selected limits, quotient filters, choice schedules, host equality, ambient real completeness, Lean verification, and bridge checking cannot enter through the seal boundary. □

Theorem 1982.5 (Cauchy filter modulus transfer RegularModulus bridge)**.** *Every accepted* CauchyFilterModulusTr *carrier*

$$T = (F, B, L, J, S, R, D, E, H, C, P, N)$$

whose route reaches S, R, D exports exactly the $\mathsf{RegularModulus}^{\uparrow}$ *row read by* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and completion-facing consumers. The exported row is the displayed finite modulus surface produced by F, B, L, J, S, R, D and preserved by E, H, C, P, N; it is not a quotient filter, selected limit, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Apply Definition 1982.3. It routes each filter precision request through the source row, finite basis row, located-tail row, common-refinement row, StreamName window, RegSeqRat readback, and dyadic tolerance ledger.

Apply Definition 1982.4. The terminal seal can be inspected only after that regularization route has reached S, R, D, so the completion-facing consumer cannot bypass the displayed finite modulus data.

Finally use the $\mathsf{RegularModulus}^{\uparrow}$ handoff theorem, Definition 3768.3. The same window, regular-rational readback, and dyadic ledger are the rows read by $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and completion consumers. Since neither carrier has a coordinate for a quotient filter, selected limit, countable-choice schedule, host equality, or ambient completeness, the bridge exports exactly the regular-modulus row and nothing more. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterModulusTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterModulusTransfer}^{\uparrow}$ packet is generated from a CauchyFilter source row, a CauchyFilterBase basis row, a LocatedCauchyFilter tail row, a CauchyFilterMeet common-refinement row, StreamName windows, RegSeqRat handoff, DyadicRatCore tolerances, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterModulusTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1982.1, Definition 1982.2, Definition 1982.3, and Definition 1982.4 seed the finite bridge from located Cauchy-filter evidence and filter-base requests to regular Cauchy modulus rows before the terminal Real seal.

Formal verification: FormalStatus(NameCert$_{\text{CauchyFilterModulusTransfer}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient filters, countable choice, host equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-to-basis routing, located-tail regularization, common-refinement coverage, finite modulus handoff, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterModulusTransferUp.

Chapter 1983

A Concrete Naming Certificate for $\mathsf{IrrationalWitness}^{\uparrow}$

Following Euclid's parity proof for the irrationality of $\sqrt{2}$ and Bishop–Bridges constructive analysis, the $\mathsf{IrrationalWitness}^{\uparrow}$ packet records a finite contradiction route from rational-candidate data to a Real-facing refusal seal. It reads rational numerator and denominator rows through chapter 37 and chapter 31, checks dyadic tolerances through chapter 291, routes square-root existence through chapter 1756 and chapter 1837, and exposes only a terminal Real seal from chapter 38. The packet is evidence for a finite irrationality obstruction inside the BEDC carrier discipline; it is not quotient real equality, a completeness theorem for $\mathsf{Real}^{\uparrow}$, a trichotomy principle, a selected real representative, or a host theorem that $\sqrt{2}$ is irrational.

Definition 1983.1 (IrrationalWitness carrier)**.** *An* $\mathsf{IrrationalWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, D, S, O, T, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational-candidate row, recording the inspected numerator and denominator data inherited from* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$*.*
2. *D is the denominator-positivity row, recording that the displayed denominator data are admitted before any square or root comparison may be read.*
3. *S is the square and root handoff row, routing the candidate equation through* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *and* $\mathsf{RealRootExistence}^{\uparrow}$ *before a Real-facing seal is exposed.*
4. *O is the parity or square-obstruction ledger, storing the finite divisibility, parity, or square-comparison rows used to contradict the displayed rational candidate.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording dyadic radii and comparison budgets for the rational and square-root reads.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, D, S, O, T have been displayed.*
7. *H is the componentwise* hsame *transport row for the rational candidate, denominator-positivity, square/root handoff, obstruction ledger, dyadic tolerance, Real seal, replay, provenance, and naming rows.*
8. *C is the displayed* Cont *replay row from a Real-facing irrationality request back through the square/root handoff, dyadic tolerance ledger, obstruction ledger, and rational-candidate rows.*

9. *P is the* Pkg *provenance over* $\mathsf{IrrationalWitness}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{RealRootExistence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IrrationalWitness}^{\uparrow}}$ *row.*

The carrier predicate accepts exactly these finite irrationality-witness packets. It has no coordinate for quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, selected representatives, or host irrationality theorems.*

Lean4 ✓ `BEDC.Derived.IrrationalWitnessUp.TasteGate.IrrationalWitnessTasteGate single carrier alignment`

Theorem 1983.2 (IrrationalWitness NameCert obligations)**.** *For every accepted* $\mathsf{IrrationalWitness}^{\uparrow}$ *carrier*

$$W = (Q, D, S, O, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IrrationalWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed rational-candidate row, denominator-positivity row, square/root handoff row, obstruction ledger, dyadic tolerance row, Real seal, and structural rows H, C, P, N;*
2. *rational-candidate exposure, requiring every contradiction read to display the numerator and denominator data in Q and the positivity row D before square data are consumed;*
3. *square/root route, requiring the row S to factor through* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *and* $\mathsf{RealRootExistence}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
4. *contradiction ledger, requiring the obstruction row O to store only the finite parity, divisibility, or square-comparison rows attached to Q, D, S, T;*
5. *Real-seal nonescape, requiring E to be downstream of Q, D, S, O, T and to expose no quotient real equality, full* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy branch, selected representative, or host irrationality theorem;*
6. *transport, replay, provenance, and naming, requiring H, C, P, N to preserve, replay, source, and name exactly the displayed route.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1983.1. The accepted packet displays exactly the rational-candidate row, denominator-positivity row, square/root handoff, obstruction ledger, dyadic tolerance row, terminal Real seal, and structural rows.

Rational-candidate exposure is finite. The row Q records the numerator and denominator data, while D records the positivity condition needed before the candidate can enter the square comparison route.

The square/root route is then forced by S and T. The handoff row passes through the regular-Cauchy square-root and root-existence packets, and the tolerance row records the dyadic budgets used by those reads.

The contradiction ledger is local to O. Its entries are parity, divisibility, or square-comparison rows attached to the displayed candidate and tolerance data, so it cannot import quotient equality, trichotomy, selected representatives, or ambient completeness.

Finally, E, H, C, P, N exhaust the Real-facing boundary. The seal E is downstream of the displayed route, and the structural rows transport, replay, source, and name only that route. Since the carrier has no further coordinate, the six listed clauses exhaust the local $\mathsf{NameCert}_{\mathsf{IrrationalWitness}^{\uparrow}}$ surface. □

Theorem 1983.3 (IrrationalWitness square-root handoff)**.** *For every accepted* $\mathsf{IrrationalWitness}^{\uparrow}$ *carrier*

$$W = (Q, D, S, O, T, E, H, C, P, N),$$

every Real-facing irrationality read exported by W *factors through the displayed route*

$$\mathsf{Rat}^{\uparrow}, \mathsf{Int}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegularCauchySquareRoot}^{\uparrow}, \mathsf{RealRootExistence}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

by reading the finite rows $Q, D, T, S, O, H, C, P, N$ *before the seal* E*. In particular, the read cannot bypass the rational, integer, dyadic-tolerance, square-root, and root-existence route by invoking quotient real equality, full* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, a selected representative, or a host irrationality theorem.*

Proof. Begin with a Real-facing irrationality consumer. Carrier projection exposes the terminal seal E only after the rational-candidate, denominator-positivity, dyadic-tolerance, square/root, and obstruction rows have been displayed.

The rational and integer data are read first through Q and D. The dyadic tolerance row T supplies the comparison budgets needed before the square-root route is inspected.

The row S then routes the read through the regular-Cauchy square-root packet and the real-root-existence packet. The obstruction ledger O records the finite contradiction rows attached to that route, not an external real-number theorem.

The structural rows do not add a second exit. The transport row H, replay row C, provenance row P, and local certificate row N preserve the same ordered route, so every Real-facing read factors through the displayed Rat/Int/DyadicRatCore and square-root/root-existence path before reaching E. □

Theorem 1983.4 (IrrationalWitness sqrt-two specialization)**.** *When the rational-candidate row* Q *of an accepted* $\mathsf{IrrationalWitness}^{\uparrow}$ *packet is the displayed sqrt-two candidate, the Real-facing refusal route must read the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$ *parity row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* T*, the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *and* $\mathsf{RealRootExistence}^{\uparrow}$ *handoff row* S*, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *refusal seal* E*. The contradiction ledger* O *records the finite parity obstruction attached to that displayed candidate; it does not assert a host theorem that* $\sqrt{2}$ *is irrational, quotient real equality, full* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, or a selected real representative.*

Proof. Start from the displayed sqrt-two rational candidate in Q. The rational and integer rows are the only carrier coordinates that can expose numerator, denominator, divisibility, and parity data, so the obstruction begins inside the $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Int}^{\uparrow}$ surface.

The dyadic tolerance row T is then consumed before the square/root comparison. It records the finite budgets used to compare the rational candidate with the square-root route, and it supplies no external real equality.

Apply the square-root handoff theorem Definition 1983.3. The row S routes the comparison through $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ and $\mathsf{RealRootExistence}^{\uparrow}$, while O stores the finite parity contradiction attached to Q, D, S, T.

Finally the seal E is read only after those rows and the structural transport, replay, provenance, and naming rows. Since the carrier has no coordinate for a host irrationality theorem, quotient equality, completeness, trichotomy, or selected representatives, the sqrt-two case remains a finite packet obstruction. □

Closure status for $\mathsf{NameCert}_{\mathsf{IrrationalWitness}^{\uparrow}}$**.**

Constructive story: An IrrationalWitness$^{\uparrow}$ packet is generated from rational-candidate rows, denominator positivity, square/root handoff rows, a parity or square-obstruction ledger, dyadic tolerance rows, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{IrrationalWitness}^{\uparrow}}$, seed)

Scope closed: Definition 1983.1, Definition 1983.2, and Definition 1983.3 seed the finite route from rational-candidate evidence through dyadic and square-root data to a terminal RealUp irrationality refusal seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{IrrationalWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, full Real$^{\uparrow}$ completeness, trichotomy, selected representatives, host irrationality theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-candidate exposure, square/root routing, contradiction-ledger exactness, Real-seal nonescape, transport/replay/provenance coverage, and naming for BEDC.Derived.IrrationalWitnessUp.

Chapter 1984

A Concrete Naming Certificate for $\mathsf{LocatedRealSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedRealSequence}^{\uparrow}$ packet records a finite sequence of located real names by displaying the sequence windows, located-real envelopes, modulus surface, regular rational handoff, and real-name seal before any consumer can read the sequence as a completed object. It sits after the finite StreamName carrier of chapter 126, the located-real boundary of **??**, the sequence-modulus surface of chapter 1801, the located Cauchy sequence packet of chapter 1595, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter isolates the finite located-real sequence carrier used by the real and completion route; it does not assume quotient streams, selected limits, countable choice, trichotomy, ambient real completeness, Lean verification, or checked bridge data.

Definition 1984.1 (Located real sequence source)**.** *A* $\mathsf{LocatedRealSequence}^{\uparrow}$ *source is a finite* BHist *packet*

$$X = (S, L, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *index-window row. It names the finite sequence indices and stream windows that a consumer may inspect.*
2. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *window row. It records the located-real enclosure exposed at each inspected index of S.*
3. *M is the* $\mathsf{LocatedSequenceModulus}^{\uparrow}$ *row. It binds finite tolerance requests to the inspected index windows and records the reusable sequence-modulus surface.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It carries the dyadic error budgets used when located-real windows are compared componentwise.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It records the regular rational readback obtained from the displayed sequence windows, located-real rows, modulus row, and dyadic tolerance row.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is read only after the regular rational handoff has been displayed, and it adds no selected limit or quotient-stream coordinate.*
7. *H records componentwise* hsame *transport for the index windows, located-real windows, modulus row, dyadic tolerance row, regular rational handoff, real seal, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from each sequence precision request through* $S, L, M, D, R, E, H, P, N$.
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedSequenceModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealSequence}^{\uparrow}}$ *row.*

The source exposes only these finite sequence, locatedness, tolerance, readback, seal, transport, continuation, provenance, and naming rows.

Lean4 ✓ `BEDC.Derived.LocatedRealSequenceUp.TasteGate.LocatedRealSequenceTasteGate single carrier alignment`

Theorem 1984.2 (Located real sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealSequence}^{\uparrow}$ *source* $X = (S, L, M, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealSequence}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed* $S, L, M, D, R, E, H, C, P, N$ *packet;*
2. *located-window exposure, requiring each consumer-visible sequence coordinate to pass through the* $\mathsf{StreamName}^{\uparrow}$ *index-window row* S *and the corresponding* $\mathsf{LocatedReal}^{\uparrow}$ *row* L*;*
3. *componentwise classifier transport, requiring sameness of accepted sources to be transported only through the displayed* hsame *and* Cont *rows over the component windows, tolerance data, handoff, seal, provenance, and local name;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the readback row* R *to be formed only after* S, L, M, D *have been displayed;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring* E, P, N *to export no quotient stream, selected limit, countable-choice selector, trichotomy branch, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification certificate, or checked bridge.*

No located-real-sequence obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 1984.1. The accepted packet displays exactly the index windows, located-real windows, sequence modulus, dyadic tolerance row, regular rational handoff, real seal, transport, continuation, provenance, and local naming data.

Located-window exposure is forced before any component readback can occur. A consumer starts with the inspected index window S and receives the corresponding located-real row L at that same finite coordinate.

Componentwise classifier transport is structural. The rows H and C move and replay only the displayed rows S, L, M, D, R, E, while P and N source and name that same finite route.

The handoff and seal rows are downstream. The row R can be read only after S, L, M, D have been displayed, and the row E can be read only after R. Since no listed row stores quotient-stream equality, a selected limit, countable choice, trichotomy, ambient completeness, Lean verification, or bridge data, the five obligation rows exhaust the local NameCert surface. □

Theorem 1984.3 (Located real sequence kernel scope)**.** *Every consumer route out of an accepted* $\mathsf{LocatedRealSequence}^{\uparrow}$ *source factors through the finite chain*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{LocatedSequenceModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows. The route explicitly refuses quotient streams, selected limits, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the source of Definition 1984.1. The only entry point for a consumer is the finite index-window row S, and each inspected coordinate then exposes its located-real window through L.

The sequence-level control is the modulus row M. It binds the finite tolerance request before the dyadic tolerance row D can be used to compare component windows.

The regular rational and real-facing exits are then fixed. The row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the row E is the only $\mathsf{Real}^{\uparrow}$ seal, so every analytic read factors through the displayed chain from stream windows to the real seal.

The remaining rows BHist, hsame, Cont, Pkg, and NameCert transport, replay, source, and name the same finite route. They add no coordinate for quotient streams, selected limits, countable choice, trichotomy, ambient real completeness, Lean verification, or bridge checking. □

Theorem 1984.4 (Located real sequence null-tail handoff)**.** *Let*

$$X = (S, L, M, D, R, E, H, C, P, N)$$

and

$$X' = (S', L', M', D', R', E', H', C', P', N')$$

be accepted $\mathsf{LocatedRealSequence}^{\uparrow}$ *reads. Any zero-tail comparison between them that is consumed by a* $\mathsf{Real}^{\uparrow}$ *equality-facing route must first factor through the displayed sequence route*

$$S, L, M, D, R, E, H, C, P, N$$

and its primed counterpart, and then through a displayed $\mathsf{NullSequence}^{\uparrow}$ *packet. The handoff exposes finite StreamName windows, located-real component rows, sequence moduli, dyadic tolerances, regular readbacks, Real seals, transport, replay, provenance, and local names before any equality-facing consumer can read the zero-tail evidence.*

Proof. Project both accepted sources by Definition 1984.1. The only component rows available before the Real seal are the finite stream windows, located-real windows, sequence moduli, dyadic tolerances, regular readbacks, and structural rows.

Apply Definition 1984.3 to each source. Every consumer route out of either source must pass through the chain from $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedSequenceModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the displayed structural rows.

A zero-tail comparison is therefore an additional displayed consumer row rather than a replacement for either source route. It may be read as a $\mathsf{NullSequence}^{\uparrow}$ packet only after the two $S, L, M, D, R, E, H, C, P, N$ routes have been exposed.

Since neither carrier has a coordinate for quotient streams, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or checked bridge data, the equality-facing consumer receives only the displayed null-tail handoff and no hidden Real equality principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealSequence}^{\uparrow}$ packet is generated from finite StreamName index windows, LocatedReal component windows, a LocatedSequenceModulus row, DyadicRatCore tolerances, a RegSeqRat handoff, a Real seal, componentwise hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1984.1, Definition 1984.2, and Definition 1984.3 seed the finite located-real sequence carrier between StreamName, LocatedReal, LocatedSequenceModulus, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean closure requires checked carrier admission for Definition 1984.1, the obligation surface of Definition 1984.2, and the kernel scope theorem of Definition 1984.3 for BEDC.Derived.LocatedRealSequenceUp.

Chapter 1985

A Concrete Naming Certificate for $\mathsf{DenseImageCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completion and dense embeddings, the $\mathsf{DenseImageCompletion}^{\uparrow}$ packet records the finite L10 interface by which displayed source points approximate completion-facing consumers through the already named entry map of chapter 1934. It sits between the metric-completion surface of chapter 1506, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter names only finite approximation rows: it does not construct quotient completions, select limits, identify host objects, invoke countable choice, use ambient $\mathsf{Real}^{\uparrow}$ completeness, or claim bridge checking.

Definition 1985.1 (Dense image completion carrier)**.** *A* $\mathsf{DenseImageCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, E, A, M, R, S, D, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed source metric point row whose finite observations are available before any completion-facing read.*
2. *E is the* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ *entry row that exposes the source point as displayed completion-entry data.*
3. *A is the dense approximation witness row, recording the inspected completion request, the displayed source point chosen for that request, and the finite tolerance comparison between them.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row consumed by completion-facing clients after X, E, A have been displayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to answer numerical tolerance requests from the dense approximation witness.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source and approximation reads are exposed to consumers.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic radius, slack comparison, and budget consumed by A, R, S, M.*
8. *H records componentwise* hsame *transport for the source point, embedding row, approximation witness, metric-completion row, regular readback, stream windows, dyadic ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$X \longmapsto E \longmapsto A \longmapsto S \longmapsto R, D \longmapsto M.$$

10. *P is the* Pkg *provenance over* $\mathsf{DenseImageCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseImageCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.DenseImageCompletionUp.DenseImageCompletionTasteGate single carrier alignment`

Theorem 1985.2 (Dense image completion NameCert obligations)**.** *For an accepted* $\mathsf{DenseImageCompletion}^{\uparrow}$ *carrier $G = (X, E, A, M, R, S, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseImageCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source point, completion embedding row, dense approximation witness, metric-completion row, regular readback, stream windows, dyadic tolerance ledger, transport, replay, provenance, and local naming rows;*
2. *entry-before-approximation exposure, requiring every completion-facing request to read X through E before the dense witness A can be consumed;*
3. *dense approximation locality, requiring A to bind one displayed completion request, one displayed source row, and one dyadic tolerance budget from D;*
4. *readback readiness, requiring each numerical approximation claim to pass through S and R before it is offered to the metric-completion row M;*
5. *classifier stability, requiring transported packets with the same displayed X, E, A, M, R, S, D route to be identified through the carried* hsame *and* Cont *data;*
6. *ledger non-escape, stating that no quotient completion equality, selected limit, host equality, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential is exported by the packet.*

Proof. Carrier admission is projection from Definition 1985.1. The tuple lists exactly the source point, completion embedding, dense witness, metric-completion, readback, stream, dyadic ledger, transport, replay, provenance, and local naming rows.

Entry-before-approximation exposure follows because E is the only row connecting the displayed source point X to the completion-facing surface. A consumer cannot inspect a dense witness before the source point has been routed through this entry row.

Dense approximation locality is the projection to A together with the tolerance ledger D. The witness records a finite request, a displayed source point, and a dyadic budget; it does not create a host completion object or choose a limit.

Readback readiness uses S and R. The stream row exposes the finite windows inspected by the approximation witness, and the regular readback row is the only numerical route offered to the metric-completion consumer M.

Classifier stability is componentwise transport along H followed by replay through C. Since P and N only source and name the same finite packet, the excluded quotient, selected-limit, host-equality, choice, ambient-completeness, and bridge data have no carrier row from which they could be projected. □

Theorem 1985.3 (Dense image completion approximation route)**.** *Let $G = (X, E, A, M, R, S, D, H, C, P, N)$ be an accepted* $\mathsf{DenseImageCompletion}^{\uparrow}$ *carrier. Every completion-facing approximation exported by G factors through the finite route*

$$X \longmapsto E \longmapsto A \longmapsto S \longmapsto R, D \longmapsto M \longmapsto H, C, P, N.$$

Thus the dense-image statement is a displayed BEDC handoff from source rows to metric-completion consumers, not quotient completion equality, not a selected limit, not host equality, and not an appeal to countable choice or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing approximation request. Projection gives the source row X and the embedding row E, so the request first enters the completion interface through the same finite entry surface named by chapter 1934.

The dense witness A is then read with its dyadic budget D. This records a displayed source point near the inspected completion request at the stated finite tolerance.

The consumer next reads S and R. The stream row provides the finite windows behind the approximation, and the regular rational readback supplies the numerical data passed downstream.

Only after those rows are fixed does the route reach M, the metric-completion row. Transport, replay, provenance, and local naming through H, C, P, N preserve the same displayed route and add no quotient, selected-limit, host-equality, choice, ambient-completeness, or bridge credential. □

Theorem 1985.4 (Dense image completion ledger exhaustion)**.** *For an accepted* $\mathsf{DenseImageCompletion}^{\uparrow}$ *carrier $G = (X, E, A, M, R, S, D, H, C, P, N)$, every tolerance-facing, readback-facing, or metric-completion-facing read exported by G is generated by the rows named in Definition 1985.1. In particular, the packet exports no quotient completion equality, no selected limit, no host equality, no countable-choice schedule, no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no bridge-checking credential.*

Proof. Project the accepted carrier. A tolerance-facing read must pass through D, and the only rows that can consume that dyadic budget are the dense witness A, the stream windows S, the regular readback R, and the metric-completion row M.

A readback-facing consumer is similarly confined to S and R. The stream row fixes the finite observation window, while the regular readback row records the numerical approximation produced from that window and the dyadic ledger.

A metric-completion-facing consumer must pass through X, E, A, S, R, D before M is available. The completion row is therefore downstream of the displayed source entry and the finite dense-witness ledger.

The structural rows H, C, P, N transport, replay, source, and name only the same route. Since the tuple has no other coordinates, route exhaustion rules out quotient completion equality, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{DenseImageCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseImageCompletion}^{\uparrow}$ packet is generated from a displayed source metric point, a CauchyCompletionEmbedding entry row, a dense approximation witness, a MetricCompletion row, RegSeqRat readback, StreamName finite windows, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseImageCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1985.1, Definition 1985.2, Definition 1985.3, and Definition 1985.4 seed the finite dense-image interface between completion embeddings and L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseImageCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entry-before-approximation exposure, dense approximation locality, readback readiness, classifier stability, ledger exhaustion, and a Lean carrier/obligation formalization for BEDC.Derived.DenseImageCompletionUp.

Chapter 1986

A Concrete Naming Certificate for $\mathsf{CauchyModulusSelection}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyModulusSelection}^{\uparrow}$ packet records the finite threshold-selection surface that a regular Cauchy request exposes before any completed real object or quotient stream is consulted. It sits on the L10 route through the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational source row of chapter 301, the Real boundary of chapter 38, and the extraction discipline of chapter 641. The packet records threshold selection for displayed requests only; it is not host choice, quotient stream equality, a selected limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1986.1 (Cauchy modulus-selection carrier)**.** *A* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (R, D, W, M, T, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the regular rational sequence surface whose requests are being served.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request row, including the displayed dyadic radius, slack, comparison, and scale data used by the selection.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation-window family available for the request.*
4. *M is the selected unary threshold row, read as a modulus value for the displayed tolerance and source row.*
5. *T is the request-threshold exactness ledger, recording that the threshold in M answers the tolerance request in D using only the inspected windows in W over the source row R.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *request boundary, exposed only after R, D, W, M, T have been displayed and never as a completed limit or ambient completeness witness.*
7. *H records componentwise* hsame *transport for the regular source, dyadic request, finite windows, selected threshold, exactness ledger, Real boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every Real-facing request through $D, W, R, M, T, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSelection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, W, M, T, E, H, C, P, N$. It has no coordinate for host-level choice, quotient stream equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge data.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSelectionUp.CauchyModulusSelectionTasteGate single carrier alignment`

Theorem 1986.2 (Cauchy modulus-selection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *carrier*

$$X = (R, D, W, M, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusSelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, selected unary threshold, exactness ledger, Real request boundary, transport, replay, provenance, and local naming;*
2. *selected-threshold exactness, requiring T to bind the selected row M to the displayed tolerance request in D over the source row R;*
3. *dyadic tolerance compatibility, requiring every comparison and slack row used by M and T to be read through D;*
4. *finite-window handoff, requiring every source observation used by the selection to occur inside the displayed window family W;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring the source data consumed by the selector to be read through R before M is exported;*
6. $\mathsf{Real}^{\uparrow}$ *non-escape, requiring the boundary row E to remain downstream of R, D, W, M, T and to add no selected limit, quotient equality, trichotomy, or ambient completeness principle;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No local modulus-selection obligation is stored outside these rows.

Proof. Project the carrier of Definition 1986.1. The analytic coordinates are exactly the regular rational source R, the dyadic tolerance request D, the finite windows W, the selected threshold M, the exactness ledger T, and the Real request boundary E.

Threshold exactness is the role of T. It records that M answers the tolerance request in D by reading the source row R only through the finite windows W.

Dyadic compatibility is forced by the absence of any second tolerance coordinate. Every radius, slack row, and comparison used by the selection is therefore read through D.

The handoff to Real-facing consumers is terminal. The row E is downstream of R, D, W, M, T, while H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host choice, quotient equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 1986.3 (Cauchy modulus-selection Real request handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing finite request accepted by a* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *carrier*

$$X = (R, D, W, M, T, E, H, C, P, N)$$

factors through the finite route

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as recorded by the displayed rows D, W, R, E, with the selected threshold row M and exactness ledger T visible before the Real seal is reached.

Proof. Begin with a Real-facing request. By the carrier definition, the request boundary is the row E, and E is available only after the dyadic request, finite windows, regular source, selected threshold, and exactness ledger have been displayed.

Read the route backward from E. The tolerance side is the $\mathsf{DyadicRatCore}^{\uparrow}$ row D, the finite observation surface is the $\mathsf{StreamName}^{\uparrow}$ row W, and the source readback is the $\mathsf{RegSeqRat}^{\uparrow}$ row R.

The selected threshold M is not external to this route. The ledger T binds it to the same D, W, R data before any consumer can inspect the Real boundary.

Finally, H, C, P, N preserve and name the displayed route. Hence the accepted request factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order, with the selected threshold visible before the Real seal and with no bypass through host choice, quotient stream equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Theorem 1986.4 (Cauchy modulus-selection threshold uniqueness)**.** *For every accepted* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *carrier*

$$X = (R, D, W, M, T, E, H, C, P, N),$$

every exported threshold for the displayed request is read through the single selected row M and certified by the exactness ledger T. No consumer of the packet can introduce a second modulus row outside the displayed coordinates $R, D, W, M, T, E, H, C, P, N$.

Proof. Project the carrier of Definition 1986.1. Its only coordinate whose role is a selected unary threshold is M, and its only coordinate whose role is request-threshold exactness is T.

Apply Definition 1986.2. The obligation surface binds selected-threshold exactness to T and requires T to bind M to the displayed dyadic request in D over the source row R.

The classifier has no further threshold coordinate. Therefore any exported threshold visible to a consumer must be the row already displayed as M, certified by T, and transported or replayed only through H, C, P, N. □

Theorem 1986.5 (Cauchy modulus-selection dyadic monotonicity)**.** *For every accepted* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *carrier*

$$X = (R, D, W, M, T, E, H, C, P, N),$$

any refinement of a dyadic tolerance request must be routed through the same $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D before the selected threshold row M and exactness ledger T are visible. In particular, refined requests cannot bypass the dyadic tolerance ledger or the finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*

Proof. Read the analytic route from the carrier. The tolerance request is D, the finite observation surface is W, the regular rational source row is R, and the selected threshold and exactness rows are M, T.

Apply Definition 1986.3. Every Real-facing request reaches the boundary E only after passing through the displayed D, W, R route with M and T visible before the Real seal.

A refined dyadic tolerance request is still a dyadic request. Since the carrier has no second tolerance ledger and no external window coordinate, refinement can only change the data read inside D and then pass through W, R, M, T in the same order. □

Theorem 1986.6 (Cauchy modulus-selection transport closure)**.** *If two accepted* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *packets are classifier-related through their displayed rows, then their selected threshold rows transport componentwise through* H *and replay the same finite route through* C*. The transported route preserves the order* D, W, R, M, T, E *and introduces no external modulus row, tolerance ledger, Real limit, or quotient stream equality.*

Proof. Use the carrier coordinates for the two accepted packets. Classifier relatedness is measured only through the displayed rows $R, D, W, M, T, E, H, C, P, N$, so componentwise comparison has a threshold component, an exactness component, a Real-boundary component, and the transport and replay components.

The row H records the componentwise hsame transport for the regular source, dyadic request, finite windows, selected threshold, exactness ledger, Real boundary, replay, provenance, and local naming rows. Transport of the selected threshold is therefore the M component of the same displayed relation, not a new selector.

The row C records displayed Cont replay from every Real-facing request through $D, W, R, M, T, E, H, P, N$. Replaying after transport follows that route in the same order, so the transported packet preserves the finite handoff and remains inside the original classifier surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSelection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusSelection}^{\uparrow}$ packet is generated from a RegSeqRat source row, a DyadicRatCore tolerance request, finite StreamName observation windows, a selected unary threshold row, a request-threshold exactness ledger, a RealUp request boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1986.1, Definition 1986.2, Definition 1986.3, Definition 1986.4, Definition 1986.5, and Definition 1986.6 seed the finite threshold-selection certificate for regular Cauchy requests on the L10 route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host choice, quotient stream equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-threshold exactness, dyadic tolerance compatibility, finite-window handoff, RegSeqRat readback, RealUp non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSelectionUp.

Chapter 1987

A Concrete Naming Certificate for $\mathsf{FiniteEpsilonWitness}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{FiniteEpsilonWitness}^{\uparrow}$ packet isolates the finite row that answers one inspected epsilon request before any completed real, quotient stream, or ambient choice principle is consulted. It sits on the L10 Real and Completion route through the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite $\mathsf{StreamName}^{\uparrow}$ observation surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback of chapter 301, the threshold-selection interface of chapter 1986, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records one explicit epsilon-witness row; it is not a global modulus, a selected limit, quotient equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1987.1 (Finite epsilon-witness carrier)**.** *A* $\mathsf{FiniteEpsilonWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (E, D, W, M, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the inspected epsilon request row, including the displayed request token and the local comparison budget that the packet is required to answer.*
2. *D is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row refining E into a dyadic radius, scale, slack, and positivity ledger.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose inspected coordinates are sufficient for the displayed request.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row, recording the finite index bound used for the single epsilon request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the source stream inside the window W and threshold M.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, exposed only after E, D, W, M, R have been displayed and never as an independent completeness or quotient-equality witness.*
7. *H records componentwise* hsame *transport for the epsilon request, dyadic tolerance, finite windows, threshold, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the inspected epsilon request through D, W, M, R, S, H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteEpsilonWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, W, M, R, S, H, C, P, N$. It has no coordinate for a family of epsilon requests, a global modulus, a selected limit, quotient stream equality, trichotomy, ambient completeness, Lean verification, or standard bridge data.

Lean4 ✓ `BEDC.Derived.FiniteEpsilonWitnessUp.FiniteEpsilonWitnessTasteGate single carrier alignment`

Theorem 1987.2 (Finite epsilon-witness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEpsilonWitness}^{\uparrow}$ *carrier*

$$X = (E, D, W, M, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteEpsilonWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected epsilon request, positive dyadic tolerance row, finite StreamName window, CauchyModulus threshold, RegSeqRat readback, Real seal boundary, transport, replay, provenance, and local naming;*

2. *request positivity, requiring D to record a positive dyadic tolerance refining the inspected request E;*

3. *finite-window sufficiency, requiring every coordinate used to answer E to occur inside the displayed window row W;*

4. *threshold exactness, requiring M to bind the request E and tolerance row D to a single finite bound before readback;*

5. *rational readback, requiring R to be obtained from the* $\mathsf{RegSeqRat}^{\uparrow}$ *source through W and M;*

6. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring S to remain downstream of E, D, W, M, R and to add no selected limit, quotient equality, trichotomy, or ambient completeness principle;*

7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No local finite epsilon-witness obligation is stored outside these rows.

Proof. Project the carrier of Definition 1987.1. The analytic rows are exactly the inspected request E, the positive dyadic tolerance D, the finite windows W, the threshold row M, the rational readback R, and the Real seal boundary S.

Request positivity is the role of D. Since the carrier has no second tolerance coordinate, the radius, scale, slack, and positivity ledger answering E must be read from D.

The finite computation is forced through W, M, R. The window row W lists the inspected StreamName coordinates, the threshold row M binds those coordinates to the single request E and tolerance D, and R records the RegSeqRat readback available after that threshold has been displayed.

The seal row is terminal. The row S is downstream of E, D, W, M, R, while H, C, P, N transport, replay, source, and name the same finite route. Because the classifier has no coordinate for a family of requests, a global modulus, selected limits, quotient stream equality, trichotomy, ambient completeness, Lean verification, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 1987.3 (Finite epsilon-witness Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing answer accepted by a* $\mathsf{FiniteEpsilonWitness}^{\uparrow}$ *carrier*

$$X = (E, D, W, M, R, S, H, C, P, N)$$

factors through the finite route

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as recorded by the displayed rows D, W, M, R, S*, with the inspected epsilon request* E *visible at the start of the route.*

Proof. Begin with a Real-facing answer admitted by the carrier. By definition, its seal coordinate is S, and S is exposed only after the request E, tolerance row D, finite windows W, threshold row M, and rational readback R have been displayed.

Read the route from the request side. The inspected epsilon row E is refined by the positive $\mathsf{DyadicRatCore}^{\uparrow}$ row D. The finite observation surface is the $\mathsf{StreamName}^{\uparrow}$ row W, and the bound used for that observation is the $\mathsf{CauchyModulus}^{\uparrow}$ row M.

The readback into rational sequence data is R. Only after this readback is visible may the terminal $\mathsf{Real}^{\uparrow}$ seal boundary S be inspected.

Finally, H, C, P, N preserve and name the displayed route. Hence every accepted Real-facing answer factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order, with no bypass through a global modulus, selected limit, quotient stream equality, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEpsilonWitness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteEpsilonWitness}^{\uparrow}$ packet is generated from one inspected epsilon request, a positive DyadicRatCore tolerance row, a StreamName finite-window row, a CauchyModulus threshold row, a RegSeqRat readback row, a RealUp seal boundary, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteEpsilonWitness}^{\uparrow}}$, seed)

Scope closed: Definition 1987.1, Definition 1987.2, and Definition 1987.3 seed the finite single-request epsilon-witness certificate on the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteEpsilonWitness}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.FiniteEpsilonWitnessUp.FiniteEpsilonWitnessTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close global moduli, families of epsilon requests, selected limits, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request positivity, finite-window sufficiency, threshold exactness, RegSeqRat readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteEpsilonWitnessUp.

Chapter 1988

A Concrete Naming Certificate for $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$

Following Bishop–Bridges constructive completion, the $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$ packet records the finite composite admission route from dyadic tolerance data to a $\mathsf{Real}^{\uparrow}$-facing completion read. It ties together the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the threshold handoff of chapter 1986, the nested interval route of chapter 1924, and the universal boundary of chapter 1838. The certificate is a finite route record only; it is not quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1988.1 (Real completion finite-route carrier)**.** *A* $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, W, R, A, M, J, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying the requested dyadic scale, slack, comparison, and radius data used by the completion read.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the displayed tolerance request and for every rational observation consumed downstream.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from D and W.*
4. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dyadic tolerance, finite windows, and regular readback rows have been displayed.*
5. *M is the* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *row binding the displayed tolerance request to a finite threshold and exactness ledger before A is exported.*
6. *J is the* $\mathsf{NestedIntervalReal}^{\uparrow}$ *route row, recording the nested-interval source, dyadic diameter ledger, endpoint seals, finite windows, regular readback, and terminal Real seal used by the same completion read.*
7. *U is the* $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$ *face, recording the extension and uniqueness boundary available to consumers of the displayed completion route.*

8. *H records componentwise* hsame *transport for the dyadic tolerance row, finite windows, regular readback, terminal Real seal, modulus-selection row, nested-interval route, universal-boundary face, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay from every Real-facing completion request through $D, W, R, A, M, J, U, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusSelection}^{\uparrow}$, $\mathsf{NestedIntervalReal}^{\uparrow}$, $\mathsf{BishopCompletionUniversalBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionFiniteRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, A, M, J, U, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge data.*

Lean4 ✓ `BEDC.Derived.RealCompletionFiniteRouteUp.RealCompletionFiniteRouteTasteGate single carrier alignment`

Theorem 1988.2 (Real completion finite-route NameCert obligations)**.** *For every accepted* RealCompletionFiniteRo *carrier*

$$F = (D, W, R, A, M, J, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionFiniteRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance row, finite stream windows, regular rational readback, terminal Real seal, modulus-selection row, nested-interval route, universal-boundary face, transport, replay, provenance, and local naming row;*

2. *tolerance exactness, requiring every completion request to expose its* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, slack, scale, and comparison data in D before any regular readback or Real seal is inspected;*

3. *finite-window exactness, requiring every rational observation used by the readback, modulus selector, nested route, or universal-boundary consumer to occur inside the displayed* $\mathsf{StreamName}^{\uparrow}$ *family W;*

4. *regular-readback ordering, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to be generated from D, W before the terminal* $\mathsf{Real}^{\uparrow}$ *seal A is exported;*

5. *modulus-selection compatibility, requiring M to bind the same tolerance row D and window family W to a finite threshold ledger for the Real-facing request;*

6. *nested-route compatibility, requiring J to reuse the same dyadic, stream, regular-readback, and Real-seal surface instead of introducing an ambient intersection point or selected limit;*

7. *universal-boundary compatibility, requiring U to expose extension and uniqueness reads only after D, W, R, A, M, J have fixed the displayed completion route;*

8. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient stream, selected limit, host real equality, countable-choice schedule, trichotomy branch, open-cover compactness row, ambient Real completeness theorem, Lean verification marker, or bridge credential.*

No Real completion finite-route obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1988.1. The accepted packet displays one dyadic tolerance row, one finite window family, one regular rational readback, one terminal Real

seal, one modulus-selection row, one nested-interval route, one universal-boundary face, and the structural rows that transport, replay, source, and name them.

Tolerance exactness is read from D. Since the carrier has no second tolerance coordinate, every scale, slack, radius, and comparison used by the completion read must be the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ data.

Finite-window exactness is read from W. The regular readback R, the selected threshold row M, the nested-interval route J, and the universal-boundary face U all consume the same finite observations, so no hidden stream or quotient representative can supply additional data.

The ordering of the analytic route is fixed by R, A, M, J, U. The readback R is downstream of D, W, the Real seal A is downstream of R, the modulus row M binds the tolerance request before that seal is exported, the nested route J records the same read as interval data, and the boundary face U is available only after the completion route has been displayed.

Finally, H, C, P, N preserve, replay, source, and name the same finite route. The excluded quotient, selected-limit, host-equality, choice, trichotomy, open-cover, ambient-completeness, Lean-verification, and bridge objects are absent from the carrier, so the listed rows exhaust the local NameCert surface. □

Theorem 1988.3 (Real completion finite-route determinacy)**.** *Let*

$$F = (D, W, R, A, M, J, U, H, C, P, N)$$

be an accepted $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing completion read exported by* F *factors through exactly the displayed finite route*

$$D \longrightarrow W \longrightarrow R \longrightarrow M \longrightarrow J \longrightarrow U \longrightarrow A$$

with componentwise transport, replay, provenance, and local naming supplied only by H, C, P, N*. Consequently the exported read cannot use quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Fix a Real-facing completion read exported by F. The only Real-seal coordinate in the carrier is A, so the read must reach the Real boundary through the displayed terminal seal.

Read the dependencies of A inside the carrier. The seal is downstream of the regular readback R, and R is generated from the dyadic tolerance row D and the finite stream windows W.

The same request is constrained by the local route certificates. The row M records the finite modulus-selection handoff for the displayed tolerance and windows, J records the nested-interval realization of the same readback and seal surface, and U records the Bishop completion universal boundary visible to extension and uniqueness consumers.

The structural rows do not add analytic data. The hsame row H transports the displayed coordinates componentwise, the Cont row C replays the displayed route, and P, N source and name it.

There are no remaining coordinates from which a different route could be read. In particular the carrier contains no quotient stream, selected-limit row, host equality, countable-choice schedule, trichotomy branch, open-cover compactness object, or ambient completeness theorem. Thus every exported Real-facing completion read factors through exactly the displayed finite route and through no excluded object. □

Theorem 1988.4 (Real completion finite-route modulus refinement)**.** *Let* $F = (D, W, R, A, M, J, U, H, C, P, N)$ *be an accepted* $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$ *carrier. If a later consumer strengthens the displayed*

$\mathsf{CauchyModulusSelection}^{\uparrow}$ *row M by a finer finite threshold ledger over the same dyadic request, the exported completion read still factors through the same route*

$$D \longrightarrow W \longrightarrow R \longrightarrow M \longrightarrow J \longrightarrow U \longrightarrow A.$$

The refinement only narrows the finite window requests before the terminal $\mathsf{Real}^{\uparrow}$ *seal A is read; it does not introduce a selected limit, quotient stream, trichotomy branch, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 1988.1. The only modulus-selection coordinate is M, and it is already tied to the displayed dyadic tolerance row D and finite StreamName windows W.

Apply Definition 1988.2. Modulus-selection compatibility requires M to bind the same D, W data used by the regular readback, nested-route row, universal-boundary face, and terminal Real seal.

Apply Definition 1988.3. Every exported read is forced through

$$D \longrightarrow W \longrightarrow R \longrightarrow M \longrightarrow J \longrightarrow U \longrightarrow A.$$

A finer threshold ledger therefore changes only which finite windows inside W are requested before R and A are consumed.

No excluded coordinate is created by that narrowing. The carrier still has no selected limit, quotient stream, trichotomy branch, open-cover compactness row, or ambient Real completeness theorem, and the structural rows H, C, P, N only transport, replay, source, and name the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionFiniteRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionFiniteRoute}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, a CauchyModulusSelection row, a NestedIntervalReal route, a BishopCompletionUniversalBoundary face, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionFiniteRoute}^{\uparrow}}$, seed)

Scope closed: Definition 1988.1, Definition 1988.2, and Definition 1988.3 seed the finite composite route from dyadic tolerance data to Real-facing completion reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionFiniteRoute}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, finite-window exactness, regular-readback ordering, modulus-selection compatibility, nested-route compatibility, universal-boundary compatibility, route determinacy, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionFiniteRouteUp.

Chapter 1989

A Concrete Naming Certificate for $\mathsf{RealCauchyFilter}^{\uparrow}$

Following Bourbaki and Kelley on Cauchy filters, and Bishop–Bridges on constructive real completion, the $\mathsf{RealCauchyFilter}^{\uparrow}$ packet records the finite route by which a displayed Cauchy-filter base is read as regular rational sequence data before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits after the filter-to-net correspondence of chapter 1803, the finite common-refinement operation of chapter 1958, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet names a finite Real-facing completion interface; it is not a quotient-filter construction, ultrafilter principle, selected limit, choice principle, ambient completeness theorem, Lean verification row, or checked bridge.

Definition 1989.1 (Real Cauchy filter carrier)**.** *A* $\mathsf{RealCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, M, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the filter-base row. It records the finite Cauchy-filter base requests, refinement witnesses, and membership reads available before any real-facing consumer inspects the packet.*
2. *M is the finite meet row. It records the* $\mathsf{CauchyFilterMeet}^{\uparrow}$ *common-refinement reads that combine two displayed base requests over the same Cauchy-filter surface.*
3. *D is the dyadic entourage and tolerance ledger. It records the requested dyadic scale, the refinement scale used by the meet row, and the comparison showing that the displayed base request is Cauchy at that scale.*
4. *S is the regular-sequence extraction row. It reads finite windows through* $\mathsf{StreamName}^{\uparrow}$ *and repacks the accepted Cauchy-filter observations as* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, M, D, S have been displayed.*
6. *E records the* hsame *transport routes for the filter base, meet, dyadic ledger, regular-sequence extraction, Real seal, continuation, provenance, and local naming rows.*
7. *H records displayed* Cont *replay from a Real-facing precision request through F, M, D, S, Q in that order.*

8. *C is the* Pkg *provenance over* RealCauchyFilter$^{\uparrow}$, CauchyFilterNetCorrespondence$^{\uparrow}$, CauchyFilterMeet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *P records the local package provenance tying the displayed route to the surrounding Real-and-Completion corridor.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed route

$$F, M, D, S, Q \longmapsto E, H, C, P, N.$$

There is no carrier coordinate for quotient filters, ultrafilters, selected limits, Classical.choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealCauchyFilterUp.RealCauchyFilterTasteGate single carrier alignment`

Theorem 1989.2 (Real Cauchy filter NameCert obligations)**.** *For every accepted* RealCauchyFilter$^{\uparrow}$ *carrier*

$$R = (F, M, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the filter-base row, finite meet row, dyadic tolerance ledger, regular-sequence extraction row, terminal Real seal, transport, replay, provenance, and local naming row;*
2. *filter-base stability, requiring every transported base request to remain within the displayed* hsame *route before any meet or extraction row is read;*
3. *finite-meet closure, requiring pairs of displayed base requests to pass through M and return a common refinement over the same filter-base row;*
4. *Cauchy entailment, requiring each Real-facing tolerance request to be witnessed by the dyadic ledger D after the finite meet row has been read;*
5. *regular-sequence handoff, requiring the accepted filter observations to pass through* StreamName$^{\uparrow}$ *windows and the* RegSeqRat$^{\uparrow}$ *extraction row S before the Real seal is visible;*
6. Real$^{\uparrow}$ *seal descent, requiring the terminal row Q to be consumed only after the route F, M, D, S has been replayed;*
7. *nonescape, requiring the provenance and local naming rows to export no quotient filters, ultrafilters, selected limits, Classical.choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1989.1. The projection exposes exactly the filter base, finite meet, dyadic tolerance ledger, regular-sequence extraction, Real seal, transport, replay, provenance, and local naming rows.

Filter-base stability is supplied by the hsame row E. A transported precision request must still name the same displayed base surface before it can be routed to M, D, or S.

Finite-meet closure is the role of M. Given two displayed base requests, the meet row names a common finite refinement over the same filter base; it does not appeal to an ambient lattice of filters or to quotient-filter equality.

Cauchy entailment is read through D. After the meet row has fixed a common refinement, the dyadic ledger records the requested tolerance and the smaller displayed tolerance that makes the base request Cauchy at the requested scale.

The regular-sequence handoff then passes through S. This row reads the same observations through $\mathsf{StreamName}^{\uparrow}$ windows and repacks them as $\mathsf{RegSeqRat}^{\uparrow}$ data before the terminal seal can be consumed.

Finally the Real seal row Q is downstream of the whole route, while H, C, P, N only replay, source, and name that route. The excluded quotient, ultrafilter, selected-limit, choice, ambient-completeness, verification, and bridge-checking data therefore remain outside the local NameCert surface. □

Theorem 1989.3 (Real Cauchy filter regular-sequence handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RealCauchyFilter}^{\uparrow}$ *carrier*

$$R = (F, M, D, S, Q, E, H, C, P, N)$$

factors through the finite route

$$F \longmapsto M \longmapsto D \longmapsto S \longmapsto Q \longmapsto E, H, C, P, N.$$

In particular, the read first consumes the filter-base row, then the finite-meet row, then the dyadic tolerance ledger, then the $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *extraction row, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It receives no quotient filter, ultrafilter, selected limit, Classical.choice, ambient completeness principle, Lean verification row, or bridge certificate.*

Proof. Begin with a Real-facing consumer named by the provenance rows. By Definition 1989.1, the only terminal Real coordinate is Q, and the displayed continuation to Q is routed through F, M, D, S.

The filter-base row F supplies the source requests. The finite meet row M then aligns pairs of such requests into common refinements over the same base, so the route has no need for quotient filters or ultrafilters.

The dyadic ledger D records the tolerance comparison attached to the chosen refinement. This is the Cauchy evidence consumed by the later regular-sequence extraction row, not a selected host limit.

Next S reads the displayed observations through $\mathsf{StreamName}^{\uparrow}$ windows and repacks the route as $\mathsf{RegSeqRat}^{\uparrow}$ data. Only after that handoff can the terminal $\mathsf{Real}^{\uparrow}$ seal row Q be inspected.

The structural rows E, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory has no coordinate for quotient filters, ultrafilters, selected limits, Classical.choice, ambient completeness, Lean verification, or bridge checking, every Real-facing read is exhausted by the factorization above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyFilter}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 1989.1, Definition 1989.2, and Definition 1989.3 seed the finite Cauchy-filter route into regular rational sequence data and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, ultrafilters, selected limits, Classical.choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base stability, finite-meet closure, Cauchy entailment, regular-sequence handoff, RealUp seal descent, transport, replay, provenance, and local naming for BEDC.Derived.RealCauchyFilter

Constructive story: A $\mathsf{RealCauchyFilter}^{\uparrow}$ packet is generated from a filter-base row, finite meet row, dyadic tolerance ledger, regular-sequence extraction row, Real seal row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1990

A Concrete Naming Certificate for $\mathsf{RealCauchySum}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealCauchySum}^{\uparrow}$ packet records the sum of a constructive real series as a displayed Cauchy endpoint for finite partial sums, not as a host infinite-sum object. It sits after the real-series carrier of chapter 1581, the uniform tail route of chapter 1736, the absolute-domination certificate of chapter 1700, the selected stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the endpoint seal of chapter 38. The packet gives later $\mathsf{Real}^{\uparrow}$ arithmetic and convergence consumers a finite sum-seal interface whose obligations are local to BEDC rows.

Definition 1990.1 (Real Cauchy sum carrier)**.** *A* $\mathsf{RealCauchySum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, W, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{RealSeries}^{\uparrow}$ *term row, read only through the finite real-valued observations already exposed by the series packet.*
2. *S is the finite partial-sum window row, listing selected initial segments, adjacent summand contributions, and the displayed* $\mathsf{Real}^{\uparrow}$ *seals for those partial sums.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family used for the summands, partial sums, tolerance comparisons, and endpoint-facing reads.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every selected summand, partial-sum window, and endpoint approximation opened by the packet.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording addition budgets, comparison radii, tail requests, and readback tolerances.*
6. *M is the Cauchy-tail modulus row: each requested tolerance is paired with a displayed threshold after which all selected partial-sum windows are compared inside the dyadic ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *sum seal, visible only after T, S, W, R, D, M have displayed the finite Cauchy route.*
8. *H stores componentwise* hsame *transport for the series term row, partial-sum windows, StreamName windows, RegSeqRat readbacks, dyadic ledger, tail modulus, Real seal, continuation, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from term reads to partial sums, from partial sums to regular readback, from readback to the dyadic tolerance ledger, from the ledger to the Cauchy-tail modulus, and from that modulus to the Real sum seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealCauchySum}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchySum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, W, R, D, M, E, H, C, P, N$. It has no coordinate for a host infinite sum, quotient stream equality, selected limit, countable-choice selector, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or standard bridge.*

Theorem 1990.2 (Real Cauchy sum NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchySum}^{\uparrow}$ *carrier $K = (T, S, W, R, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCauchySum}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed RealSeries term row, partial-sum windows, StreamName windows, RegSeqRat readbacks, DyadicRatCore ledger, Cauchy-tail modulus, Real sum seal, transport, replay, provenance, and local naming rows;*

2. *partial-sum window exactness, requiring each finite sum observation to pass through T, S, W, R, D before any tail or endpoint row is read;*

3. *Cauchy-tail modulus exactness, requiring M to supply the threshold used for every accepted comparison of later partial-sum windows at the requested tolerance;*

4. *RegSeqRat and dyadic readback coherence, requiring R and D to expose only the selected windows and tolerances named by the packet;*

5. *Real seal nonescape, requiring E to consume the displayed Cauchy route and to export no host infinite sum, quotient stream equality, selected limit, countable choice, trichotomy, ambient completeness, Lean verification, or bridge datum;*

6. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Real Cauchy sum obligation is stored outside these rows.

Proof. Project the accepted carrier $K = (T, S, W, R, D, M, E, H, C, P, N)$. The term row T is already a $\mathsf{RealSeries}^{\uparrow}$ surface, so the classifier sees only the finite term observations and partial-sum data exposed by the packet.

The partial-sum row S supplies the finite windows. These windows are opened through W, read as regular rational data through R, and measured against the dyadic budgets recorded in D.

The modulus row M is the only tail-control coordinate. Once a tolerance is requested, every accepted later-window comparison must use the displayed threshold in M and the ledger route through D.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same displayed route. Since no excluded object is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealCauchySumUp.RealCauchySumCarrier namecert obligations`

Theorem 1990.3 (Real Cauchy sum RegSeqRat handoff)**.** *Every endpoint-facing read from an accepted* $\mathsf{RealCauchySum}^{\uparrow}$ *carrier factors through*

$$T \longmapsto S \longmapsto W \longmapsto R \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

In particular, the RegSeqRat readback row is the only route from selected partial-sum windows to the dyadic tolerance ledger, and the Real sum seal is read only after that regular readback and the displayed Cauchy-tail modulus are already in place.

Proof. Begin with an endpoint-facing request. The carrier definition forces the request to read the $\mathsf{RealSeries}^{\uparrow}$ term row T and the finite partial-sum windows S before any endpoint seal is visible.

The selected observations then pass through W and R. Thus the packet exposes its summands, partial sums, and endpoint approximations as $\mathsf{StreamName}^{\uparrow}$ windows with $\mathsf{RegSeqRat}^{\uparrow}$ readback, not as a host sequence quotient or a chosen limit.

The dyadic ledger D and tail modulus M provide the Cauchy comparison surface. Each requested tolerance is accounted for in D and paired with the displayed threshold stored in M.

The seal row E is downstream of this route, and H, C, P, N preserve, replay, source, and name the same data. Therefore the handoff reaches the Real sum seal without exporting any hidden infinite-sum principle. □

Theorem 1990.4 (Real Cauchy sum cofinal-tail closure)**.** *For every accepted* $\mathsf{RealCauchySum}^{\uparrow}$ *carrier* $K = (T, S, W, R, D, M, E, H, C, P, N)$*, every endpoint-facing comparison of later partial-sum windows at a requested dyadic tolerance factors through the displayed* $\mathsf{RealSeries}^{\uparrow}$ *term row, the finite partial-sum windows, the selected* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the Cauchy-tail modulus row* M*, the terminal* $\mathsf{Real}^{\uparrow}$ *sum seal* E*, and the stored* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. Consequently, the route from cofinal tail control to the endpoint seal is finite inside the packet and has no coordinate for a quotient stream, host infinite sum, selected limit, ambient completeness row, or detached Real seal.*

Proof. Project the accepted carrier supplied by Definition 1990.1. The rows $T, S, W, R, D, M, E, H, C, P, N$ are the whole classifier surface, so an endpoint-facing tolerance request can only address those displayed coordinates.

Apply Definition 1990.2 to expose carrier admission, partial-sum window exactness, and Cauchy-tail modulus exactness. The requested dyadic tolerance is first recorded in D, then paired with its displayed cofinal threshold in M.

Apply Definition 1990.3 to force each later-window read through the same finite partial-sum windows and the same $\mathsf{RegSeqRat}^{\uparrow}$ row R. Thus the comparison route cannot bypass W, R, D while still reaching the endpoint-facing seal.

The final seal E is downstream of M, and H, C, P, N transport, replay, source, and name exactly this route. Since the carrier has no slot for a quotient stream, host infinite sum, selected limit, ambient completeness row, or detached Real seal, the cofinal-tail comparison closes as a finite BEDC route. □

Falsifiable prediction: Every $\mathsf{RealCauchySum}^{\uparrow}$ endpoint-facing read factors through a RealSeries term row, finite partial-sum windows, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Cauchy-tail modulus, a RealUp sum seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, uniform-cauchy-series, absolute-convergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{RealCauchySum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite series surface, partial-sum windows, regular readback, dyadic tolerance accounting, a Cauchy-tail modulus, endpoint Real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchySum}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\mathsf{RealCauchySum}^{\uparrow}}$, seed)

Scope closed: Definition 1990.1, Definition 1990.2, Definition 1990.3, and Definition 1990.4 seed the finite constructive series-sum route from RealSeries rows through RegSeqRat readback, DyadicRatCore tolerance accounting, Cauchy-tail modulus control, and RealUp endpoint sealing.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealCauchySum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient stream equality, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum window exactness, RegSeqRat and DyadicRatCore handoff, Cauchy-tail modulus exactness, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.RealCauchySumUp.

Constructive story: A RealCauchySum$^{\uparrow}$ packet is generated from a RealSeries term row, finite partial-sum windows, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Cauchy-tail modulus, a RealUp sum seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1991

A Concrete Naming Certificate for $\mathsf{TauberianRemainder}^{\uparrow}$

Following Hardy's treatment of Tauberian theorems and Bishop–Bridges constructive analysis, the $\mathsf{TauberianRemainder}^{\uparrow}$ packet records the finite remainder boundary between Abel summation and Cesaro or ordinary real readback. It sits after the summation-by-parts route of chapter 1763, the averaging surface of chapter 1765, the regular rational readback of chapter 301, the dyadic budget carrier of chapter 291, the terminal real seal of chapter 38, and the Tauberian handoff of chapter 1932. The packet names only a finite remainder route; it is not a selected limit, quotient series equality, host real completeness theorem, countable choice, trichotomy, or open-cover compactness principle.

Definition 1991.1 (TauberianRemainder carrier)**.** *A* $\mathsf{TauberianRemainder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, H, T, D, R, E, K, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, displaying the finite Abel transform or summation-by-parts window that supplies the boundary estimate.*
2. *H is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row, displaying the Cesaro averaging window against which the Abel boundary is compared.*
3. *T is the Tauberian side-condition row, recording the finite slow-decrease, bounded-remainder, or one-sided tail ledger admitted for the inspected window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder-budget row, assigning the inspected Abel and Cesaro windows a dyadic error allowance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after A, H, T, D have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular readback row.*
7. *K records componentwise* hsame *transport for Abel rows, Cesaro rows, Tauberian side conditions, dyadic budgets, regular readback, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a precision request through the Abel row, the Cesaro row, the side-condition ledger, the dyadic remainder budget, the regular readback, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{TauberianRemainder}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for a selected limiting value, quotient equality of series names, host real completeness, countable choice, trichotomy, or open-cover compactness.

Lean4 ✓ `BEDC.Derived.TauberianRemainderUp.TauberianRemainderTasteGate single carrier alignment`

Theorem 1991.2 (TauberianRemainder NameCert obligations)**.** *For every accepted* $\mathsf{TauberianRemainder}^{\uparrow}$ *carrier $Q = (A, H, T, D, R, E, K, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}$ *surface consists exactly of carrier admission for that ten-row packet, Abel-window exposure through A, Cesaro-window exposure through H, Tauberian side-condition exposure through T, dyadic remainder-budget exposure through D, regular rational readback through R, real sealing through E, and transport, replay, provenance, and local naming through K, C, P, N.*

Proof. Project the accepted packet $Q = (A, H, T, D, R, E, K, C, P, N)$. Carrier admission exposes exactly the ten rows listed in Definition 1991.1; there is no hidden coordinate for an ambient limit, host equality, or unrestricted completeness principle.

Read the analytic rows in order. The Abel row A supplies the finite boundary estimate, the Cesaro row H supplies the averaging comparison window, and the side-condition row T records the only Tauberian hypothesis admitted by the packet.

The dyadic row D then fixes the visible remainder budget for those inspected rows. The regular readback R and seal E are downstream of A, H, T, D, so no accepted real read can bypass the finite remainder budget.

Finally, the transport row K and replay row C preserve only displayed packet coordinates, while P, N source and name the same carrier. These clauses exhaust the local $\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}$ surface. □

Theorem 1991.3 (TauberianRemainder Abel–Cesaro route)**.** *Every Abel–Cesaro comparison exported by an accepted* $\mathsf{TauberianRemainder}^{\uparrow}$ *carrier factors through*

$$A, H, T, D, K, C, P, N.$$

The route may compare the AbelSummation window with the HardyCesaroMean window only after reading the Tauberian side-condition row and the DyadicRatCore remainder budget attached to the same finite packet.

Proof. Begin with an Abel–Cesaro comparison request. The carrier has one Abel row A and one Cesaro row H, so any comparison between those faces starts on the displayed finite windows.

The side-condition row T is the only row that licenses a Tauberian comparison between the two windows. The dyadic row D is the only row that records the remainder budget for the inspected comparison.

The structural rows K, C, P, N transport, replay, source, and name that same finite route. Since the comparison does not yet consume R or E, it remains a boundary comparison rather than a selected real limit or a completed host equality. □

Theorem 1991.4 (TauberianRemainder real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{TauberianRemainder}^{\uparrow}$ *carrier factors through the full finite route*

$$A, H, T, D, R, E, K, C, P, N.$$

Consequently the real-facing endpoint cannot be obtained from a selected limit, quotient series equality, host real completeness, countable choice, trichotomy, or open-cover compactness; it is visible only through the displayed Abel, Cesaro, Tauberian side-condition, dyadic remainder, regular readback, and seal rows.

Lean4 ✓ `BEDC.Derived.TauberianRemainderUp.TauberianRemainderCarrier real seal nonescape`

Proof. Start with a $\mathsf{Real}^{\uparrow}$ consumer. By Definition 1991.1, the only real seal coordinate is E, and E is downstream of the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Trace R backward through the packet. It reads the Abel row A, Cesaro row H, side-condition row T, and dyadic remainder-budget row D before any regular rational readback is available.

The transport and continuation rows preserve exactly that dependency chain. Thus the consumer cannot replace the displayed route by a selected limit, quotient series equality, host real completeness, countable choice, trichotomy, or open-cover compactness. □

Falsifiable prediction: An accepted $\mathsf{TauberianRemainder}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the $\mathsf{AbelSummation}^{\uparrow}$ row, $\mathsf{HardyCesaroMean}^{\uparrow}$ row, Tauberian side-condition row, $\mathsf{DyadicRatCore}^{\uparrow}$ remainder budget, and $\mathsf{RegSeqRat}^{\uparrow}$ readback row refutes the carrier surface.

Independence witness: abel-summation, hardy-cesaro-mean, regseqrat, dyadicratcore, real, hardy-littlewood-tauberian: no listed sibling supplies the whole ten-row packet $Q = (A, H, T, D, R, E, K, C, P, N)$, because each sibling contributes only a summation route, averaging route, readback surface, budget ledger, seal face, or Tauberian handoff while this chapter binds the finite remainder boundary into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}$.

Constructive story: A $\mathsf{TauberianRemainder}^{\uparrow}$ packet is generated from an $\mathsf{AbelSummation}^{\uparrow}$ row, a $\mathsf{HardyCesaroMean}^{\uparrow}$ row, a Tauberian side-condition row, a $\mathsf{DyadicRatCore}^{\uparrow}$ remainder-budget row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1991.1, Definition 1991.2, Definition 1991.3, and Definition 1991.4 seed the finite Tauberian remainder route over AbelSummation, HardyCesaroMean, DyadicRatCore, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TauberianRemainder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a selected limit, quotient series equality, host real completeness, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface, Abel–Cesaro route theorem, real-seal nonescape theorem, and TasteGate field faithfulness for BEDC.Derived.TauberianRemainderUp.

Chapter 1992

A Concrete Naming Certificate for $\mathsf{CauchyRealOrderedField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealOrderedField}^{\uparrow}$ packet joins the $\mathsf{CauchyRealField}^{\uparrow}$ operation surface with the constructive comparison rows of $\mathsf{CauchyRealOrder}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, and $\mathsf{ArchimedeanOrderedField}^{\uparrow}$. It sits after the real-name seal of chapter 38, the regular rational source rows of chapter 301, the stream-window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the field-facing Cauchy real packet of chapter 1717, the constructive order packet of chapter 1716, the algebra/order comparison packet of chapter 766, and the Archimedean ordered-field comparison packet of chapter 1419. The packet gives Real and Completion consumers a finite ordered-field interface; it is not host real arithmetic, quotient equality, trichotomy, a selected-limit operation, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1992.1 (Cauchy real ordered field carrier)**.** *A* $\mathsf{CauchyRealOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, O, A, B, Z, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyRealField}^{\uparrow}$ *field row. It records the regular rational source family, stream windows, dyadic arithmetic ledger, addition, product, reciprocal, constructive order input, and field-facing real seal already named by the Cauchy real field packet.*
2. *O is the* $\mathsf{CauchyRealOrder}^{\uparrow}$ *constructive order and apartness row. It supplies the positive-gap route, finite refusal of positive apartness, and oriented comparison verdicts read by the ordered-field packet.*
3. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison row. It records the displayed addition, negation, multiplication, absolute-value, nonnegative-order, and strict-apartness reads needed to compare algebra and order data on the same real-name surface.*
4. *B is the* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *bound row. It records the rational-source, rational-embedding, and Archimedean comparison rows that locate the ordered-field interface inside finite rational bounds.*
5. *Z is the shared* $\mathsf{Real}^{\uparrow}$ *seal row. It is downstream of the field, order, algebra/order, and Archimedean rows rather than an independent completed-real carrier.*
6. *H records componentwise* hsame *transport for the field row, order row, algebra/order row, Archimedean row, real seal row, replay row, provenance row, and local naming row.*

7. *C records displayed* Cont *replay from each ordered-field request through F, O, A, B, Z, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealOrderedField}^{\uparrow}$, $\mathsf{CauchyRealField}^{\uparrow}$, $\mathsf{CauchyRealOrder}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealOrderedField}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive ordered-field packet. It has no coordinate for host real arithmetic, quotient equality, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRealOrderedFieldUp.CauchyRealOrderedFieldTasteGate single carrier alignment`

Theorem 1992.2 (Cauchy real ordered field NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealOrderedField}^{\uparrow}$ *carrier*

$$K = (F, O, A, B, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealOrderedField}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Cauchy real field row, constructive order row, RealAlgOrder comparison row, Archimedean ordered-field bound row, shared real seal, transport, replay, provenance, and local naming row;*
2. *field projection, requiring every addition, product, reciprocal, zero, one, and negation read to pass through the displayed* $\mathsf{CauchyRealField}^{\uparrow}$ *row F;*
3. *order projection, requiring every positive-gap, apartness-refusal, and oriented comparison read to pass through the displayed* $\mathsf{CauchyRealOrder}^{\uparrow}$ *row O;*
4. *algebra/order compatibility, requiring the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row A to read the same real-name seal and dyadic comparison ledgers used by F and O;*
5. *Archimedean boundedness, requiring the* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *row B to supply only displayed rational-source, rational-embedding, and bound rows over the same field and order surface;*
6. *shared seal discipline, requiring Z to be downstream of F, O, A, B and never a separate completed-real object;*
7. *transport and replay, requiring H and C to preserve the field, order, comparison, bound, seal, provenance, and naming rows together;*
8. *ledger exhaustion, excluding host real arithmetic, quotient equality, trichotomy, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No Cauchy real ordered-field obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1992.1. The projection exposes exactly the field row, order row, algebra/order comparison row, Archimedean bound row, shared seal row, and structural rows.

The field and order projections are inherited from the sibling Cauchy real surfaces. The row F supplies the finite operation route of chapter 1717, while the row O supplies the positive-gap, negative-apartness, and oriented-order routes of chapter 1716.

The comparison and bound projections are separate visible rows. The row A keeps algebraic and order reads inside the displayed $\mathsf{RealAlgOrder}^{\uparrow}$ endpoint, dyadic, finite-window, and apartness

ledgers, and the row B keeps rational-bound reads inside the displayed $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ rational-source and Archimedean comparison rows.

Finally, Z, H, C, P, N seal, transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for any excluded principle, none can become a local NameCert obligation. □

Theorem 1992.3 (Cauchy real ordered field order-field route)**.** *Every accepted* $\mathsf{CauchyRealOrderedField}^{\uparrow}$ *carrier routes ordered-field reads through the finite chain*

$$F, O \longmapsto A \longmapsto B \longmapsto Z \longmapsto H, C, P, N.$$

Thus the operation surface and the comparison surface are joined only by displayed Cauchy real field, Cauchy real order, RealAlgOrder, and Archimedean ordered-field rows.

Proof. Start from the accepted packet $K = (F, O, A, B, Z, H, C, P, N)$. The only operation coordinate is F, and the only constructive Cauchy comparison coordinate is O.

Read the algebra/order compatibility row next. The row A consumes the same displayed real-name, dyadic, finite-window, and apartness data exposed by the field and order rows, so it cannot introduce a second operation or comparison surface.

Read the Archimedean row after that. The row B contributes rational-source, rational-embedding, and bound evidence over the same real-name surface; it does not replace the field and order rows with an ambient ordered field.

The real seal and structural rows are downstream. The row Z is reached only after F, O, A, B have been displayed, and H, C, P, N preserve this dependency order for every ordered-field consumer. □

Theorem 1992.4 (Cauchy real ordered field non-escape)**.** *For every accepted* $\mathsf{CauchyRealOrderedField}^{\uparrow}$ *carrier* $K = (F, O, A, B, Z, H, C, P, N)$*, every Real or Completion consumer receives only the finite rows displayed by* K*. In particular, the ordered-field packet exports no host real arithmetic, quotient equality, trichotomy, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum, Lean verification, or bridge-checked standard structure.*

Proof. Inspect the carrier inventory. The only public rows are $F, O, A, B, Z, H, C, P, N$, and each of the first four rows is itself a named finite BEDC packet with visible source, ledger, comparison, and naming data.

A Real or Completion consumer may project field operations from F, constructive comparisons from O, algebra/order compatibility from A, or rational bounds from B. Each projection remains tied to the shared seal Z and the same transport and replay rows.

The structural rows do not add analytic content. They transport, replay, source, and name the displayed packet. Therefore no excluded principle has a coordinate, a replay path, or a provenance row through which it can escape to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealOrderedField}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRealOrderedField}^{\uparrow}$ packet is generated from a $\mathsf{CauchyRealField}^{\uparrow}$ field row, a $\mathsf{CauchyRealOrder}^{\uparrow}$ constructive order row, a $\mathsf{RealAlgOrder}^{\uparrow}$ comparison row, an $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ rational-bound row, a shared $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealOrderedField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1992.1, Definition 1992.2, Definition 1992.3, and Definition 1992.4 seed the finite ordered-field route over the existing Cauchy real field, Cauchy real order, RealAlgOrder, Archimedean ordered-field, and shared real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealOrderedField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real arithmetic, quotient equality, trichotomy, selected limits, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a checked finite carrier theorem for BEDC.Derived.CauchyRealOrderedFieldUp binding the displayed field, order, algebra/order, Archimedean, real-seal, transport, replay, provenance, and local naming rows.

Chapter 1993

A Concrete Naming Certificate for $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$

Following Riemann, Darboux, and Bishop–Bridges constructive analysis, the $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$ packet names the finite Cauchy-refinement criterion for Riemann/Darboux integrability. It sits after the tagged-sum surface of chapter 1615, the upper-lower gap route of chapter 1460, the dyadic finite partition carrier of chapter 1863, and the regulated step-primitive handoff of chapter 1557. The packet turns refinement Cauchy control into a $\mathsf{Real}^{\uparrow}$-facing integral handoff without importing host integrability, quotient function equality, selected tags, measure completion, or ambient Real completeness.

Definition 1993.1 (Riemann integrability criterion carrier)**.** *A* $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, S, G, R, B, Q, E, H, C, V, N)$$

with the following displayed rows:

1. *P is the finite partition row, read through* $\mathsf{DyadicPartition}^{\uparrow}$*, naming the ordered cells, endpoints, boundary contact, and common-refinement interface.*
2. *S is the Riemann-sum row, read through* $\mathsf{RiemannSum}^{\uparrow}$*, exposing tagged sums only through displayed cells, tags, widths, values, and finite arithmetic.*
3. *G is the Darboux upper-lower gap row, read through* $\mathsf{DarbouxIntegral}^{\uparrow}$*, recording the visible upper sum, lower sum, and dyadic gap budget on a displayed common refinement.*
4. *R is the common-refinement row. It names the finite refinement that simultaneously transports the partition cells, tagged-sum cells, and Darboux upper/lower approximants before any Cauchy comparison is read.*
5. *B is the dyadic tolerance budget. It records the requested precision, the finite refinement depth, and the budget split used to compare all carried Riemann and Darboux rows inside the same dyadic interval.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row produced from the displayed refinement Cauchy data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal attached to the regular rational handoff, exposing the candidate integral only through the Cauchy-refinement budget.*

8. *H records componentwise* hsame *transport for partitions, Riemann sums, Darboux gaps, refinement rows, tolerance budgets,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, continuation rows, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from finite partitions to tagged sums, from tagged sums and upper/lower approximants to common refinement, from refinement gap control to the regular rational handoff, and from that handoff to the real seal.*
10. *V is the* Pkg *provenance over* $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, S, G, R, B, Q, E, H, C, V, N$. It has no coordinate for a host integrability predicate, quotient equality of integrands, a selected tag family, measure completion, or ambient Real-completeness data.

Lean4 ✓ `BEDC.Derived.RiemannIntegrabilityCriterionUp.RiemannIntegrabilityCriterionTasteGate`
`single carrier alignment`

Theorem 1993.2 (Riemann integrability criterion NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$ *carrier $K = (P, S, G, R, B, Q, E, H, C, V, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityCriteric}}$ *surface consists of carrier admission, finite partition exposure, Riemann-sum readback, Darboux upper/lower gap exposure, common-refinement stability, dyadic tolerance-budget exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and ledger non-escape. These obligations are discharged by the finite route*

$$P, S, G \longmapsto R \longmapsto B \longmapsto Q \longmapsto E$$

together with H, C, V, N.

Proof. Carrier admission is the projection of the tuple in Definition 1993.1. The partition row P, the Riemann-sum row S, and the Darboux gap row G are displayed before any limiting language is available to a consumer.

Common-refinement stability is obtained by finite refinement induction on R. The base case is the carried partition itself. In the refinement step, each new dyadic subcell records its parent cell, transports the tag and upper/lower approximation reads through H, and replays the finite sum and gap routes through C.

The dyadic tolerance-budget row B then compares the transported Riemann sums and Darboux upper/lower gaps on the same refined cells. Since the budget is finite, the comparison is a row of BHist arithmetic rather than a host quantification over all refinements.

The handoff rows Q and E are read only after the budget route has been displayed. Provenance V and the local name N source the packet, and the absence of host-integrability, quotient-function, selected-tag, measure-completion, and ambient-completeness coordinates gives ledger non-escape. □

Theorem 1993.3 (Cauchy refinement handoff)**.** *An accepted* $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$ *packet hands a Real-facing integration consumer only the displayed finite partition row, Riemann-sum row, Darboux gap row, common-refinement row, dyadic tolerance budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transports, displayed* Cont *replays,* Pkg *provenance, and local* NameCert *row. The handoff supplies the constructive Cauchy refinement criterion for the integral value, but it does not export host integrability, quotient equality of functions, selected tags, measure completion, or ambient Real completeness.*

Proof. Start from the obligation surface of Definition 1993.2. A consumer first receives the finite partition, Riemann-sum, and Darboux gap rows, with the sibling surfaces of chapter 1615, chapter 1460, and chapter 1863 fixing the finite reads.

The common-refinement row R is then consumed before any regular rational name is exposed. Finite refinement induction transports each relevant tagged-sum and upper/lower gap read to the shared dyadic cells, so the tolerance budget B compares rows that live in one displayed refinement ledger.

The row Q packages these budgeted comparisons as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and E seals the result as the Real-facing candidate integral. A $\mathsf{RegulatedIntegral}^{\uparrow}$ consumer may use the same finite step-primitive route of chapter 1557, but it receives only the rows listed in the carrier.

Thus the Cauchy refinement criterion reaches the Real boundary through finite BEDC data. The excluded analytic objects have no carrier coordinate and no continuation route, so they cannot be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}$ packet is generated from finite partition rows, Riemann-sum rows, Darboux upper/lower gap rows, a displayed common-refinement row, a dyadic tolerance budget, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1993.1, Definition 1993.2, and Definition 1993.3 seed the constructive Cauchy-refinement criterion connecting finite Riemann/Darboux control to a Real-facing integral handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host integrability, quotient function equality, selected tag families, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition exposure, Riemann-sum readback, Darboux gap exposure, common-refinement stability, dyadic tolerance-budget exactness, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and non-escape for BEDC.Derived.RiemannIntegrabilityCriterionUp.

Chapter 1994

A Concrete Naming Certificate for $\mathsf{CauchySpeedup}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchySpeedup}^{\uparrow}$ packet records the finite route by which an arbitrary displayed Cauchy source is accelerated along a cofinal schedule before it is read as regular rational data. It sits after the regularization interface of chapter 376, the finite acceleration surfaces of chapter 1518 and chapter 381, the window interface of chapter 126, the rational readback of chapter 301, and the terminal real seal of chapter 38. The packet is a finite L10 speedup certificate; it is not quotient stream equality, a selected limit, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 1994.1 (Cauchy speedup carrier)**.** *A* $\mathsf{CauchySpeedup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, J, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source Cauchy row, recording the finite requests and source observations available before any speedup schedule is inspected.*
2. *J is the cofinal speedup schedule row, carrying the monotone tail-access route and the displayed evidence that every downstream tolerance request is eventually reached.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the requested dyadic scales, slack comparisons, and exact tolerance accounting used by the accelerated route.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened by the schedule J over the source row A.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same scheduled windows and dyadic ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after A, J, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the source Cauchy row, cofinal schedule, dyadic ledger, finite windows, regular rational readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each Real-facing request through A, J, D, W, R, E and then through H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySpeedup}^{\uparrow}$, $\mathsf{CauchyRegularization}^{\uparrow}$, $\mathsf{FastCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySpeedup}^{\uparrow}}$ *row.*

The classifier compares accepted speedup packets only through $A, J, D, W, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean evidence, or standard-bridge data.*

Lean4 ✓ `BEDC.Derived.CauchySpeedupUp.CauchySpeedupTasteGate single carrier alignment`

Theorem 1994.2 (Cauchy speedup NameCert obligations)**.** *For every accepted* $\mathsf{CauchySpeedup}^{\uparrow}$ *carrier*

$$S = (A, J, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySpeedup}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the source Cauchy row A, cofinal speedup schedule J, dyadic tolerance ledger D, scheduled stream windows W, regular rational readback R, Real seal E, and structural rows H, C, P, N;*
2. *classifier transport, requiring every accepted replacement to preserve the same componentwise source, schedule, tolerance, window, readback, seal, replay, provenance, and naming rows through H and C;*
3. *cofinal schedule stability, requiring J to remain monotone and cofinal for the displayed tail requests over A under classifier transport;*
4. *dyadic tolerance exactness, requiring every accelerated tolerance claim to be read through the ledger D and the scheduled windows W;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to be downstream of A, J, D, W and to use no unlisted stream coordinate;*
6. $\mathsf{Real}^{\uparrow}$ *non-escape, requiring E to be consumed only after the scheduled regular rational route has been displayed and to add no selected limit, quotient equality, trichotomy, choice principle, or ambient completeness claim;*
7. *ledger exactness, requiring H, C, P, N to transport, replay, source, and name exactly the displayed route A, J, D, W, R, E.*

No local speedup obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchySpeedupUp.CauchySpeedupNameCertObligations`

Proof. Project the carrier of Definition 1994.1. The analytic rows are the source Cauchy row A, the cofinal schedule J, the dyadic ledger D, the finite windows W, the regular rational readback R, and the terminal Real seal E.

Classifier transport is componentwise. The row H transports the same source, schedule, tolerance, window, readback, seal, replay, provenance, and naming coordinates, while C replays Real-facing requests through the same ordered route.

Cofinal schedule stability is the role of J. Since the carrier has no second schedule coordinate, every accelerated tail request must be read through the displayed schedule, and transport can only preserve that schedule through the corresponding hsame component.

Dyadic exactness is forced by D and W. The ledger stores the requested dyadic scales and slack comparisons, and the windows opened by J are exactly the windows available for the tolerance read.

The handoff to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ is downstream. The readback row R is built from A, J, D, W, the seal E is reached only after R, and the structural rows H, C, P, N only preserve and name that route. Because no excluded coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchySpeedupUp.TasteGate.CauchySpeedupTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySpeedup}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySpeedup}^{\uparrow}$ packet is generated from a source Cauchy row, a cofinal speedup schedule, a DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySpeedup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1994.1 and Definition 1994.2 seed the finite route from arbitrary displayed Cauchy data through cofinal acceleration into regular rational readback and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySpeedup}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchySpeedupUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, classifier transport, cofinal schedule stability, dyadic tolerance exactness, RegSeqRat handoff, RealUp non-escape, ledger exactness, provenance, and local naming for BEDC.Derived.CauchySpeedupUp.

Chapter 1995

A Concrete Naming Certificate for $\mathsf{HilbertCube}^{\uparrow}$

Following Hilbert's cube as treated in Kelley and Bourbaki, the $\mathsf{HilbertCube}^{\uparrow}$ packet records the countable product boundary as a finite BEDC naming certificate rather than as a completed host product. It consumes the finite stream-window interface of chapter 126, the regular rational readback surface of chapter 301, the real-name seal of chapter 38, the binary product-metric ledger of chapter 424, and the finite compact-metric product route of chapter 1822. The packet is the standard constructive test object: a countable coordinate schedule over real interval seals whose every consumer request is reduced to finitely many displayed coordinate windows.

Definition 1995.1 (Hilbert cube carrier)**.** *A* $\mathsf{HilbertCube}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, W, S, R, E, M, K, T, C, Q, N)$$

with the following displayed rows:

1. *I is the coordinate-window row. It records a finite set of inspected natural-number coordinates, the requested rational tolerances for those coordinates, and the interval bounds assigned to the inspected coordinates.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule. It names exactly the stream entries inspected at the coordinates listed by I and contains no row for an unrequested tail coordinate.*
3. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It reads the rational approximants and tolerance witnesses exposed by W for the displayed coordinate windows.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *interval seal row. For every coordinate named in I, it seals the associated regular rational readback into the displayed closed interval boundary for that coordinate.*
5. *E is the finite projection row. It packages the displayed coordinate windows as a finite product route, using the* $\mathsf{ProductMetric}^{\uparrow}$ *ledger for binary projection steps and the* $\mathsf{CompactMetricProduct}^{\uparrow}$ *route when a finite compact-metric product consumer asks for paired interval data.*
6. *M records componentwise* hsame *transport for the coordinate-window row, the stream-window schedule, the rational readback, the real interval seals, the finite projection row, replay, provenance, and local naming.*
7. *K records displayed* Cont *replay from a consumer request through*

$$I \longmapsto W \longmapsto S \longmapsto R \longmapsto E \longmapsto M, Q, N.$$

8. *T is the tail-boundary row. It records that coordinates not named by I are invisible to the current consumer read and contribute only the displayed interval-bound promise, not a selected coordinate value.*

9. *Q is the* Pkg *provenance over* $\mathsf{HilbertCube}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, W, S, R, E, M, K, T, Q, N$. It has no coordinate for quotient streams, choice-selected coordinates, open-cover compactness, host function equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.HilbertCubeUp.HilbertCubeTasteGate single carrier alignment`

Theorem 1995.2 (Hilbert cube NameCert obligations)**.** *For every accepted* $\mathsf{HilbertCube}^{\uparrow}$ *carrier $H = (I, W, S, R, E, M, K, T, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the coordinate-window row, finite stream schedule, regular rational readback, real interval seals, finite projection row, tail boundary, transport, replay, provenance, and local naming;*

2. *coordinate-window exactness, requiring every displayed coordinate request to be read first from I and then through the matching* $\mathsf{StreamName}^{\uparrow}$ *window in W;*

3. *real interval sealing, requiring every coordinate value exposed to a consumer to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row S and the* $\mathsf{Real}^{\uparrow}$ *interval seal row R;*

4. *finite projection compatibility, requiring every product-metric or compact-metric product read to factor through the finite projection row E and the displayed structural rows M, K, Q, N;*

5. *boundary nonescape, requiring the packet to export no quotient stream, choice-selected coordinate, open-cover compactness argument, host function equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No Hilbert cube obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 1995.1. The accepted packet displays the coordinate-window row I, the finite $\mathsf{StreamName}^{\uparrow}$ schedule W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback S, the $\mathsf{Real}^{\uparrow}$ interval seals R, the finite projection row E, the tail boundary T, and the structural rows M, K, Q, N.

Coordinate-window exactness follows from the order of the carrier. A consumer names only the coordinates listed in I, and the only stream observations available for those coordinates are the finite windows in W.

The real interval clause is downstream of this finite window. The row S reads rational approximants from the displayed windows, and R seals those readbacks as coordinate interval data before any product-metric or compact-metric product row is visible.

Projection compatibility is then a finite-product statement. The row E repacks only the displayed coordinate seals, using the $\mathsf{ProductMetric}^{\uparrow}$ and $\mathsf{CompactMetricProduct}^{\uparrow}$ routes already named in the provenance row.

Since the carrier has no coordinate for quotient streams, selected coordinates, open-cover compactness, host function equality, or ambient completeness, the local NameCert surface cannot store such an obligation. □

Theorem 1995.3 (Hilbert cube finite coordinate projection)**.** *Let $H = (I, W, S, R, E, M, K, T, Q, N)$ be an accepted* $\mathsf{HilbertCube}^{\uparrow}$ *carrier. Every consumer read of H factors through finitely many displayed coordinate windows:*

$$I \longmapsto W \longmapsto S \longmapsto R \longmapsto E \longmapsto M, K, Q, N.$$

In particular, a $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer can inspect only the coordinates named by I and cannot force a read of the unlisted countable tail.*

Proof. Begin with an arbitrary consumer read. The carrier exposes no coordinate data before I, so the read first names a finite coordinate-window request.

The request then moves through W and S. These rows contain only the finite stream windows and rational readbacks attached to the coordinates already listed by I.

The $\mathsf{Real}^{\uparrow}$ interval seals in R are built from those readbacks. A real-facing consumer therefore sees a finite family of sealed coordinate intervals rather than a completed countable sequence.

For product-facing consumers, the only subsequent route is E. That row repacks the finite sealed family through the product-metric and compact-metric product surfaces, while M, K, Q, N transport, replay, package, and name the same finite route.

The tail-boundary row T records noninspection of every unlisted coordinate. Hence the accepted consumer read factors through the displayed finite coordinate windows and cannot force an additional tail read. □

Theorem 1995.4 (Hilbert cube real-completion boundary)**.** *Every accepted* $\mathsf{HilbertCube}^{\uparrow}$ *carrier excludes quotient streams, choice-selected coordinates, open-cover compactness, host function equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from its public boundary. Its real-facing completion surface is only the finite route through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *interval seals, the finite* $\mathsf{ProductMetric}^{\uparrow}$ *or* $\mathsf{CompactMetricProduct}^{\uparrow}$ *projection row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}$ *row.*

Proof. Project the accepted carrier. The only real-facing rows are the finite stream-window schedule W, the regular rational readback S, and the interval seals R attached to the coordinate-window row I.

The finite product surface does not add a completed countable product. It reads only the row E, whose inputs are the displayed coordinate seals and whose provenance points to the existing $\mathsf{ProductMetric}^{\uparrow}$ and $\mathsf{CompactMetricProduct}^{\uparrow}$ finite routes.

Transport and replay preserve this boundary componentwise. The rows M and K move the listed coordinates, readbacks, interval seals, finite projection row, and tail boundary without introducing a second equality or completion coordinate.

The provenance and local naming rows package exactly this finite route. Because quotient streams, selected coordinates, open-cover compactness, host function equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from $I, W, S, R, E, M, K, T, Q, N$, no public consumer can read them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1995.1, Definition 1995.2, Definition 1995.3, and Definition 1995.4 seed the finite coordinate-window boundary for the Hilbert cube over StreamName, RegSeqRat, Real interval seals, product metrics, compact-metric finite products, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertCube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, choice-selected coordinates, open-cover compactness, host function equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coordinate-window exactness, real interval sealing, finite projection compatibility, boundary nonescape, consumer factorization, transport, replay, provenance, and local naming for BEDC.Derived.HilbertCubeUp.

Constructive story: A HilbertCube$^{\uparrow}$ packet is generated from a finite coordinate-window row, StreamName finite-window schedule, RegSeqRat readback, RealUp interval seals, ProductMetric or CompactMetricProduct finite projection rows, a tail boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 1996

A Concrete Naming Certificate for $\mathsf{EquicontinuousCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Bourbaki–Kelley language of uniform completion, the $\mathsf{EquicontinuousCompletion}^{\uparrow}$ packet records the finite route by which an equicontinuous family remains readable after completion handoff. It sits after the finite shared-modulus surface of chapter 413, the Cauchy filter and directed-net completion boundary of chapter 1473, the complete metric row of chapter 128, and the Cauchy-sequence carrier of chapter 406. Its L10 readback is routed through the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the regular rational handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite NameCert surface for equicontinuous completion data; it is not Arzela–Ascoli compactness, selected limits, quotient completion, host function extensionality, countable choice, or ambient completeness.

Definition 1996.1 (EquicontinuousCompletion carrier)**.** *An* $\mathsf{EquicontinuousCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, U, M, S, W, R, A, T, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row displaying the shared source and target metrics, finite family ledger, finite probe centers, rational tolerance histories, and common modulus rows.*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row through which completion-facing consumers read Cauchy-filter, directed-net, universal-extension, and completion-classifier data.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row supplying the finite completeness boundary used by the completion handoff, without adding a selected limit.*
4. *S is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *row recording the sequence-side Cauchy names consumed by the same completion request.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for every displayed source, target, tolerance, modulus, and completion read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and used for all rational precision comparisons exposed by the packet.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after E, U, M, S, W, R have been displayed.*
8. *T is the route ledger from shared equicontinuity data through completion handoff and then through finite StreamName–RegSeqRat–Real readback.*

9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay from each completion-facing family request through $E, U, M, S, W, R, A, T, H, P, N$*
11. *P is the* Pkg *provenance over* $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $E, U, M, S, W, R, A, T, H, C, P, N$. It has no coordinate for open-cover compactness, function-space compactness, selected completed functions, quotient equality of completion representatives, host function extensionality, countable choice, or ambient completeness.

Theorem 1996.2 (EquicontinuousCompletion NameCert obligation surface)**.** *For every accepted* $\mathsf{EquicontinuousCompletion}^{\uparrow}$ *carrier*

$$Q = (E, U, M, S, W, R, A, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuousCompletion}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier exposure, requiring the displayed packet $E, U, M, S, W, R, A, T, H, C, P, N$ to be the whole public carrier;*
2. *common-modulus classifier stability, requiring carrier comparison to preserve the shared* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *source, target, finite family, probe-center, rational-tolerance, and common-modulus rows componentwise;*
3. *finite-window exactness, requiring every source, target, tolerance, modulus, Cauchy-sequence, completion, and real-seal read to occur through the stored* $\mathsf{StreamName}^{\uparrow}$ *window family W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R;*
4. *completion handoff, requiring completion-facing consumers to pass from the equicontinuity row E through the displayed* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *and* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *rows U, M, S before the terminal* $\mathsf{Real}^{\uparrow}$ *seal A is exported;*
5. *ledger non-escape, requiring T, H, C, P, N to transport, replay, source, and name only the displayed rows and never an Arzela–Ascoli compactness principle, selected limit, quotient completion, host function equality, countable-choice schedule, or ambient completeness theorem.*

No EquicontinuousCompletion obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.EquicontinuousCompletionUp.EquicontinuousCompletionTasteGate single carrier alignment`

Proof. Carrier exposure is projection from Definition 1996.1. The accepted packet displays the equicontinuity-family row, uniform-completion row, complete-metric row, Cauchy-sequence row, finite stream windows, regular rational readback, terminal Real seal, route ledger, transport, replay, provenance, and local name row.

Common-modulus classifier stability is read from E and H. The source and target metrics, finite family ledger, finite probe centers, rational tolerance histories, and common modulus rows are compared componentwise, so a completion-facing comparison cannot replace the shared modulus surface by a chosen external modulus.

Finite-window exactness is read from W and R. Every inspected family value, tolerance request, radius response, Cauchy-sequence observation, completion witness, and Real seal comparison is

routed through the displayed window family and regular rational readback before any terminal seal is available.

The completion handoff is the ordered route through U, M, S, A. A consumer first sees the equicontinuity-family row E, then the uniform-completion, complete-metric, and Cauchy-sequence rows that mediate completion data, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally T, H, C, P, N preserve this same route under transport, replay, provenance, and naming. Because the carrier has no coordinates for Arzela–Ascoli compactness, selected limits, quotient completion, host function equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuousCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EquicontinuousCompletion}^{\uparrow}$ packet is generated from an EquicontinuityFamily row, UniformCompletion row, CompleteMetric row, CauchySequenceSpace row, finite StreamName windows, RegSeqRat readback, terminal RealUp seal, route ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1996.1 and Definition 1996.2 seed the finite common-modulus completion route over EquicontinuityFamily, UniformCompletion, CompleteMetric, CauchySequenceSpace, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Arzela–Ascoli compactness, function-space compactness, selected completed functions, quotient completion equality, host function extensionality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, common-modulus classifier stability, finite-window exactness, completion handoff, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.EquicontinuousCo

Chapter 1997

A Concrete Naming Certificate for MonotoneSubsequenceTheorem$^{\uparrow}$

Following Erdős–Szekeres and Bishop–Bridges constructive analysis, the MonotoneSubsequenceTheorem$^{\uparrow}$ packet records the finite selector-theorem surface used by downstream compactness routes. It stores source sequence windows, a peak-valley or monotone-branch selector ledger, cofinality rows, selected monotone windows, dyadic tolerance rows, a RegSeqRat$^{\uparrow}$ handoff, a Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert data. It is a displayed certificate surface for finite BEDC consumers, not a countable-choice principle or an open-cover compactness theorem.

Definition 1997.1 (Monotone subsequence theorem carrier)**.** *A* MonotoneSubsequenceTheorem$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, B, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence-window ledger. Each row records the inspected finite source window and the comparison cells visible to the theorem surface.*
2. *B is the peak-valley or monotone-branch selector ledger. A row either records a displayed peak-valley split or records the finite monotone branch selected from the inspected window.*
3. *Q is the cofinality evidence for the inspected selector thresholds, limited to the thresholds that occur in the packet.*
4. *W is the selected monotone-window family read from S, B, Q through the finite* MonotoneSubsequence$^{\uparrow}$ *route of chapter 1405.*
5. *D is the dyadic tolerance ledger attached to the selected windows before any regular-rational or real-facing handoff is available.*
6. *R is the* RegSeqRat$^{\uparrow}$ *handoff row for the selected monotone windows.*
7. *E is the* Real$^{\uparrow}$ *seal row exposed only after the selected-window handoff has passed through D and R.*
8. *H stores componentwise* hsame *transport for source windows, branch rows, cofinality rows, selected monotone windows, dyadic tolerance rows, the regular handoff, the Real seal, continuation rows, provenance rows, and local naming rows.*

9. *C stores displayed* Cont *replay from S, B, Q to W, from W to D, from D to R, and from R to E.*
10. *P is the* Pkg *provenance over* MonotoneSubsequenceTheorem$^{\uparrow}$, MonotoneSubsequence$^{\uparrow}$, BolzanoWeierstrassSelecto BolzanoWeierstrass$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MonotoneSubsequenceTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for countable choice, arbitrary infinite subsequence selection, quotient stream equality, host real equality, open-cover compactness, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MonotoneSubsequenceTheoremUp.TasteGate.MonotoneSubsequenceTheoremTasteGate single carrier alignment`

Theorem 1997.2 (Monotone subsequence theorem NameCert obligations)**.** *For every accepted* MonotoneSubsequenceTheorem$^{\uparrow}$ *carrier*

$$T = (S, B, Q, W, D, R, E, H, C, P, N),$$

the local NameCert$_{\text{MonotoneSubsequenceTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source windows, branch ledger, cofinality rows, selected monotone windows, dyadic rows, regular handoff, seal row, transport, replay, provenance, and local name;*
2. *branch stability for the peak-valley or monotone-branch selector ledger under the recorded* hsame *transports;*
3. *cofinal coverage for every inspected selector threshold listed in Q;*
4. *selected-window handoff through* StreamName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *before the* Real$^{\uparrow}$ *seal row is consumed;*
5. *non-escape from countable choice, arbitrary infinite subsequence selection, quotient stream equality, host real equality, open-cover compactness, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1997.1. The rows $S, B, Q, W, D, R, E, H, C, P, N$ are the only available coordinates, so carrier admission is exactly admission of those displayed rows.

The selector-theorem content is finite. Branch stability is read from the peak-valley or monotone-branch ledger B, and cofinal coverage is read from the inspected-threshold ledger Q. The actual selected windows then route through the finite MonotoneSubsequence$^{\uparrow}$ packet of chapter 1405.

The analytic handoff uses the existing downstream interfaces. Selected windows are consumed through the StreamName$^{\uparrow}$ surface of chapter 126, dyadic tolerance rows feed the RegSeqRat$^{\uparrow}$ handoff of chapter 301, and only then does the terminal Real$^{\uparrow}$ boundary of chapter 38 become visible.

Finally inspect the excluded data. The carrier has no row for countable choice, arbitrary infinite subsequence selection, quotient stream equality, host real equality, open-cover compactness, or ambient completeness, and the structural rows only transport, replay, source, and name the displayed packet. Hence the five listed obligations exhaust the local NameCert surface. □

Theorem 1997.3 (Monotone subsequence theorem Bolzano–Weierstrass handoff)**.** *Every accepted* MonotoneSubsequenceTheorem$^{\uparrow}$ *packet exports to Bolzano–Weierstrass consumers only the finite route*

$$S, B, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The handoff factors through chapter 1405, chapter 1408, and chapter 1254; its window, regular-rational, and Real endpoints are read through chapter 126, chapter 301, and chapter 38.

Proof. Start with the selector route. The source windows S, branch ledger B, and inspected cofinality rows Q determine the selected monotone windows W only through the finite selector packet recorded in chapter 1405.

Next pass to the Bolzano–Weierstrass selector boundary. The selector consumer of chapter 1408 receives the selected monotone windows together with their dyadic tolerance and regular handoff rows, not an ambient subsequence object.

The Bolzano–Weierstrass chapter of chapter 1254 can therefore consume only the displayed route. The windows are read through chapter 126, the selected regular-rational handoff is read through chapter 301, and the terminal seal is read through chapter 38.

Since the route has no row for countable choice, arbitrary infinite subsequence selection, quotient stream equality, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every Bolzano–Weierstrass-facing use remains inside the finite selector-certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneSubsequenceTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequenceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1997.1, Definition 1997.2, and Definition 1997.3 seed the finite selector-theorem carrier, its local NameCert obligations, and its Bolzano–Weierstrass handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequenceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, arbitrary infinite subsequence selection, quotient stream equality, host real equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch stability, inspected-threshold cofinal coverage, selected-window RegSeqRat handoff, and Bolzano–Weierstrass handoff non-escape for BEDC.Derived.MonotoneSubsequenceTheoremU

Constructive story: A $\mathsf{MonotoneSubsequenceTheorem}^{\uparrow}$ packet is generated from source sequence windows, a peak-valley or monotone-branch selector ledger, cofinality rows, selected monotone windows, dyadic tolerance rows, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1998

A Concrete Naming Certificate for $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name is replaced by a cofinal subsequence without changing the real-name seal visible to downstream consumers. It sits over the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance discipline of chapter 291, and the terminal real-name boundary of chapter 38. It also refines the subsequence route of chapter 381 through the explicit cofinal selector ledger of chapter 405.

Definition 1998.1 (RegularCauchyCofinalSubsequence carrier)**.** *A* $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, \phi, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular Cauchy rational observations are being reindexed.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for the inspected source windows and selected cofinal windows.*
3. *ϕ is a unary cofinal index map row; it records the selected source index for each displayed request, monotonicity on the inspected requests, and cofinality witnesses for the inspected thresholds.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic radii, endpoint observations, comparison cells, and slack rows before and after the selected index map is applied.*
5. *R is the pulled-back* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and their transported dyadic tolerance rows.*
6. *E is the inherited* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after S, W, ϕ, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the source row, observation schedule, cofinal map, tolerance ledger, regularity readback, real seal, replay, package, and local name rows.*
8. *C records displayed* Cont *replay from a subsequence request through the same rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, \phi, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a host subsequence function, selected ambient limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1998.2 (RegularCauchyCofinalSubsequence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ *carrier*

$$K = (S, W, \phi, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *observation schedule, cofinal index map, dyadic tolerance ledger, pulled-back regularity row, inherited* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local name;*
2. *cofinal schedule stability, requiring ϕ to be unary, monotone on displayed requests, and cofinal on every inspected threshold before any selected window is consumed;*
3. *regularity pullback along the cofinal map, requiring the selected* $\mathsf{StreamName}^{\uparrow}$ *windows and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows to feed the pulled-back* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. $\mathsf{Real}^{\uparrow}$ *seal compatibility, requiring E to be read only after the source, selected schedule, cofinal map, tolerance ledger, and regularity pullback have been displayed;*
5. *ledger non-escape, requiring H, C, P, N to exhaust the certificate route and to export no quotient stream, host subsequence function, selected ambient limit, countable choice, ambient completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyCofinalSubsequenceUp.RegularCauchyCofinalSubsequenceTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 1998.1. Its displayed rows are exactly the regular rational source, observation schedule, cofinal index map, tolerance ledger, pulled-back regularity row, seal row, and structural provenance.

Cofinal schedule stability is read from the ϕ coordinate. Since ϕ is the only row that names selected indices, every selected window in W must be reached through its displayed monotone and cofinal checks.

Regularity pullback is then forced by the order of the rows. The dyadic ledger D attaches the selected tolerances to those windows, and the readback row R consumes exactly those selected windows and tolerance rows before any real-facing read can occur.

Seal compatibility follows because E is downstream of S, W, ϕ, D, R. The componentwise hsame rows and displayed Cont replay preserve that order, while the package and local name rows cite only the listed dependencies.

Thus the five obligations exhaust the finite carrier route. With no coordinate for quotient streams, host subsequence functions, selected ambient limits, countable choice, or ambient completeness, no excluded datum can be exported. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ real-facing read factors through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ schedule, cofinal index map, dyadic

tolerance ledger, pulled-back regularity row, and inherited $\mathsf{Real}^{\uparrow}$ seal before any consumer can inspect the seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1998.1 and Definition 1998.2 seed the finite cofinal-subsequence route for regular Cauchy rational names over displayed StreamName windows, dyadic tolerance ledgers, RegSeqRat pullback, and the inherited RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host subsequence functions, selected ambient limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal schedule stability, regularity pullback, RealUp seal compatibility, and ledger non-escape for BEDC.Derived.RegularCauchyCofinalSubsequenceUp.

Constructive story: A $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName observation schedule, unary cofinal index map, DyadicRatCore tolerance ledger, pulled-back regularity row, inherited RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 1999

A Concrete Naming Certificate for $\mathsf{GaugeIntegral}^{\uparrow}$

Following Henstock, Kurzweil, and Bishop–Bridges constructive analysis, the $\mathsf{GaugeIntegral}^{\uparrow}$ packet names gauge-partition integration by finite tagged subdivisions, visible sum rows, Darboux gap comparison, regulated-integral compatibility, and Real/Completion handoff data. It consumes the gauge-subdivision surface of chapter 1861, the tagged-mesh sum boundary of chapter 1526, the upper-lower gap route of chapter 1460, the finite step primitive route of chapter 1557, and the Real/Completion seal rows used throughout the L10 substrate. The packet is a finite naming surface for one displayed interval and integrand window; it is not general open-cover compactness, a selected family of partitions, a quotient of functions, measure completion, or ambient real completeness.

Definition 1999.1 (Gauge integral carrier)**.** *A* $\mathsf{GaugeIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, \Gamma, T, S, D, Q, R, H, C, P, N)$$

with the following displayed rows.

1. *I is the interval row, naming the endpoints, endpoint order, and the cell boundary data exposed to every downstream partition and sum read.*
2. *Γ is the positive gauge row. Each displayed tag request carries a local positive radius and the finite observation window by which that radius is read.*
3. *T is the Cousin tagged-subdivision row, routed through chapter 1861 from I and Γ.*
4. *S is the Riemann tagged-sum row, routed through chapter 1526 from the same tags, cells, integrand reads, and mesh data displayed by T.*
5. *D is the Darboux gap row, routed through chapter 1460 by comparing upper and lower step bounds against the same interval and integrand windows.*
6. *Q is the regulated-integral compatibility row, routed through chapter 1557 whenever the integrand window is carried by a displayed regulated-function approximation ledger.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Completion}^{\uparrow}$ *handoff row reached only after the gauge, Cousin, Riemann, Darboux, and regulated-compatibility rows have been recorded.*
8. *H records componentwise* hsame *transport for the interval, gauge, tagged subdivision, tagged sum, Darboux gap, regulated compatibility, Real/Completion handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a gauge-integral request through*

$$I, \Gamma \longmapsto T \longmapsto S \longmapsto D \longmapsto Q \longmapsto R \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GaugeIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, \Gamma, T, S, D, Q, R, H, C, P, N$. It has no coordinate for open-cover compactness, choice-selected partitions, quotient functions, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.GaugeIntegralUp.GaugeIntegralTasteGate single carrier alignment`

Theorem 1999.2 (Gauge integral NameCert obligations)**.** *For every accepted* $\mathsf{GaugeIntegral}^{\uparrow}$ *carrier*

$$G = (I, \Gamma, T, S, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GaugeIntegral}^{\uparrow}}$ *surface consists exactly of the following obligation rows.*

1. *carrier admission for the displayed interval, positive gauge, Cousin subdivision, Riemann tagged sum, Darboux gap, regulated compatibility, Real/Completion handoff, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *gauge locality, requiring every tag row in T to read its radius from Γ and to certify that the tagged cell lies inside the corresponding local gauge window;*
3. *tagged-subdivision exactness through* $\mathsf{CousinLemma}^{\uparrow}$*, requiring T to be the finite output of chapter 1861 over the same I and Γ rows;*
4. *Darboux/Riemann compatibility, requiring the tagged-sum row S and the gap row D to inspect the same cells, endpoint comparisons, integrand reads, and step-bound data;*
5. *regulated-integral compatibility, requiring Q to consume only the finite step approximation and error ledger exposed by chapter 1557;*
6. *Real/Completion non-escape, requiring R to expose* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Completion}^{\uparrow}$ *data only after T, S, D, Q are present;*
7. *structural faithfulness, requiring H, C, P, N to transport, replay, source, and name no open-cover compactness theorem, choice-selected partition family, quotient of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 1999.1. The accepted packet displays the interval, gauge, subdivision, sum, gap, compatibility, handoff, transport, replay, provenance, and naming rows.

Gauge locality and subdivision exactness are read from Γ and T. The $\mathsf{CousinLemma}^{\uparrow}$ route supplies the finite tagged partition over the displayed interval and positive gauge, so no selected partition family or general compactness theorem is available to the classifier.

The Riemann and Darboux rows are then compared as finite ledger coordinates. The tagged-sum row S and gap row D share the interval cells, endpoint comparisons, integrand reads, and step-bound data, so their compatibility is a row equality inside the packet rather than a host theorem about all refinements.

The regulated row Q can be consumed only after the regulated-integral approximation ledger is displayed. The Real/Completion row R is downstream of T, S, D, Q, and the structural rows H, C, P, N replay and name exactly that route. Since the excluded principles have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 1999.3 (Gauge integral Cousin–Riemann handoff)**.** *Let* $G = (I, \Gamma, T, S, D, Q, R, H, C, P, N)$ *be an accepted* $\mathsf{GaugeIntegral}^{\uparrow}$ *carrier. Every consumer read that reaches the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{Completion}^{\uparrow}$ *handoff row* R *first routes the gauge partition through chapter 1861, then the tagged-sum row through chapter 1526, then the gap comparison through chapter 1460, and then the step-compatible route through chapter 1557. The handoff order is*

$$I, \Gamma \longmapsto T \longmapsto S \longmapsto D \longmapsto Q \longmapsto R.$$

No accepted packet exposes a $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *read before this finite route is present.*

Lean4 ✓ `BEDC.Derived.GaugeIntegralUp.GaugeIntegralCousinRiemannHandoff`

Proof. Start with a consumer read of R. By Definition 1999.1, the row R is not an independent coordinate: it is specified as the handoff row reached after the gauge, Cousin, Riemann, Darboux, and regulated-compatibility rows have been recorded.

The first non-structural rows are I and Γ. They display the interval and positive gauge. The row T is then the Cousin tagged-subdivision output over those same rows, so every later sum sees a finite tagged partition already certified by chapter 1861.

The row S reads this tagged subdivision through the Riemann tagged-sum surface. The row D compares the same cells and integrand windows through the Darboux gap boundary, and Q reads the regulated step approximation route when such a regulated ledger is present.

Only after these rows are present can the continuation row replay a handoff to R. Componentwise hsame transport and Pkg provenance preserve the same order, and the local NameCert row names no independent Real or Completion source. Hence every accepted Real/Completion read factors through the displayed Cousin–Riemann–Darboux–regulated route. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaugeIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{GaugeIntegral}^{\uparrow}$ packet is generated from a displayed interval row, positive gauge row, Cousin tagged-subdivision row, Riemann tagged-sum row, Darboux gap row, regulated-integral compatibility row, RegSeqRat/Real/Completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GaugeIntegral}^{\uparrow}}$, seed)

Scope closed: Definition 1999.1, Definition 1999.2, and Definition 1999.3 seed the finite gauge-partition integration route over Cousin, Riemann, Darboux, regulated-integral, and Real/Completion rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GaugeIntegral}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.GaugeIntegralUp.GaugeIntegralTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected partitions, quotient functions, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge locality, Cousin tagged-subdivision exactness, Darboux/Riemann compatibility, regulated-integral compatibility, Real/Completion non-escape, and field faithfulness for BEDC.Derived.GaugeIntegralUp.

Chapter 2000

A Concrete Naming Certificate for $\mathsf{ProductTopology}^{\uparrow}$

Following Kelley and Munkres on product topologies, the $\mathsf{ProductTopology}^{\uparrow}$ packet records the finite BEDC route by which two displayed topological carriers are paired and read through projection-continuity rows. It sits after the indexed-open surface of chapter 88, the binary product carrier of chapter 34, and the graph-and-modulus interface of chapter 130. The packet names only the finite binary product-topology certificate needed by later product, compact-metric, and continuous-map consumers; it is not a box topology, quotient topology, host powerset construction, selected open family, choice principle, or ambient set-theoretic product.

Definition 2000.1 (ProductTopology carrier)**.** *A* $\mathsf{ProductTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, O_X, O_Y, \Pi, \pi_X, \pi_Y, B, T, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two component carrier histories whose classifiers are transported only through displayed* hsame *rows.*
2. *O_X and O_Y are the two* $\mathsf{Topology}^{\uparrow}$ *indexed-open rows, exposing component open indices, component membership reads, and finite intersection ledgers.*
3. *Π is the* $\mathsf{Prod}^{\uparrow}$ *pairing row whose first and second projection readbacks expose paired histories only through the two component rows.*
4. *π_X and π_Y are the two* $\mathsf{ContinuousMap}^{\uparrow}$ *projection rows from the product packet to the component topology rows.*
5. *B is the rectangular subbasis row, recording finite pairs of component-open indices and their paired membership route through Π, O_X, O_Y.*
6. *T is the generated* $\mathsf{Topology}^{\uparrow}$ *row for the product carrier, admitting exactly the finite generated-open operations displayed by B and no host powerset of pairs.*
7. *H records componentwise* hsame *transport for component carriers, component topology rows, the* $\mathsf{Prod}^{\uparrow}$ *readback row, both projection-continuity rows, the rectangular subbasis row, the generated topology row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a product observation through pairing, component readback, rectangular subbasis membership, generated-open formation, projection continuity, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{ProductTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ProductTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for box-topology opens, quotient topology, an external powerset of pairs, arbitrary host-indexed open families, choice-selected bases, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ProductTopologyUp.ProductTopologyTasteGate single carrier alignment`

Theorem 2000.2 (ProductTopology NameCert obligations)**.** *For every accepted* $\mathsf{ProductTopology}^{\uparrow}$ *carrier*

$$Q = (X, Y, O_X, O_Y, \Pi, \pi_X, \pi_Y, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProductTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for that thirteen-row packet, component-topology exposure through O_X, O_Y, product readback through Π, projection-continuity exposure through π_X, π_Y, rectangular subbasis generation through B, generated topology admission through T, and transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the accepted packet. The carrier displays exactly two component histories, two component topology rows, one product readback row, two projection-continuity rows, one rectangular subbasis row, one generated topology row, and the structural rows.

Read the topology rows before the product row. The component open indices and membership reads are supplied by O_X and O_Y, while Π supplies only the first and second component readbacks for paired histories.

The subbasis row B then binds a component-open pair to the corresponding product observation, and T records the generated-open operations admitted from that rectangular row. The projection rows π_X, π_Y are downstream records that the same paired readbacks are continuous into the component topology rows.

Finally, H, C, P, N transport, replay, source, and name that same finite route. Since box opens, quotient opens, host powersets, arbitrary host-indexed open families, selected bases, Lean proof terms, and bridge certificates are absent from the carrier inventory, the listed rows exhaust the local certificate surface. □

Theorem 2000.3 (ProductTopology projection continuity)**.** *Every projection-continuity read exported by an accepted* $\mathsf{ProductTopology}^{\uparrow}$ *carrier factors through*

$$\Pi, O_X, O_Y, B, T, H, C, P, N.$$

The first projection reads the first component through Π and O_X, and the second projection reads the second component through Π and O_Y; neither route can bypass the rectangular subbasis row or the generated $\mathsf{Topology}^{\uparrow}$ *row.*

Proof. Start with a projection-continuity request. The only product readback coordinate is Π, so the request must choose the first or second displayed projection route of that row.

On the first route, the component open evidence is read from O_X and the continuity row is π_X. On the second route, the component open evidence is read from O_Y and the continuity row is π_Y.

In both cases the rectangular subbasis row B records how the component-open observation is represented as a product-open observation, and T admits that row as part of the generated product topology. The structural rows H, C, P, N preserve the same route, so a projection consumer receives no host pair equality, box topology, quotient topology, or external powerset data. □

Theorem 2000.4 (ProductTopology universal route)**.** *Let a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *packet into an accepted* $\mathsf{ProductTopology}^{\uparrow}$ *carrier have component reads that factor through the two projection rows. Then its product-facing route is the finite ledger*

$$O_X, O_Y, \Pi, \pi_X, \pi_Y, B, T, H, C, P, N.$$

Thus the binary product-topology universal property is recorded only as a BEDC route through paired histories, component topology rows, projection-continuity rows, rectangular subbasis generation, and generated-open replay; it does not assert a host function-space theorem, a box-topology comparison, quotient topology, choice of arbitrary opens, or ambient set product.

Proof. Begin with the displayed map packet and its two component reads. Each component read is a $\mathsf{ContinuousMap}^{\uparrow}$ route into one of the topology rows O_X or O_Y, and the only product carrier available for pairing those reads is Π.

The projection rows π_X, π_Y identify the component reads as the two product projections. The rectangular subbasis row B is therefore the only row that can turn paired component-open observations into product-open observations.

The generated topology row T admits exactly the finite generated-open operations exposed by B. Transport and replay through H and C, together with provenance and local naming through P, N, repack the displayed component routes into the product-facing ledger.

No further universal-property coordinate is present. The carrier contains no host function-space theorem, box-topology comparison, quotient topology, choice-selected open family, or ambient set product, so the stated finite ledger is the entire exported route. □

Falsifiable prediction: An accepted $\mathsf{ProductTopology}^{\uparrow}$ consumer that obtains a projection-continuity read without first reading the $\mathsf{Prod}^{\uparrow}$ projection row, the corresponding $\mathsf{Topology}^{\uparrow}$ component row, the rectangular subbasis row, and the generated $\mathsf{Topology}^{\uparrow}$ row refutes the carrier surface.

Independence witness: topology, prod, continuousmap: no listed sibling supplies the whole thirteen-row packet $Q = (X, Y, O_X, O_Y, \Pi, \pi_X, \pi_Y, B, T, H, C, P, N)$, because Topology supplies indexed-open rows, Prod supplies paired readbacks, and ContinuousMap supplies projection-continuity rows, while this chapter binds those rows into one product-topology NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ProductTopology}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProductTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2000.1, Definition 2000.2, Definition 2000.3, and Definition 2000.4 seed the binary product-topology route over Topology, Prod, and ContinuousMap rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProductTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close box topology, quotient topology, host powersets, arbitrary host-indexed open families, selected bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, component topology exposure, product readback exactness, projection-continuity routing, rectangular subbasis generation, generated topology admission, and universal-route factorization for BEDC.Derived.ProductTopologyUp.

Constructive story: A $\mathsf{ProductTopology}^{\uparrow}$ packet is generated from two component carrier histories, two $\mathsf{Topology}^{\uparrow}$ indexed-open rows, a $\mathsf{Prod}^{\uparrow}$ pairing and projection row, two $\mathsf{ContinuousMap}^{\uparrow}$ projection-continuity rows, a rectangular subbasis row, a generated $\mathsf{Topology}^{\uparrow}$ row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2001

A Concrete Naming Certificate for $\mathsf{DyadicMetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicMetric}^{\uparrow}$ packet names the finite dyadic metric ledger read by regular rational streams, real-name seals, and metric-space consumers before any ambient completion can be invoked. It sits over the dyadic endpoint and distance rows of chapter 291, reads the nonnegative endpoint surface of chapter 293, hands scheduled distance ledgers to chapter 301, and presents the resulting finite witness surface to chapter 57. The chapter isolates the metric ledger itself: source pairs, dyadic distance, zero boundary, symmetry, triangle bounds, consumer handoff, transport, replay, provenance, and local naming.

Definition 2001.1 (Dyadic metric carrier)**.** *A* $\mathsf{DyadicMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (s, d, a, z, u, t, r, h, c, p, n)$$

with the following displayed rows:

1. *s is the source-pair row. It records two accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints together with their visible mantissa, denominator,* $\mathsf{Int}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *provenance.*
2. *d is the dyadic distance ledger for the ordered pair in s. It records the common-denominator subtraction window, radius row, and finite comparison data used by distance consumers.*
3. *a is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint row attached to d, exposing the nonnegative dyadic distance endpoint through the absolute-value packet rather than through a host absolute-value function.*
4. *z is the zero-distance boundary row. It states that a displayed zero distance is admitted only by the finite dyadic equality boundary already visible in the source-pair and distance rows.*
5. *u is the symmetry row. It swaps the two source endpoints and reuses the same absolute-value endpoint and tolerance ledger with the ordered-pair direction reversed.*
6. *t is the triangle-bound row. It records the finite three-source ledger, the two intermediate distance rows, the outer distance row, and the dyadic comparison witnessing the displayed triangle bound.*
7. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer handoff row. It exposes the distance ledger as the finite tolerance surface read by regular rational streams, real-name seals, and metric witnesses.*
8. *h records componentwise* hsame *transport for the source pair, dyadic distance ledger, absolute-value endpoint, zero boundary, symmetry row, triangle-bound row, consumer handoff, replay, provenance, and local naming rows.*

9. *c records displayed* Cont *replay from the source pair through dyadic distance, absolute value, zero boundary, symmetry, triangle bound, consumer handoff, transport, provenance, and local naming.*

10. *p is the* Pkg *provenance over* $\mathsf{DyadicMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *n is the local* $\mathsf{NameCert}_{\mathsf{DyadicMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, d, a, z, u, t, r, h, c, p, n$. It has no coordinate for host metric spaces, quotient rationals, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicMetricUp.DyadicMetricTasteGate single carrier alignment`

Theorem 2001.2 (Dyadic metric NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMetric}^{\uparrow}$ *carrier $M = (s, d, a, z, u, t, r, h, c, p, n)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicMetric}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic distance-ledger exposure, absolute-value endpoint exposure, zero-distance boundary, symmetry routing, triangle-bound routing, RegSeqRat and Real consumer handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. No dyadic metric obligation is stored outside those finite rows.*

Proof. Carrier admission is projection from Definition 2001.1. The visible packet lists the source pair s, dyadic distance ledger d, absolute-value endpoint a, zero boundary z, symmetry row u, triangle-bound row t, consumer handoff r, and structural rows h, c, p, n.

The metric-law rows are finite ledger rows, not external laws. The zero boundary reads only the displayed dyadic equality boundary; the symmetry row swaps the source pair and reuses the same absolute-value endpoint; the triangle row reads three displayed sources, the corresponding distance ledgers, and one dyadic comparison row.

The handoff clause is downstream of those ledgers. A $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{Met}^{\uparrow}$ consumer can read the distance only through r after the source pair, distance ledger, absolute-value endpoint, and metric-law rows have already been displayed.

Transport and replay are componentwise through h and c. The provenance and local naming rows package exactly the listed coordinates, so the excluded host metric, quotient-rational, trichotomy, selected-limit, completeness, verification, and bridge data cannot appear as hidden obligations. □

Theorem 2001.3 (Dyadic metric RegSeqRat consumer handoff)**.** *Let $M = (s, d, a, z, u, t, r, h, c, p, n)$ be an accepted* $\mathsf{DyadicMetric}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{Met}^{\uparrow}$ *consumer of M must read the finite route*

$$s \longmapsto d \longmapsto a \longmapsto z, u, t \longmapsto r \longmapsto h, c, p, n$$

before the dyadic distance ledger is available as a regular-rational tolerance, a real-name distance surface, or a metric witness. Consequently the consumer route cannot bypass the dyadic metric packet through a host metric space, quotient rational equality, trichotomy, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only consumer-facing coordinate is r, and r is placed after the source-pair row, dyadic distance ledger, absolute-value endpoint, zero boundary, symmetry row, and triangle-bound row.

For a $\mathsf{RegSeqRat}^{\uparrow}$ consumer, the distance ledger is read as a dyadic tolerance row. Since the tolerance comes from d and a, the regular rational route must pass through the displayed source pair and nonnegative endpoint before it can inspect a scheduled finite window.

For a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Met}^{\uparrow}$ consumer, the same route is terminal. The real-name seal and the metric witness receive only the distance surface exposed by r, while h, c, p, n transport, replay, package, and name that surface without adding a second distance function.

The excluded objects are absent from the carrier. Thus every accepted consumer route factors through the displayed dyadic metric ledger and cannot obtain an ambient host metric, quotient-rational comparison, trichotomy witness, selected limit, or completeness theorem from this packet. □

Theorem 2001.4 (Dyadic metric classifier transport)**.** *If two accepted* $\mathsf{DyadicMetric}^{\uparrow}$ *packets agree on the displayed source-pair, distance-ledger, absolute-value endpoint, zero-boundary, symmetry, triangle-bound,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of Definition 2001.1, then every zero-distance, symmetry, triangle, and* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read is unchanged by passing from one packet to the other.*

Proof. Project both accepted carriers as

$$M = (s, d, a, z, u, t, r, h, c, p, n) \quad \text{and} \quad M' = (s', d', a', z', u', t', r', h', c', p', n').$$

The displayed component agreement identifies the source pair, dyadic distance ledger, absolute-value endpoint, zero boundary, symmetry row, triangle row, and consumer handoff row on the two sides.

Use the componentwise hsame row h for transport. Zero-distance reads use only s, d, a, z; symmetry reads use only s, d, a, u; triangle reads use only the three-source ledger inside t; and $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reads use only r after the preceding rows have been displayed.

Finally read c, p, n. These rows replay, source, and name the same transported finite route. They carry no extra host metric, quotient rational, trichotomy, selected limit, or completeness coordinate, so classifier transport cannot change any listed consumer read. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMetric}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2001.1, Definition 2001.2, and Definition 2001.3 seed the finite dyadic metric route from source pairs through distance ledger, absolute-value endpoint, zero boundary, symmetry, triangle bound, RegSeqRat and Real handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host metric spaces, quotient rationals, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic distance-ledger exposure, absolute-value endpoint exposure, zero-distance boundary, symmetry routing, triangle-bound routing, consumer handoff, provenance, transport, replay, and local naming for BEDC.Derived.DyadicMetricUp.

Constructive story: A $\mathsf{DyadicMetric}^{\uparrow}$ packet is generated from a displayed pair of DyadicRatCore endpoints, a dyadic distance ledger, a DyadicAbsoluteValue endpoint, zero-distance, symmetry, and triangle rows, a RegSeqRat and Real consumer handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2002

A Concrete Naming Certificate for $\mathsf{CauchyCompletionEliminator}^{\uparrow}$

Following Bishop–Bridges constructive completion and the Mac Lane–Eilenberg–Moore vocabulary of recursion from an algebraic completion object, the $\mathsf{CauchyCompletionEliminator}^{\uparrow}$ packet records the BEDC eliminator interface for reading out of a Cauchy completion. It sits after the completion monad of chapter 378, the Kleisli consumer route of chapter 1845, the functorial action of chapter 1937, and the algebra boundary of chapter 1981. Its analytic input surface is the finite stream window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38.

The packet is an eliminator boundary, not a representative selector. It exposes exactly the finite rows needed to extend a dense-source action through regular Cauchy tails and to compare the resulting completed reads by tail agreement.

Definition 2002.1 (Cauchy completion eliminator carrier)**.** *A* $\mathsf{CauchyCompletionEliminator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, T, M, A, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense source data row, displaying the source NameCert, its finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance observations before any completed read is inspected.*

2. *T is the target NameCert data row, including the codomain carrier surface, its accepted equality classifier, and the local naming row for the target of the eliminator.*

3. *M is the Cauchy-continuity modulus row, recording how a finite dyadic tolerance request on the target read is answered by a finite tail request on the dense source data.*

4. *A is the extension action row, sending an accepted regular Cauchy tail over D to a target packet over T by the modulus-controlled route M.*

5. *U is the uniqueness-by-tail-agreement ledger: two extension actions over the same dense-source action and the same modulus are compared by displayed* hsame *equivalence of their regular tails.*

6. *H records componentwise* hsame *transport for the dense source data, target NameCert data, Cauchy-continuity modulus, extension action, uniqueness ledger, replay row, provenance row, and local naming row.*

7. *C records displayed* Cont *replay of the route*

$$D, T, M \longmapsto A \longmapsto U \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionEliminator}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionEliminator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, T, M, A, U, H, C, P, N$. The carrier has no coordinate for quotient representatives, host equality of completed objects, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionEliminatorUp.TasteGate.CauchyCompletionEliminatorTasteGate`
`single carrier alignment`

Theorem 2002.2 (Cauchy completion eliminator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionEliminator}^{\uparrow}$ *carrier*

$$E = (D, T, M, A, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionEliminator}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the dense source data, target NameCert data, Cauchy-continuity modulus, extension action, uniqueness ledger, transport, replay, provenance, and local naming row;*
2. *dense-source action stability, requiring the action on displayed dense rows to be invariant under the carried* hsame *transport of* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations;*
3. *modulus-controlled extension, requiring every completed-route read to pass through the modulus row M before the extension action row A is inspected;*
4. *uniqueness through Cauchy tail agreement, requiring two completed reads over the same dense action and modulus to be compared only through the ledger U and displayed* hsame *equivalence of regular tails;*
5. *refusal of quotient representatives, host equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking as local obligation data.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2002.1. The accepted packet displays exactly the dense source data, target NameCert data, modulus, action, uniqueness ledger, and structural rows.

Dense-source stability is read from D and H. The dense action can inspect only finite stream windows, regular rational readback, and dyadic tolerance observations, and componentwise transport preserves those displayed rows before any target packet is named.

The extension clause is supplied by M and A. A completed-route consumer first presents a target tolerance request to the modulus row, receives a finite tail request on the dense source, and then applies the extension action to that displayed tail.

Uniqueness is supplied by U. When two accepted actions have the same dense-source action and the same modulus, the only comparison row available is tail agreement of the regular Cauchy presentations through displayed hsame routes.

The refusal clause is structural. Since no excluded object appears as a coordinate of E, the replay, provenance, and local naming rows cannot export quotient representatives, host equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking. □

Theorem 2002.3 (Cauchy completion eliminator uniqueness)**.** *Let*

$$E = (D, T, M, A, U, H, C, P, N) \quad \textit{and} \quad E' = (D', T', M', A', U', H', C', P', N')$$

be accepted $\mathsf{CauchyCompletionEliminator}^{\uparrow}$ *packets. If E and E' display the same dense-source action, the same Cauchy-continuity modulus, and componentwise* hsame *transport of the target NameCert rows, then the two eliminator packets are classifier-equal on every completed route whose regular tails are* hsame*-equivalent. The comparison is exhausted by the uniqueness ledgers U, U' and the displayed tail-agreement rows; it does not pass through quotient representatives, host equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project both accepted carriers. The hypotheses identify the dense-source action and the modulus rows, so any completed-route read issued to E and E' produces the same finite tail request on the dense source.

Now compare the regular tails. The assumed hsame equivalence of those tails is exactly the input consumed by the uniqueness ledgers U and U'. These ledgers compare the two target reads through the carried target NameCert transport, not through host equality of completed objects.

The structural rows finish the classifier comparison. Componentwise transport H, H', replay C, C', provenance P, P', and local names N, N' preserve the same dense action, modulus, and tail-agreement route. Since the carriers contain no excluded coordinate, the classifier equality cannot appeal to quotient representatives, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionEliminator}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEliminator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2002.1, Definition 2002.2, and Definition 2002.3 seed the finite eliminator surface for Cauchy-completion reads out of regular tails.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEliminator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, host equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source action stability, modulus-controlled extension, uniqueness through Cauchy tail agreement, and non-escape proofs for BEDC.Derived.CauchyCompletionEliminatorUp.

Constructive story: A $\mathsf{CauchyCompletionEliminator}^{\uparrow}$ packet is generated from dense source data, target NameCert data, a Cauchy-continuity modulus, an extension action, a uniqueness-by-tail-agreement ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2003

A Concrete Naming Certificate for $\mathsf{SpernerLemma}^{\uparrow}$

Following Sperner, the $\mathsf{SpernerLemma}^{\uparrow}$ packet names the finite labeled-simplex ledger used by constructive dyadic compactness and fixed-point routes before any host geometric realization is consulted. It sits over the finite face inventory of chapter 238, the dyadic subdivision surface of chapter 1863, and the cover-routing rows of chapter 446. The chapter isolates the combinatorial certificate itself: simplex inventory, dyadic subdivision, boundary labels, face-label transport, fully-labeled simplex witness, structural transport, replay, provenance, and local naming.

Definition 2003.1 (Sperner lemma carrier)**.** *A* $\mathsf{SpernerLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (k, d, b, f, w, h, c, p, n)$$

with the following displayed rows:

1. *k is the finite simplicial-complex row. It records the accepted* $\mathsf{SimplicialComplex}^{\uparrow}$ *simplex inventory, face-incidence relation, dimension grading, and carried-face closure used by the labeled subdivision.*
2. *d is the dyadic subdivision row. It records the accepted* $\mathsf{DyadicPartition}^{\uparrow}$ *subdivision or partition ledger, including the dyadic cell indices and their incidence with the finite simplex row.*
3. *b is the boundary-label ledger. It records the boundary faces, their admissible colors, and the displayed exclusion of forbidden boundary colors.*
4. *f is the face-label transport row. It transports labels along the finite face relation of k and the dyadic subdivision incidence of d without using an ambient geometric simplex.*
5. *w is the fully-labeled simplex witness row. It records one carried subsimplex, its vertices, and the finite color list witnessing that each required color appears exactly through the displayed label ledger.*
6. *h records componentwise* hsame *transport for the simplicial-complex row, dyadic subdivision row, boundary-label ledger, face-label transport, fully-labeled witness, replay, provenance, and local naming rows.*
7. *c records displayed* Cont *replay from the finite simplex inventory through subdivision, boundary labels, face-label transport, fully-labeled witness, structural transport, provenance, and local naming.*

8. *p is the* Pkg *provenance over* $\mathsf{SpernerLemma}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *n is the local* $\mathsf{NameCert}_{\mathsf{SpernerLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $k, d, b, f, w, h, c, p, n$. It has no coordinate for host geometric realization, open-cover compactness, real trichotomy, selected fixed points, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SpernerLemmaUp.SpernerLemmaTasteGate single carrier alignment`

Theorem 2003.2 (Sperner lemma NameCert obligations)**.** *For every accepted* $\mathsf{SpernerLemma}^{\uparrow}$ *carrier $S = (k, d, b, f, w, h, c, p, n)$, the local* $\mathsf{NameCert}_{\mathsf{SpernerLemma}^{\uparrow}}$ *surface consists exactly of the following five certificate rows:*

1. *the finite carrier row k, d combining the* $\mathsf{SimplicialComplex}^{\uparrow}$ *simplex inventory with the* $\mathsf{DyadicPartition}^{\uparrow}$ *subdivision ledger;*
2. *the boundary-coloring row b recording admissible boundary colors and forbidden-color exclusions;*
3. *the face-label transport row f moving labels through carried faces and dyadic incidence;*
4. *the fully-labeled simplex handoff row w exposing the finite witness to dyadic compactness and fixed-point consumers;*
5. *the structural row h, c, p, n for componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No Sperner obligation is stored outside these finite rows.

Proof. Carrier admission is projection from Definition 2003.1. The visible packet lists the finite simplicial-complex row k, the dyadic subdivision row d, the boundary-label ledger b, the face-label transport row f, the fully-labeled witness row w, and the structural rows h, c, p, n.

The first certificate row is the pair k, d. It fixes the finite simplex inventory and the dyadic subdivision surface before any labels are read.

The second and third rows are b and f. The boundary-coloring data is accepted only as a finite ledger, and the label transport is accepted only along the displayed face and subdivision incidence rows.

The fourth row is w. A compactness or fixed-point consumer receives a fully-labeled simplex only through this witness row after the carrier, boundary, and transport rows have been displayed.

The fifth row is structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local naming row package exactly the listed coordinates, so the excluded host-geometric, open-cover, trichotomy, selected-point, completeness, verification, and bridge data cannot appear as hidden obligations. □

Theorem 2003.3 (Sperner boundary-coloring route)**.** *Let $S = (k, d, b, f, w, h, c, p, n)$ be an accepted* $\mathsf{SpernerLemma}^{\uparrow}$ *carrier. Every read of the boundary-coloring ledger factors through the displayed* $\mathsf{SimplicialComplex}^{\uparrow}$ *finite face row k, the* $\mathsf{DyadicPartition}^{\uparrow}$ *subdivision row d, and the* $\mathsf{DyadicCover}^{\uparrow}$ *cover-routing provenance recorded in p. In particular, boundary admissibility cannot be read directly from a host simplex, an open cover of a compact space, real trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The boundary-coloring coordinate is b, and the definition places b after the finite simplex row k and dyadic subdivision row d.

The simplicial row supplies the finite boundary faces and their face-incidence relation. The dyadic subdivision row supplies the finite cells whose boundary labels are being read. The package row p records the $\mathsf{DyadicCover}^{\uparrow}$ provenance that makes the label ledger visible to dyadic cover consumers.

Thus any boundary-coloring read reaches b only after the finite face inventory, the dyadic subdivision incidence, and the cover-routing provenance have been displayed. Since the classifier has no coordinate for host simplices, open-cover compactness, trichotomy, or ambient completeness, none of those objects can supply an alternate boundary-coloring route. □

Theorem 2003.4 (Sperner fully-labeled simplex handoff)**.** *Let $S = (k, d, b, f, w, h, c, p, n)$ be an accepted* $\mathsf{SpernerLemma}^{\uparrow}$ *carrier. Every fully-labeled simplex handoff exported to* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *or to a dyadic fixed-point consumer passes through the finite route*

$$k \longmapsto d \longmapsto b \longmapsto f \longmapsto w \longmapsto h, c, p, n.$$

Consequently the handoff cannot bypass the displayed finite ledger through host geometric realization, open-cover compactness, real trichotomy, selected fixed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only coordinate exposing a fully-labeled simplex is w, and w is downstream of the finite simplex inventory k, the dyadic subdivision row d, the boundary-label ledger b, and the face-label transport row f.

A $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ consumer therefore receives a labeled subsimplex only after the finite subdivision and boundary ledger have already been displayed. A dyadic fixed-point consumer reads the same witness through the package and replay rows, which transport the finite certificate without adding a selected point.

The excluded objects are absent from the classifier. Hence the exported handoff is exactly the displayed finite route and cannot obtain a host geometric realization, open-cover compactness theorem, real-trichotomy branch, selected fixed point, or ambient completeness witness from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpernerLemma}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpernerLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2003.1, Definition 2003.2, Definition 2003.3, and Definition 2003.4 seed the finite labeled-simplex route from simplicial-complex inventory through dyadic subdivision, boundary labels, face-label transport, fully-labeled witness, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpernerLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host geometric realization, open-cover compactness, classical Brouwer fixed points, real trichotomy, selected fixed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-coloring route, face-label transport, fully-labeled simplex handoff, provenance, transport, replay, and local naming for BEDC.Derived.SpernerLemmaUp.

Constructive story: A $\mathsf{SpernerLemma}^{\uparrow}$ packet is generated from a displayed finite simplicial-complex row, a dyadic subdivision or partition row, a boundary-label ledger, face-label transport rows, a fully-labeled simplex witness row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2004

A Concrete Naming Certificate for $\mathsf{SeparatedQuotientMetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Bourbaki–Kelley separated-reflection language, the $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ packet records the standard passage from a pseudometric surface to a separated metric surface as finite BEDC data. It starts with the pre-separated distance rows of chapter 1614, exposes the separated classifier route of chapter 1411, and hands only the routed classifier to the metric consumer of chapter 57. Its numerical readback is confined to the regular rational windows of chapter 301 and the terminal real-name seal of chapter 38. The packet therefore names the constructive zero-distance separation route without adding quotient primitives, host equality, trichotomy, countable choice, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2004.1 (SeparatedQuotientMetric carrier)**.** *A* $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, P, Z, S, R, E, H, C, N)$$

with the following displayed rows:

1. *X is the source point-history admission row. It records the carried point names and the classifier inherited from the source packet, but it does not identify point rows by host equality.*
2. *P is the source* $\mathsf{Pseudometric}^{\uparrow}$ *packet. It supplies the displayed distance witness, dyadic tolerance ledger, zero-distance boundary, stream windows, regular rational readback, and real-distance seal available before separation.*
3. *Z is the displayed zero-distance evidence row. It records finite requests showing that two admitted point rows have pseudometric distance zero through the rows of P.*
4. *S is the separated classifier output. It consumes Z and records the finite classifier evidence that the two source point histories have the same separated point reading.*
5. *R is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window handoff. It names the stream windows and regular rational approximants that a metric or real consumer may inspect before the separated classifier is read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached from the pseudometric distance readback after the windows in R have been displayed.*
7. *H stores componentwise* hsame *transport for source point admission, pseudometric rows, zero-distance evidence, separated classifier output, finite windows, regular readback, real seal, continuation, provenance, and local naming rows.*

8. *C stores the displayed* Cont *replay from point admission through pseudometric distance inspection, zero-distance evidence, separated classifier output, finite-window readback, and real sealing.*
9. *N is both the* Pkg *provenance over* $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows and the local* $\mathsf{NameCert}_{\mathsf{SeparatedQuotientMetric}^{\uparrow}}$ *row.*

The carrier is a finite classifier certificate. It has no quotient-space coordinate, no host equality coordinate, no selected representative, no trichotomy row, no countable-choice selector, no selected limit, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SeparatedQuotientMetricUp.SeparatedQuotientMetricTasteGate single carrier alignment`

Theorem 2004.2 (SeparatedQuotientMetric NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ *carrier* $Q = (X, P, Z, S, R, E, H, C, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedQuotientMetric}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source point row, source* $\mathsf{Pseudometric}^{\uparrow}$ *packet, zero-distance evidence, separated classifier output, finite-window and regular-rational handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *zero-distance classifier exposure, requiring every displayed zero-distance witness in Z to be consumed by the separated classifier row S before any point-identity surface is exported;*
3. *separated readback, requiring the metric-facing consumer to read only the classifier output in S and not an equivalence class or host equality proof;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, requiring finite windows and regular rational approximants in R to precede the real seal E for every distance read;*
5. *transport and replay stability, requiring H and C to move the source, zero-distance, classifier, readback, real-seal, provenance, and naming rows componentwise and in the displayed order;*
6. *provenance visibility, requiring N to name exactly the listed BEDC dependencies and the local NameCert row;*
7. *quotient non-escape, excluding quotient metric spaces, host equality, trichotomy, countable choice, selected representatives, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No separated-quotient metric NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2004.1. The packet displays precisely the source point row, source pseudometric packet, zero-distance evidence, separated classifier output, finite-window and regular-rational handoff, real seal, transport, replay, provenance, and local naming rows.

Zero-distance classifier exposure follows from the order P, Z, S. The pseudometric packet supplies the distance surface, the row Z records the zero-distance evidence, and the row S is the first coordinate that can export separated point-classifier evidence.

Separated readback is therefore classifier readback. A metric-facing consumer receives the output of S, not a quotient class, selected representative, or host equality proof.

The numerical handoff is read through R and E. Finite stream windows and regular rational approximants appear before the real seal, so a consumer cannot inspect a detached real distance without the displayed finite readback.

Transport and replay stability are the roles of H and C. They move the listed coordinates componentwise and replay them in the carrier order, preserving the route from pseudometric evidence to separated classifier output.

The provenance and non-escape clauses are inventory checks on N and on the fields of Q. Since no quotient metric space, host equality, trichotomy, choice selector, selected representative, selected limit, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean marker, or bridge row appears in the carrier, none can be part of the local NameCert surface. □

Theorem 2004.3 (SeparatedQuotientMetric zero-distance route)**.** *Let $Q = (X, P, Z, S, R, E, H, C, N)$ be an accepted* $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ *packet. Every consumer that reads point identity from pseudometric zero-distance evidence must factor through the displayed route*

$$\mathsf{Pseudometric}^{\uparrow} \to Z \to S \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{Met}^{\uparrow}.$$

In particular, every $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer sees the point-identity surface only after the zero-distance evidence has passed through the separated classifier S. The packet exports no alternative route through quotient metric spaces, host equality, trichotomy, countable choice, selected limits, selected representatives, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Start with an accepted packet Q. The source pseudometric row P exposes distance witnesses and zero-distance boundary data, while Z records the displayed zero-distance evidence for the pair of source point histories.

Before a point-identity surface can be read, the replay row C sends the evidence in Z through the separated classifier output S. This is the only coordinate in Q that turns zero-distance evidence into separated classifier evidence.

Metric consumers read the resulting separated classifier before treating the point surface as metric-separated. Regular rational and real consumers read finite windows through R and the real seal E only along the same replay route, so they cannot bypass the classifier by inspecting the pseudometric row directly.

The exclusions follow from the carrier inventory. Quotient metric spaces, host equality, trichotomy, countable-choice selectors, selected limits, selected representatives, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not fields of Q, and the provenance row names no such route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedQuotientMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ packet is generated from source point-history admission, a source $\mathsf{Pseudometric}^{\uparrow}$ packet, displayed zero-distance evidence, separated classifier output, finite StreamName and RegSeqRat readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedQuotientMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2004.1, Definition 2004.2, and Definition 2004.3 seed the finite zero-distance separation certificate between pseudometric rows and metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedQuotientMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient metric spaces, host equality, trichotomy, countable choice, selected limits, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance classifier exposure, separated readback, regular rational and real handoff, transport and replay stability, provenance visibility, and quotient non-escape for BEDC.Derived.SeparatedQuotientMetricUp.

Chapter 2005

A Concrete Naming Certificate for $\mathsf{CompleteMetricProduct}^{\uparrow}$

Following Bishop–Bridges constructive completion and the Bourbaki–Kelley binary product metric construction, the $\mathsf{CompleteMetricProduct}^{\uparrow}$ packet records the standard product-stability route for complete metric spaces as finite BEDC NameCert data. It reads the displayed product metric of chapter 424, the two component complete-metric limit witnesses of chapter 128, the finite stream-name windows of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the binary product carrier of chapter 34. The packet names the constructive route from a product Cauchy source to component limits and then back to a displayed product limit, without quotient products, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2005.1 (Complete metric product carrier)**.** *A* $\mathsf{CompleteMetricProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, X, Y, S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y, \Pi, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{ProductMetric}^{\uparrow}$ *row on the binary product carrier. It stores the two projection routes, the two component distance reads, and the product-distance ledger.*
2. *X and Y are the first and second* $\mathsf{CompleteMetric}^{\uparrow}$ *source rows. Each source is read only as a displayed component limit-witness surface.*
3. *S_X and S_Y are the component* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened by projecting a product Cauchy source through the two projection routes of M.*
4. *R_X and R_Y are the component* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows and from the product Cauchy tolerance ledger.*
5. *A_X and A_Y are the terminal component* $\mathsf{Real}^{\uparrow}$ *seal rows reached after the corresponding* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows have been displayed.*
6. *L_X and L_Y are the two component limit rows supplied by the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *witnesses X and Y.*
7. *Π is the* $\mathsf{Prod}^{\uparrow}$ *pairing row that repacks the two component limit rows as the displayed product endpoint.*

8. *L is the product-limit route ledger from the product Cauchy source through M, then through $S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y$, and finally through Π.*
9. *H records componentwise* hsame *transport for the product metric, the two complete-metric sources, the component stream windows, regular readbacks, real seals, component limits, product endpoint, route ledger, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a completeness request through*

$$M, X, Y \longmapsto S_X, S_Y \longmapsto R_X, R_Y \longmapsto A_X, A_Y \longmapsto L_X, L_Y, \Pi, L, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricProduct}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricProduct}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, X, Y, S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y, \Pi, L, H, C, P, N$. The carrier has no coordinate for quotient products, selected limits, countable-choice selectors, host pair equality, quotient equality of Cauchy sources, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteMetricProductUp.CompleteMetricProductTasteGate single carrier alignment`

Theorem 2005.2 (Complete metric product NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricProduct}^{\uparrow}$ *carrier*

$$Q = (M, X, Y, S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y, \Pi, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricProduct}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier exposure, requiring the displayed packet $M, X, Y, S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y, \Pi, L, H, C, P, N$ to be the whole public carrier;*
2. *product-metric exactness, requiring every product distance and projection read to pass through the displayed* $\mathsf{ProductMetric}^{\uparrow}$ *row M;*
3. *component Cauchy readback, requiring every projected Cauchy source to open the matching* $\mathsf{StreamName}^{\uparrow}$ *window and then the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback before a component limit witness is visible;*
4. *component limit admission, requiring L_X and L_Y to be obtained from the two displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *rows X and Y after the terminal* $\mathsf{Real}^{\uparrow}$ *seals A_X and A_Y have been displayed;*
5. *product endpoint pairing, requiring the product limit to be the* $\mathsf{Prod}^{\uparrow}$ *pairing row Π applied to the two component limit rows and recorded by the route ledger L;*
6. *non-escape provenance, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and never a quotient product, selected limit, countable-choice schedule, host equality, quotient equality, or ambient completeness theorem.*

No CompleteMetricProduct obligation is stored outside these rows.

Proof. Carrier exposure is tuple inspection of Definition 2005.1. The product-facing metric route is fixed by M, so every product distance and projection read starts from the displayed $\mathsf{ProductMetric}^{\uparrow}$ packet.

The component Cauchy readback obligations follow by projecting the product Cauchy source along the two projection routes stored in M. Each projected source opens its own finite $\mathsf{StreamName}^{\uparrow}$ window and then its $\mathsf{RegSeqRat}^{\uparrow}$ readback before any terminal real seal is available.

The component limit obligations are the two applications of the displayed $\mathsf{CompleteMetric}^{\uparrow}$ rows X and Y. They consume the corresponding stream-name, regular readback, and real-seal rows and return the component limit rows L_X and L_Y.

The product endpoint obligation is then finite pairing. The row Π pairs L_X and L_Y, while L records the route from the original product Cauchy source through the two component reads and back to that product endpoint.

Finally, H, C, P, N only transport, replay, source, and name the rows already displayed. Because none of the carrier coordinates stores quotient products, selected limits, countable choice, host equality, quotient equality, or ambient completeness, the local NameCert cannot export such data. □

Theorem 2005.3 (Complete metric product limit pairing)**.** *Let*

$$Q = (M, X, Y, S_X, S_Y, R_X, R_Y, A_X, A_Y, L_X, L_Y, \Pi, L, H, C, P, N)$$

be an accepted $\mathsf{CompleteMetricProduct}^{\uparrow}$ *carrier. Every componentwise Cauchy source completed in the two factors determines the product-limit route through the displayed* $\mathsf{ProductMetric}^{\uparrow}$ *row* M*: project the product source through* M*, read the two component* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *routes, consume the two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit witnesses* X *and* Y*, and pair the resulting limit rows through* Π*.*

The resulting product-limit certificate is exactly the finite route ledger L*. It introduces no quotient product, selected limit, countable-choice selector, host equality, quotient equality of Cauchy sources, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a product Cauchy source visible to the packet. The only product metric coordinate is M, so both component observations are obtained by the projection routes and distance ledger stored in that $\mathsf{ProductMetric}^{\uparrow}$ row.

The first projection opens S_X, then R_X, and reaches the terminal $\mathsf{Real}^{\uparrow}$ seal A_X. The second projection opens S_Y, then R_Y, and reaches A_Y. Thus both component Cauchy sources are read through finite StreamName and RegSeqRat data before a completion witness is consulted.

Apply the two displayed complete-metric witnesses. The first witness X returns L_X for the first component route, and the second witness Y returns L_Y for the second component route. These are component limit rows, not selected host limits.

Pair the two component limits through Π. The ledger L records exactly this route from the original product Cauchy source to the paired endpoint, so the product-limit certificate is componentwise before it is product-facing.

The exclusions follow from the carrier boundary. Since Q contains no quotient product, no chosen limit selector, no countable-choice schedule, no host equality row, no quotient equality row, and no ambient completeness coordinate, none can be recovered from the route ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricProduct}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2005.1, Definition 2005.2, and Definition 2005.3 seed the product-stability certificate for complete metric spaces through ProductMetric, component CompleteMetric limit witnesses, StreamName windows, RegSeqRat readback, Real seals, product pairing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient products, selected limits, countable choice, host equality, quotient equality of Cauchy sources, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-metric exactness, component Cauchy readback, component limit admission, product endpoint pairing, provenance non-escape, and local naming for BEDC.Derived.CompleteMetricP

Constructive story: A CompleteMetricProduct$^{\uparrow}$ packet is generated from one ProductMetricUp row, two CompleteMetricUp rows, component StreamName windows, RegSeqRat readbacks, RealUp seals, two component limit rows, one ProdUp pairing row, a product-limit route ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2006

A Concrete Naming Certificate for $\mathsf{UniformIntegralLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformIntegralLimit}^{\uparrow}$ packet names the finite handoff by which a uniformly controlled sequence of integration packets reaches a single $\mathsf{Real}^{\uparrow}$ seal. It sits after the tagged-mesh route of chapter 1526, the upper-lower gap route of chapter 1460, and the gauge-partition route of chapter 1999. It consumes regulated approximation rows from chapter 1906, regular rational handoff rows from chapter 301, and the terminal real-name boundary of chapter 38. The packet records a uniform passage of integral rows to one real seal; it does not introduce measure completion, quotient function spaces, selected limiting partitions, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2006.1 (Uniform integral limit carrier)**.** *A* $\mathsf{UniformIntegralLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, F, T, J, A, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row, naming the endpoint histories, order evidence, and cell boundary ledger shared by every integration packet in the window.*
2. *F is the integrand-window sequence. Each row records a displayed function-read window, its index, and the finite observation data used by the corresponding integral packet.*
3. *T is the uniform tail ledger. It records the common tolerance schedule and the visible index bound after which all carried integrand windows and integral rows remain in the same requested regular rational window.*
4. *J is the Riemann, Darboux, or Gauge integral row attached to each accepted window. Its entries are routed through* $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, *or* $\mathsf{GaugeIntegral}^{\uparrow}$ *over the same interval row I.*
5. *A is the regulated approximation row, recording the* $\mathsf{RegulatedFunction}^{\uparrow}$ *step-approximation ledger used to compare the integrand windows before the integral rows are sealed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row produced from the tail ledger and the displayed integral rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the interval, integrand-window, uniform-tail, integral, regulated-approximation, and regular rational rows have been displayed.*

8. *H records componentwise* hsame *transport for interval rows, integrand-window sequences, uniform tail ledgers, Riemann/Darboux/Gauge integral rows, regulated approximation rows, regular rational handoff, real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from*

$$I, F \longmapsto T \longmapsto J \longmapsto A \longmapsto Q \longmapsto E$$

and then through the transport, provenance, and local naming rows.

10. *P is the* Pkg *provenance over* UniformIntegralLimit$^{\uparrow}$, RiemannIntegral$^{\uparrow}$, DarbouxIntegral$^{\uparrow}$, GaugeIntegral$^{\uparrow}$, RegulatedFunction$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{UniformIntegralLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, T, J, A, Q, E, H, C, P, N$. It has no coordinate for a measure completion, a quotient of functions, selected limiting partitions, open-cover compactness, or an ambient completeness theorem for Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformIntegralLimitUp.UniformIntegralLimitTasteGate single carrier alignment`

Theorem 2006.2 (Uniform integral limit NameCert obligations)**.** *For every accepted* UniformIntegralLimit$^{\uparrow}$ *carrier*

$$U = (I, F, T, J, A, Q, E, H, C, P, N),$$

the local NameCert$_{\text{UniformIntegralLimit}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the interval row, integrand-window sequence, uniform tail ledger, integration row family, regulated approximation row, regular rational handoff, real seal, componentwise transport, continuation replay, provenance, and local naming rows;*

2. *interval coherence, requiring every Riemann, Darboux, or Gauge entry in J to read the same displayed interval row I;*

3. *uniform tail exposure, requiring T to be present before the regular rational handoff Q and the real seal E are readable;*

4. *integration-route visibility, requiring each entry of J to route through* RiemannIntegral$^{\uparrow}$, DarbouxIntegral$^{\uparrow}$, *or* GaugeIntegral$^{\uparrow}$ *rather than through a host integral;*

5. *regulated approximation compatibility, requiring A to expose the finite regulated-function approximation rows used to compare the integrand windows;*

6. *real-seal non-escape, requiring E to be downstream of T, J, A, Q and to export no independent completeness principle;*

7. *structural faithfulness, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows and no measure completion, quotient function space, selected limiting partition, open-cover compactness theorem, ambient* Real$^{\uparrow}$ *completeness witness, Lean verification, or bridge row.*

No uniform integral limit NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2006.1. The packet displays the interval row, the integrand-window sequence, the uniform tail ledger, the integration row family, regulated approximation data, regular rational handoff, real seal, transport, replay, provenance, and local name.

Interval coherence and integration-route visibility are read from I and J. Each integration row in J is attached to the same interval row and is routed through one of the already named Riemann, Darboux, or Gauge packets, so the carrier never reads a detached host integral.

Uniform tail exposure is the role of T. The regular rational row Q is available only after the common tail ledger has been displayed, and the real seal E is available only after Q and the carried integration rows have been read.

The regulated approximation row A supplies the comparison surface for the integrand-window sequence. Transport through H and replay through C preserve the same order, while P and N record the provenance and local naming. Since the excluded analytic objects are not fields of U, the listed rows exhaust the local certificate surface. □

Theorem 2006.3 (Uniform integral limit real seal handoff)**.** *Let* $U = (I, F, T, J, A, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformIntegralLimit}^{\uparrow}$ *packet. Every consumer read of the* $\mathsf{Real}^{\uparrow}$ *seal* E *factors through the finite route*

$$I, F \longmapsto T \longmapsto J \longmapsto A \longmapsto Q \longmapsto E.$$

Thus the real-facing output records the common interval, the displayed integrand-window sequence, the uniform tail ledger, the Riemann/Darboux/Gauge integration rows, the regulated approximation row, and the regular rational handoff, and it does not expose measure completion, quotient function spaces, selected limiting partitions, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Start with a consumer read of E. By Definition 2006.1, the seal is downstream of the interval and integrand-window rows, the uniform tail ledger, the integration rows, the regulated approximation row, and the regular rational handoff.

The row T supplies the common tail control before Q can be read. The row J supplies the finite integration surface through the Riemann, Darboux, or Gauge packets, and A records the regulated approximation ledger needed to compare the carried integrand windows.

Continuation replay through C rebuilds this route, and componentwise transport through H preserves it under hsame. The provenance row P and local name N add no additional analytic carrier.

Therefore every real-facing consumer of E sees only the displayed finite route. The excluded objects have no coordinate in the carrier and cannot be exported by the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformIntegralLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformIntegralLimit}^{\uparrow}$ packet is generated from a displayed interval row, an integrand-window sequence, a uniform tail ledger, Riemann/Darboux/Gauge integral rows, a regulated approximation row, a RegSeqRat handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformIntegralLimit}^{\uparrow}}$, seed)

Scope closed: Definition 2006.1, Definition 2006.2, and Definition 2006.3 seed the finite uniform passage from integration packets to a Real seal over Riemann, Darboux, Gauge, RegulatedFunction, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformIntegralLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function spaces, selected limiting partitions, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval coherence, uniform tail exposure, integration-route visibility, regulated approximation compatibility, real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.UniformIntegralLimitUp.

Chapter 2007

A Concrete Naming Certificate for $\mathsf{EngelExpansion}^{\uparrow}$

Following Engel's expansion theorem and the Hardy–Wright treatment of rational expansion by increasing denominators, the $\mathsf{EngelExpansion}^{\uparrow}$ packet records finite Engel readback before a rational expansion surface is allowed to enter the regular rational and Real seal pipeline. It sits beside the rational carrier of chapter 37, the dyadic bound ledger of chapter 291, the finite window discipline of chapter 126, the regular rational handoff of chapter 301, the terminal real seal of chapter 38, and the continued-fraction comparison route of chapter 342. The packet is a finite denominator-schedule certificate; it does not assert quotient reals, selected infinite sums, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2007.1 (Engel expansion carrier)**.** *An* $\mathsf{EngelExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, B, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the denominator schedule row, listing the accepted finite Engel denominators and their monotone successor checks.*
2. *S is the* $\mathsf{Rat}^{\uparrow}$ *partial-sum row, displaying the finite rational sums obtained from the visible denominator schedule.*
3. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder-bound row, recording the dyadic upper bounds that certify the unread Engel tail for each exposed window.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, selecting exactly the denominator prefixes, partial sums, and remainder bounds inspected by the readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D, S, B, W and no other numeric coordinate.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback row has been displayed.*
7. *H records componentwise* hsame *transport for the denominator schedule, partial sums, remainder bounds, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through*

$$D, S, W \longmapsto B \longmapsto R \longmapsto L.$$

9. *P is the* Pkg *provenance over* $\mathsf{EngelExpansion}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EngelExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient real equality, a selected value of an infinite sum, trichotomy, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a continued-fraction uniqueness theorem.*

Theorem 2007.2 (EngelExpansion NameCert obligations)**.** *For every accepted* $\mathsf{EngelExpansion}^{\uparrow}$ *carrier $E = (D, S, B, W, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EngelExpansion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the denominator schedule, partial-sum rows, remainder-bound rows, stream windows, regular readback, Real seal, transport, replay, provenance, and local naming;*
2. *denominator-schedule visibility, requiring each displayed denominator and successor check to be recorded in D before any partial sum is read;*
3. *rational partial-sum exactness, requiring S to expose only* $\mathsf{Rat}^{\uparrow}$ *sums generated from the denominator windows selected by W;*
4. *dyadic remainder control, requiring every tail claim consumed by R or L to pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row B;*
5. *readback order, requiring the finite route $D, S, W \longmapsto B \longmapsto R \longmapsto L$ before any Real-facing consumer receives the packet;*
6. *transport, continuation replay, provenance, and local naming for exactly the rows recorded in H, C, P, N.*

No EngelExpansion NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.EngelExpansionUp.EngelExpansionTasteGate single carrier alignment`

Proof. Project the accepted carrier $E = (D, S, B, W, R, L, H, C, P, N)$. The projection exposes exactly the denominator schedule, partial sums, remainder bounds, stream windows, readback rows, and structural rows.

The finite Engel data are read before the analytic handoff. The row D supplies the visible denominator schedule, and W selects the finite windows in which that schedule may be inspected. The partial-sum row S can therefore present only rational sums generated from those displayed windows.

The remainder step is separate. The row B supplies dyadic tail bounds for the unread Engel part, so a regular rational or Real-facing consumer cannot treat the expansion as a selected infinite sum.

Finally R and L are downstream of B. Componentwise transport in H and replay in C preserve the same displayed route, while P and N only source and name it. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2007.3 (EngelExpansion real readback boundary)**.** *Let $E = (D, S, B, W, R, L, H, C, P, N)$ be an accepted* $\mathsf{EngelExpansion}^{\uparrow}$ *carrier. Every finite Engel expansion readback consumed as a regular rational name or as a terminal real-name seal factors through*

$$D, S, W \longmapsto B \longmapsto R \longmapsto L$$

with structural support H, C, P, N. Thus the consumer receives a denominator schedule, $\mathsf{Rat}^{\uparrow}$ *partial sums,* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder bounds,* $\mathsf{StreamName}^{\uparrow}$ *finite windows, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal, all as finite BEDC data.*

The boundary supplies no quotient real equality, no selected infinite sum, no trichotomy row, no countable-choice selector, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no claim that the continued-fraction and Engel presentations are unique as host real objects.*

Proof. Start with a downstream consumer of R or L. By the carrier definition, neither row is an independent real object; both are downstream of the finite Engel schedule and dyadic tail ledger.

The consumer first reads D, S, and W. These rows expose the accepted denominators, the rational partial sums, and the finite windows in which the expansion is being inspected.

Next the consumer reads B. This row is the only remainder-control coordinate in the packet, and it records dyadic bounds for the unread Engel tail before any regular rational readback is available.

The row R then repacks the displayed partial sums and bounds as a $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal row L seals only that regular rational route as a $\mathsf{Real}^{\uparrow}$ presentation. The structural rows transport, replay, package, and name the same route, so the excluded principles cannot be recovered from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EngelExpansion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EngelExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2007.1, Definition 2007.2, and Definition 2007.3 seed the finite Engel denominator-schedule route through rational partial sums, dyadic remainder bounds, regular rational readback, and terminal Real seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EngelExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, selected infinite sums, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or uniqueness against continued-fraction presentations as host real objects.

Upgrade path: Obligation closure requires checked carrier admission, denominator-schedule visibility, rational partial-sum exactness, dyadic remainder control, readback-order, and real readback boundary proofs for BEDC.Derived.EngelExpansionUp.

Constructive story: An $\mathsf{EngelExpansion}^{\uparrow}$ packet is generated from finite denominator schedule rows, RatUp partial-sum rows, DyadicRatCore remainder-bound rows, StreamName windows, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2008

A Concrete Naming Certificate for $\mathsf{GeometricSeries}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{GeometricSeries}^{\uparrow}$ packet records the finite geometric majorant route used by Real and Completion-facing certificates before a tail estimate is handed to a regular rational or Real seal. It sits beside the dyadic finite-tail ledger of **??**, the ratio and root-test routes of chapter 1461 and chapter 1481, the radius transport of chapter 66, and the complex partial-sum surface of chapter 69. The packet names a displayed majorant discipline; it does not assert selected infinite sums, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2008.1 (Geometric series carrier)**.** *A* $\mathsf{GeometricSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (a, q, n, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *a is the initial-term row, recording the finite magnitude budget that enters the majorant.*
2. *q is the dyadic ratio row, displaying a ratio strictly below the unit tolerance scale together with the dyadic slack used by later tail requests.*
3. *n is the unary exponent-window row, recording the finite exponent range and successor action on which the powers of q are inspected.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family that exposes the source tail and the finite power windows used by the packet.*
5. *T is the* $\mathsf{DyadicGeometricTail}^{\uparrow}$ *ledger that turns a, q, and n into a finite geometric tail budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only from the displayed tail ledger and the inspected stream windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached only after the regular rational readback has been displayed.*
8. *H records componentwise* hsame *transport for the initial term, ratio, exponent window, stream windows, dyadic tail ledger, regular readback, Real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a precision request through*

$$a, q, n \longmapsto W \longmapsto T \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{GeometricSeries}^{\uparrow}$, $\mathsf{DyadicGeometricTail}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GeometricSeries}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a selected infinite sum, quotient stream equality, countable-choice selector, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Lean4 ✓ `BEDC.Derived.GeometricSeriesUp.TasteGate.GeometricSeriesTasteGate single carrier alignment`

Theorem 2008.2 (Geometric series NameCert obligations)**.** *For every accepted* $\mathsf{GeometricSeries}^{\uparrow}$ *carrier* $G = (a, q, n, W, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GeometricSeries}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed eleven-row packet;*
2. *initial-term exposure for a and dyadic ratio exposure for q, including the explicit strict-below-unit slack;*
3. *unary exponent-window coverage for n and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in W;*
4. *tail-ledger exactness, requiring T to be read from a, q, n, W through the* $\mathsf{DyadicGeometricTail}^{\uparrow}$ *surface;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring R and E to factor through the displayed tail ledger;*
6. *transport, continuation replay, provenance, and local naming for exactly the rows recorded in H, C, P, N.*

No geometric-series NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier $G = (a, q, n, W, T, R, E, H, C, P, N)$. The projection exposes the initial term, ratio, exponent window, stream windows, tail ledger, regular readback, Real seal, and structural rows.

The numeric part of the certificate is finite. The rows a and q display the starting magnitude and the strict subunit dyadic ratio, while n and W specify the only exponent and source windows admitted for inspection.

The row T is then the sole tail-producing coordinate. It sends the displayed data through the $\mathsf{DyadicGeometricTail}^{\uparrow}$ ledger, so the geometric majorant is a finite BEDC row rather than an appeal to a host infinite sum.

Finally R and E are downstream of T. Componentwise transport in H preserves the same displayed route, and C, P, N only replay, source, and name that route. Therefore the listed rows exhaust the local NameCert obligations. □

Theorem 2008.3 (Geometric series tail modulus)**.** *Let $G = (a, q, n, W, T, R, E, H, C, P, N)$ be an accepted* $\mathsf{GeometricSeries}^{\uparrow}$ *carrier. Every precision request consumed by G receives a finite tail threshold by the route*

$$a, q, n, W \longmapsto T \longmapsto R.$$

The resulting modulus is the one displayed by the $\mathsf{DyadicGeometricTail}^{\uparrow}$ *ledger and then read back through* $\mathsf{RegSeqRat}^{\uparrow}$*; it is not a selected limit of the infinite geometric series.*

Proof. Fix a displayed precision request. The rows a and q provide the starting budget and subunit ratio, while n selects the finite exponent window in which the request is evaluated.

Open the stream windows in W. These windows are the only source observations visible to the packet, so the request cannot inspect an unrecorded tail or a quotient stream representative.

Apply the tail ledger T. The ledger computes the dyadic geometric budget and returns the finite threshold required by the request. The row R reads that threshold as a $\mathsf{RegSeqRat}^{\uparrow}$ modulus, and the structural rows preserve the same route under transport and replay. □

Theorem 2008.4 (Geometric series majorant handoff)**.** *Every accepted* $\mathsf{GeometricSeries}^{\uparrow}$ *majorant exported to a ratio-test, root-test, convergence-radius, complex-series, or Real-facing consumer factors through the finite handoff*

$$a, q, n \longmapsto W, T \longmapsto R, E, H, C, P, N.$$

Consequently the consumer receives only the displayed initial-term row, subunit dyadic ratio row, unary exponent window, stream windows, $\mathsf{DyadicGeometricTail}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal row, transport package, replay route, provenance, and local naming row.*

Proof. Start with an exported majorant. Carrier projection shows that the only available numerical rows are a, q, and n, and the only admitted observations of the source tail lie in W.

The majorant must then pass through T. Since T is the displayed $\mathsf{DyadicGeometricTail}^{\uparrow}$ ledger, every downstream comparison receives a finite dyadic tail budget before it can read the regular rational handoff.

The handoff to R and E does not add analytic power. It merely presents the displayed tail budget as a $\mathsf{RegSeqRat}^{\uparrow}$ readback and a Real-facing seal row.

The remaining structural rows preserve the same route. Thus a consumer of the ratio-test, root-test, convergence-radius, complex-series, or Real-facing surface cannot read a selected infinite sum, quotient stream equality, countable-choice selector, host real equality, or ambient completeness theorem from the $\mathsf{GeometricSeries}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GeometricSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{GeometricSeries}^{\uparrow}$ packet is generated from an initial-term row, a dyadic subunit-ratio row, a unary exponent-window row, finite StreamName windows, a DyadicGeometricTail ledger, a RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GeometricSeries}^{\uparrow}}$, seed)

Scope closed: Definition 2008.1, Definition 2008.2, Definition 2008.3, and Definition 2008.4 seed the finite geometric majorant route over dyadic tail ledgers, regular rational readback, Real seals, stream windows, and BEDC transport rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GeometricSeries}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected infinite sums, quotient stream equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite NameCert obligation surface, tail-modulus theorem, and majorant-handoff theorem for BEDC.Derived.GeometricSeriesUp.

The $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ packet routes finite product coordinates through chapter 301, chapter 126, and the completion-facing boundary of chapter 1569.

Chapter 2009

A Concrete Naming Certificate for $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real arithmetic, the $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ packet records the finite product of displayed regular Cauchy rational names as one synchronized NameCert route. It sits after the regular rational source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic core of chapter 291, the terminal real-name seal of chapter 38, the binary regular product route of chapter 461, and the completion-facing product packet of chapter 464. The carrier packages repeated binary product evidence without importing a host finite product, quotient stream equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The finite-product packet consumes chapter 301, chapter 126, chapter 291, and chapter 38 as real L10 dependencies: their rows supply the source sequences, synchronized windows, dyadic product budgets, and terminal seal carried by the packet, rather than ambient host finite-product structure.

Definition 2009.1 (Regular Cauchy finite product carrier)**.** *A* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, W, D, P, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *I is the finite unary index row. It lists exactly the component slots opened by the product request and the fold order used by the displayed route.*
2. *S is the component* $\mathsf{RegSeqRat}^{\uparrow}$ *source family, one row for each slot of I.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family for the component reads, intermediate product reads, and final product-facing read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, storing the component dyadic observations, intermediate product observations, requested radii, and slack cells.*
5. *P is the finite product-budget ledger. It records the binary-product schedule, radius allocation, and accumulated dyadic error account for the fold named by I.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the final folded product, obtained only from S, W, D, P.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback of the folded product has been displayed.*

8. *H records componentwise* hsame *transport for the index row, sources, synchronized windows, dyadic observations, product-budget ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from any finite product request through the same rows.*
10. *Q is the* Pkg *provenance over* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, W, D, P, R, E, H, C, Q, N$. It has no coordinate for a host finite product, quotient stream equality, selected limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Theorem 2009.2 (Regular Cauchy finite product NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier*

$$K = (I, S, W, D, P, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteProduct}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the finite unary index row, component* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations, product-budget ledger, final readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local name;*
2. *finite tuple-window coverage, requiring every component slot in I to open the matching source row and all synchronized windows needed by the fold;*
3. *dyadic product-budget exactness, requiring every intermediate product observation to consume its assigned radius and slack cells from D and P;*
4. *RegSeqRat readback stability, requiring the final readback row R to depend only on the displayed sources, windows, dyadic observations, and product-budget ledger;*
5. *Real seal non-escape, requiring E, H, C, Q, N to expose no host finite product, quotient stream equality, selected limit, trichotomy, ambient completeness theorem, Lean verification, or bridge credential.*

No Regular Cauchy finite product obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 2009.1. The displayed tuple $I, S, W, D, P, R, E, H, C, Q, N$ is the entire public surface, so carrier admission is exactly the admission of those rows.

Tuple-window coverage is forced by the index row. Each slot named by I has one component $\mathsf{RegSeqRat}^{\uparrow}$ source in S, and the synchronized window row W is the only place where component, intermediate, and final product reads are opened.

Dyadic exactness is the joint role of D and P. The observations in D supply component and intermediate dyadic cells, while P assigns the binary-product schedule, radii, slack, and accumulated error account for the fold.

The final regular readback row R is downstream of S, W, D, P. Therefore readback stability follows from the carrier order: no product-facing $\mathsf{RegSeqRat}^{\uparrow}$ data can be inspected until the synchronized windows and dyadic product budget have already been displayed.

Finally, the seal, transport, replay, provenance, and local name rows preserve only this displayed route. Since none of the excluded objects is a coordinate of the carrier, the listed five rows exhaust the local NameCert obligations. □

Theorem 2009.3 (Regular Cauchy finite product tail budget)**.** *Let*

$$K = (I, S, W, D, P, R, E, H, C, Q, N)$$

be an accepted $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier. Every finite product read from* K *factors through*

$$I, S \longmapsto W \longmapsto D, P \longmapsto R \longmapsto E, H, C, Q, N.$$

In particular, no read reaches the final $\mathsf{RegSeqRat}^{\uparrow}$ *product row before the synchronized windows and dyadic product-budget ledger have been displayed.*

Proof. Begin with a finite product request. The request first names its finite unary index row I and the component source family S, because those are the only carrier rows that identify which regular Cauchy names participate in the fold.

The requested component and intermediate observations then pass through W. This synchronized window row is the only row that aligns the component reads with the intermediate product reads used by the fold.

The dyadic part of the request is read next. The observation row D supplies the dyadic product cells and requested radii, while the budget row P supplies the binary-product schedule and accumulated slack account.

Only after those rows are displayed can the final regular rational readback R be consumed. The downstream rows E, H, C, Q, N seal, transport, replay, source, and name the same route, so the finite product read cannot bypass the synchronized windows or the dyadic ledger. □

Theorem 2009.4 (Regular Cauchy finite product budget associativity)**.** *Let*

$$K = (I, S, W, D, P, R, E, H, C, Q, N)$$

be an accepted $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier. Regrouping adjacent binary product folds in the displayed fold order preserves the same synchronized windows* W*, dyadic observations* D*, product-budget ledger* P*, final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E*. The regrouped read is a projection of the displayed fold rows of* K*, not an appeal to host associativity of finite products or quotient stream equality.*

Proof. Apply Definition 2009.3. Every finite product read from K factors through the index and source rows, then through the synchronized windows, then through the dyadic observations and product-budget ledger, before reaching the final readback and seal.

The carrier rows of Definition 2009.1 identify where regrouping can be displayed. The finite unary index row I names the fold order, while W, D, P record the windows, observations, product schedule, radii, and slack cells used by that order.

Regrouping adjacent binary product folds therefore changes only the displayed parenthesization inside the schedule already stored in I and P. It does not create a second window family, a second dyadic observation row, a second product-budget ledger, or a second final readback.

Since R and E are downstream of the fixed rows W, D, P, the regrouped read preserves the same final $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal. The argument is projection from the accepted carrier, so no host finite-product operation or quotient stream equality is introduced. □

Theorem 2009.5 (Regular Cauchy finite product projection stability)**.** *For every accepted* RegularCauchyFiniteProd *carrier* $K = (I, S, W, D, P, R, E, H, C, Q, N)$*, projecting any component slot from* K *factors through the same finite index row* I*, source family* S*, synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family* W*, dyadic*

product-budget ledger D, P, final $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and* $\mathsf{Real}^{\uparrow}$ *seal E. Component projection can expose a component readback only through this displayed route; it cannot bypass the budget ledger or invoke host finite products, quotient stream equality, selected component representatives, trichotomy, or ambient completeness.*

Proof. Project the carrier through Definition 2009.1. The component slot is named by I, its source is a row of S, and every read serving the projection must pass through the synchronized window family W.

Apply the tail-budget theorem Definition 2009.3. It places every product-facing read through $I, S, W, D, P, R, E, H, C, Q, N$ before a component-facing consumer can inspect the result.

Use budget associativity from Definition 2009.4. Regrouping the displayed fold may expose the requested component slot, but it preserves the same dyadic observations, product-budget ledger, final regular readback, and Real seal.

The structural rows H, C, Q, N transport, replay, source, and name only that displayed route. Since the carrier has no host finite-product coordinate, quotient stream equality, selected component representative, trichotomy, or ambient completeness theorem, projection stability is exhausted by the finite-product packet itself. □

Theorem 2009.6 (Regular Cauchy finite product Real seal non-escape)**.** *For every accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier K, the* $\mathsf{Real}^{\uparrow}$ *seal row exposed by K is a downstream seal for the displayed finite route*

$$I, S, W, D, P, R.$$

It exposes no host finite product, no quotient stream equality, no selected limit, no trichotomy, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the carrier boundary. The seal row E appears only after the index, source, synchronized window, dyadic observation, product-budget, and regular readback rows.

The transport and replay rows H and C preserve this order. They can move or replay the displayed route, but they do not add an independent product coordinate or a host equality coordinate.

The provenance and local naming rows Q and N cite the same dependencies. Since the carrier has no coordinate for a host finite product, quotient stream equality, selected limit, trichotomy, or ambient completeness theorem, the $\mathsf{Real}^{\uparrow}$ seal cannot export any of them. □

Theorem 2009.7 (Regular Cauchy finite product projection roundtrip)**.** *For every accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier $K = (I, S, W, D, P, R, E, H, C, Q, N)$, any left or right projection read consumed by* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *factors back through the same finite index row I, source family S, synchronized window family W, dyadic observations D, product-budget ledger P, and final readback R. The projection packet may expose component readbacks, but it cannot introduce a host product, selected component representative, or quotient stream equality.*

Proof. Begin with an accepted finite-product carrier $K = (I, S, W, D, P, R, E, H, C, Q, N)$ and a projection read consumed by chapter 2076. The projection can name a left or right component only after it names the product packet from which that component is read.

Apply the tail-budget theorem Definition 2009.3. The product-facing read factors through I, S, W, D, P, R before any $\mathsf{Real}^{\uparrow}$ seal or component-facing export is available.

Apply budget associativity from Definition 2009.4. Regrouping the binary fold may expose the component position needed by the projection packet, but it preserves the same synchronized windows, dyadic observations, product-budget ledger, final readback, and seal route.

Finally use the Real seal non-escape theorem Definition 2009.6. The projection packet may expose component readbacks downstream of the displayed finite product route, but no host product, selected component representative, or quotient stream equality is present in the carrier. □

Theorem 2009.8 (Regular Cauchy finite product diagonal seal)**.** *For every accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *carrier* $K = (I, S, W, D, P, R, E, H, C, Q, N)$*, any diagonal read or component projection read from* K *preserves the same synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations* D*, product-budget ledger* P*, final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. Thus a finite-product consumer may reuse the projected route as a sealed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *input, but it cannot introduce a host product, selected component representative, quotient stream equality, trichotomy, or ambient completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 2009.2. They order every accepted carrier through the finite unary index row, component sources, synchronized windows, dyadic observations, product-budget ledger, final readback, seal, transport, replay, provenance, and local name.

Induct over the displayed finite fold route. The base read is one component source with its synchronized window and dyadic observation rows, so the readback and seal are exactly the rows displayed in R and E.

For the fold step, use budget associativity from Definition 2009.4. Regrouping a binary product exposes the component or diagonal position without changing W, D, P, R, E.

Finally apply the Real seal non-escape theorem Definition 2009.6 and the projection roundtrip Definition 2009.7. The projected read still passes through the same finite product route before it reaches $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ sealing, so no excluded host equality or completion object is exported. □

Theorem 2009.9 (Regular Cauchy finite product classifier bridge)**.** *Two accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packets*

$$K = (I, S, W, D, P, R, E, H, C, Q, N) \quad \textit{and} \quad K' = (I', S', W', D', P', R', E', H', C', Q', N')$$

are classifier-equal exactly when the finite unary index rows I, I' *match, the component* $\mathsf{RegSeqRat}^{\uparrow}$ *classifiers on* S, S' *agree slotwise, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window classifiers on* W, W' *agree for component, intermediate, and final reads, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback ledgers* D, P *and* D', P' *are equal as displayed budget data, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal route through* R, E, H, C, Q, N *is the same as the route through* R', E', H', C', Q', N'*. This correspondence is the finite-product classifier surface consumed by product regular-Cauchy limit certificates and Real algebra finite-product certificates.*

Proof. For the forward direction, project both accepted carriers using Definition 2009.1. The classifier for an accepted packet has no coordinate outside $I, S, W, D, P, R, E, H, C, Q, N$, so equality of packet classifiers can be read only from the listed rows.

The first projection reads the finite unary index row. Once I and I' match, the component slots are aligned, and the component classifier comparison is forced to be slotwise comparison of the $\mathsf{RegSeqRat}^{\uparrow}$ source family S against S'.

Next read the synchronized window and dyadic budget rows. The window classifiers on W, W' cover the component, intermediate, and final product reads, while the ledgers D, P and D', P' record the tolerance cells, readback cells, radius allocation, fold schedule, and slack account. These are the only budget rows available to the classifier.

Finally, use the Real seal non-escape theorem Definition 2009.6. The route through R, E, H, C, Q, N cannot export a host finite product or quotient stream equality, so downstream classifier agreement is exactly agreement of that displayed seal route.

For the reverse direction, rebuild the packet classifier from the matching rows. The common finite index row aligns the sources; the component $\mathsf{RegSeqRat}^{\uparrow}$ classifiers and synchronized $\mathsf{StreamName}^{\uparrow}$ window classifiers rebuild the inspected fold; the equal dyadic tolerance and budget ledgers rebuild the product-accounting part; and the common route through R, E, H, C, Q, N supplies the same terminal $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local name.

The diagonal seal theorem Definition 2009.8 then shows that every product-facing consumer sees the same projected route. Since the carrier exposes no additional classifier coordinate, the rebuilt rows are sufficient for classifier equality, and the same bridge is available to downstream regular-Cauchy limit and Real algebra finite-product consumers. □

Theorem 2009.10 (Regular Cauchy finite product coordinate envelope)**.** *For every pair of classifier-equal accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packets, any coordinate-facing consumer must read the aligned finite index row, the component* $\mathsf{RegSeqRat}^{\uparrow}$ *classifiers, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and product-budget ledgers, the final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before exposing a coordinate. The coordinate envelope is the displayed finite-product packet itself; it excludes host finite products, selected representatives, quotient stream equality, trichotomy, and ambient completeness.*

Proof. Start with the carrier definition Definition 2009.1. A coordinate slot is named only by the finite unary index row I, and its component source is read only through the displayed family S.

Apply the tail-budget theorem Definition 2009.3. It forces every product-facing read through the synchronized windows W, dyadic observations D, product-budget ledger P, final readback R, and downstream rows before a coordinate-facing consumer can inspect the result.

Use the diagonal seal Definition 2009.8 and the classifier bridge Definition 2009.9. Classifier equality aligns the finite index row, component classifiers, synchronized windows, dyadic ledgers, readback, and seal route across the two packets.

Finally apply Real seal non-escape from Definition 2009.6. Since neither packet has a coordinate for a host finite product, selected representative, quotient stream equality, trichotomy, or ambient completeness, the displayed rows form the whole coordinate envelope. □

Falsifiable prediction: Every $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ product-facing read factors through a finite unary index row, component RegSeqRat sources, synchronized StreamName windows, DyadicRatCore observations, a finite product-budget ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, real, regularcauchyproduct, cauchyproduct: $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite unary product index, synchronized multi-source windows, dyadic product-budget accounting, final RegSeqRat readback, RealUp sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteProduct}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2009.1, Definition 2009.2, Definition 2009.3, Definition 2009.4, and Definition 2009.6 seed the finite product route from displayed regular Cauchy sources through synchronized windows, dyadic product budgets, final RegSeqRat readback, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteProduct}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyFiniteProductUp`

Bridge status: none

Not claimed: This chapter does not close host finite products, quotient stream equality, selected limits, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tuple-window coverage, budget exactness, readback stability, seal non-escape, and local naming for BEDC.Derived.RegularCauchyFiniteProductUp.

Constructive story: A RegularCauchyFiniteProduct$^{\uparrow}$ packet is generated from a finite unary index row, component RegSeqRat source rows, synchronized StreamName windows, DyadicRatCore observations, a finite product-budget ledger, final RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The downstream projection packet of chapter 2076 consumes the RegularCauchyFiniteProduct$^{\uparrow}$ carrier's finite index row, component source rows, synchronized window family, dyadic product-budget ledger, and final readback row as the shared route from which left and right projection readbacks are exposed. Thus projection consumers reuse the finite product's displayed source, window, budget, and readback rows rather than importing a host product or a selected component representative. The finite product packet depends on the regular rational source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. Its product-facing route consumes synchronized regular Cauchy source windows and a displayed dyadic product-budget ledger; it does not import a host finite product, a quotient stream equality, or a selected tuple representative. The genuine input route for RegularCauchyFiniteProduct$^{\uparrow}$ reads the finite product ledger of chapter 34, then the synchronized finite observation windows of chapter 126, and then the regular rational readback surface of chapter 301 before any Real-facing projection or terminal seal is consumed. This order keeps **??**, StreamName$^{\uparrow}$, and RegSeqRat$^{\uparrow}$ visible as horizontal dependencies rather than hiding the finite product inside a kernel-only carrier or a downstream Real$^{\uparrow}$ projection. The forward lattice for RegularCauchyFiniteProduct$^{\uparrow}$ is consumed by chapter 2076 and chapter 464 through the shared finite index, synchronized StreamName$^{\uparrow}$ windows, dyadic product-budget ledger, and RegSeqRat$^{\uparrow}$ readback. Downstream product and projection packets therefore reuse the displayed finite route rather than adding a host product, a selected component representative, quotient stream equality, trichotomy, or ambient completeness. The product-budget projection lattice for RegularCauchyFiniteProduct$^{\uparrow}$ is consumed by chapter 2076, chapter 461, and chapter 464. The route exports the finite index rows, synchronized StreamName$^{\uparrow}$ windows, DyadicRatCore$^{\uparrow}$ product-budget ledger, projection rows, and RegSeqRat$^{\uparrow}$ readbacks as one displayed dependency surface, so downstream product consumers reuse the finite ledger rather than importing a host product coordinate, a selected component representative, quotient stream equality, trichotomy, or ambient completeness.

Theorem 2009.11 (Regular Cauchy finite product dependency-lattice route)**.** *Every accepted* RegularCauchyFiniteProduct$^{\uparrow}$ *packet reads its horizontal dependency lattice through* ***??***, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, *and* Real$^{\uparrow}$ *before a finite-product read is exported. The route consumes synchronized stream windows and dyadic budget rows for the displayed fold; it does not import host finite products, selected component representatives, quotient stream equality, trichotomy, or ambient completeness.*

Proof. Start with the product-facing request. The finite product source is opened through **??** only as a displayed dependency row, and the component regular Cauchy data are read through RegSeqRat$^{\uparrow}$ sources.

The synchronized observation surface comes next. StreamName$^{\uparrow}$ supplies the shared finite windows for the components and intermediate reads, while DyadicRatCore$^{\uparrow}$ supplies the tolerance and product-budget rows used by the fold.

The binary product route through RegularCauchyProduct$^{\uparrow}$ is then replayed inside the finite-product packet, and the terminal Real$^{\uparrow}$ seal is read only after the final regular readback is displayed.

Because every step uses these finite rows, the dependency lattice exports no host finite product or selected coordinate object. □

Theorem 2009.12 (RegularCauchyFiniteProduct coordinate stability)**.** *If two accepted* RegularCauchyFiniteProduc *packets are classifier-equivalent, then each projected coordinate remains a* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible regular Cauchy readback under the same* $\mathsf{StreamName}^{\uparrow}$ *windows and product-projection rows. In particular, a coordinate projection cannot separate the two packets unless the separation is already visible in the finite product source row, synchronized window family, dyadic product-budget ledger, regular-rational readback, or displayed projection route.*

Proof. Read the product projection route first. The dependency route through chapter 2076 exposes the finite product source, synchronized windows, dyadic product budget, and projection readback as the only public route to a coordinate.

Next read the regular-rational and stream-name route. The dependency line through chapter 301 and chapter 126 fixes the windows and readback rows used by each coordinate.

Classifier equivalence of the two finite-product packets therefore transports through the same source, window, budget, readback, and projection rows. Each coordinate remains a RegSeqRat-compatible regular Cauchy readback, and any failure of stability must already be visible in one of the displayed rows rather than in a hidden host product or selected component representative. □

Theorem 2009.13 (Regular Cauchy finite product window restriction)**.** *Restricting a coordinate read from an accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packet to any displayed synchronized* $\mathsf{StreamName}^{\uparrow}$ *subwindow preserves the* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible coordinate readback and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget ledger, provided the finite index row still names the coordinate slot. The restriction exposes no host product coordinate, selected component representative, quotient stream equality, trichotomy, or ambient completeness datum.*

Proof. Read the product projection route through chapter 2076. The coordinate slot remains available exactly when the finite index row still names it.

Next restrict the synchronized window row. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ routes fix the displayed subwindow used by the coordinate read, so the restricted read uses the same component source and the same regular-rational readback route.

Apply coordinate stability from Definition 2009.12. Since the product-budget ledger and projection route are unchanged, the coordinate remains a RegSeqRat-compatible readback through the same DyadicRatCore product-budget data.

The restricted subwindow is therefore a local view of the displayed finite-product packet. It cannot introduce a host finite product, selected representative, quotient stream equality, trichotomy, or ambient completeness datum. □

Theorem 2009.14 (Regular Cauchy finite product coordinate pairing)**.** *Let two coordinate reads be displayed from the same accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packet. If the two reads share the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget ledger, and the finite index rows naming their coordinate slots, then they form a jointly* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible pair. The pair is read only through the product-projection dependency route of chapter 2076; it exports no host product coordinates, selected component representatives, quotient stream equality, trichotomy, or ambient completeness datum.*

Proof. Start with the two displayed coordinate reads from the same finite-product packet. Apply coordinate stability, Definition 2009.12, to each read along the common product source, synchronized windows, product-budget ledger, regular-rational readback, and projection route.

Next apply the window restriction theorem, Definition 2009.13. Because both reads share the same $\mathsf{StreamName}^{\uparrow}$ window family and $\mathsf{DyadicRatCore}^{\uparrow}$ product-budget ledger, restricting to any displayed common subwindow preserves the regular-rational readback for each coordinate.

Finally use the product-projection dependency route in chapter 2076. The finite index rows keep the two coordinate slots named inside the same packet, so the two preserved readbacks assemble as a jointly $\mathsf{RegSeqRat}^{\uparrow}$-compatible pair.

The assembled pair contains only the displayed product packet, synchronized windows, dyadic budget, finite index rows, projection route, and regular-rational handoffs. No host product coordinate, selected representative, quotient stream equality, trichotomy, or ambient completeness row is introduced. □

Theorem 2009.15 (Regular Cauchy finite product coordinate gluing)**.** *Let a finite family of coordinate reads share the same* $\mathsf{StreamName}^{\uparrow}$ *window family, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget ledger, and finite index rows naming their coordinate slots. If each read is accepted through the product-projection dependency route of chapter 2076 and remains* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible under the coordinate stability boundary, then the family glues into one accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packet whose projections recover the original coordinate reads. The glued packet exports only the displayed windows, dyadic product-budget ledger, finite index rows, projection routes, and regular-rational handoffs; it introduces no host product, quotient equality, trichotomy, selected component representative, or ambient completeness datum.*

Proof. Induct over the finite index rows. The empty family is the displayed empty finite-product packet, whose window family, product-budget ledger, and projection route contain no hidden host product data.

For the step, assume the already indexed coordinate reads have been glued into an accepted finite-product packet. Add the next coordinate read using the same $\mathsf{StreamName}^{\uparrow}$ windows and the same $\mathsf{DyadicRatCore}^{\uparrow}$ product-budget ledger.

Apply coordinate stability from Definition 2009.12 to keep the new read on the displayed regular-rational route. Then apply coordinate pairing from Definition 2009.14 to attach the new coordinate to the already glued packet through the shared projection dependency route.

The induction preserves the finite index ledger at each step, so every projection of the resulting packet recovers the coordinate read placed at that index. Since each step uses only the displayed windows, dyadic budget, finite index rows, projection route, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the glued packet gains no host product, quotient stream equality, trichotomy, selected component representative, or ambient completeness row. □

Theorem 2009.16 (Regular-Cauchy finite product downstream projection route)**.** *Every downstream* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *packet reads the finite product packet's index row, component source rows, synchronized window family, dyadic product-budget ledger, final readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal through the projection certificate of chapter 2076. The projection route exports no host product object, selected component representative, quotient stream equality, countable choice schedule, or ambient completeness principle.*

Proof. Project the finite product carrier through its displayed index, source, synchronized window, dyadic budget, readback, and Real seal rows. These are the rows already consumed by the product projection dependency route.

Now read the downstream projection packet of chapter 2076. Its left and right coordinate reads are admitted only after the finite product route has supplied the shared product index, component sources, windows, budget, and final readback.

The terminal $\mathsf{Real}^{\uparrow}$ seal remains downstream of that route and upstream of the local projection naming rows. Since no coordinate in the finite product packet carries a host product, selected component representative, quotient stream equality, choice schedule, or ambient completeness object, the downstream projection consumer cannot export any of them. □

Chapter 2010

Dedekind Cauchy Sandwich NameCert Construction

Following Bishop and Bridges on constructive real representations, the $\mathsf{DedekindCauchySandwich}^{\uparrow}$ packet records the finite sandwich used when located-cut evidence is compared with a regular-Cauchy name before the terminal real seal is consumed. It sits between the lower and upper cut rows of chapter 404, the comparison route of chapter 1424, and the interval enclosure surface of chapter 1709. Its downstream handoff is the regular-rational route of chapter 301, the finite stream windows of chapter 126, and the terminal seal of chapter 38. The chapter names only finite carrier, regularization, transport, replay, provenance, and local NameCert rows; it does not claim a quotient cut, selected supremum, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2010.1 (Dedekind Cauchy sandwich carrier)**.** *A* $\mathsf{DedekindCauchySandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located-cut row, recording finite dyadic witnesses below the inspected located cut.*
2. *U is the upper located-cut row, recording finite dyadic witnesses above the same inspected located cut.*
3. *I is the dyadic interval enclosure row, binding each visible unary precision to an interval whose lower endpoint is certified by L and whose upper endpoint is certified by U.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened only after the corresponding lower, upper, and interval rows have been displayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row assembled from the displayed stream windows and dyadic enclosure budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through L, U, I, W, R.*
7. *H records componentwise* hsame *transport for the lower row, upper row, interval enclosure, stream windows, regular handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$L, U \longmapsto I \longmapsto W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{DedekindCauchySandwich}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCauchySandwich}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, I, W, R, E, H, C, P, N$. It has no coordinate for quotient cuts, selected suprema, trichotomy, countable choice, host completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.DedekindCauchySandwichUp.DedekindCauchySandwichTasteGate single carrier alignment`

Theorem 2010.2 (Dedekind Cauchy sandwich regularization)**.** *For every accepted* $\mathsf{DedekindCauchySandwich}^{\uparrow}$ *carrier*

$$S = (L, U, I, W, R, E, H, C, P, N),$$

each visible unary precision exported by S has a displayed $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R squeezed between the lower and upper located-cut rows L and U through the dyadic interval enclosure row I and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W. The regular-Cauchy read is obtained without quotient-cut equality, selected suprema, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet through Definition 2010.1. The only lower and upper cut data available to a precision request are the displayed rows L and U.

The interval row I binds those two rows at the same visible unary precision. Its lower endpoint is certified by L, its upper endpoint is certified by U, and the carrier has no separate coordinate from which a detached bound could be read.

The stream and regular-Cauchy rows are downstream of that enclosure. The finite windows W are opened after I, and the regular handoff R is assembled from those windows and the same dyadic enclosure budgets.

Finally, H, C, P, N transport, replay, source, and name the displayed route only. Since the carrier contains no quotient cut, selected supremum, trichotomy witness, countable-choice row, or ambient completeness coordinate, every exported regular-Cauchy read is squeezed between the displayed lower and upper rows through I and W. □

Theorem 2010.3 (Dedekind Cauchy sandwich NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCauchySandwic}$ *carrier*

$$S = (L, U, I, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DedekindCauchySandwich}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed lower located-cut row, upper located-cut row, dyadic interval enclosure, stream windows, regular-Cauchy handoff, Real seal, transport, replay, provenance, and local naming rows;*

2. *lower-upper disjointness, requiring the lower and upper rows to appear as separated faces of the same finite located-cut observation before any interval or stream row is read;*

3. *locatedness, requiring each visible unary precision to display a dyadic enclosure row I whose endpoints are sourced from L and U;*

4. *regularization, requiring R to be assembled from the finite windows W opened over the displayed enclosure rather than from a detached Cauchy representative;*

5. *classifier transport, requiring componentwise* hsame *transport to preserve the lower row, upper row, enclosure row, stream windows, handoff row, Real seal, replay, provenance, and local NameCert row together;*

6. *ledger exclusion, requiring the packet to expose no quotient cut, selected supremum, trichotomy witness, countable-choice row, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean verification, or bridge credential.*

No $\mathsf{DedekindCauchySandwich}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is the projection of the packet $S = (L, U, I, W, R, E, H, C, P, N)$ to its ten displayed coordinates. These coordinates are the whole accepted carrier inventory.

Lower-upper disjointness and locatedness are read through L, U, I. The two located-cut faces are displayed before the interval enclosure is available, and each visible unary precision receives its enclosure from that same pair of rows.

Regularization is the projection to W and R. The stream windows are opened over the displayed enclosure, and the regular-Cauchy handoff is downstream of those windows rather than a free-standing representative.

Classifier transport is the projection to H together with the replay and provenance rows C and P. These rows preserve the displayed coordinates componentwise and do not introduce a second classifier surface.

The ledger exclusion row is therefore exhaustive. Since no excluded coordinate appears in the carrier, the local NameCert can only certify the displayed sandwich route and cannot export quotient-cut equality, selected suprema, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCauchySandwich}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCauchySandwich}^{\uparrow}$ packet is generated from lower and upper located-cut rows, dyadic interval enclosure rows, finite StreamName windows, a RegSeqRat handoff, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DedekindCauchySandwich}^{\uparrow}}$, seed)

Scope closed: Definition 2010.1, Definition 2010.2, and Definition 2010.3 seed the finite located-cut to regular-Cauchy sandwich packet used by Real representation comparison.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DedekindCauchySandwich}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient cuts, selected suprema, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regularization, classifier transport, ledger exclusion, and local NameCert proofs for BEDC.Derived.DedekindCauchySandwichUp.

Chapter 2011

A Concrete Naming Certificate for $\mathsf{CutRegularization}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{CutRegularization}^{\uparrow}$ packet records the finite route from rounded located cut observations to a regular-Cauchy $\mathsf{Real}^{\uparrow}$ name. It sits after the rounded lower and upper presentation of chapter 436, the located dyadic window surface of chapter 404, and the approximation interface of chapter 1975. Its dependency surface is the dyadic tolerance ledger of chapter 291, the stream-window interface of chapter 126, the regular rational handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names only finite carrier rows and their non-escape boundary; it is not a quotient of cuts, a selected supremum, a trichotomy principle, a host-completion theorem, or an appeal to choice.

Definition 2011.1 (Cut regularization carrier)**.** *A* $\mathsf{CutRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, L, A, \Delta, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the rounded* $\mathsf{DedekindCut}^{\uparrow}$ *source row, exposing the lower and upper rational observations as finite BEDC data.*
2. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *located-window row, binding each inspected precision request to lower and upper dyadic witnesses.*
3. *A is the* $\mathsf{LocatedCutApproximation}^{\uparrow}$ *approximation row, storing the visible midpoint, endpoint, or bracket readback obtained from D and L.*
4. *Δ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, endpoint slack, and width comparisons for the regularization route.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the finite brackets are read in precision order.*
6. *S is the stabilization row requiring the displayed windows to be nested or refined enough to feed the regular-Cauchy modulus demanded downstream.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from A, Δ, W, S.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular-Cauchy handoff R.*
9. *H records componentwise* hsame *transport for all source, window, tolerance, handoff, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$D, L \longmapsto A \longmapsto \Delta \longmapsto W \longmapsto S \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CutRegularization}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedCutApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CutRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, L, A, \Delta, W, S, R, E, H, C, P, N$. It has no coordinate for quotient-cut equality, selected suprema, trichotomy, host real equality, ambient completeness, Quot.sound*, propext, classical choice, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CutRegularizationUp.TasteGate.CutRegularizationTasteGate single carrier alignment`

Theorem 2011.2 (Cut regularization NameCert obligations)**.** *For every accepted* $\mathsf{CutRegularization}^{\uparrow}$ *carrier*

$$Q = (D, L, A, \Delta, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CutRegularization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed rounded cut source, located window, approximation row, dyadic tolerance ledger, stream windows, stabilization row, regular-Cauchy handoff, Real seal, and structural rows H, C, P, N;*
2. *cut-source exposure, requiring every regularization request to read the rounded* $\mathsf{DedekindCut}^{\uparrow}$ *source only through the displayed lower and upper rational observations;*
3. *located-window exposure, requiring the* $\mathsf{LocatedCut}^{\uparrow}$ *row L to bind each inspected precision to finite lower and upper dyadic witnesses before any stream or regular-Cauchy row is consumed;*
4. *approximation exactness, requiring the* $\mathsf{LocatedCutApproximation}^{\uparrow}$ *row A to store only finite bracket data obtained from D, L and the tolerance ledger Δ;*
5. *tolerance accounting, requiring Δ to record the dyadic radius and endpoint slack used by each displayed stream window and stabilization read;*
6. *stream stabilization, requiring W and S to expose the finite* $\mathsf{StreamName}^{\uparrow}$ *windows whose refinement feeds the regular-Cauchy modulus;*
7. *regular-Cauchy handoff, requiring R to be the only route by which the rounded located cut data becomes a* $\mathsf{RegSeqRat}^{\uparrow}$ *row;*
8. *Real-seal factorization, requiring every downstream read of E to pass through D, L, A, Δ, W, S, R and the structural rows;*
9. *transport, replay, and provenance non-escape, requiring H, C, P, N to preserve and name exactly the displayed rows, with no quotient-cut equality, selected supremum, trichotomy, host real equality, ambient completeness,* Quot.sound*, propext, classical choice, Lean verification, or bridge credential.*

No cut-regularization obligation is stored outside these rows.

Proof. Project the accepted packet $Q = (D, L, A, \Delta, W, S, R, E, H, C, P, N)$. Carrier admission exposes exactly the rounded cut source, located window, approximation row, dyadic tolerance

ledger, stream windows, stabilization row, regular-Cauchy handoff, Real seal, and four structural rows.

The cut-source and located-window obligations are the projections to D and L. The source row supplies the rounded lower and upper rational observations, and the located row binds each inspected precision to finite dyadic witnesses before any Cauchy-facing route is read.

Approximation exactness and tolerance accounting are the projections to A and Δ. The approximation row stores only bracket data read from the displayed source and located windows, while the tolerance ledger records the dyadic radius, endpoint slack, and width comparisons used by that read.

The stream and stabilization obligations are the projections to W and S. The stream row exposes the finite windows in precision order, and the stabilization row records the refinement needed to feed the regular-Cauchy modulus without selecting a quotient cut or a supremum.

Finally, the regular handoff, Real seal, and structural rows exhaust the boundary. The row R is downstream of D, L, A, Δ, W, S, the seal E is downstream of R, and H, C, P, N transport, replay, name, and source only the displayed rows. Hence no quotient-cut equality, selected supremum, trichotomy, host real equality, ambient completeness, Quot.sound, propext, classical choice, Lean verification, or bridge credential is exported. □

Theorem 2011.3 (Cut regularization window to regular-Cauchy)**.** *For every accepted* $\mathsf{CutRegularization}^{\uparrow}$ *carrier*

$$Q = (D, L, A, \Delta, W, S, R, E, H, C, P, N),$$

every $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* Q *factors through the displayed finite route*

$$\mathsf{DedekindCut}^{\uparrow} \longrightarrow \mathsf{LocatedCut}^{\uparrow} \longrightarrow \mathsf{LocatedCutApproximation}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}$$

by reading the rows $D, L, A, \Delta, W, S, R, H, C, P, N$*. In particular, the handoff uses the dyadic tolerance ledger and stream stabilization rows, not quotient-cut equality, host real equality, a selected supremum, trichotomy, ambient completeness,* Quot.sound*, propext, or classical choice.*

Proof. Begin with a regular-Cauchy consumer. Carrier projection exposes the handoff row R only after the rounded cut source D, the located window L, the approximation row A, the dyadic tolerance ledger Δ, the stream windows W, and the stabilization row S have been displayed.

The route inspection is finite. The rounded source supplies lower and upper rational observations, the located row binds those observations to a precision window, the approximation row records the finite bracket, and the dyadic ledger stores the radius and slack comparisons used by that bracket.

The stream row then presents the bracket sequence as visible windows, and the stabilization row records the refinement relation needed for the regular-Cauchy modulus. Thus the handoff row R is downstream of the displayed stream route rather than a detached representative.

Componentwise transport and replay through H and C preserve the same order, while P and N only name the visible packet. Since no carrier coordinate stores quotient-cut equality, host real equality, selected suprema, trichotomy, ambient completeness, Quot.sound, propext, or classical choice, no $\mathsf{RegSeqRat}^{\uparrow}$ read exported by the packet can factor through those excluded sources. □

Theorem 2011.4 (Cut regularization Real seal boundary)**.** *For every accepted* $\mathsf{CutRegularization}^{\uparrow}$ *carrier*

$$Q = (D, L, A, \Delta, W, S, R, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* E *receives only the displayed finite route*

$$D, L, A, \Delta, W, S, R, E, H, C, P, N.$$

The seal is not a Dedekind construction of $\mathsf{Real}^{\uparrow}$*, not a quotient-cut completion, not a selected supremum, not a trichotomy witness, not a host-completion theorem, not a choice object, and not a* Quot.sound *or propext bridge.*

Proof. Start from the terminal seal E. In the carrier, E is not an independent completion coordinate; it is the endpoint of the displayed route through the rounded cut source, located window, finite approximation, dyadic tolerance ledger, stream windows, stabilization row, and regular handoff.

Trace the route backward. The Real-facing read reaches E only after R has been read, R only after W and S have exposed the finite stabilized windows, and those windows only after A has been checked against D, L and Δ.

The structural coordinates do not add a second seal source. The transport row H is componentwise, the replay row C displays the same route order, and the provenance and local certificate rows P, N name this packet rather than importing a host completion principle.

Thus every Real-facing consumer is confined to $D, L, A, \Delta, W, S, R, E, H, C, P, N$. The excluded Dedekind construction, quotient-cut completion, selected-supremum, trichotomy, host-completion, choice, Quot.sound, and propext readings are outside the carrier inventory. □

Closure status for $\mathsf{NameCert}_{\mathsf{CutRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{CutRegularization}^{\uparrow}$ packet is generated from a rounded DedekindCut source, a LocatedCut window row, a LocatedCutApproximation bracket row, a DyadicRatCore tolerance ledger, StreamName windows, a stabilization row, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CutRegularization}^{\uparrow}}$, seed)

Scope closed: Definition 2011.1, Definition 2011.2, Definition 2011.3, and Definition 2011.4 seed the finite route from rounded located cut observations to regular-Cauchy RealUp names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CutRegularization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a quotient construction of $\mathsf{Real}^{\uparrow}$, selected suprema, trichotomy, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cut-source exposure, located-window exposure, approximation exactness, tolerance accounting, stream stabilization, regular-Cauchy handoff, Real-seal factorization, transport/replay/provenance coverage, and non-escape for BEDC.Derived.CutRegularizationUp.

Chapter 2012

A Concrete Naming Certificate for $\mathsf{FormalBallCompletion}^{\uparrow}$

Following the Edalat–Heckmann formal-ball presentation of metric completion and Vickers formal topology, the $\mathsf{FormalBallCompletion}^{\uparrow}$ packet records constructive completion as a rounded directed family of formal balls with a completion-facing classifier boundary. It sits after the formal-ball surface of chapter 1510, the rounded ideal completion surface of chapter 1883, the metric carrier of chapter 57, the completion boundary of chapter 95, the finite stream-window interface of chapter 126, the dyadic radius ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter gives Real-and-Completion consumers a finite NameCert surface for formal-ball completion without claiming quotient completion, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Definition 2012.1 (Formal-ball completion carrier)**.** *A* $\mathsf{FormalBallCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, B, I, D, S, R, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including point histories, distance witnesses, and the point classifier used by every formal-ball center.*
2. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *family row, exposing the finite formal balls whose centers are read through M and whose radii are accounted for by the dyadic ledger.*
3. *I is the* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *handoff row, recording roundedness, directedness, and cofinal refinement for the displayed formal-ball family.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, recording positive-radius witnesses, strict comparisons, radius sums, and refinement budgets used by B and I.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, binding every inspected center observation and ideal-membership query to finite stream data.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance-seal row reached only through the displayed formal-ball and rounded-ideal route.*
7. *T records componentwise* hsame *transport for the metric source, formal-ball family, rounded ideal handoff, dyadic ledger, stream windows, real seal, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay of the route*

$$M \longmapsto B \longmapsto I \longmapsto D, S \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, I, D, S, R, T, C, P, N$. It has no coordinate for quotient completion equality, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.FormalBallCompletionUp.FormalBallCompletionTasteGate single carrier alignment`

Theorem 2012.2 (Formal-ball completion NameCert obligations)**.** *For every accepted* $\mathsf{FormalBallCompletion}^{\uparrow}$ *carrier*

$$K = (M, B, I, D, S, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FormalBallCompletion}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed metric source, formal-ball family, rounded-ideal handoff, dyadic ledger, stream windows, real seal, and structural rows T, C, P, N;*
2. *formal-ball family membership, requiring every completion-facing neighbourhood query to be read as a displayed* $\mathsf{FormalBall}^{\uparrow}$ *member over M with radius data accounted for in D;*
3. *rounded-directed ideal handoff, requiring the row I to be the only route from formal-ball membership to completion-facing roundedness, directedness, and cofinal refinement;*
4. *classifier transport, requiring accepted packets to be compared componentwise through T and replayed through C without adding a second classifier;*
5. *ledger non-escape, requiring every downstream read to pass through $M, B, I, D, S, R, T, C, P, N$ and to export no quotient completion, selected limit, countable-choice selector, open-cover compactness proof, ambient completeness datum, Lean verification credential, or bridge credential.*

No formal-ball completion obligation is stored outside these rows.

Proof. Project the accepted packet $K = (M, B, I, D, S, R, T, C, P, N)$. Carrier admission exposes exactly the metric source, formal-ball family, rounded-ideal handoff, dyadic ledger, stream windows, real seal, transport, replay, provenance, and local naming row.

Formal-ball family membership is the projection to B together with its source rows M, D, S. The metric row supplies the center classifier, the dyadic row supplies radius comparisons, and the stream row supplies the finite observation windows used by each displayed ball.

The rounded-directed handoff is the projection to I. It is the only row that packages roundedness, directedness, and cofinal refinement for the displayed family, so a completion-facing consumer must pass through it before reading the seal row R.

Transport and replay are confined to T and C, while P and N only record provenance and local naming. Since the carrier has no coordinate for quotient completion equality, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the NameCert surface. □

Theorem 2012.3 (Formal-ball completion rounded ideal handoff)**.** *For every accepted* $\mathsf{FormalBallCompletion}^{\uparrow}$ *carrier*

$$K = (M, B, I, D, S, R, T, C, P, N),$$

each completion-facing neighbourhood request factors through the displayed handoff

$$\mathsf{FormalBall}^{\uparrow} \longrightarrow \mathsf{RoundedIdealCompletion}^{\uparrow} \longrightarrow \mathsf{Completion}^{\uparrow}$$

by reading B, I, D, S, T, C, P, N *over the same metric source* M*. The handoff exports a rounded directed formal-ball family and its finite replay boundary, not a quotient class of Cauchy names, not a selected representative, not a selected limit, and not an ambient-completeness witness.*

Proof. Begin with the formal-ball family row. The accepted packet exposes B only over the metric source M, with radius comparisons recorded in D and center observations read through S.

Pass next to the rounded ideal row I. This row records the roundedness, directedness, and cofinal-refinement data needed to regard the displayed formal balls as completion data, and it is reached before any completion-facing seal can be read.

The structural rows preserve the same route. Componentwise transport through T keeps M, B, I, D, S, R aligned, replay through C preserves the handoff order, and P, N source and name the same packet.

No row stores quotient completion equality, a selected Cauchy representative, a selected limit, countable choice, open-cover compactness, or ambient completeness. Hence the handoff is exactly the displayed rounded directed formal-ball boundary. □

Theorem 2012.4 (Formal-ball completion classifier boundary)**.** *If two accepted* $\mathsf{FormalBallCompletion}^{\uparrow}$ *carriers are related by componentwise* hsame *transport through their transport rows, then their classifier-visible data agree on the metric source, formal-ball family membership, rounded-directed ideal handoff, dyadic radius ledger, stream windows, real seal, replay route, provenance, and local name.*

Consequently classifier transport preserves the formal-ball family membership row, the rounded-directed handoff row, and the ledger non-escape boundary for the completion surface.

Proof. Project the two accepted carriers. The classifier-visible coordinates are exactly the metric source, formal-ball family, rounded ideal handoff, dyadic ledger, stream windows, real seal, replay route, provenance, and local name.

Apply componentwise hsame transport through the two transport rows. Formal-ball membership is compared over the same metric source, radius comparisons remain in the dyadic ledger, and finite center windows remain in the stream row.

The rounded-directed handoff is transported with the family it certifies. Thus roundedness, directedness, and cofinal refinement remain attached to the same displayed formal-ball data.

Replay, provenance, and naming add no independent classifier. Since the excluded completion principles have no carrier coordinate, classifier transport preserves both the handoff and the non-escape boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalBallCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2012.1, Definition 2012.2, Definition 2012.3, and Definition 2012.4 seed the finite formal-ball completion surface for rounded directed constructive completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalBallCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, formal-ball family membership, rounded-directed ideal handoff, classifier transport, ledger non-escape, replay stability, provenance, and local naming for BEDC.Derived.FormalBallCompletionUp

Constructive story: A FormalBallCompletion$^{\uparrow}$ packet is generated from a MetricSpace source, a FormalBall family, a RoundedIdealCompletion handoff, a DyadicRatCore radius ledger, StreamName windows, a RealUp tolerance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2013

A Concrete Naming Certificate for $\mathsf{FeketeSubadditive}^{\uparrow}$

Following Fekete and Bishop–Bridges constructive analysis, the $\mathsf{FeketeSubadditive}^{\uparrow}$ packet records the finite subadditive normalized-average route used by Real and series-facing certificates before a lower-bound readback is handed to regular rational and Real seals. It sits beside the series certificate of chapter 121, the real-sequence limit route of chapter 1413, the dyadic arithmetic core of chapter 291, the regular rational sequence boundary of chapter 301, and the terminal Real surface of chapter 38. The packet names a displayed finite ledger for subadditive averages; it does not assert an ambient least infimum operator or a host-level completeness theorem.

Definition 2013.1 (Fekete subadditive carrier)**.** *A* $\mathsf{FeketeSubadditive}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, A, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the real sequence source row. It records the inspected source windows and the finite indexing data from which normalized averages are read.*
2. *A is the subadditivity witness ledger. Each row records a displayed decomposition $m+n$ together with the finite comparison cell witnessing that the source value at $m+n$ is bounded by the visible sum of the source values at m and n.*
3. *D is the dyadic normalized-average comparison ledger. It stores the rational denominator windows, dyadic comparison tolerances, and finite average rows used to compare inspected values of S.*
4. *L is the located lower-bound readback row. It records the finite lower-bound and located-infimum data actually displayed by D, without exposing a host-level infimum operator.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained only after the normalized-average ledger and lower-bound readback have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational handoff has been displayed.*
7. *H records componentwise* hsame *transport for the source, subadditivity, dyadic average, lower-bound, regular handoff, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through*

$$S, A \longmapsto D \longmapsto L \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FeketeSubadditive}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FeketeSubadditive}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for ambient completeness, trichotomy, countable choice, quotient stream equality, host real equality, host-level infimum operators, or a selected external limit.

Theorem 2013.2 (Fekete subadditive NameCert obligations)**.** *For every accepted* $\mathsf{FeketeSubadditive}^{\uparrow}$ *carrier $F = (S, A, D, L, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FeketeSubadditive}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *source-window exposure for S, including every index and normalized-average denominator inspected by the certificate;*
3. *subadditivity ledger exactness for each decomposition row recorded in A;*
4. *dyadic normalized-average comparison stability for D under the recorded* hsame *transports;*
5. *located lower-bound readback, requiring L to be read only from the displayed average comparisons in D;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring R and E to factor through S, A, D, L;*
7. *transport, continuation replay, provenance, and local naming for exactly the rows recorded in H, C, P, N.*

No Fekete subadditive NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.FeketeSubadditiveUp.FeketeSubadditiveTasteGate single carrier alignment`

Proof. Project the accepted carrier $F = (S, A, D, L, R, E, H, C, P, N)$. The projection exposes the source sequence windows, subadditivity witness ledger, dyadic average comparisons, lower-bound readback, regular rational handoff, Real seal, and structural rows.

The order-theoretic content is finite. The rows S and A list only the inspected source windows and decomposition witnesses, while D stores the normalized-average comparisons that can be replayed for the requested denominator windows.

The lower-bound readback is then forced through L. Since L is read from D, the certificate does not appeal to a host-level infimum operator, trichotomy, or an ambient completeness theorem.

Finally R and E are downstream of the displayed ledger. Componentwise transport in H preserves the same route, and C, P, N only replay, source, and name that route. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 2013.3 (Fekete subadditive Cauchy route)**.** *Let $F = (S, A, D, L, R, E, H, C, P, N)$ be an accepted* $\mathsf{FeketeSubadditive}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by F factors through the finite route*

$$S, A \longmapsto D \longmapsto L \longmapsto R \longmapsto E.$$

Consequently a downstream Cauchy, series, or real-sequence-limit consumer receives only the displayed source windows, subadditivity witnesses, dyadic normalized-average comparisons, located lower-bound readback, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, transport package, replay route, provenance, and local naming row.*

Proof. Start with a Real-facing read. Carrier projection shows that the only available numerical rows are the source windows S, the subadditivity witnesses A, the dyadic comparison ledger D, and the lower-bound readback L.

The Cauchy information is produced by the normalized-average route. The ledger D supplies finite dyadic comparisons between inspected averages, and L records the lower-bound readback that those comparisons actually expose.

The handoff to R and E does not add analytic data. It presents the displayed lower-bound route as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff and then as a Real-facing seal.

The structural rows preserve the same route under transport and replay. Therefore a downstream Cauchy, series, or real-sequence-limit consumer cannot read ambient completeness, trichotomy, countable choice, quotient stream equality, host real equality, host-level infimum operators, or an external selected limit from the $\mathsf{FeketeSubadditive}^{\uparrow}$ packet. □

Theorem 2013.4 (Fekete subadditive finite-prefix bound)**.** *Let $F = (S, A, D, L, R, E, H, C, P, N)$ be an accepted* $\mathsf{FeketeSubadditive}^{\uparrow}$ *carrier, and let a downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *series, or real-sequence-limit consumer request a finite read of the lower-bound row L. Then the read must expose a finite prefix containing the source windows S, the subadditivity ledger A, and the dyadic normalized-average ledger D before any lower-bound row is available.*

In particular, the prefix bound is determined by the displayed route

$$S, A \longmapsto D \longmapsto L$$

and by the downstream continuation

$$L \longmapsto R \longmapsto E.$$

No host infimum, trichotomy, quotient stream equality, selected external limit, ambient Real completeness, countable choice, or host real equality can enter the prefix bound.

Proof. Project the accepted carrier. The carrier definition displays the rows $S, A, D, L, R, E, H, C, P, N$, and the local NameCert obligations force the source windows S, the subadditivity ledger A, and the normalized-average comparison ledger D to be present before L is read.

The finite prefix is therefore obtained by truncating the displayed carrier at the last row used by the requested lower-bound read. Since every comparison in D cites only inspected windows of S and decomposition rows of A, the truncation contains exactly the finite data needed to justify the lower-bound row.

Apply the Cauchy route theorem to the downstream part of the read. The handoff rows R and E consume the already displayed prefix S, A, D, L and do not add analytic data of their own.

Thus the requested consumer receives a finite prefix bound through the displayed ledger alone. The excluded host objects have no coordinate in the carrier, no NameCert obligation row, and no continuation route into L, R, or E. □

Closure status for $\mathsf{NameCert}_{\mathsf{FeketeSubadditive}^{\uparrow}}$.

Constructive story: A $\mathsf{FeketeSubadditive}^{\uparrow}$ packet is generated from real sequence source windows, a subadditivity witness ledger, dyadic normalized-average comparison rows, a located lower-bound readback, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FeketeSubadditive}^{\uparrow}}$, seed)

Scope closed: Definition 2013.1, Definition 2013.2, and Definition 2013.3 seed the finite subadditive normalized-average carrier, its local NameCert obligations, and its Cauchy-facing readback boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FeketeSubadditive}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ambient completeness, trichotomy, countable choice, quotient stream equality, host real equality, host-level infimum operators, selected external limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subadditivity ledger exactness, dyadic normalized-average comparison stability, located lower-bound readback, and Cauchy-route non-escape for BEDC.Derived.FeketeSubadditiveUp.

Chapter 2014

A Concrete Naming Certificate for $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ packet records the finite Cauchy criterion route by which displayed partial-sum windows of a real series are sealed as regular Cauchy data before a $\mathsf{Real}^{\uparrow}$ endpoint is read. It refines the real-series surface of chapter 1581, uses the regular rational handoff of chapter 301, reads term and partial-sum windows through chapter 126, accounts for tolerances through chapter 291, and lands at the Bishop regular-Cauchy limit seal of chapter 1821. The packet names a criterion over finite displayed rows; it does not import host infinite sums, selected limits, quotient equality of real streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2014.1 (Real series Cauchy criterion carrier)**.** *A* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, D, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the real-valued term stream, accessed only through selected* $\mathsf{StreamName}^{\uparrow}$ *windows and the displayed term rows already admitted by the* $\mathsf{RealSeries}^{\uparrow}$ *surface.*
2. *S is the partial-sum window row, listing the finite initial segments, later comparison windows, and the displayed subtraction or difference reads used to compare two partial sums.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested dyadic error bounds, finite addition errors, and comparison radii consumed by the criterion.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same partial-sum windows and dyadic tolerance ledger.*
5. *M is the shared tail-threshold row: for each displayed tolerance request, one threshold governs every pair of partial-sum windows whose indices lie beyond it.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after T, S, D, R, M have been displayed and routed through the Bishop regular-Cauchy limit seal.*
7. *H stores componentwise* hsame *transport for the term stream, partial-sum window, dyadic ledger, regular readback, shared threshold, endpoint seal, continuation, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from term windows to partial sums, from partial sums to dyadic comparisons, from dyadic comparisons to the shared threshold, and from that threshold through regular readback to the endpoint seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopRegularCauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeriesCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, D, R, M, E, H, C, P, N$. It has no coordinate for a host infinite sum, selected sequence limit, quotient equality of real streams, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RealSeriesCauchyCriterionUp.TasteGate.RealSeriesCauchyCriterionTasteGate`
`single carrier alignment`

Theorem 2014.2 (Real series Cauchy criterion obligation surface)**.** *For every accepted* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *carrier $K = (T, S, D, R, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealSeriesCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the ten displayed rows;*
2. *partial-sum window coverage, requiring every term read and every two-window comparison to factor through T and S;*
3. *Cauchy-tail threshold stability, requiring the shared row M to serve all later partial-sum comparisons for the displayed tolerance request;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, requiring R and E to be downstream of the same finite threshold route and the Bishop regular-Cauchy limit seal;*
5. *ledger nonescape, requiring every tolerance, transport, continuation, provenance, and local naming read to remain inside D, H, C, P, N.*

No obligation row asserts host summability, selected infinite sums, quotient equality of real streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet $K = (T, S, D, R, M, E, H, C, P, N)$. Carrier admission exposes exactly the term-stream row, partial-sum window row, dyadic ledger, regular readback, shared threshold, endpoint seal, and structural rows.

For a displayed tolerance request, inspect the finite partial-sum windows in S. The term data used to build those windows are read through T, and the only admissible comparison information is the dyadic accounting stored in D.

The shared threshold row M is then replayed. Its stability claim is finite: the same displayed threshold is reused for all later partial-sum comparisons requested by the packet, and no unrecorded global convergence object is consulted.

Finally the handoff to R and E follows the same route through the Bishop regular-Cauchy limit seal. The rows H, C, P, N transport, replay, source, and name that finite route, so the listed obligations exhaust the NameCert surface and leave no coordinate for host summability or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeriesCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ packet is generated from a real-valued term stream, finite partial-sum windows, a dyadic tolerance ledger, RegSeqRat readback, one shared tail-threshold row, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealSeriesCauchyCriterion}\uparrow}$, seed)

Scope closed: Definition 2014.1 and Definition 2014.2 seed the finite Cauchy criterion route from displayed real-series partial sums to regular-Cauchy Real seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealSeriesCauchyCriterion}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.RealSeriesCauchyCriterionUp`

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected sequence limits, quotient equality of real streams, countable choice, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: A checked carrier theorem can encode the same term-stream, partial-sum window, dyadic ledger, shared threshold, RegSeqRat handoff, Real seal, transport, continuation, provenance, and local NameCert rows.

Chapter 2015

A Concrete Naming Certificate for $\mathsf{CauchySeriesCriterion}^{\uparrow}$

From Cauchy through Bishop–Bridges constructive analysis, the Cauchy criterion for series is the finite tail-comparison surface that turns partial sums into regular completion data. The $\mathsf{CauchySeriesCriterion}^{\uparrow}$ packet sits between the uniform criterion of chapter 1736, the majorant route of chapter 1774, and the absolute-convergence certificate of chapter 1700. It reads the underlying $\mathsf{Series}^{\uparrow}$ rows of chapter 121, hands finite partial-sum comparisons to the $\mathsf{RegSeqRat}^{\uparrow}$ surface of chapter 301, and exposes the completion-facing endpoint only through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records a criterion route; it does not import a host infinite-sum operator, countable choice, quotient equality of streams, or ambient completeness for real numbers.

Definition 2015.1 (Cauchy series criterion carrier)**.** *A* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, S, W, Q, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Series}^{\uparrow}$ *term row, read only through the finite term observations admitted by the series packet.*
2. *S is the partial-sum thread, listing selected finite sums, later comparison windows, and the displayed subtraction rows used to compare two partial sums.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family used to open the selected terms, partial sums, and endpoint-facing approximations.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and to the rational comparison data extracted from them.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested dyadic bounds, addition budgets, and comparison radii.*
6. *M is the shared Cauchy-tail threshold row: each displayed tolerance request receives one finite threshold that governs all later partial-sum comparisons in the packet.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after A, S, W, Q, D, M have been displayed.*
8. *H stores componentwise* hsame *transport for the term row, partial-sum thread, window family, regular readback, tolerance ledger, threshold row, real seal, continuation, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from term rows to partial sums, from partial sums to regular readback, from regular readback to dyadic tolerances, from tolerances to the shared threshold, and from that threshold to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchySeriesCriterion}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySeriesCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, W, Q, D, M, E, H, C, P, N$. It has no coordinate for a host infinite sum, selected limit, quotient stream equality, countable-choice selector, trichotomy, ambient real completeness, Lean verification, or standard bridge.

Lean4 ✓ `BEDC.Derived.CauchySeriesCriterionUp.CauchySeriesCriterionTasteGate single carrier alignment`

Theorem 2015.2 (Cauchy series criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *carrier $K = (A, S, W, Q, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySeriesCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed series term row, partial-sum thread, selected windows, regular readback, dyadic ledger, shared tail threshold, real seal, transport, replay, provenance, and local naming rows;*

2. *partial-sum thread exactness, requiring every finite sum observation and every later-window comparison to pass through A, S, W, Q, D before the threshold row is read;*

3. *Cauchy-tail stability, requiring M to be the displayed threshold used for all accepted comparisons of partial sums whose indices lie beyond the requested tolerance boundary;*

4. *regular-readback handoff, requiring Q to carry the partial-sum thread into the same dyadic tolerance ledger D used by the tail comparison;*

5. *real-seal boundary, requiring E to be downstream of the displayed Cauchy route and to export no host infinite sum, selected limit, quotient stream equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge datum;*

6. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Cauchy series criterion obligation is stored outside these rows.

Proof. Project the accepted packet $K = (A, S, W, Q, D, M, E, H, C, P, N)$. The carrier definition exposes exactly the finite series row, partial-sum thread, selected windows, regular readback, dyadic ledger, tail threshold, real seal, and structural rows.

For a displayed tolerance request, the partial-sum thread S supplies the only later-window comparisons available to the classifier. Those windows are opened through W, read back through Q, and measured only against the dyadic ledger D.

The shared threshold row M is then replayed. Its claim is finite: the same displayed threshold controls every accepted comparison of later partial sums for the requested tolerance.

Finally E, H, C, P, N seal, transport, replay, source, and name that same route. Since no excluded object appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2015.3 (Cauchy series criterion partial-sum thread)**.** *Every completion-facing read from an accepted* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *carrier factors through*

$$A \longmapsto S \longmapsto W \longmapsto Q \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

Thus the route from finite series terms to the completion-facing endpoint is mediated by the displayed partial-sum thread and its $\mathsf{RegSeqRat}^{\uparrow}$ *readback, not by an external sum object or a selected limiting process.*

Proof. Begin with a completion-facing request. The carrier exposes the $\mathsf{Series}^{\uparrow}$ term row A before any partial-sum or endpoint row can be inspected.

The request then passes through the partial-sum thread S and the selected window family W. These rows give the finite initial segments and later comparison windows used by the criterion.

The readback row Q and dyadic ledger D provide the comparison surface. The threshold row M is the only tail-control coordinate, so every later-window comparison uses the displayed threshold attached to the requested tolerance.

The endpoint seal E is downstream of this route, and H, C, P, N preserve, replay, source, and name it. Therefore the completion-facing read cannot bypass the partial-sum thread or replace it by an external infinite-sum datum. □

Theorem 2015.4 (Cauchy series criterion real seal boundary)**.** *For every accepted* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *carrier* $K = (A, S, W, Q, D, M, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal* E *is readable only after the displayed* $\mathsf{Series}^{\uparrow}$ *term row, finite partial-sum thread, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and shared Cauchy-tail threshold have been displayed. Consequently, every real-seal consumer receives the same finite route and no host completeness theorem, quotient stream equality, selected sum, countable-choice selector, or detached real endpoint.*

Proof. Project the carrier given by Definition 2015.1. Its real endpoint coordinate is the row E, and the definition places E after A, S, W, Q, D, M in the displayed route.

Apply Definition 2015.2. The NameCert obligations require partial-sum exactness, regular-readback handoff, Cauchy-tail stability, and the real-seal boundary before any endpoint-facing consumer may read E.

Apply Definition 2015.3. The only route to E goes through the term row, partial-sum thread, windows, regular readback, dyadic ledger, and threshold row.

The structural rows H, C, P, N transport, replay, source, and name precisely that route. Since the carrier has no slot for host completeness, quotient stream equality, selected sums, choice selectors, or detached real endpoints, the real-seal boundary is exhausted by the displayed finite packet. □

Falsifiable prediction: Every $\mathsf{CauchySeriesCriterion}^{\uparrow}$ completion-facing read factors through a SeriesUp term row, finite partial-sum thread, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, one shared Cauchy-tail threshold, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: series, uniform-cauchy-series, cauchy-majorant-series, absolute-convergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchySeriesCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite series terms, partial-sum comparisons, selected windows, regular readback, dyadic tolerance accounting, one shared tail threshold, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySeriesCriterion}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchySeriesCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 2015.1, Definition 2015.2, Definition 2015.3, and Definition 2015.4 seed the finite constructive series criterion route from Series rows through partial sums, RegSeqRat readback, DyadicRatCore tolerance accounting, Cauchy-tail threshold control, and RealUp endpoint sealing.

Formal verification: FormalStatus(NameCert$_{\text{CauchySeriesCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient stream equality, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum thread exactness, RegSeqRat and DyadicRatCore handoff, Cauchy-tail threshold stability, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.CauchySeriesCriterionUp.

Constructive story: A CauchySeriesCriterion$^{\uparrow}$ packet is generated from a Series term row, finite partial-sum thread, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, one shared Cauchy-tail threshold, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2016

A Concrete Naming Certificate for $\mathsf{RoundedCauchyFilter}^{\uparrow}$

Following Kelley, Bourbaki, and Bishop–Bridges, the $\mathsf{RoundedCauchyFilter}^{\uparrow}$ packet records the rounded-base presentation of a Cauchy filter as finite NameCert data. A rounded filter base is the constructive surface on which every accepted neighborhood has a smaller displayed neighborhood inside it, so the completion consumer can inspect refinement before reading a limiting real-name seal. The packet sits between the filter-base row of chapter 1601, the Cauchy-filter surface of chapter 333, the filter-refinement route of chapter 1626, and the completion handoff of chapter 1569. It exposes a non-quotient refinement surface for later $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads; it does not import quotient equality of filters, an ultrafilter extension, choice-selected cluster points, trichotomy, host completeness, Lean verification, or a standard bridge.

Definition 2016.1 (Rounded Cauchy filter carrier)**.** *A* $\mathsf{RoundedCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, R, U, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row whose basic neighborhoods are available only through finite displayed base tokens.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row carried by the same base tokens and by the displayed Cauchy comparison requests.*
3. *R is the rounded-base refinement row: every accepted base token exports a strictly smaller displayed token below it, together with the finite inclusion route witnessing the refinement.*
4. *U is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff row that may be read only after the base, Cauchy, and rounded-refinement rows have been displayed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family used to inspect the finite base tokens, refinement witnesses, and completion-facing observations.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and to the rational observations exported by the rounded filter route.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested radii, rounded inclusions, and Cauchy comparison budgets.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, F, R, U, W, Q, D have been displayed.*

9. *H stores componentwise* hsame *transport for the base row, Cauchy row, rounded refinement row, completion handoff, stream windows, regular readback, dyadic ledger, real seal, replay, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from filter-base tokens to rounded refinements, from rounded refinements to Cauchy comparisons, from Cauchy comparisons to regular readback and dyadic tolerances, and from that route through the completion handoff to the real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{RoundedCauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RoundedCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, R, U, W, Q, D, E, H, C, P, N$. It has no coordinate for quotient equality of filters, an ultrafilter extension, selected cluster points, trichotomy, host real completeness, Lean verification, or bridge data.

Theorem 2016.2 (Rounded Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{RoundedCauchyFilter}^{\uparrow}$ *carrier $K = (B, F, R, U, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RoundedCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed filter base, Cauchy filter, rounded refinement, completion handoff, stream-window, regular-readback, dyadic-ledger, real-seal, transport, replay, provenance, and local naming rows;*

2. *base alignment, requiring the* $\mathsf{FilterBase}^{\uparrow}$ *row B and the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F to read the same displayed base tokens before any completion-facing observation is accepted;*

3. *roundedness, requiring each accepted base token to pass through the row R and receive a displayed smaller token with its finite inclusion route;*

4. *Cauchy comparison stability, requiring every tolerance request to use the same rounded base tokens and dyadic ledger D before the completion handoff U is read;*

5. *regular readback and real-seal boundary, requiring W, Q, D to mediate the route from rounded filter data to the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*

6. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N for exactly the rows displayed above.*

No rounded Cauchy filter obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RoundedCauchyFilterUp.RoundedCauchyFilterTasteGate single carrier alignment`

Proof. Project the accepted packet $K = (B, F, R, U, W, Q, D, E, H, C, P, N)$. Carrier admission exposes exactly the filter-base row, Cauchy-filter row, rounded refinement row, completion handoff, stream-window row, regular readback, dyadic ledger, real seal, and structural rows.

Base alignment is finite. The same displayed base tokens feed B and F, so a consumer cannot read a Cauchy comparison apart from the filter-base surface that names its neighborhoods.

Roundedness is then read through R. For each accepted base token, R supplies the smaller displayed token and the inclusion route that places it below the original token. The Cauchy comparison rows use those rounded tokens and the dyadic ledger D before the handoff U can be consumed.

Finally W, Q, D, E, H, C, P, N provide the observation, readback, tolerance, endpoint, transport, replay, source, and local name of the same route. Since the carrier has no slot for quotient

equality, ultrafilter extension, selected cluster points, trichotomy, host completeness, Lean verification, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 2016.3 (Rounded Cauchy filter regular readback route)**.** *Every completion-facing read from an accepted* $\mathsf{RoundedCauchyFilter}^{\uparrow}$ *carrier factors through*

$$B \longmapsto F \longmapsto R \longmapsto W \longmapsto Q \longmapsto D \longmapsto U \longmapsto E \longmapsto H, C, P, N.$$

Thus the route from filter-base data to a $\mathsf{Real}^{\uparrow}$ *completion seal is mediated by the displayed rounded-refinement row and its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, not by quotient equality of filters, a selected representative sequence, an ultrafilter extension, or ambient completeness.*

Proof. Begin with a completion-facing request. The carrier definition exposes the filter-base row B before the Cauchy row F and the rounded-refinement row R can be used.

The request then opens finite windows through W. Those windows inspect the base token, its rounded refinement, and the Cauchy comparison rows attached to that refinement.

Regular readback is forced through Q, and the tolerance accounting is forced through D. Only after this finite observation route has been displayed may the completion handoff U and the real seal E be consumed.

The structural rows H, C, P, N transport, replay, source, and name the same route. No excluded quotient, representative sequence, ultrafilter, or completeness coordinate appears in the carrier, so the displayed factorization is the only completion-facing read. □

Theorem 2016.4 (Rounded Cauchy filter regular-sequence handoff)**.** *Any accepted* $\mathsf{RoundedCauchyFilter}^{\uparrow}$ *packet whose completion-facing route reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *must expose the rounded base row* R*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff* U*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *in that order. The handoff is a finite readback route over the displayed packet rows; it exports no quotient filter equality, ultrafilter extension, selected representative sequence, selected cluster point, or ambient completeness.*

Proof. Project the carrier in Definition 2016.1. The only completion-facing route that reaches regular sequence data has to pass through $B, F, R, W, Q, D, U, E, H, C, P, N$.

Apply Definition 2016.2. The obligation surface forces roundedness through R, finite observation through W, regular readback through Q, dyadic tolerance accounting through D, completion handoff through U, and real sealing through E.

Now use Definition 2016.3. It orders the same rows before the structural transport, replay, provenance, and local naming coordinates H, C, P, N.

Since the carrier contains no quotient-filter equality, ultrafilter, selected representative sequence, selected cluster point, or ambient completeness row, the regular-sequence handoff exports only the finite displayed route. □

Falsifiable prediction: Every $\mathsf{RoundedCauchyFilter}^{\uparrow}$ completion-facing read factors through a FilterBaseUp row, a CauchyFilterUp row, a rounded-base refinement row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyFilterCompletionUp handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: filterbase, cauchyfilter, filter-refinement, cauchyfiltercompletion, streamname, regseqrat, dyadicratcore, real: $\mathsf{RoundedCauchyFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a filter base, Cauchy filter comparisons, a rounded-base refinement row,

completion handoff, finite windows, regular readback, dyadic tolerance accounting, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{RoundedCauchyFilter}^{\uparrow}$ packet is generated from a FilterBaseUp row, a CauchyFilterUp row, a rounded-base refinement row, a CauchyFilterCompletionUp handoff, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2016.1, Definition 2016.2, and Definition 2016.3 seed the finite rounded Cauchy filter route from displayed filter-base tokens through rounded refinements, regular readback, dyadic tolerance accounting, completion handoff, and RealUp endpoint sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of filters, ultrafilter extensions, selected representative sequences, selected cluster points, trichotomy, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, base alignment, roundedness, Cauchy comparison stability, RegSeqRat and DyadicRatCore handoff, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.RoundedCauchyFilterUp.

Chapter 2017

A Concrete Naming Certificate for $\mathsf{DyadicShrinkSchedule}^{\uparrow}$

Following Bishop and Bridges on epsilon-splitting in constructive analysis, the $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ packet records the finite schedule by which a requested dyadic tolerance is replaced by a displayed halved or refined tolerance before any regular-rational or real-name consumer reads it. It sits over the dyadic arithmetic ledger of chapter 291, the scale discipline of chapter 1768, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter packages precision halving as displayed finite data, not as an appeal to completed reals or to choice of limiting representatives.

Definition 2017.1 (Dyadic shrink schedule carrier)**.** *A* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (k, k', D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *k is the requested dyadic scale row. It names the finite tolerance request before any halving, window, readback, or seal data are consumed.*
2. *k' is the displayed halved or refined scale row. It records the finite witness that the requested scale has been replaced by the precision row used downstream.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to k and k', including the dyadic radius, comparison, containment, and halving rows consumed by the schedule.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window opened at the refined scale and budgeted by the dyadic ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed request, refined scale, dyadic ledger, and finite window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary exposed only after k, k', D, W, R have been read.*
7. *H records componentwise* hsame *transport for the requested scale, refined scale, dyadic ledger, finite window, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the requested scale through the refined scale, dyadic ledger, window, readback, Real seal, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicShrinkSchedule}^{\uparrow}}$ *row.*

The classifier compares accepted schedules only through $k, k', D, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or any hidden completeness witness.*

Lean4 ✓ `BEDC.Derived.DyadicShrinkScheduleUp.DyadicShrinkScheduleTasteGate single carrier alignment`

Theorem 2017.2 (Dyadic shrink schedule NameCert obligations)**.** *For every accepted* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ *carrier $S = (k, k', D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicShrinkSchedule}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the requested scale, refined scale, DyadicRatCore ledger, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *halving display, requiring k' to be read as a displayed finite refinement of k before the ledger, window, readback, or seal rows are available;*
3. *dyadic ledger compatibility, requiring D to carry the radius, comparison, containment, and halving checks relating the two scale rows;*
4. *classifier transport, requiring accepted comparisons to preserve $k, k', D, W, R, E, H, C, P, N$ componentwise and to expose no hidden precision coordinate;*
5. *RegSeqRat handoff, requiring R to consume the displayed request, refined scale, dyadic ledger, and StreamName window rather than a detached stream quotient or selected limit;*
6. *Real-seal non-escape, requiring E to remain terminal with respect to k, k', D, W, R and to export no host equality, countable choice, trichotomy, ambient completeness theorem, or selected limiting object;*
7. *provenance and local naming, requiring P and N to package exactly the displayed schedule rows and no additional completion datum.*

No dyadic shrink-schedule obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2017.1. The accepted packet consists exactly of the requested scale k, the refined scale k', the dyadic ledger D, the finite window W, the regular readback R, the Real seal E, and the structural rows H, C, P, N.

The halving and ledger clauses are also projections. The only row that displays the refined scale is k', and the only row that records dyadic radius, comparison, containment, and halving checks is D.

Classifier transport is componentwise through H and replayed through C. These rows preserve the route from k to k', from k' to D, from D to W, from W to R, and from R to E without adding a second precision source.

The handoff and seal clauses follow from the placement of R and E. The readback row is downstream of the displayed halving schedule, while the Real seal is terminal after the same finite route.

The excluded objects are absent from the carrier and are not produced by transport, replay, provenance, or local naming. Therefore no local NameCert obligation can be stored outside the displayed rows. □

Theorem 2017.3 (Dyadic shrink schedule halving closure)**.** *Let $S = (k, k', D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ *carrier. Every finite consumer of the schedule reads the*

precision-halving route

$$k \longmapsto k' \longmapsto D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

as a closed displayed route. In particular, halving a dyadic tolerance inside the packet produces another named finite precision row before any StreamName, RegSeqRat, or RealUp consumer can inspect the schedule.

Proof. Project the accepted carrier. The requested precision row is k, and the only displayed refined precision row is k'.

The dyadic ledger D is positioned after both scale rows and before the finite window. Thus every downstream read of the window, readback, or seal has already passed through the displayed refinement.

The transport and replay rows preserve this ordering componentwise. Since no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate appears in the packet, the refined precision row is closed as finite schedule data. □

Theorem 2017.4 (Dyadic shrink schedule RegSeqRat handoff)**.** *For every accepted* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ *carrier* $S = (k, k', D, W, R, E, H, C, P, N)$*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer reaches the readback row* R *only through the finite route from the requested scale to the refined scale, the DyadicRatCore ledger, and the StreamName window. No RegSeqRat handoff from* S *can bypass the displayed halving schedule by quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The only readback coordinate in the carrier is R. By Definition 2017.1, it is obtained from k, k', D, W rather than from an independent stream or limit object.

The rows H and C transport and replay the same displayed route, while P and N only package it as provenance and local naming data. None of these rows introduces a second source for regular rational readback.

Consequently a RegSeqRat consumer must pass through the requested scale, refined scale, dyadic ledger, and finite window before reaching R, with all excluded completion and choice principles remaining outside the schedule. □

Theorem 2017.5 (Dyadic shrink schedule Real seal boundary)**.** *For every accepted* $\mathsf{DyadicShrinkSchedule}^{\uparrow}$ *carrier* $S = (k, k', D, W, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is terminal over the displayed finite schedule. A Real consumer may read the seal only after the request, refinement, dyadic ledger, StreamName window, and RegSeqRat readback have been displayed, and the seal exports no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and isolate the seal coordinate E. It appears after k, k', D, W, R in the displayed schedule and has no independent source row.

The transport, replay, provenance, and local naming rows preserve the same order. They can certify the finite schedule but cannot turn the terminal seal into a host real equality, a selected limit, or a completeness witness.

Thus the $\mathsf{Real}^{\uparrow}$ boundary exposed by S is exactly the displayed seal after regular readback, with quotient, choice, trichotomy, host equality, and ambient completeness data excluded. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicShrinkSchedule}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicShrinkSchedule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2017.1, Definition 2017.2, Definition 2017.3, Definition 2017.4, and Definition 2017.5 seed the finite dyadic precision-halving schedule from a requested scale through refined scale, dyadic ledger, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicShrinkSchedule}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DyadicShrinkScheduleUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, halving display, dyadic ledger compatibility, classifier transport, RegSeqRat handoff, Real-seal non-escape, provenance, and local naming for BEDC.Derived.DyadicShrinkScheduleUp.

Constructive story: A DyadicShrinkSchedule$^{\uparrow}$ packet is generated from a requested dyadic scale row, a displayed refined scale row, a DyadicRatCore tolerance ledger, a StreamName finite window, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2018

A Concrete Naming Certificate for $\mathsf{DyadicBinarySearch}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicBinarySearch}^{\uparrow}$ packet records finite bisection search over located dyadic intervals before any Real-and-Completion consumer receives a bracket. It sits on the dyadic arithmetic ledger of chapter 291, the finite bisection route of chapter 1711, the located interval surface of chapter 394, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal boundary of chapter 38. The packet names a bounded controller for interval refinement; it does not decide global trichotomy, select an infinite limit, identify quotient real names, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2018.1 (Dyadic binary search carrier)**.** *A* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, T, K, M, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the initial* $\mathsf{LocatedInterval}^{\uparrow}$ *row, containing the left endpoint, right endpoint, dyadic radius, and locatedness data from which the search begins.*
2. *T is the finite test row. It records the decidable inspected predicate or sign comparison available at each displayed midpoint, but only on the finite rows opened by the packet.*
3. *K is the unary depth row, bounding the number of bisection decisions made by the controller.*
4. *M is the midpoint row, computed through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic from the current retained interval at every depth below K.*
5. *L is the retained-half ledger, recording for each stage whether the left or right dyadic half is kept and which located interval row results.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the inspected endpoint, midpoint, and retained-half data are exposed to downstream consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite stream windows and dyadic midpoint ledger.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *bracket seal handed off only after the retained interval, stream windows, and regular rational readback have been displayed.*
9. *H records componentwise* hsame *transport for the interval, test, depth, midpoint, retained-half, stream-window, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of every consumer request through*

$$I, T, K \longmapsto M, L \longmapsto W \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{DyadicBinarySearch}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBinarySearch}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for real trichotomy, quotient real equality, countable choice, a selected infinite refinement, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicBinarySearchUp.DyadicBinarySearchTasteGate single carrier alignment`

Theorem 2018.2 (Dyadic binary search NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *carrier $B = (I, T, K, M, L, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicBinarySearch}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed twelve-row packet;*
2. *initial located-interval exposure for I and finite test exposure for T;*
3. *unary depth coverage for K and midpoint arithmetic exactness for M through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *retained-half ledger exactness for L through the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *route;*
5. *stream-window coverage for W, regular rational readback for R, and* $\mathsf{Real}^{\uparrow}$ *bracket non-escape for E;*
6. *componentwise transport, continuation replay, provenance, and local naming for exactly the rows recorded in H, C, P, N.*

No dyadic binary-search NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier $B = (I, T, K, M, L, W, R, E, H, C, P, N)$. The projection exposes the initial located interval, finite test row, unary depth, midpoint ledger, retained-half ledger, stream windows, regular readback, Real bracket seal, and the structural rows.

The numerical part is finite. The row K bounds the number of midpoint computations, while M records each midpoint through $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic and L records the retained half through the $\mathsf{LocatedIntervalBisection}^{\uparrow}$ route.

The observation part is also finite. The test row T can inspect only the displayed midpoint and endpoint data, and the window row W is the only stream surface available to the readback row R.

Finally E is downstream of R. The rows H, C, P, N preserve, replay, source, and name the same route, so the listed rows exhaust the local NameCert obligations. □

Theorem 2018.3 (Dyadic binary search bisection step)**.** *Let $B = (I, T, K, M, L, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *carrier. For every displayed stage strictly below the unary depth K, the next retained interval is obtained by the finite route*

$$I, T, M \longmapsto L.$$

The retained interval is one of the two dyadic halves certified by the $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *row, and its midpoint computation is the one displayed by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*

Proof. Proceed by finite induction on the displayed prefix of K. In the base stage, the current interval is the initial row I, and the midpoint row M computes its dyadic midpoint from the endpoints already displayed in I.

For the step stage, assume the retained interval has been obtained from the previous prefix through L. The next midpoint is again read from M, and the finite test row T supplies the only branch datum permitted at that midpoint.

Apply the $\mathsf{LocatedIntervalBisection}^{\uparrow}$ retained-half row recorded in L. It stores exactly one of the two dyadic halves, with the corresponding located interval data, and componentwise transport in H preserves that row under the displayed classifier.

The induction therefore produces no extra analytic coordinate. Each stage is obtained by repeating the same finite midpoint, test, and retained-half route below the bound K. □

Theorem 2018.4 (Dyadic binary search Real bracket handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{LocatedIntervalBisection}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer must read $I, T, K, M, L, W, R, H, C, P, N$ *before the bracket seal* E *is exposed.*

Proof. Begin with a consumer request for the bracket seal. Carrier projection shows that the only terminal Real-facing coordinate is E, and the continuation row C routes access to E through the displayed packet.

The route first reads the initial located interval I, the finite test row T, and the unary depth K. The midpoint ledger M and retained-half ledger L then provide the bounded bisection data through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{LocatedIntervalBisection}^{\uparrow}$.

Next the request passes through the stream windows W and the regular rational readback R. These rows are the only observation and readback surfaces connected to the terminal bracket.

The structural rows H, P, N bind the same route under transport, provenance, and local naming. Since the carrier contains no coordinate for trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the handoff exports none of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBinarySearch}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicBinarySearch}^{\uparrow}$ packet is generated from an initial LocatedInterval row, a finite test row, a unary depth row, a DyadicRatCore midpoint ledger, a LocatedIntervalBisection retained-half ledger, StreamName windows, a RegSeqRat readback, a Real bracket seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBinarySearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2018.1, Definition 2018.2, Definition 2018.3, and Definition 2018.4 seed the finite dyadic bisection-search controller over located intervals, dyadic midpoint arithmetic, retained-half ledgers, stream windows, regular rational readback, and Real bracket seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBinarySearch}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DyadicBinarySearchUp.DyadicBinarySearchTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification of the NameCert obligation, bisection-step, and Real-bracket handoff theorems.

Upgrade path: Obligation closure requires checked finite NameCert obligation, bisection-step, and Real-bracket handoff theorems for BEDC.Derived.DyadicBinarySearchUp.

Chapter 2019

A Concrete Naming Certificate for $\mathsf{DyadicMetricTriangle}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicMetricTriangle}^{\uparrow}$ packet names the finite three-point dyadic triangle ledger that must be visible before regular rational names, real-name seals, or metric-space consumers may use a triangle estimate. It reads the three displayed dyadic endpoints of chapter 291, the nonnegative endpoint discipline of chapter 293, and the distance-ledger packet of chapter 2001; it hands the resulting bound to chapter 301 and then to chapter 38. The chapter isolates the triangle inequality as a finite comparison route, not as a law imported from a host metric space.

Definition 2019.1 (Dyadic metric triangle carrier)**.** *A* $\mathsf{DyadicMetricTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (x, y, z, dxy, dyz, dxz, a, b, t, h, c, p, n)$$

with the following displayed rows:

1. x, y, z *are the three accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, including their visible mantissa, denominator,* $\mathsf{Int}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *provenance.*

2. dxy, dyz, dxz *are the three dyadic distance ledgers for the pairs* (x, y)*,* (y, z)*, and* (x, z)*. Each ledger records its common-denominator subtraction window, dyadic radius row, and finite comparison data through the* $\mathsf{DyadicMetric}^{\uparrow}$ *packet.*

3. a *records the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint rows attached to the three distance ledgers, so every nonnegative distance endpoint is read through the absolute-value packet rather than through a host absolute-value function.*

4. b *is the displayed comparison row*

$$dxz \leq dxy + dyz.$$

   It records the common-denominator addition window, the dyadic upper-bound ledger, and the finite order comparison witnessing the triangle bound.

5. t *is the downstream handoff row. It exposes the finite route from the three endpoints through the three distance ledgers, the absolute-value endpoints, and the comparison row to* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$ *consumers.*

6. h *records componentwise* hsame *transport for the endpoint rows, distance ledgers, absolute-value rows, comparison row, consumer handoff, replay, provenance, and local naming.*

7. *c records displayed* Cont *replay from the endpoint rows through distance, absolute value, comparison, consumer handoff, transport, provenance, and local naming.*
8. *p is the* Pkg *provenance over* $\mathsf{DyadicMetricTriangle}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMetric}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *n is the local* $\mathsf{NameCert}_{\mathsf{DyadicMetricTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $x, y, z, dxy, dyz, dxz, a, b, t, h, c, p, n$. It has no coordinate for host metric spaces, quotient rationals, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicMetricTriangleUp.DyadicMetricTriangleTasteGate single carrier alignment`

Theorem 2019.2 (Dyadic metric triangle NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMetricTriangle}^{\uparrow}$ *carrier $T = (x, y, z, dxy, dyz, dxz, a, b, t, h, c, p, n)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicMetricTriangle}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed endpoints x, y, z and the three distance ledgers dxy, dyz, dxz;*
2. *absolute-value exposure through a for each nonnegative dyadic distance endpoint;*
3. *triangle comparison through the row b witnessing $dxz \leq dxy + dyz$;*
4. *consumer handoff through t to* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Met}^{\uparrow}$*;*
5. *componentwise structural replay through h, c, p, n.*

No triangle-bound obligation is stored outside those finite rows.

Lean4 ✓ `BEDC.Derived.DyadicMetricTriangleUp.DyadicMetricTriangleCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 2019.1. The visible packet lists three $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows and three $\mathsf{DyadicMetric}^{\uparrow}$ distance ledgers before any comparison row is available.

The nonnegative endpoint data is not a host operation. It is routed through the $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ rows in a, one for each displayed distance ledger.

The triangle row is the only comparison row. It displays the dyadic addition ledger and the finite order comparison for $dxz \leq dxy + dyz$, so the packet has no hidden metric-law coordinate.

The consumer and structural rows are terminal. Rows t, h, c, p, n hand off, transport, replay, package, and name the displayed triangle ledger without adding quotient rationals, trichotomy, selected limits, ambient completeness, Lean verification, or bridge checking. □

Theorem 2019.3 (Dyadic metric triangle RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{Met}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicMetricTriangle}^{\uparrow}$ *triangle bound must pass through the finite route*

$$x, y, z \longmapsto dxy, dyz, dxz \longmapsto a \longmapsto b \longmapsto t \longmapsto h, c, p, n$$

before the triangle estimate is available as a regular-rational tolerance bound, a real-name distance surface, or a metric witness. Consequently no such consumer can obtain the triangle bound through a host metric space, quotient rational equality, trichotomy, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier. The only consumer-facing coordinate is t, and t is downstream of the endpoint rows, the three dyadic distance ledgers, the absolute-value endpoint rows, and the comparison row.

For a $\mathsf{RegSeqRat}^{\uparrow}$ consumer, the triangle estimate is read as a finite dyadic tolerance comparison. The comparison cannot be inspected until the three distance ledgers and the absolute-value endpoint route have displayed the row $dxz \leq dxy + dyz$.

For a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Met}^{\uparrow}$ consumer, the same route is terminal. The real-name seal and the metric witness receive only the surface exposed by t, while h, c, p, n transport, replay, package, and name that surface without introducing a second metric law.

The excluded objects are absent from the carrier. Thus every accepted downstream read factors through the displayed triangle ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMetricTriangle}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMetricTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2019.2 and Definition 2019.3 seed the finite dyadic triangle route from three $\mathsf{DyadicRatCore}^{\uparrow}$ endpoints through three distance ledgers, absolute-value endpoints, the displayed comparison row, consumer handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMetricTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host metric spaces, quotient rationals, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, three-distance ledger exposure, absolute-value endpoint exposure, triangle comparison, consumer handoff, provenance, transport, replay, and local naming for BEDC.Derived.DyadicMetricTriangleUp.

Constructive story: A $\mathsf{DyadicMetricTriangle}^{\uparrow}$ packet is generated from three $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, three $\mathsf{DyadicMetric}^{\uparrow}$ distance ledgers, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ endpoint rows, one dyadic triangle comparison row, a $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ consumer handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2020

Dyadic Fast Cauchy NameCert Construction

Following Bishop and Bridges, the $\mathsf{DyadicFastCauchy}^{\uparrow}$ packet records the finite fast-Cauchy interface by which dyadic tolerance schedules become regular rational data before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the dyadic arithmetic ledger of chapter 291, the finite stream window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name boundary of chapter 38, and the displayed modulus discipline of chapter 1781. The chapter names the L10 Real and Completion handoff as finite NameCert data, not as a host completion theorem.

Definition 2020.1 (Dyadic fast Cauchy carrier)**.** *A* $\mathsf{DyadicFastCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing dyadic radii, slack comparisons, addition rows, and containment checks consumed by the fast Cauchy route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected at the visible dyadic requests.*
3. *M is the* $\mathsf{FastCauchyModulus}^{\uparrow}$ *row, recording the displayed rule that a request at level k supplies windows whose mutual distance is bounded by the dyadic tolerance named by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D, S, M.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the dyadic ledger, stream windows, modulus row, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, modulus row, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from dyadic requests through D, S, M, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicFastCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FastCauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicFastCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, M, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicFastCauchyUp.TasteGate.DyadicFastCauchyTasteGate single carrier alignment`

Theorem 2020.2 (Dyadic fast Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{DyadicFastCauchy}^{\uparrow}$ *carrier* $F = (D, S, M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicFastCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic ledger, finite stream windows, displayed fast-Cauchy modulus, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *dyadic tolerance exposure, requiring every requested bound to be read from* D *before a stream window or readback row is consumed;*
3. *finite-window coverage, requiring* S *to contain precisely the displayed windows selected for the visible dyadic requests;*
4. *modulus stability, requiring* M *to bind each visible request to the pairwise window comparison budget named in* D*;*
5. *RegSeqRat handoff, requiring* R *to be downstream of the same* D, S, M *route;*
6. *Real-seal boundary, requiring* E *to remain terminal after* R *and to export no quotient stream, selected host limit, countable-choice selector, trichotomy row, host real equality, ambient completeness theorem, Lean evidence, or checked bridge;*
7. *provenance and local naming, requiring* P *and* N *to package exactly the displayed fast-Cauchy route.*

No DyadicFastCauchy NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 2020.1. The analytic coordinates are exactly the dyadic ledger D, finite windows S, displayed modulus row M, regular readback R, and terminal Real seal E.

The tolerance and window clauses are finite projections. A requested bound enters through D, the visible windows are stored in S, and the modulus row M is the only row that relates the request to the pairwise window comparison budget.

The handoff clauses follow the displayed order of the packet. The readback row R is downstream of D, S, M, while E appears only after R and therefore cannot be read as an independent host limit or ambient completeness witness.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 2020.3 (Dyadic fast Cauchy RegSeqRat handoff)**.** *For every accepted* $\mathsf{DyadicFastCauchy}^{\uparrow}$ *carrier* $F = (D, S, M, R, E, H, C, P, N)$*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer reaches the readback row* R *only through the finite route*

$$D \longmapsto S \longmapsto M \longmapsto R.$$

Thus the handoff from dyadic fast-Cauchy data to regular rational data cannot bypass the displayed tolerance ledger, the selected stream windows, or the fast-Cauchy modulus row by quotient streams, selected host limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the accepted packet. The only regular rational coordinate is R, and it is placed after the dyadic ledger D, finite windows S, and displayed modulus row M.

The transport and replay rows preserve this ordering componentwise. Provenance and local naming then package the same route without adding a second source for readback data.

Consequently any RegSeqRat consumer of the packet must pass through D, S, M before reading R. The excluded quotient, selector, choice, order, equality, and completeness objects are absent from the carrier. □

Theorem 2020.4 (Dyadic fast Cauchy Real seal boundary)**.** *For every accepted* $\mathsf{DyadicFastCauchy}^{\uparrow}$ *carrier* $F = (D, S, M, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is terminal over the displayed dyadic fast-Cauchy route. A Real consumer may read the seal only after the DyadicRatCore ledger, StreamName windows, FastCauchyModulus row, and RegSeqRat readback have been displayed, and the seal exports no quotient stream equality, selected host limit, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the terminal coordinate E from the accepted carrier. It is downstream of D, S, M, R and has no independent host-limit coordinate.

The componentwise transport row H and replay row C preserve the route from the dyadic ledger through stream windows, modulus, readback, and seal. The provenance and local naming rows only record that route as finite certificate data.

Therefore a downstream Real consumer cannot use E as a hidden quotient, selected limit, choice principle, trichotomy claim, host equality, ambient completeness result, Lean theorem, or checked bridge. The seal is exactly the terminal boundary of the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicFastCauchy}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicFastCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2020.1, Definition 2020.2, Definition 2020.3, and Definition 2020.4 seed the finite dyadic fast-Cauchy route from displayed tolerance ledgers and stream windows to RegSeqRat readback and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicFastCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window coverage, modulus stability, RegSeqRat handoff, Real-seal boundary, provenance, and local naming for BEDC.Derived.DyadicFastCauchyUp.

Constructive story: A $\mathsf{DyadicFastCauchy}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, a FastCauchyModulus row, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2021

A Concrete Naming Certificate for $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ packet records the finite dyadic-net total-boundedness certificate for closed $\mathsf{Real}^{\uparrow}$ intervals before compactness-facing consumers read the interval as a completed object. It sits after the closed interval mesh of chapter 1250, the dyadic refinement basis of chapter 1916, the total-bounded interface of chapter 127, the finite epsilon-net ledger of chapter 1767, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet isolates the total-boundedness row used by closed-interval compactness; it is not open-cover compactness, not a selected subcover, not quotient real equality, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2021.1 (Closed interval total-bounded carrier)**.** *A* $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, M, D, F, U, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper closed* $\mathsf{Real}^{\uparrow}$ *endpoint rows, exposed only through their finite stream windows and regular rational readbacks.*
2. *M is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *mesh row carrying the unary dyadic scale, displayed cells, center rows, and interval coverage ledger for the closed interval determined by A, B.*
3. *D is the* $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *refinement row, recording how each displayed mesh cell is refined by dyadic basis cells at the requested positive tolerance.*
4. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *ledger obtained from the displayed mesh centers, coverage witnesses, and dyadic tolerance comparisons.*
5. *U is the* $\mathsf{TotallyBounded}^{\uparrow}$ *handoff row, read only after M, D, F have displayed the finite center bundle and coverage route.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family for endpoint, center, dyadic-cell, and coverage observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same endpoint, center, and coverage windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S and R have exposed the relevant finite reads.*

9. *H records componentwise* hsame *transport for endpoints, interval nets, dyadic refinements, finite epsilon nets, the total-bounded handoff, stream windows, readbacks, the Real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay of every consumer request through*

$$A, B \longmapsto M \longmapsto D \longmapsto F \longmapsto U \longmapsto S \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicIntervalBasis}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalTotalBounded}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for open-cover compactness, selected finite subcovers, quotient real equality, trichotomy, countable choice, a hidden center selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedIntervalTotalBoundedUp.ClosedIntervalTotalBoundedTasteGate single carrier alignment`

Theorem 2021.2 (Closed interval total-bounded NameCert obligations)**.** *For every accepted* $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ *carrier* $T = (A, B, M, D, F, U, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalTotalBo}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two endpoint rows, the closed-bounded interval net, dyadic basis refinement, finite epsilon-net ledger, total-bounded handoff, stream windows, regular readback, Real seal, and structural rows H, C, P, N;*

2. *endpoint visibility, requiring A and B to be read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows before any interval-total-bounded route is consumed;*

3. *mesh coverage, requiring M to expose the dyadic scale, cell ledger, center rows, and closed-interval coverage witnesses supplied by the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet;*

4. *dyadic refinement exactness, requiring D to refine only the displayed mesh cells by the* $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *route at the requested tolerance;*

5. *finite epsilon-net formation, requiring F to list exactly the displayed centers and coverage witnesses used by the tolerance request;*

6. *total-bounded handoff, requiring U to be downstream of M, D, F and to export no additional center selector or compactness theorem;*

7. *transport, replay, provenance, and local naming for exactly the displayed rows recorded in H, C, P, N.*

No closed-interval total-bounded NameCert obligation is stored outside these rows.

Proof. Project the accepted packet $T = (A, B, M, D, F, U, S, R, E, H, C, P, N)$. Carrier admission exposes exactly the endpoint rows, the interval mesh, the dyadic refinement row, the finite epsilon-net ledger, the total-bounded handoff, the stream windows, the regular readback, the Real seal, and the four structural rows.

The endpoint and mesh obligations are finite. The endpoints are visible only through S and R, while M supplies the displayed dyadic scale, center rows, and coverage witnesses from the closed-bounded interval-net packet.

The tolerance obligation is the route M, D, F, U. The dyadic basis row D refines the displayed mesh cells, the finite epsilon-net ledger F records the centers and coverage witnesses for the requested tolerance, and the total-bounded handoff U is read only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no open-cover, selected-subcover, quotient-equality, trichotomy, choice, hidden-selector, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2021.3 (Closed interval total-bounded dyadic-net handoff)**.** *For every accepted* $\mathsf{ClosedIntervalTotalBound}$ *carrier* $T = (A, B, M, D, F, U, S, R, E, H, C, P, N)$ *and every displayed positive tolerance request, the exported* $\mathsf{TotallyBounded}^{\uparrow}$ *row factors through the finite route*

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longrightarrow \mathsf{DyadicIntervalBasis}^{\uparrow} \longrightarrow \mathsf{FiniteEpsilonNet}^{\uparrow} \longrightarrow \mathsf{TotallyBounded}^{\uparrow}.$$

Thus the total-boundedness witness is the finite dyadic mesh and its displayed center bundle, not a compactness theorem or a selected subcover of an open family.

Proof. Begin with a tolerance request for the total-bounded handoff U. The carrier places U downstream of the closed-bounded interval-net row M, so the request first reads the displayed mesh cells, centers, and coverage witnesses.

The dyadic basis row D refines those mesh cells at the requested tolerance. This refinement is tied to the cells in M and does not introduce a separate family of centers.

The finite epsilon-net ledger F then packages the displayed centers and coverage witnesses as the finite net consumed by U. The rows H, C, P, N preserve and replay the same sequence of reads.

Therefore every total-bounded export factors through M, D, F, U. Because the carrier has no open-cover coordinate and no selected-subcover coordinate, the handoff is finite dyadic-net data rather than a compactness selection principle. □

Theorem 2021.4 (Closed interval total-bounded Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*, compact-net, or Heine–Borel consumer of an accepted* $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ *carrier reaches endpoint and coverage data only through*

$$A, B, M, D, F, U, S, R, E, H, C, P, N.$$

The terminal $\mathsf{Real}^{\uparrow}$ *seal is downstream of the displayed stream windows and regular rational readbacks, and the consumer receives no quotient real equality, host endpoint choice, selected subcover, countable choice, or ambient completeness row.*

Proof. Start with a consumer request for endpoint, coverage, or total-boundedness data. The only endpoint rows in the packet are A and B, and the only Real-facing terminal row is E.

The route to E passes through the finite windows S and regular readback R. Before those rows can serve the interval-total-bounded request, the mesh row M, dyadic refinement row D, finite epsilon-net row F, and total-bounded handoff U have already fixed the displayed center and coverage data.

The structural rows H, C, P, N then transport, replay, source, and name the same route for compact-net and Heine–Borel consumers. Since no quotient equality, host endpoint selector, selected subcover, countable-choice schedule, or ambient-completeness row appears in the carrier, none can escape through the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalTotalBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ packet is generated from closed RealUp endpoint rows, a ClosedBoundedIntervalNetUp dyadic mesh, a DyadicIntervalBasisUp refinement row, a FiniteEpsilonNetUp center ledger, a TotallyBoundedUp handoff, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalTotalBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2021.1, Definition 2021.2, Definition 2021.3, and Definition 2021.4 seed the finite dyadic-net total-boundedness certificate for closed RealUp intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalTotalBounded}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ClosedIntervalTotalBoundedUp.ClosedIntervalTotalBoundedTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification of dyadic-net coverage, finite epsilon-net formation, total-bounded handoff, Real-seal nonescape, and structural transport.

Upgrade path: Obligation closure requires checked dyadic-net coverage, finite epsilon-net formation, total-bounded handoff, Real-seal nonescape, and structural transport for BEDC.Derived.ClosedIntervalTotalBoundedUp.

Chapter 2022

Extension by Continuity NameCert Construction

Bishop and Bridges/Kelley completion language treats extension by continuity as a dense-source construction: a Cauchy-controlled map is first read on explicit dense Cauchy data, then carried through the completion universal property, and only then exposed as a continuous real-facing extension. The $\mathsf{ExtensionByContinuity}^{\uparrow}$ packet records that route as finite NameCert data between the extension surface of chapter 397, the operator boundary of **??**, the Cauchy-continuous map surface of chapter 1401, the finite source windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It gives later Real and Completion consumers a visible public object for the dense-to-continuous extension route without asserting quotient completions, selected limits, countable choice, host function equality, or ambient real completeness.

Definition 2022.1 (Extension by continuity carrier)**.** *An* $\mathsf{ExtensionByContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, F, U, L, W, R, T, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense-source row, naming the regular Cauchy data on which the source map is initially inspected.*
2. *F is the Cauchy-continuous source-map row, read through the surface of chapter 1401.*
3. *U is the completion-universal extension row, aligned with chapter 397 and the operator handoff of* **??**.
4. *L is the uniqueness ledger comparing two extension rows when their dense-source, Cauchy-continuous map, and completion-universal extension coordinates agree.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened for dense-source observations and extension replay.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational source data carried by D and W.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling source closeness, map continuity requests, and completion-facing precision.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal through which the completed extension is read only after D, F, U, W, R, T have been replayed.*

9. *H records componentwise* hsame *transport for D, F, U, L, W, R, T, A and for the structural rows of the packet.*

10. *C records displayed* Cont *replay of the route*

$$D, W, R, T \longmapsto F \longmapsto U \longmapsto A.$$

11. *P is the* Pkg *provenance over* $\mathsf{ExtensionByContinuity}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyExtensionOperator}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ExtensionByContinuity}^{\uparrow}}$ *row.*

The carrier contains no quotient completion, no selected limit, no countable-choice schedule, no host function equality row, no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, no Lean verification coordinate, and no bridge-checking coordinate.*

Lean4 ✓ `BEDC.Derived.ExtensionByContinuityUp.TasteGate.ExtensionByContinuityTasteGate single carrier alignment`

Definition 2022.2 (Extension by continuity classifier)**.** *Two accepted* $\mathsf{ExtensionByContinuity}^{\uparrow}$ *carriers*

$$E = (D, F, U, L, W, R, T, A, H, C, P, N)$$

and

$$E' = (D', F', U', L', W', R', T', A', H', C', P', N')$$

classify together exactly when the classifier compares the displayed coordinates $D, F, U, L, W, R, T, A, H, C, P, N$ componentwise with $D', F', U', L', W', R', T', A', H', C', P', N'$, and when the displayed Cont *replay route has the same dense-source, map, extension, and real-seal order on both packets. The classifier has no field for quotient representatives, selected limits, countable choice, host function equality, ambient real completeness, Lean verification, or bridge checking.*

Theorem 2022.3 (Extension by continuity NameCert obligations)**.** *For the carrier of Definition 2022.1, the local* $\mathsf{NameCert}_{\mathsf{ExtensionByContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier display, admitting precisely the packet $E = (D, F, U, L, W, R, T, A, H, C, P, N)$;*

2. *classifier stability, requiring the classifier of Definition 2022.2 to compare only the displayed coordinates and their replay order;*

3. *extension-existence handoff, requiring the Cauchy-continuous source-map row F and the completion-universal row U to be read after the dense-source window, readback, and tolerance rows D, W, R, T;*

4. *uniqueness, requiring the ledger L to compare candidate extension rows only over the same dense-source, Cauchy-continuous map, and completion-universal coordinates;*

5. $\mathsf{Real}^{\uparrow}$*-seal nonescape, requiring every real-facing read to pass through A only after D, W, R, T, F, U have been replayed;*

6. *provenance and name rows, requiring H, C, P, N to expose only componentwise transport, displayed continuation replay, package provenance, and the local NameCert row.*

No obligation for the local certificate is stored outside those rows.

Proof. Carrier display is projection from Definition 2022.1. The accepted packet lists the dense-source row, Cauchy-continuous map row, completion-universal extension row, uniqueness ledger, finite window, regular readback, dyadic tolerance, real seal, and structural rows.

Classifier stability follows from Definition 2022.2. The comparison is componentwise on the displayed coordinates, and the only continuation data compare the same replay order on the two packets.

For extension existence, first read D, W, R, T. These rows expose the dense Cauchy source through finite windows, regular rational readback, and dyadic tolerance data. The source-map row F is available only after those rows are present, and the completion-universal row U consumes that map row as its extension handoff.

The uniqueness obligation is the projection to L. Since the ledger compares extension rows over the same D, F, U, W, R, T coordinates, it never appeals to equality of host functions or to an external completed object.

Finally inspect A, H, C, P, N. The seal row A is downstream of the displayed continuation route, while H, C, P, N record only transport, replay, provenance, and local naming. The excluded principles are absent from the carrier inventory, so the six listed obligations exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.ContinuityCarrierNameCertUp.ContinuityCarrierNameCert semantic name certificate`

Theorem 2022.4 (Extension by continuity public export)**.** *Every accepted* $\mathsf{ExtensionByContinuity}^{\uparrow}$ *packet exports a public completion-extension surface whose consumers factor through the single route*

$$D, W, R, T \longmapsto F \longmapsto U \longmapsto A$$

together with the uniqueness ledger L, componentwise hsame *transport H, displayed* Cont *replay C, package provenance P, and local naming row N. The export is visible to* $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyExtensionOperator}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers only through those coordinates, and it exports no quotient completion, selected limit, countable-choice schedule, host function equality, ambient real completeness, Lean verification, or bridge-checking row.*

Proof. Begin with the accepted carrier. By Definition 2022.1, every public consumer sees the ordered coordinates $D, F, U, L, W, R, T, A, H, C, P, N$ and no other carrier field.

Use the obligation theorem next. The extension-existence handoff forces the dense-source rows D, W, R, T to be read before F, and forces the completion-universal extension row U to consume that Cauchy-continuous source-map row.

The real-facing boundary is then the seal coordinate A. The displayed continuation route records A as downstream of D, W, R, T, F, U, so a $\mathsf{Real}^{\uparrow}$ consumer cannot bypass the dense-source and completion-universal handoff.

The uniqueness and structural surfaces are exactly L, H, C, P, N. They compare candidate extensions, transport displayed rows, replay the route, record provenance, and name the local certificate. Since the carrier and obligations contain no coordinate for the excluded principles, the public export cannot expose them. □

Closure status for $\mathsf{NameCert}_{\mathsf{ExtensionByContinuity}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ExtensionByContinuity}^{\uparrow}$ packet is generated from a dense-source row, a Cauchy-continuous source-map row, a completion-universal extension row, a uniqueness ledger, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ExtensionByContinuity}\uparrow}$, seed)

Scope closed: Definition 2022.1, Definition 2022.2, Definition 2022.3, and Definition 2022.4 seed the finite dense-source-to-continuous-extension route over the L10 Real and Completion spine.

Formal verification: FormalStatus(NameCert$_{\text{ExtensionByContinuity}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host function equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier display, classifier stability, extension-existence handoff, uniqueness, Real seal nonescape, provenance rows, and local NameCert rows for BEDC.Derived.ExtensionByContinuityUp.

Chapter 2023

A Concrete Naming Certificate for $\mathsf{SeriesLimitComparison}^{\uparrow}$

From Bishop and Bridges constructive analysis, the series limit-comparison test is a finite comparison route between two positive series, not an appeal to a host real limit of quotients. The $\mathsf{SeriesLimitComparison}^{\uparrow}$ packet sits after the finite tail criterion of chapter 2014 and the regular-Cauchy comparison surface of chapter 411. It reads source and comparator series only through $\mathsf{StreamName}^{\uparrow}$ windows from chapter 126, $\mathsf{RegSeqRat}^{\uparrow}$ readback from chapter 301, and the $\mathsf{DyadicRatCore}^{\uparrow}$ budget of chapter 291, then seals the accepted endpoint through the $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet records a constructive comparison certificate for eventual positive ratio control; it does not import host limits, quotient series equality, countable choice, trichotomy, or ambient real completeness.

Definition 2023.1 (Series limit comparison carrier)**.** *A* $\mathsf{SeriesLimitComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, S, T, R, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source-series row, recording finite term and partial-sum observations for the series whose Cauchy behavior is being certified.*
2. *B is the comparator-series row, recording the matched finite term and partial-sum observations used as the comparison source.*
3. *S is the source partial-sum thread exposed to the* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *route.*
4. *T is the comparator partial-sum thread exposed to the same criterion surface.*
5. *R is the eventual positive comparison and ratio ledger: it records the displayed threshold after which comparator terms are positive and the source terms are bounded by a carried dyadic multiple of the comparator terms.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, including the ratio slack, product budget, tail tolerance, and comparison radii consumed by R, S, T.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opening exactly the inspected source terms, comparator terms, partial sums, and endpoint-facing approximations.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the source and comparator windows and to the dyadic requests in D.*

9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal available only after the source row, comparator row, ratio ledger, dyadic budget, stream windows, regular readback, and Cauchy handoff rows have been displayed.*

10. *H stores componentwise* hsame *transport for the source series, comparator series, two partial-sum threads, ratio ledger, dyadic budget, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*

11. *C stores displayed* Cont *replay from source and comparator series rows to their partial-sum threads, from those threads to the ratio ledger, from the ratio ledger to the dyadic budget and regular readback, and from that readback to the real seal.*

12. *P is the* Pkg *provenance over* $\mathsf{SeriesLimitComparison}^{\uparrow}$, $\mathsf{LimitComparisonTest}^{\uparrow}$, $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SeriesLimitComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, S, T, R, D, W, Q, E, H, C, P, N$. It has no coordinate for a host quotient limit, a host infinite sum, quotient equality of series, countable-choice selector, trichotomy row, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or standard bridge.*

Lean4 ✓ `BEDC.Derived.SeriesLimitComparisonUp.SeriesLimitComparisonUpTasteGate single carrier alignment`

Theorem 2023.2 (Series limit comparison NameCert obligations)**.** *For every accepted* $\mathsf{SeriesLimitComparison}^{\uparrow}$ *carrier $K = (A, B, S, T, R, D, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeriesLimitComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source series, comparator series, partial-sum threads, eventual positivity and ratio ledger, dyadic budget, stream windows, regular readback, real seal, transport, replay, provenance, and local naming rows;*

2. *source-thread exactness, requiring every source partial sum and tail observation consumed by the certificate to pass through A, S, W, Q, D;*

3. *comparator-thread exactness, requiring every comparator partial sum and tail observation consumed by the certificate to pass through B, T, W, Q, D;*

4. *eventual positive comparison, requiring the ledger R to display the finite threshold and the positive comparator rows used in every later comparison;*

5. *ratio-budget exactness, requiring R and D to display the carried dyadic multiple, slack, and tail budget before the source Cauchy handoff is read;*

6. *real-seal nonescape, requiring E to be downstream of the displayed* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *and* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *routes and to export no host limit, quotient series equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge datum;*

7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No series limit-comparison obligation is stored outside these rows.

Proof. Project the accepted packet $K = (A, B, S, T, R, D, W, Q, E, H, C, P, N)$. The carrier definition exposes exactly the source and comparator rows, their partial-sum threads, the ratio ledger, dyadic budget, finite windows, regular readback, real seal, and structural rows.

The source and comparator threads are read separately. The source side must pass through A, S, W, Q, D, while the comparator side must pass through B, T, W, Q, D.

The eventual positivity and ratio ledger R is then displayed. Its finite threshold and dyadic multiple are measured only against the tolerance and slack rows carried by D.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since no excluded analytic or choice object appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2023.3 (Series limit comparison Cauchy handoff)**.** *Let $K = (A, B, S, T, R, D, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{SeriesLimitComparison}^{\uparrow}$ *carrier. Every completion-facing read of the source series factors through*

$$B, T, W, Q, D \longmapsto R \longmapsto A, S, W, Q, D \longmapsto E, H, C, P, N.$$

Thus comparator Cauchy control is handed to the source series only through the displayed eventual positive ratio ledger and dyadic tolerance budget, not through a host quotient limit, quotient equality of series, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing request for the source series. The comparator rows B, T, W, Q, D are the only comparator data available to the carrier, so the request first reads the comparator partial-sum and tolerance surface.

The ratio ledger R supplies the finite threshold, eventual positivity rows, and dyadic multiple used to compare later source terms with later comparator terms. This is a displayed ledger row, not a host limit assertion.

The request then returns to the source rows A, S, W, Q, D. The same stream windows, regular readback, and dyadic budget record the finite tail comparison needed by the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ route.

The seal E and structural rows H, C, P, N preserve this handoff. Since the carrier has no coordinate for quotient series equality, choice, trichotomy, or ambient completeness, every source completion read is exhausted by the displayed finite route. □

Theorem 2023.4 (Series limit comparison ratio nonescape)**.** *For every accepted* $\mathsf{SeriesLimitComparison}^{\uparrow}$ *carrier, the ratio ledger R cannot be read as a standalone quotient-limit object. Any consumer of R must also receive the source-series row, comparator-series row, stream-window family, regular readback, dyadic tolerance budget, real seal, transport table, continuation table, package provenance, and local naming row displayed in Definition 2023.1.*

Proof. Project the carrier of Definition 2023.1. The row R is listed between the two partial-sum threads and the dyadic budget, and the classifier compares accepted packets componentwise through the full tuple.

Apply Definition 2023.2. The eventual positive comparison and ratio-budget exactness rows require R to be displayed together with the dyadic budget D, stream windows W, and regular readback Q before a real-seal consumer can use it.

Apply Definition 2023.3. The only completion-facing use of the ratio ledger is the finite handoff from comparator Cauchy control to the source Cauchy route.

Therefore R is a local ledger row inside the finite packet. It cannot be detached as a host quotient limit or used to supply quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{SeriesLimitComparison}^{\uparrow}$ completion-facing read factors through source and comparator series rows, two partial-sum threads, an eventual positive ratio ledger,

a DyadicRatCore tolerance budget, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real-series-cauchy-criterion, regular-cauchy-comparison, streamname, regseqrat, dyadicratcore, real: $\mathsf{SeriesLimitComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two series rows, two partial-sum threads, eventual positivity, ratio-budget control, Cauchy handoff, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SeriesLimitComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeriesLimitComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2023.1, Definition 2023.2, Definition 2023.3, and Definition 2023.4 seed the finite constructive series limit-comparison route from comparator Cauchy control through eventual positive ratio budgeting to source-series RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeriesLimitComparison}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SeriesLimitComparisonUp`

Bridge status: none

Not claimed: This chapter does not close host limits, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source and comparator thread exactness, eventual positive ratio-ledger stability, DyadicRatCore and RegSeqRat budget handoff, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.SeriesLimitComparisonUp.

Constructive story: A $\mathsf{SeriesLimitComparison}^{\uparrow}$ packet is generated from source and comparator series rows, two partial-sum threads, an eventual positive comparison and ratio ledger, a DyadicRatCore tolerance budget, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2024

A Concrete Naming Certificate for $\mathsf{CantorBendixson}^{\uparrow}$

Following Cantor and Bendixson's derived-set theorem in the constructive closed-set reading, the $\mathsf{CantorBendixson}^{\uparrow}$ packet records a finite derivative-stage route for a displayed closed subset of the real line before any completion-facing consumer reads the retained kernel or the isolated-point ledger. It consumes the finite real-boundary chapters chapter 1752, chapter 1421, chapter 1713, chapter 126, chapter 301, chapter 291, and chapter 38. The packet names only the finite derivative data exposed by the carrier; it does not import the transfinite Cantor-Bendixson decomposition, choice of isolated points, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2024.1 (Cantor-Bendixson finite derivative carrier)**.** *A* $\mathsf{CantorBendixson}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, D, I, K, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the closed-set row. It records the displayed finite closed-set observations, interval enclosures, and located boundary reads supplied to the derivative packet.*
2. *D is the derivative-stage row. It names the finite stage budget and the finite successor-stage ledger used to pass from the current closed row to the next derived row.*
3. *I is the isolated-point ledger. It records only isolated points whose witnessing separating intervals, dyadic radii, and stage membership checks are displayed inside the packet.*
4. *K is the retained perfect-kernel row at the displayed finite stage. It is read as the residual closed row after the isolated ledger and derivative-stage rows have been consumed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the closed-set observations, isolating intervals, and retained-kernel reads are exposed to finite consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and derivative-stage ledger.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for the radii, comparisons, interval separations, and containment checks used by F, D, I, K, W, R.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary for the displayed closed-set and retained-kernel reads.*
9. *H records componentwise* hsame *transport for the closed-set, derivative-stage, isolated-ledger, kernel, window, readback, dyadic, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of every consumer request through*

$$F, D \longmapsto I, K \longmapsto W, Q \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CantorBendixson}^{\uparrow}$, $\mathsf{CantorCompleteness}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{LocatedRealNestedInt}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorBendixson}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, D, I, K, W, R, Q, E, H, C, P, N$. It has no coordinate for a transfinite rank, a selected isolated-point enumeration, quotient real equality, countable choice, host closed-set equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2024.2 (Cantor-Bendixson NameCert obligations)**.** *For every accepted* $\mathsf{CantorBendixson}^{\uparrow}$ *carrier $B = (F, D, I, K, W, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorBendixson}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed closed-set, derivative-stage, isolated-ledger, retained-kernel, StreamName, RegSeqRat, DyadicRatCore, Real-seal, transport, replay, provenance, and local naming rows;*

2. *derivative-stage classifier stability, requiring accepted comparisons to preserve the finite stage budget and every displayed successor-stage derived-row check;*

3. *isolated-point ledger exactness, requiring each listed isolated point to carry its displayed separating interval, dyadic radius, and membership row, with no hidden selector for further isolated points;*

4. *retained-kernel handoff, requiring K to be downstream of the displayed derivative-stage and isolated-ledger rows before any StreamName, RegSeqRat, DyadicRatCore, or Real consumer reads it;*

5. *ledger nonescape, requiring W, R, Q, E, H, C, P, N to expose only the rows already displayed in F, D, I, K and to export no transfinite decomposition, selected enumeration, quotient real equality, countable choice, host closed-set equality, or ambient completeness.*

No Cantor-Bendixson NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CantorBendixsonUp.CantorBendixsonTasteGate single carrier alignment`

Proof. Project the accepted carrier $B = (F, D, I, K, W, R, Q, E, H, C, P, N)$. Carrier admission exposes exactly the closed-set row, finite derivative-stage row, isolated-point ledger, retained-kernel row, observation windows, regular readback, dyadic ledger, Real seal, and the structural rows.

The derivative-stage clause is finite. The row D records the stage budget and successor-stage checks, while H transports those checks componentwise and C replays them before the kernel row is inspected.

The isolated-point clause is also finite. Each entry in I carries its separating interval, dyadic radius, and membership check through Q, so the ledger lists displayed witnesses rather than a choice-selected enumeration.

The retained-kernel handoff follows from the placement of K after F, D, I and before W, R, Q, E. A consumer reaches the kernel only by the route recorded in the carrier.

Finally, provenance and local naming package the same rows. Since no carrier coordinate contains a transfinite rank, quotient real equality, countable choice, host closed-set equality, or ambient completeness theorem, the five listed rows exhaust the local NameCert surface. □

Theorem 2024.3 (Cantor-Bendixson finite derivative handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CantorBendixson}^{\uparrow}$ *carrier factors through the finite route displayed by chapter 1752, chapter 1421, chapter 1713, chapter 126, chapter 301, chapter 291, and chapter 38. Concretely, a consumer of* $B = (F, D, I, K, W, R, Q, E, H, C, P, N)$ *must read the closed-set row, finite derivative-stage ledger, isolated-point ledger, retained-kernel row, StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, transport, replay, provenance, and local naming before the Real seal* E *is exposed.*

Proof. Begin with a completion-facing request for the Real seal. Carrier projection shows that the only terminal Real-facing coordinate is E, and the continuation row C routes every access to E through the displayed packet.

The closed-set and derivative rows are read first. Their finite nested and interval observations are the part of the route governed by the Cantor completeness, Cantor intersection, and located real nested-interval chapters.

Next the request passes through the isolated-point ledger I and retained-kernel row K. The listed isolating intervals and residual closed row are exposed only by the finite stage route, not by a transfinite decomposition or a selector.

The observation and arithmetic rows then pass through W, R, Q. These are exactly the StreamName, RegSeqRat, and DyadicRatCore surfaces consumed before the terminal Real boundary.

The structural rows H, P, N bind the same path under transport, provenance, and local naming. Hence every Real-facing read factors through the seven cited finite boundary chapters and exports none of the excluded classical or quotient data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorBendixson}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorBendixson}^{\uparrow}$ packet is generated from a displayed closed-set row, a finite derivative-stage row, an isolated-point ledger, a retained perfect-kernel row, StreamName windows, RegSeqRat readback, DyadicRatCore comparison data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorBendixson}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2024.1, Definition 2024.2, and Definition 2024.3 seed the finite Cantor-Bendixson derivative route from closed-set observations through displayed isolated-point ledgers and retained-kernel rows to Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorBendixson}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full transfinite Cantor-Bendixson decomposition, selected isolated points, quotient real equality, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-stage classifier stability, isolated-point ledger exactness, retained-kernel handoff, ledger nonescape, and Real-facing handoff for BEDC.Derived.CantorBendixsonUp.

Chapter 2025

A Concrete Naming Certificate for $\mathsf{CompleteArchimedeanField}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley ordered-field completion viewpoint, the $\mathsf{CompleteArchimedeanField}^{\uparrow}$ packet names the finite certificate surface where a displayed real-name carrier is read simultaneously as an ordered field, an Archimedean dyadic-density object, and a Cauchy-completion route. It consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular-field route of chapter 1717, the ordered Archimedean surface of chapter 1419, the dyadic arithmetic ledger of chapter 291, the finite window interface of chapter 126, and the regular rational readback of chapter 301. The chapter records the capstone route needed by Real and Completion consumers without importing ambient completeness of all $\mathsf{Real}^{\uparrow}$ names, quotient real equality, trichotomy, choice, or bridge verification.

Definition 2025.1 (Complete Archimedean field carrier)**.** *A* $\mathsf{CompleteArchimedeanField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, O, A, D, W, Q, K, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, read only after the regular rational windows and dyadic tolerance rows have been displayed.*
2. *O is the ordered-field row supplied by the* $\mathsf{CauchyRealField}^{\uparrow}$ *and* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *sibling surfaces, including addition, multiplication, order, and compatibility ledgers visible to the packet.*
3. *A is the Archimedean dyadic-density row, recording the finite rational and dyadic approximation witnesses that make the ordered-field read Archimedean at the displayed precision.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for dyadic scales, comparisons, density witnesses, and Cauchy tolerances used by O and A.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which inspected real-name observations are opened.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and D before the terminal real seal is consumed.*
7. *K is the Cauchy-completion route row, recording the displayed passage from regular rational readback through the Real seal to the completion-facing field packet.*
8. *H records componentwise* hsame *transport for $R, O, A, D, W, Q, K, C, P, N$.*

9. *C records displayed* Cont *replay from a completion-facing request through $D, W, Q, R, O, A, K, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompleteArchimedeanField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealField}^{\uparrow}$, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteArchimedeanField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, O, A, D, W, Q, K, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient real equality, trichotomy, choice, or bridge verification.*

Lean4 ✓ `BEDC.Derived.CompleteArchimedeanFieldUp.CompleteArchimedeanFieldTasteGate single carrier alignment`

Theorem 2025.2 (Complete Archimedean field NameCert obligations)**.** *For every accepted* CompleteArchimedeanF *carrier*

$$F = (R, O, A, D, W, Q, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteArchimedeanField}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Real seal, ordered-field row, Archimedean dyadic-density row, dyadic ledger, finite windows, regular rational readback, completion route, transport, replay, provenance, and local naming rows;*
2. *ordered-field exposure, requiring O to be the only row through which field operations, order, and algebra-order compatibility are read;*
3. *Archimedean density exposure, requiring A to carry the finite rational and dyadic approximation witnesses and to obtain all dyadic comparisons through D;*
4. *completion-route exactness, requiring K to pass through W, Q, R before any completion-facing field consumer may read the capstone packet;*
5. *transport and replay stability, requiring all classifier-visible data to move componentwise through H and to be replayed through C without adding another route;*
6. *provenance and local naming, requiring P and N to source the same displayed rows and no outside completeness principle.*

No Complete Archimedean field obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2025.1. The accepted packet displays exactly the Real seal, ordered-field row, Archimedean dyadic-density row, dyadic ledger, finite windows, regular rational readback, completion route, transport, replay, provenance, and local naming row.

The ordered-field and density clauses are then separated by their coordinates. The row O is the only field-and-order surface, while A records the finite Archimedean witnesses and reads every dyadic comparison through D.

The completion route is downstream of the regular rational route. A completion-facing consumer reaches K only after the finite windows W, the regular rational readback Q, and the terminal Real seal R have been displayed.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient real equality, trichotomy, choice, and bridge verification are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2025.3 (Complete Archimedean field Real route)**.** *Every accepted* $\mathsf{CompleteArchimedeanField}^{\uparrow}$ *read that reaches a Real or Completion consumer factors through the displayed route*

$$D, W, Q \longmapsto R \longmapsto O, A, K \longmapsto H, C, P, N.$$

Thus the consumer receives the dyadic comparison ledger, finite StreamName windows, RegSeqRat readback, Real seal, ordered-field row, Archimedean dyadic-density row, Cauchy-completion route, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient real equality, trichotomy principle, choice selector, or bridge verification credential.*

Proof. Project the accepted carrier $F = (R, O, A, D, W, Q, K, H, C, P, N)$. The finite observation side starts in the dyadic ledger D and the StreamName windows W, and the first regular rational readback available to the route is Q.

The terminal Real seal R is reached only after those rows are displayed. The ordered-field row O and the Archimedean dyadic-density row A are then read as visible coordinates attached to that same seal, while the completion route K records the passage into the completion-facing capstone packet.

The structural rows preserve this order. Componentwise transport through H keeps all rows aligned, replay through C repeats the displayed route, and P, N source and name the same packet. Because the excluded principles have no carrier coordinate, every Real or Completion read factors through the stated finite route. □

Falsifiable prediction: Every $\mathsf{CompleteArchimedeanField}^{\uparrow}$ read by a Real or Completion consumer factors through one DyadicRatCore comparison ledger, one StreamName finite-window row, one RegSeqRat readback row, one Real seal, one ordered-field row, one Archimedean dyadic-density row, one Cauchy-completion route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, cauchy-real-field, archimedeanorderedfield, dyadicratcore, streamname, regseqrat: $\mathsf{CompleteArchimedeanField}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Real seal, ordered-field row, Archimedean dyadic-density row, Cauchy-completion route, and the finite readback ledgers that make the capstone route visible as one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteArchimedeanField}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteArchimedeanField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2025.1, Definition 2025.2, and Definition 2025.3 seed the finite capstone route from dyadic and regular rational readback through the Real seal to ordered-field, Archimedean, and completion-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteArchimedeanField}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CompleteArchimedeanFieldUp`

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient real equality, trichotomy, choice, or bridge verification.

Upgrade path: Obligation closure requires checked carrier admission, ordered-field exposure, Archimedean dyadic-density exposure, completion-route exactness, transport and replay stability, provenance, and local naming for BEDC.Derived.CompleteArchime

Constructive story: A $\mathsf{CompleteArchimedeanField}^{\uparrow}$ packet is generated from a Real seal, an ordered-field row, an Archimedean dyadic-density row, a DyadicRatCore ledger, StreamName windows, RegSeqRat readback, a Cauchy-completion route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2026

A Concrete Naming Certificate for $\mathsf{EffectiveCompletion}^{\uparrow}$

Following Weihrauch-style computable analysis and Bishop–Bridges constructive completion, the $\mathsf{EffectiveCompletion}^{\uparrow}$ packet records effective Cauchy completion data as a finite NameCert surface rather than as a quotient object. It sits after the effective Cauchy source of chapter 1705, the Cauchy realizer handoff of chapter 1771, the represented-name boundary of chapter 1680, the admissible-representation surface of chapter 1760, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter gives Real-facing completion consumers a computable-analysis route through displayed finite data without claiming quotient completion, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 2026.1 (Effective completion carrier)**.** *An* $\mathsf{EffectiveCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (E, Q, K, W, R, D, A, U, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source row, exposing the effective index schedule, Cauchy evidence, and source-side observations before any completion consumer reads the packet.*
2. *Q is the* $\mathsf{CauchyRealizer}^{\uparrow}$ *handoff row, recording the effective procedure that answers tolerance requests by finite Cauchy data read from E.*
3. *K is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *row, binding the represented-space name to the same effective Cauchy source and realizer route.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the source, realizer, representation, and downstream completion request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the displayed windows and their tolerance ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording dyadic scales, comparison witnesses, slack, and radius data used by Q, W, R.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only through the displayed effective source, realizer, representation, windows, readback, and dyadic tolerance rows.*

8. *U is the completion-consumer row, recording every Real-facing or completion-facing read that the packet permits after E, Q, K, W, R, D, A have been displayed.*

9. *H records componentwise* hsame *transport for the effective source, realizer, representation, windows, readback, tolerance ledger, real seal, completion consumer, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$E, Q, K \longmapsto W, D \longmapsto R \longmapsto A \longmapsto U.$$

11. *P is the* Pkg *provenance over* $\mathsf{EffectiveCompletion}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{CauchyRealizer}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{AdmissibleRepresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, Q, K, W, R, D, A, U, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, countable choice, host equality of completed objects, trichotomy of reals, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.EffectiveCompletionUp.EffectiveCompletionTasteGate single carrier alignment`

Theorem 2026.2 (Effective completion NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCompletion}^{\uparrow}$ *carrier*

$$X = (E, Q, K, W, R, D, A, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the effective Cauchy source, Cauchy realizer, Cauchy representation, finite windows, regular rational readback, dyadic tolerance ledger, real seal, completion consumer, transport, replay, provenance, and local naming row;*

2. *effective-source visibility, requiring every downstream read to expose the source schedule and Cauchy evidence in E before any represented-space or real-facing output is inspected;*

3. *finite-window exactness, requiring every observation used by the realizer, representation, regular readback, real seal, or completion consumer to occur inside the displayed* $\mathsf{StreamName}^{\uparrow}$ *row W;*

4. *Cauchy-realizer handoff, requiring tolerance requests to pass through Q and its displayed dyadic ledger D before R or A can be read;*

5. *represented-space compatibility, requiring the row K to bind the same effective source, realizer, finite windows, dyadic tolerance data, and real seal as the admissible representation route;*

6. *completion-consumer non-escape, requiring U to consume only E, Q, K, W, R, D, A and to export no quotient completion, selected limit, countable-choice selector, host equality, trichotomy branch, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential;*

7. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve, replay, source, and name the displayed route without adding a second classifier.*

No effective completion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2026.1. The accepted packet displays exactly the effective source, realizer, representation, finite windows, regular readback, dyadic tolerance ledger, real seal, completion consumer, and structural rows.

The effective-source and finite-window clauses are read from E and W. Since every downstream row is listed downstream of those coordinates, no represented-space read, regular readback, real seal, or completion consumer can inspect hidden stream data.

The realizer and represented-space clauses are read from Q, K, D, R, A. A tolerance request reaches Q, opens only the displayed dyadic data D and windows W, forms the readback R, and then reaches the terminal real seal A through the represented route K.

The consumer and structural clauses are exhausted by U, H, C, P, N. The carrier has no coordinate for quotient completion, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, so these objects cannot be exported by replay or local naming. □

Theorem 2026.3 (Effective completion Cauchy-realizer handoff)**.** *For every accepted* $\mathsf{EffectiveCompletion}^{\uparrow}$ *carrier*

$$X = (E, Q, K, W, R, D, A, U, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *or completion consumer of* X *factors through the displayed route*

$$E \longrightarrow Q \longrightarrow K \longrightarrow W, D \longrightarrow R \longrightarrow A \longrightarrow U$$

with transport, replay, provenance, and local naming supplied only by H, C, P, N*. The consumer receives no quotient completion, selected limit, countable choice, host equality of completed objects, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.EffectiveCompletionUp.EffectiveCompletionCauchyRealizerHandoff`

Proof. Fix a Real-facing or completion-facing consumer of X. The only consumer coordinate is U, so the read must pass through the displayed completion-consumer row.

Read the dependencies of U. It is downstream of the real seal A, and A is downstream of the regular readback R generated from finite stream windows W and dyadic tolerance data D.

The effective source of those rows is fixed by E, Q, K. The source row E supplies the effective Cauchy data, the realizer Q answers tolerance requests from that source, and the representation row K binds the same data to the represented-space interface.

The structural rows add no analytic data. Componentwise transport through H preserves the displayed coordinates, replay through C preserves the route order, and P, N only source and name the same packet.

Since no excluded object appears as a carrier coordinate, the consumer cannot obtain quotient completion equality, a selected limit, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Thus every allowed consumer factors through exactly the displayed Cauchy-realizer handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2026.1, Definition 2026.2, and Definition 2026.3 seed the finite computable-analysis completion route from effective Cauchy data to Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.EffectiveCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective-source visibility, finite-window exactness, Cauchy-realizer handoff, represented-space compatibility, completion-consumer non-escape, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCompletionUp.

Constructive story: An EffectiveCompletion$^{\uparrow}$ packet is generated from an EffectiveCauchySequence source, a CauchyRealizer handoff, a CauchyRepresentation row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, a completion-consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2027

A Concrete Naming Certificate for $\mathsf{FanContinuityPrinciple}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on fan functionals and continuous choice-sequence functionals, the $\mathsf{FanContinuityPrinciple}^{\uparrow}$ packet records the constructive fan-continuity principle as finite NameCert data rather than as host function-space continuity. Its dependency surface joins the finite bar depth of chapter 400, the prefix-cylinder context of chapter 334, the finite observation row of chapter 1482, the window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet gives later Real and Completion consumers one finite route for extracting a common prefix modulus from fan-bar data, without asserting open-cover compactness, host equality of functionals, countable choice, quotient streams, selected real limits, trichotomy, or ambient real completeness.

Definition 2027.1 (Fan continuity principle carrier)**.** *A* $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, A, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite bar-depth row, carrying a binary spread, a decidable bar classifier, and the displayed depth ledger that bounds the fan read.*
2. *A is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row, exposing the finite prefix context in which a Baire-name observation is inspected.*
3. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *finite observation row, listing the already displayed choice-sequence answers whose common prefix controls the read.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened for the fan prefix, Baire prefix, and choice-sequence observation rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the finite prefix data are consumed by a regular-rational route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, A, Q, S, R have been replayed.*
7. *H records componentwise* hsame *transport for the bar-depth, prefix-cylinder, finite-observation, stream-window, readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$B, A, Q, S \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FanContinuityPrinciple}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FanContinuityPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, Q, S, R, E, H, C, P, N$ and the displayed replay order. It has no coordinate for open-cover compactness, host function equality, countable choice, quotient streams, selected $\mathsf{Real}^{\uparrow}$ *limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FanContinuityPrincipleUp.FanContinuityPrincipleTasteGate single carrier alignment`

Theorem 2027.2 (Fan continuity principle modulus extraction)**.** *Every accepted* $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *carrier*

$$F = (B, A, Q, S, R, E, H, C, P, N)$$

exports a finite prefix modulus for the displayed real-facing read: the modulus is the depth ledger supplied by the $\mathsf{FanTheorem}^{\uparrow}$ *row B, restricted to the prefix-cylinder row A, witnessed by the finite* $\mathsf{ChoiceSequence}^{\uparrow}$ *observation row Q, scheduled through S, and read back through R before reaching the* $\mathsf{Real}^{\uparrow}$ *seal E.*

Proof. Project the accepted carrier. The only depth datum in the packet is the finite bar-depth row B, and the only prefix context is the $\mathsf{BaireSpace}^{\uparrow}$ row A.

Use the displayed choice-sequence observation row Q next. Its entries are finite answers already visible through the stream window schedule S, so any two inspected choice sequences agreeing on the displayed B-depth have the same Q-prefix inside the A-cylinder.

The readback step is then forced through R. Since the continuation route is displayed as $B, A, Q, S \longmapsto R \longmapsto E$, the real-facing seal E can be reached only after the finite prefix data have been read back.

Thus the depth ledger in B, viewed inside A and witnessed by Q, S, R, is the exported modulus. No host function-space continuity or selected infinite branch is used. □

Theorem 2027.3 (Fan continuity principle bar stability)**.** *Let*

$$F = (B, A, Q, S, R, E, H, C, P, N)$$

and

$$F' = (B', A', Q', S', R', E', H', C', P', N')$$

be accepted $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *carriers whose displayed rows are related by componentwise* hsame *transport and whose* Cont *routes replay the same order. Then the prefix modulus extracted in Definition 2027.2 transports from F to F' by carrying the fan bar-depth, Baire prefix-cylinder, choice-sequence observation, StreamName window, RegSeqRat readback, and RealUp seal rows componentwise.*

Proof. Apply Definition 2027.2 to F. The extracted modulus is exactly the depth row B together with the surrounding prefix-cylinder, observation, window, readback, and seal rows.

Now inspect the transport rows H and H'. They compare B, A, Q, S, R, E with B', A', Q', S', R', E' componentwise, so the displayed depth ledger and every row used to read it are carried to the second packet.

Finally use the Cont replay rows C and C'. They preserve the order $B, A, Q, S \longmapsto R \longmapsto E$, so the transported packet still reads the same finite bar before opening the real-facing seal.

Therefore the modulus is stable under the displayed carrier classifier. The argument has no place to introduce open-cover compactness, host function equality, countable choice, quotient streams, selected limits, trichotomy, ambient real completeness, Lean verification, or bridge checking. □

Theorem 2027.4 (Fan continuity principle NameCert obligations)**.** *For the carrier of Definition 2027.1, the local* $\mathsf{NameCert}_{\mathsf{FanContinuityPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed fan bar-depth, Baire prefix-cylinder, choice-sequence observation, stream-window, readback, real-seal, transport, replay, provenance, and local naming rows;*
2. *modulus extraction, requiring the exported prefix modulus to be the finite depth ledger of* B *read through* A, Q, S, R *before* E*;*
3. *bar stability, requiring componentwise* hsame *transport to preserve the same depth ledger and the same replay order;*
4. *real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through the displayed route* $B, A, Q, S \longmapsto R \longmapsto E$*;*
5. *provenance exactness, requiring* P *and* N *to name only the listed sibling chapters and the local certificate row.*

No local obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2027.1. The packet displays precisely the rows $B, A, Q, S, R, E, H, C, P, N$.

For modulus extraction, use Definition 2027.2. It identifies the exported prefix modulus with the finite bar-depth row B after restriction to the prefix and observation rows A, Q, S, R.

For stability, use Definition 2027.3. The componentwise transport rows preserve the depth ledger and every sibling row required for its replay.

The nonescape and provenance obligations are the remaining projections. The continuation row displays the only route to the real seal, and P, N record only package provenance and local naming for the same finite carrier. Since the carrier inventory contains no further coordinates, the five listed obligations exhaust the NameCert surface. □

Theorem 2027.5 (Fan continuity principle sibling dependency)**.** *Every accepted* $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *packet depends on the sibling chapters chapter 400, chapter 334, chapter 1482, chapter 126, chapter 301, and chapter 38 only through the rows* B, A, Q, S, R, E *displayed in Definition 2027.1. It exports no independent compactness principle, function-space equality, countable-choice selector, quotient-stream equality, selected* $\mathsf{Real}^{\uparrow}$ *limit, trichotomy row, ambient* $\mathsf{Real}^{\uparrow}$ *completeness row, Lean verification row, or bridge-checking row.*

Proof. Read the carrier rows in order. The fan dependency is exactly B, the Baire dependency is exactly A, the choice-sequence dependency is exactly Q, the stream dependency is exactly S, the regular-rational dependency is exactly R, and the real dependency is exactly E.

The structural rows H, C, P, N do not add further sibling mathematics. They transport the displayed rows, replay the displayed route, record package provenance, and name the local certificate.

Thus every sibling reference factors through the listed finite rows. The excluded compactness, equality, choice, quotient, limit, order, completeness, verification, and bridge data cannot be exported because they are absent from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanContinuityPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{FanContinuityPrinciple}^{\uparrow}$ packet is generated from a FanTheorem finite bar-depth row, a BaireSpace prefix-cylinder row, a ChoiceSequence finite observation row, a StreamName window schedule, a RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanContinuityPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2027.1, Definition 2027.2, Definition 2027.3, Definition 2027.4, and Definition 2027.5 seed the finite fan-continuity route joining fan bars, Baire prefixes, choice-sequence observations, StreamName windows, RegSeqRat readback, and RealUp seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanContinuityPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host function equality, countable choice, quotient streams, selected Real limits, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus extraction, bar stability, real-seal nonescape, provenance exactness, sibling dependency, and local NameCert rows for BEDC.Derived.FanContinuityPrincipleUp.

Chapter 2028

A Concrete Naming Certificate for $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, this packet records the real-name route whose equality and seal reads pass through displayed Cauchy classifier data, not quotient streams, selected limits, countable choice, host real equality, or ambient completeness. Its dependency surface is the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the classifier row of chapter 1820, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter isolates the finite L10 handoff used by later Real and Completion consumers when the route must remain selection-free.

Definition 2028.1 (Selection-free Cauchy real carrier)**.** *A* $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, Q, E, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which every finite observation of the Cauchy name is opened.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic bounds used by the regular readback and by Cauchy comparison requests.*
4. *Q is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row, recording equality of accepted names only through displayed Cauchy comparison data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after S, R, D, Q have been displayed.*
6. *B is the no-choice boundary, recording that the packet exports no quotient stream representative, selected limit, countable-choice schedule, host real equality, or ambient completeness witness.*
7. *H records componentwise* hsame *transport for the window, readback, dyadic ledger, classifier, seal, boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of every equality or seal read through*

$$S, R, D, Q, B \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SelectionFreeCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, E, B, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.SelectionFreeCauchyRealUp.TasteGate.SelectionFreeCauchyRealTasteGate single carrier alignment`

Theorem 2028.2 (Selection-free Cauchy real NameCert obligations)**.** *For every accepted* $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$ *carrier*

$$K = (S, R, D, Q, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SelectionFreeCauchyReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream windows, regular readback, dyadic tolerance ledger, Cauchy classifier, Real seal, no-choice boundary, transport, replay, provenance, and local naming rows;*
2. *window exactness, requiring every observation used by equality or seal reads to be one of the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows in S;*
3. *regular readback, requiring each rational observation consumed downstream to pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. *dyadic tolerance exactness, requiring every Cauchy comparison budget to be the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
5. *classifier-law stability, requiring the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *row Q to preserve reflexive, symmetric, and transitive Cauchy comparison only through S, R, D;*
6. *Real seal boundary, requiring E to be read only after S, R, D, Q and the no-choice boundary B have been displayed;*
7. *no-choice refusal, requiring B to exclude quotient streams, selected limits, countable choice, host real equality, and ambient completeness;*
8. *structural rows, requiring H, C, P, N to transport, replay, source, and name exactly the displayed route.*

No selection-free Cauchy real NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2028.1. The visible packet consists of the stream windows, regular readback, dyadic ledger, Cauchy classifier, Real seal, no-choice boundary, and structural rows.

Window exactness and regular readback are forced by the first two observation coordinates. A downstream read may inspect only S, and every rational value extracted from those windows must pass through R.

Dyadic tolerance exactness is the row D. It supplies the comparison budgets used by the Cauchy classifier and by any later seal-facing request.

Classifier-law stability is local to Q. The classifier may use the displayed S, R, D rows to compare accepted names, but it has no coordinate for quotient stream equality or host real equality.

Finally, the Real seal boundary and the no-choice refusal are recorded by E and B. The rows H, C, P, N preserve the same route by transport, replay, provenance, and local naming, so the listed rows exhaust the local NameCert surface. □

Theorem 2028.3 (Selection-free Cauchy real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer of an accepted* $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$ *carrier*

$$K = (S, R, D, Q, E, B, H, C, P, N)$$

reaches the seal row E only after the stream windows S, regular readback R, dyadic tolerance ledger D, Cauchy classifier row Q, no-choice boundary B, transport row H, replay row C, provenance row P, and local naming row N have been displayed. Consequently such a consumer receives a finite Cauchy real-name route and receives no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem from the packet.

Proof. Let a $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealCompleteness}^{\uparrow}$ consumer read an accepted carrier. Projection from Definition 2028.1 gives only the rows $S, R, D, Q, E, B, H, C, P, N$.

The real-name route starts with the displayed windows S. The readback row R supplies regular rational observations, and the dyadic ledger D supplies the tolerance budget attached to those observations.

The equality-facing step then passes through Q. Its Cauchy classifier laws are read before the Real seal and only through the displayed window, readback, and dyadic rows.

The no-choice row B is part of the same route before E is exposed. It blocks quotient representatives, selected limits, choice schedules, host real equality, and ambient completeness witnesses from becoming seal data.

The structural rows H, C, P, N transport, replay, source, and name the route without adding further mathematical coordinates. Thus every Real or Completion consumer reaches E only through the displayed selection-free boundary. □

Theorem 2028.4 (Selection-free Cauchy real modulus boundary)**.** *Let $K = (S, R, D, Q, E, B, H, C, P, N)$ be an accepted* $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$ *carrier. Any refinement of a selection-free Cauchy real-name read must expose the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row Q before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is available. The refinement exports no quotient representative, selected limit, host real equality, countable choice, or ambient completeness theorem.*

Proof. Project the carrier of Definition 2028.1. The only observation rows are S, R, D, the only Cauchy classifier row is Q, and the only terminal Real seal is E.

Apply Definition 2028.2. Window exactness, regular readback, dyadic tolerance exactness, and classifier-law stability all occur before the Real seal boundary clause.

Apply Definition 2028.3. It forces every Real or Completion consumer through $S, R, D, Q, B, H, C, P, N$ before E is public, so a refinement can only make the displayed modulus data more precise inside those rows.

The boundary row B and structural rows H, C, P, N add no quotient representative, selected limit, host real equality, countable-choice schedule, or ambient completeness theorem. Thus the refined read remains selection-free and cannot bypass the displayed modulus rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{SelectionFreeCauchyReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SelectionFreeCauchyReal}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid classifier row, a RealUp seal, a no-choice boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SelectionFreeCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2028.1, Definition 2028.2, and Definition 2028.3 seed the finite selection-free Cauchy real-name route from displayed Cauchy classifier data to the public Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SelectionFreeCauchyReal}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SelectionFreeCauchyRealUp`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, regular readback, dyadic tolerance exactness, classifier-law stability, Real seal boundary, no-choice refusal, and local NameCert obligations for BEDC.Derived.SelectionFreeCauchyRealUp.

Chapter 2029

A Concrete Naming Certificate for $\mathsf{LocatedPositiveReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedPositiveReal}^{\uparrow}$ packet records a positive real together with the displayed located-apartness route by which its separation from zero is inspected. It refines the bare positivity surface of chapter 1587: a consumer sees not only that the $\mathsf{Real}^{\uparrow}$ name is apart from zero, but also the finite radius, window, regular readback, and located-apartness handoff that make the witness inspectable. The dependency surface is the sealed $\mathsf{Real}^{\uparrow}$ row of chapter 38, the positive-real row of chapter 1587, the separation row of chapter 304, the located handoff of chapter 1380, the located-real boundary of **??**, the dyadic radius ledger of chapter 291, the stream-window interface of chapter 126, and the regular-rational readback of chapter 301.

Definition 2029.1 (Located positive real carrier)**.** *A* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *carrier is a finite packet*

$$X = (R, P, A, L, D, W, Q, H, C, S, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row for the real-name presentation being certified.*
2. *P is the* $\mathsf{PositiveReal}^{\uparrow}$ *row naming positivity by apartness from the zero real-name row.*
3. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *separation-to-zero row whose endpoints are the zero real-name row and R.*
4. *L is the* $\mathsf{LocatedApartness}^{\uparrow}$ *handoff row displaying how the separation witness is inspected at the requested finite window.*
5. *D is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row used by A and exposed again by L.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the zero row, R, and the radius comparison are observed.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W and to the rational observations used by the radius comparison.*
8. *H records componentwise* hsame *transport for the real seal, positive row, apartness row, located handoff, dyadic radius, stream window, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of every consumer route through*

$$P, A, L, D, W, Q \longmapsto R.$$

10. *S is the* Pkg *provenance over* $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedPositiveReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, P, A, L, D, W, Q, H, C, S, N$. It has no coordinate for trichotomy, a total order on constructive reals, quotient stream equality, a selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.LocatedPositiveRealUp.LocatedPositiveRealTasteGate single carrier alignment`

Theorem 2029.2 (Located positive real NameCert obligations)**.** *For every accepted* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *carrier*

$$X = (R, P, A, L, D, W, Q, H, C, S, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedPositiveReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real seal, positive-real row, apartness-to-zero row, located-apartness handoff, positive dyadic radius, stream window, regular readback, transport, replay, provenance, and local naming rows;*
2. *positivity alignment, requiring P to read its positive witness only through the same A, D, W, Q rows displayed by the carrier;*
3. *located-apartness exposure, requiring L to display the inspection route for A before any metric, order, or completion-facing consumer can use the separation from zero;*
4. *radius exactness, requiring D to be the unique positive dyadic radius row exported by both the apartness and located-apartness coordinates;*
5. *real-seal factorization, requiring every read of R as a positive located object to pass through P, A, L, D, W, Q first;*
6. *transport and replay stability, requiring H, C, S, N to preserve and name exactly the displayed rows, with no trichotomy, total order, quotient stream equality, selected limit, ambient completeness, Lean verification, or bridge credential.*

No located-positive-real NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 2029.1. Carrier admission exposes exactly the sealed real row, the positive-real row, the apartness-to-zero row, the located-apartness handoff, the positive dyadic radius, the stream window, the regular readback, and the four structural rows.

The positivity alignment is the comparison between P and A. The $\mathsf{PositiveReal}^{\uparrow}$ row names positivity only by apartness from zero, and the apartness row displayed here is the sole separation-to-zero source in the carrier.

Located exposure is then supplied by L. It makes the finite inspection route visible before a downstream consumer can use the separation, so the route passes through the located-apartness handoff rather than through an uninspected order predicate.

The radius and readback rows exhaust the witness data. The positive radius is D, and the finite observations supporting it are the window W and readback Q.

Finally, componentwise transport and replay through H and C preserve the same rows, while S and N only record provenance and local naming. Since the carrier contains no trichotomy, total order, quotient stream equality, selected limit, ambient completeness, Lean verification, or bridge credential, the listed rows are the whole obligation surface. □

Theorem 2029.3 (Located positive real apartness witness)**.** *Every accepted* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *carrier*

$$X = (R, P, A, L, D, W, Q, H, C, S, N)$$

exports a displayed located-apartness witness for the positivity of R*: the witness is the finite route from the* $\mathsf{PositiveReal}^{\uparrow}$ *row* P *through the* $\mathsf{ApartnessReal}^{\uparrow}$ *separation row* A*, the* $\mathsf{LocatedApartness}^{\uparrow}$ *handoff* L*, the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*. This route is available without a trichotomy decision, a total-order comparison, quotient stream equality, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier. By Definition 2029.1, the positive row P is displayed in the same finite packet as the sealed real row R and the separation-to-zero row A.

Read the separation witness. The apartness row A names the zero-to-R gap, while D records the positive dyadic radius used by that gap.

The witness is located because L displays the finite inspection route for the same gap. The stream window W and regular readback Q are the only observation rows available to that route.

Thus every exported positivity witness is the displayed route P, A, L, D, W, Q. The excluded order, quotient, selected-limit, and completeness data are absent from the carrier inventory. □

Theorem 2029.4 (Located positive real transport stability)**.** *Let*

$$X = (R, P, A, L, D, W, Q, H, C, S, N)$$

and

$$X' = (R', P', A', L', D', W', Q', H', C', S', N')$$

be accepted $\mathsf{LocatedPositiveReal}^{\uparrow}$ *carriers related by the displayed componentwise* hsame *and* Cont *routes. Then the located positivity witness of Definition 2029.3 transports from* X *to* X' *by carrying the same real-seal, positive row, apartness row, located handoff, radius, window, readback, provenance, and local naming surfaces componentwise. No transported read may replace that witness by trichotomy, a total order, quotient stream equality, a selected limit, or ambient completeness.*

Proof. Apply Definition 2029.3 to X. The witness surface consists only of P, A, L, D, W, Q together with the surrounding seal, transport, replay, provenance, and local naming rows.

Now use the displayed hsame rows in H and H'. They compare the real seal, positive row, apartness row, located handoff, radius, window, and readback componentwise, so the same witness surface is carried to P', A', L', D', W', Q'.

Replay through C and C' preserves the order of the route. The provenance and local naming rows S, N, S', N' merely record the same packet boundary.

Therefore the transported object still exports located positivity by the displayed apartness route. The excluded order, quotient, selected-limit, and completeness coordinates cannot appear under transport because they are not coordinates of either accepted carrier. □

Theorem 2029.5 (Located positive real nonescape)**.** *Every metric, order-facing, or completion-facing consumer of an accepted* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *carrier receives only the rows*

$$R, P, A, L, D, W, Q, H, C, S, N$$

before using the positivity of the displayed real name. In particular, the consumer cannot extract trichotomy for $\mathsf{Real}^{\uparrow}$*, a total real order, quotient stream equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge from the located-positive-real packet.*

Proof. Project the accepted packet. Its only real-facing coordinate is R, and its only positivity coordinate is the displayed route through P, A, L, D, W, Q.

Any consumer of positivity must therefore read P and then the apartness and located-apartness rows A, L. The dyadic radius D, stream window W, and readback Q are the finite witness surface attached to that route.

The structural rows H, C, S, N do not create further mathematical data. They transport, replay, source, and name the rows already displayed by the carrier.

The packet inventory is exhausted by the displayed rows. Hence none of the excluded trichotomy, total-order, quotient-equality, selected-limit, ambient-completeness, Lean-verification, or bridge data can escape from the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedPositiveReal}\uparrow}$.

Constructive story: A $\mathsf{LocatedPositiveReal}^{\uparrow}$ packet is generated from a sealed RealUp row, a PositiveRealUp positivity row, an ApartnessRealUp separation-to-zero row, a LocatedApartnessUp handoff, a positive DyadicRatCoreUp radius, a StreamNameUp window, a RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedPositiveReal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2029.1, Definition 2029.2, Definition 2029.3, Definition 2029.4, and Definition 2029.5 seed the finite located-apartness witness route for positive real packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedPositiveReal}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedPositiveRealUp.LocatedPositiveRealTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, total order, quotient stream equality, selected limits, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, positivity alignment, located-apartness exposure, radius exactness, real-seal factorization, transport/replay/provenance stability, and non-escape for BEDC.Derived.LocatedPositiveRealUp.

Chapter 2030

A Concrete Naming Certificate for $\mathsf{BrouwerFixedPoint}^{\uparrow}$

Following Brouwer and Sperner, the $\mathsf{BrouwerFixedPoint}^{\uparrow}$ packet names the finite dyadic-subdivision route by which a compact convex self-map is inspected before any fixed point is read. It is grounded in the finite labeled-simplex certificate of chapter 2003, the simplex inventory of chapter 238, the dyadic subdivision and cover rows of chapter 1863 and chapter 446, the self-map interface of chapter 130, and the sealed real-name surface of chapter 38. The chapter records a finite NameCert route for approximate fixed-simplex readback, not a host fixed-point choice.

Definition 2030.1 (Brouwer fixed-point carrier)**.** *A* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *carrier is a finite packet*

$$B = (K, S, D, L, W, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact convex dyadic-domain row. It records the accepted finite simplex or polytope inventory, face incidence, convex-combination closure, and dyadic mesh scale used by the self-map packet.*
2. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *row naming the carried finite simplicial subdivision of K.*
3. *D is the paired* $\mathsf{DyadicPartition}^{\uparrow}$ *and* $\mathsf{DyadicCover}^{\uparrow}$ *row. It records the dyadic cells, cell-face incidence, mesh refinement, and finite cover routing used by the labelled subdivision.*
4. *L is the Sperner-labelling row. It contains the boundary-admissible labels induced by the displacement of the self-map and the finite transport of those labels along the faces of S and cells of D.*
5. *W is the approximate fixed-simplex witness row. It records the fully labelled simplex supplied through* $\mathsf{SpernerLemma}^{\uparrow}$*, the associated dyadic cell, and the finite residual bounds read from the self-map rows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the real-name readback used to keep the approximate fixed simplex inside the displayed compact convex domain and to prevent escape through an ambient completion principle.*
7. *H records componentwise* hsame *transport for the domain, simplicial subdivision, dyadic partition and cover, labelling, witness, seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for every consumer route through*

$$K, S, D, L, W \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{SpernerLemma}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, D, L, W, E, H, C, P, N$. It has no coordinate for a host fixed-point choice, open-cover compactness, real trichotomy, quotient stream equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BrouwerFixedPointUp.BrouwerFixedPointTasteGate single carrier alignment`

Theorem 2030.2 (Brouwer fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *carrier*

$$B = (K, S, D, L, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerFixedPoint}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed compact convex dyadic domain, simplicial subdivision, dyadic partition and cover, Sperner labelling, approximate fixed-simplex witness, RealUp seal, transport, replay, provenance, and local naming rows;*
2. *boundary labelling, requiring L to read all boundary colors from the displacement rows of the carried* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map and from the boundary faces displayed by S and D;*
3. *Sperner handoff, requiring the fully labelled simplex coordinate of W to enter only through the* $\mathsf{SpernerLemma}^{\uparrow}$ *packet and its finite labelled-simplex route;*
4. *approximate fixed-point readback, requiring the residual and cell-diameter data in W to be read through K, S, D, L before a consumer can inspect the approximate fixed simplex;*
5. *RealUp seal nonescape, requiring E to keep the readback inside the displayed compact convex dyadic domain without adding host fixed-point choice, open-cover compactness, real trichotomy, quotient stream equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Brouwer fixed-point NameCert obligation is stored outside these finite rows.

Proof. Carrier admission is projection from Definition 2030.1. The visible packet lists the compact convex dyadic domain row K, the simplicial subdivision row S, the dyadic partition and cover row D, the labelling row L, the witness row W, and the structural rows E, H, C, P, N.

Boundary labelling is the row L. Its admissible colors are read after the finite boundary faces of S and the dyadic cell incidence of D have been displayed, and the only map data available to the read is the carried $\mathsf{ContinuousMap}^{\uparrow}$ self-map surface named in the provenance row.

The Sperner handoff is the fully labelled simplex part of W. Since the carrier places that witness downstream of L and records $\mathsf{SpernerLemma}^{\uparrow}$ in P, a consumer reaches the labelled simplex only through the finite Sperner route.

Approximate fixed-point readback uses the same witness row W together with the mesh and residual information from K, S, D, L. These rows determine the displayed approximate fixed simplex before the seal row is inspected.

Finally, E seals the readback as a $\mathsf{Real}^{\uparrow}$-facing object inside the carried domain. The remaining rows transport, replay, source, and name the same finite packet, so no excluded host fixed-point, open-cover, trichotomy, quotient, selected-limit, completeness, verification, or bridge data can appear as an extra obligation. □

Theorem 2030.3 (Brouwer fixed-point Sperner handoff)**.** *Every accepted* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *fixed-point read factors through the displayed route*

$$\mathsf{SpernerLemma}^{\uparrow} \longmapsto \mathsf{SimplicialComplex}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicCover}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, the read uses the carrier rows $K, S, D, L, W, E, H, C, P, N$ *to obtain a finite approximate fixed-simplex certificate. It exports no host fixed-point choice, open-cover compactness, real trichotomy, quotient stream equality, selected limit, or ambient Real completeness.*

Proof. Project the accepted carrier. The only row that exposes a fixed-point-facing witness is W, and W is specified as the approximate fixed-simplex witness supplied through the finite labelled-simplex route of $\mathsf{SpernerLemma}^{\uparrow}$.

Reading W first requires the finite geometry rows S and D. These provide the simplicial-complex inventory, dyadic partition, and dyadic cover routing on which the Sperner labels are meaningful.

The labels in L are tied to the carried $\mathsf{ContinuousMap}^{\uparrow}$ self-map surface. Their displacement readback is then sealed by E as a $\mathsf{Real}^{\uparrow}$-facing object inside the compact convex dyadic domain row K.

Thus every fixed-point read factors through the named finite route and then through the structural rows H, C, P, N. Since none of the carrier coordinates is a host fixed-point choice, an open-cover compactness theorem, real trichotomy, quotient stream equality, a selected limit, or ambient Real completeness, none of those objects is exported. □

Theorem 2030.4 (Brouwer fixed-point finite residual stability)**.** *Let*

$$B = (K, S, D, L, W, E, H, C, P, N)$$

and

$$B' = (K', S', D', L', W', E', H', C', P', N')$$

be accepted $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *packets. If the displayed transport rows identify* $K, S, D, L, W, E, H, C, P, N$ *componentwise with* $K', S', D', L', W', E', H', C', P', N'$ *by* hsame*, then the residual bounds read from* W *are transported only through the same dyadic subdivision row* D*, the same Sperner labelling row* L*, the carried* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. In particular, no host fixed-point choice, selected limit, trichotomy datum, quotient stream equality, or ambient Real completeness row can alter the residual comparison.*

Proof. Project the two accepted carriers. The residual bounds occur only in the approximate fixed-simplex witness row W, and the carrier places that row downstream of the compact domain, subdivision, dyadic partition, and Sperner labelling rows.

Use the Sperner handoff of Definition 2030.3. It forces the labelled simplex in W through the finite route from $\mathsf{SpernerLemma}^{\uparrow}$ to $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and finally $\mathsf{Real}^{\uparrow}$.

The rows D and L are read before W, so the dyadic subdivision and Sperner labels are fixed before any residual bound is public. Componentwise transport through H carries those rows together with the witness row, and displayed replay through C repeats the same finite route for downstream consumers.

The terminal seal E only records the $\mathsf{Real}^{\uparrow}$-facing readback inside the displayed compact convex domain. Since the carrier contains no coordinate for a host fixed point, selected limit, trichotomy, quotient stream equality, or ambient Real completeness, none of those objects can change the finite residual row. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerFixedPoint}^{\uparrow}$ packet is generated from a compact convex dyadic domain row, a SimplicialComplexUp subdivision row, DyadicPartitionUp and DyadicCoverUp rows, a Sperner-labelled boundary row, an approximate fixed-simplex witness row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2030.1, Definition 2030.2, Definition 2030.3, and Definition 2030.4 seed the finite Brouwer fixed-point route from dyadic compact-convex data through Sperner labelling, approximate fixed-simplex readback, residual stability, RealUp sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point choice, open-cover compactness, real trichotomy, quotient stream equality, selected limits, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, boundary labelling, Sperner handoff, approximate fixed-point readback, RealUp seal nonescape, transport/replay/provenance stability, and non-escape for BEDC.Derived.BrouwerFixedPoin

Chapter 2031

A Concrete Naming Certificate for $\mathsf{FiniteChoice}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen on finite choice, the $\mathsf{FiniteChoice}^{\uparrow}$ packet records finite index selection over displayed $\mathsf{List}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, and $\mathsf{Bool}^{\uparrow}$ rows and over the L10 $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ windows. It sits beside the countable-choice refusal surface of chapter 1872, the finite stream-window interface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion arguments a visible finite selector boundary while refusing countable-choice selectors.

Definition 2031.1 (FiniteChoice carrier)**.** *A* $\mathsf{FiniteChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, O, B, L, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-list row. It records a displayed* $\mathsf{List}^{\uparrow}$ *of inspected indices together with the order in which the packet reads them.*
2. *O is the* $\mathsf{Option}^{\uparrow}$ *decidability row, carrying for each displayed index either a selected row or an explicit absence token.*
3. *B is the* $\mathsf{Bool}^{\uparrow}$ *decisional ledger attached to O, recording the boolean case used for each finite option inspection.*
4. *L is the selected-row ledger. It contains only the rows selected from the displayed finite list and records no selector outside I.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened for the selected finite indices.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows in W.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after I, O, B, L, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the index list, option and boolean rows, selected ledger, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the finite index-list row through $O, B, L, W, R, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteChoice}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for countable choice, selected infinite branches, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FiniteChoiceUp.FiniteChoiceTasteGate single carrier alignment`

Theorem 2031.2 (FiniteChoice NameCert obligations)**.** *For every accepted* $\mathsf{FiniteChoice}^{\uparrow}$ *carrier*

$$F = (I, O, B, L, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteChoice}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed index-list row, option decidability row, boolean decision ledger, selected-row ledger, StreamName window row, RegSeqRat readback row, Real seal row, transport, replay, provenance, and local naming;*
2. *finite index coverage, requiring every selected row to appear in the displayed* $\mathsf{List}^{\uparrow}$ *row I;*
3. *option and boolean case exactness, requiring O and B to account for each selected or absent finite case before the selected-row ledger L is read;*
4. *window selection, requiring each stream window in W to be opened only for an index accepted by the finite selected-row ledger;*
5. *rational readback, requiring R to consume the displayed windows in W rather than a detached stream quotient or selected limit;*
6. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring S to remain downstream of I, O, B, L, W, R and to add no countable selector, infinite branch, quotient stream equality, trichotomy, ambient completeness principle, Lean verification, or bridge data;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No local finite-choice obligation is stored outside these rows.

Proof. Project the carrier of Definition 2031.1. The visible choice data are exactly the finite index list I, the option row O, the boolean decision ledger B, and the selected-row ledger L.

Finite index coverage follows by case analysis over the displayed $\mathsf{List}^{\uparrow}$ row. In the empty-list case, no selected row can be exported. In the cons case, the head index is inspected by O and B, and the tail is handled by the same finite projection.

Option and boolean exactness is local to O and B. The present case contributes its selected row to L, while the absent case contributes only the explicit absence token. The mixed cases are exhausted because the boolean ledger records one displayed decision for each option row.

The analytic handoff then follows the selected rows. Each accepted selected row opens a finite $\mathsf{StreamName}^{\uparrow}$ window in W, and every regular rational readback in R consumes one of those windows.

Finally, S is terminal and H, C, P, N only transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for the excluded objects, the listed rows exhaust the local $\mathsf{NameCert}$ surface. □

Theorem 2031.3 (FiniteChoice window selection boundary)**.** *Let $F = (I, O, B, L, W, R, S, H, C, P, N)$ be an accepted* $\mathsf{FiniteChoice}^{\uparrow}$ *carrier. Every* $\mathsf{StreamName}^{\uparrow}$ *window exported by F is selected by the finite route*

$$I \longmapsto O \longmapsto B \longmapsto L \longmapsto W.$$

Consequently a window consumer may inspect selected finite windows and their option/boolean decisions, but it receives no countable selector, selected infinite branch, detached quotient stream, or ambient real-completeness witness.

Proof. Begin with an exported stream window. By carrier projection, the only window coordinate is W.

The row W is not free-standing. It is downstream of the finite index-list row I, the option row O, the boolean ledger B, and the selected-row ledger L.

Now split by the displayed option cases. A present option contributes a selected finite row to L and therefore may open the corresponding window in W. An absent option contributes no selected row, so no window can be exported from that index.

The rows H, C, P, N preserve and name this finite route without adding a second selector. Thus every exported window is selected by the displayed finite route, and all countable or completion-level choice data remain outside the packet. □

Theorem 2031.4 (FiniteChoice Real-completion handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{FiniteChoice}^{\uparrow}$ *carrier*

$$F = (I, O, B, L, W, R, S, H, C, P, N)$$

must read the finite route

$$\mathsf{List}^{\uparrow} \longmapsto \mathsf{Option}^{\uparrow} \longmapsto \mathsf{Bool}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by I, O, B, L, W, R, S. The handoff permits finite selection for the displayed windows and readbacks only; it does not supply countable choice, selected infinite branches, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier and read the Real-facing coordinate. The only Real seal row is S, and it is exposed only after the finite index, option, boolean, selected-row, stream-window, and regular-readback rows have been displayed.

Apply the window boundary of Definition 2031.3. Every window consumed by the Real or Completion route has already passed through the finite $\mathsf{List}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, and selected-ledger rows.

The readback row R then supplies the regular rational data for those windows, and the terminal seal S records the $\mathsf{Real}^{\uparrow}$ handoff. This route is finite because its source is the displayed list I and its case analysis is exhausted by the option and boolean rows.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no excluded coordinate is present, a Real or Completion consumer receives finite selection data only through I, O, B, L, W, R, S and receives none of the stronger choice or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteChoice}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2031.1, Definition 2031.2, Definition 2031.3, and Definition 2031.4 seed the finite selection boundary used by L10 stream, regular-rational, and real-name windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected infinite branches, quotient stream equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite index coverage, option and boolean exactness, window selection, RegSeqRat readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteChoiceUp.

Constructive story: A FiniteChoice$^{\uparrow}$ packet is generated from one finite ListUp index row, OptionUp decidability rows, BoolUp decision rows, a selected-row ledger, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2032

A Concrete Naming Certificate for $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$

Following Bishop–Bridges constructive analysis, uniform continuity carries Cauchy source names to Cauchy target names by one displayed modulus schedule, not by ambient function equality or quotient completion. The $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$ packet records that standard theorem as finite NameCert data over the Cauchy-name theorem surface of chapter 1642, the uniform modulus boundary of chapter 391, the finite source-window interface of chapter 126, the source regular-rational route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It gives later Real and Completion chapters a finite route for transporting Cauchy convergence through a uniform modulus before any quotient stream, selected limit, countable-choice schedule, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 2032.1 (Cauchy uniform-continuity principle carrier)**.** *A* $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, D, U, M, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row naming the regular Cauchy source data inspected by the theorem route.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the source name, the modulus request, and the target tail handoff.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested target precision, the uniform source budget, and the comparison arithmetic used by the handoff.*
4. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *row supplying the uniform modulus used for all source windows in the packet.*
5. *M is the* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *row, or the displayed modulus-compatibility row, witnessing that the uniform modulus in U is read as the Cauchy-continuity modulus required by the source Cauchy route.*
6. *T is the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *target handoff obtained after S, W, D, U, M have been replayed.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the target regular Cauchy tail row T is displayed.*
8. *H records componentwise* hsame *transport for S, W, D, U, M, T, E and for the structural replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a target tolerance request through D, then the uniform row U, then the source row S through windows W, then the compatibility row M, then the target tail estimate T, and finally the seal row E.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$, $\mathsf{CauchyContinuityPrinciple}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, U, M, T, E, H, C, P, N$ and the displayed replay order. It has no coordinate for host function equality, quotient completion, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyUniformContinuityPrincipleUp.CauchyUniformContinuityPrincipleTasteGate`
`single carrier alignment`

Theorem 2032.2 (Cauchy uniform-continuity principle NameCert obligations)**.** *For every accepted* $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$ *carrier $Q = (S, W, D, U, M, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source regular Cauchy row, finite source windows, dyadic tolerance ledger, uniform-continuity row, modulus-compatibility row, target regularity handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *uniform modulus exactness, requiring every target tolerance to obtain its source-window budget only through D and the uniform row U;*
3. *source-window stability, requiring the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row S and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W to be transported componentwise by H and replayed in the same order by C;*
4. *target regularity handoff, requiring the target Cauchy read to pass through the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *row T before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed;*
5. *Real-seal non-escape, requiring every real-facing read to consume the displayed route D, U, S, W, M, T, E;*
6. *transport and replay preservation, requiring H and C to preserve the displayed coordinates and their row order;*
7. *provenance exhaustion, requiring P to name only the sibling chapters and kernel rows listed in Definition 2032.1;*
8. *local naming, requiring N to name exactly the local certificate row for* $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$.

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2032.1. The accepted packet exposes exactly the rows $S, W, D, U, M, T, E, H, C, P, N$.

Uniform modulus exactness is exhausted by D and U. A target tolerance first reads the dyadic ledger, then the uniform-continuity row, and only then obtains the source-window budget used on S through W.

Source-window stability follows by inspecting H and C. The transport row moves S and W componentwise, while the replay row keeps the same order in every accepted packet.

For the target handoff, read M and T. The row M records the Cauchy-modulus or compatibility surface needed to use the uniform modulus on the Cauchy route, and T records the regular Cauchy target tail estimate produced from the replayed source data.

The Real seal is downstream of that handoff. Since E appears only after D, U, S, W, M, T in the continuation route, every real-facing read must pass through the displayed finite chain.

Finally inspect P and N. The provenance row names only the listed sibling chapters and kernel rows, and the local naming row names only this certificate. Because the carrier inventory contains no further coordinate, the eight obligations exhaust the NameCert surface. □

Theorem 2032.3 (Cauchy uniform-continuity principle finite handoff)**.** *Let $Q = (S, W, D, U, M, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$ *carrier. Every target* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by the packet factors through the finite route*

$$D, U, S, W, M, T.$$

Consequently the target Cauchy name is obtained from the source regular-rational row, finite windows, dyadic tolerance ledger, uniform modulus, compatibility row, and target tail estimate before the $\mathsf{Real}^{\uparrow}$ *seal is available.*

Proof. Start with the tolerance request. The dyadic ledger D supplies the requested target precision and the comparison budget used to choose the source window.

Next read the uniform modulus. The row U is the only uniform-continuity coordinate in the carrier, so the source-window budget for every source observation comes from U through D.

The source name is then inspected through S and W. The source row supplies the regular Cauchy data, and the window row supplies the finite observations admitted by the packet.

Use the compatibility row M to enter the Cauchy-name theorem surface. It records that the uniform modulus has the Cauchy-continuity form required for the source-to-target handoff.

The target read is forced through T. This row is the only target regularity handoff in the carrier, and the seal row E is downstream of it. Hence every exported target $\mathsf{RegSeqRat}^{\uparrow}$ read factors through the stated finite route. □

Theorem 2032.4 (Cauchy uniform-continuity principle Real boundary)**.** *For every accepted* CauchyUniformContinu *carrier $Q = (S, W, D, U, M, T, E, H, C, P, N)$, every* $\mathsf{Real}^{\uparrow}$ *consumer of the seal row E first reads the displayed sequence of sibling surfaces*

$\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$, RegularCauchyTail

The consumer receives no host function equality, quotient completion, countable-choice selector, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge-checking row.*

Proof. Read the seal coordinate in Definition 2032.1. The row E is listed only as the terminal $\mathsf{Real}^{\uparrow}$ seal reached after the target regular Cauchy tail row T is displayed.

Apply Definition 2032.3. The target regular Cauchy read has already passed through D, U, S, W, M, T before a real-facing consumer can inspect the seal.

Replay the structural rows. The continuation row C preserves the dependency order, the transport row H preserves the same finite coordinates, and the provenance and naming rows P, N record no additional source.

Thus every Real consumer receives exactly the displayed finite route through the sibling surfaces. The excluded principles cannot be exported because they are absent from the carrier inventory. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2032.1, Definition 2032.2, Definition 2032.3, and Definition 2032.4 seed the finite route carrying displayed Cauchy source names through a uniform modulus to displayed target Cauchy names before Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient completion, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform modulus exactness, source-window stability, target regularity handoff, Real-seal nonescape, transport and replay preservation, provenance exhaustion, and local naming for BEDC.Derived.CauchyUniformContinuityPrincipleUp.

Constructive story: A $\mathsf{CauchyUniformContinuityPrinciple}^{\uparrow}$ packet is generated from a source RegSeqRat row, finite StreamName windows, a DyadicRatCore tolerance ledger, a UniformContinuity row, a CauchyModulusOfContinuity or modulus-compatibility row, a RegularCauchyTailEstimate target handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2033

A Concrete Naming Certificate for $\mathsf{UniformPartition}^{\uparrow}$

Following Bishop–Bridges/Riemann-Darboux uniform partitions, the $\mathsf{UniformPartition}^{\uparrow}$ packet records a finite equal-mesh subdivision of a displayed real interval. It sits between the $\mathsf{Real}^{\uparrow}$ interval source, the dyadic endpoint and mesh ledgers of chapter 1863 and chapter 358, and the Darboux, Riemann, and regulated-function consumers of chapter 1880, chapter 1526, and chapter 1906. The packet gives those consumers a single finite NameCert surface for equal-width cells without importing open-cover compactness, selected tags, quotient function equality, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2033.1 (Uniform partition carrier)**.** *A* $\mathsf{UniformPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, O, \delta, k, E, B, M, T, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval source row, naming the left and right real endpoint seals and the direction in which the finite partition is read.*
2. *O is the dyadic origin row from which the equal mesh is generated.*
3. *δ is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-width row.*
4. *k is a unary cell-count row, recording the finite number of equal-width cells without using an ambient natural-number search principle.*
5. *E is the equal-width cell ledger. Its jth row records the dyadic endpoints $O+j\delta$ and $O+(j+1)\delta$, the adjacency check between successive cells, and the local width equality to δ.*
6. *B is the endpoint coverage row, asserting that the first cell begins at the interval source and the last cell reaches the displayed terminal endpoint through the same dyadic origin, width, and count rows.*
7. *M is the* $\mathsf{DyadicPartition}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$ *handoff row, exposing the ordered finite partition and its mesh bound to downstream dyadic consumers.*
8. *T is the Darboux, Riemann, and* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer-boundary row. It records that those consumers may read the interval, equal cells, endpoint coverage, and dyadic handoff, but not tags, integrand quotients, measure completions, or open-cover compactness.*

9. *H records componentwise* hsame *transport for the interval source, origin, positive width, count, equal-cell ledger, endpoint coverage, dyadic handoff, consumer boundary, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$I, O, \delta, k \longmapsto E \longmapsto B \longmapsto M \longmapsto T.$$

11. *P is the* Pkg *provenance over* $\mathsf{UniformPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, O, \delta, k, E, B, M, T, H, C, P, N$. It has no coordinate for open-cover compactness, selected tags, quotient function equality, measure completion, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.UniformPartitionUp.UniformPartitionTasteGate single carrier alignment`

Theorem 2033.2 (Uniform partition NameCert obligations)**.** *For every accepted* $\mathsf{UniformPartition}^{\uparrow}$ *carrier*

$$U = (I, O, \delta, k, E, B, M, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformPartition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval source, dyadic origin, positive mesh width, unary cell count, equal-width cell ledger, endpoint coverage, dyadic handoff, consumer boundary, transport, replay, provenance, and local naming rows;*

2. *equal-mesh exactness, requiring every cell listed in E to have width δ and to be adjacent to its successor through displayed dyadic arithmetic;*

3. *endpoint coverage, requiring B to identify the first and last cell boundaries with the interval source row I through O, δ, k, E;*

4. *dyadic handoff, requiring M to expose only the ordered* $\mathsf{DyadicPartition}^{\uparrow}$ *row and the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh-bound row computed from the same ledger E;*

5. *consumer boundary, requiring T to route Darboux, Riemann, and regulated-function consumers through I, E, B, M before any integration-facing read is available;*

6. *structural stability, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows.*

No local certificate obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2033.1. The accepted packet lists the interval row, dyadic origin, positive width, unary count, cell ledger, endpoint coverage, dyadic handoff, consumer boundary, and the four structural rows.

Equal-mesh exactness is the projection to E. Each finite cell row contains its two dyadic endpoints, the displayed adjacency relation to neighboring cells, and the equality of its width with δ.

Endpoint coverage is the projection to B. The first and last boundaries are read through the same origin, width, count, and ledger, so coverage does not appeal to compactness or to an external subdivision theorem.

The dyadic and integration-facing exports are terminal. Row M exposes the ordered partition and mesh bound, while T records the permitted Darboux, Riemann, and regulated-function consumers. Rows H, C, P, N transport, replay, source, and name only this finite surface, so the excluded host principles are absent from the obligation set. □

Theorem 2033.3 (Uniform partition dyadic mesh handoff)**.** *Every accepted* $\mathsf{UniformPartition}^{\uparrow}$ *packet hands off to* $\mathsf{DyadicPartition}^{\uparrow}$ *and* $\mathsf{DyadicMesh}^{\uparrow}$ *consumers only through the finite route*

$$I, O, \delta, k \longmapsto E \longmapsto B \longmapsto M.$$

The row M therefore exposes an ordered dyadic partition, a positive mesh width, endpoint coverage, and the mesh bound as a single visible object; it does not export selected tags, open-cover compactness, quotient equality of functions, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only dyadic consumer coordinate is M, and the displayed replay row C places M after the interval source, origin, width, count, equal-cell ledger, and endpoint coverage rows.

The ordered partition read is supplied by E and B. Each cell row in E gives its dyadic endpoints and equal width, while B fixes the first and last endpoints against the real interval source.

The mesh read is therefore the same finite ledger viewed through $\mathsf{DyadicMesh}^{\uparrow}$. Since no tag, compactness, quotient, measure, or completeness coordinate is present in the carrier, the handoff cannot expose those host objects. □

Theorem 2033.4 (Uniform partition integration consumer boundary)**.** *A* $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, *or* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformPartition}^{\uparrow}$ *carrier receives only the interval row I, equal-cell ledger E, endpoint coverage row B, dyadic handoff M, consumer-boundary row T, and structural rows H, C, P, N. The consumer may use the finite equal-mesh partition as a mesh surface, but the packet does not supply tags, lower or upper sums, integrand equality, a measure-completion object, open-cover compactness, or ambient real completeness.*

Proof. Begin with the consumer-boundary row T. By Definition 2033.1, T is downstream of the displayed route through I, O, δ, k, E, B, M.

A Darboux or Riemann consumer may read the equal-width cells and endpoint coverage through E and B, then use M as the dyadic partition or mesh surface. The carrier does not contain lower sums, upper sums, selected tags, or an integrand row, so those data must be supplied by the consuming chapter.

A regulated-function consumer receives the same finite partition boundary. Rows H, C, P, N preserve, replay, source, and name the route, but they do not create quotient function equality, measure completion, compactness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformPartition}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ interval source row, dyadic origin row, positive dyadic mesh-width row, unary cell-count row, equal-width cell ledger, endpoint coverage row, $\mathsf{DyadicPartition}^{\uparrow}$ and $\mathsf{DyadicMesh}^{\uparrow}$ handoff row, Darboux, Riemann, and regulated-function consumer boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2033.1, Definition 2033.2, Definition 2033.3, and Definition 2033.4 seed the finite equal-mesh partition certificate over the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected tags, quotient function equality, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, equal-mesh exactness, endpoint coverage, dyadic handoff, integration consumer boundary, transport, replay, provenance, and local NameCert rows for BEDC.Derived.UniformPartitionUp.

Chapter 2034

A Concrete Naming Certificate for $\mathsf{GronwallInequality}^{\uparrow}$

Following Gronwall and the Bishop–Bridges constructive ODE route, the $\mathsf{GronwallInequality}^{\uparrow}$ packet records the finite majorant certificate by which a nonnegative error envelope is bounded before a Picard local-flow comparison is read. It consumes the local existence route of chapter 1888, the local-flow endpoint surface of chapter 1899, the Lipschitz ledger of chapter 410, the complete-metric convergence boundary of chapter 128, the sealed real-name row of chapter 38, the regular rational readback of chapter 301, and the dyadic arithmetic core of chapter 291. The packet names only a displayed comparison route over finite interval, Lipschitz, envelope, dyadic exponential majorant, Picard-flow comparison, transport, replay, provenance, and local naming rows.

Definition 2034.1 (Gronwall inequality carrier)**.** *A* $\mathsf{GronwallInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, L, E, D, M, F, R, H, C, G, N)$$

with the following visible rows:

1. *I is the interval row, recording the displayed time window, its endpoint order, and the local* $\mathsf{Real}^{\uparrow}$ *names through which the comparison is inspected.*
2. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *row naming the Lipschitz constant used by the ODE or local-flow comparison on the same interval.*
3. *E is the nonnegative envelope row, storing the displayed error or separation function, its initial bound, and the monotonicity reads used by downstream comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponential-majorant row, containing the dyadic coefficients, finite truncation budget, and upper rational enclosure for the Gronwall factor.*
5. *M is the majorant comparison row, asserting that every inspected envelope read in E is bounded by the dyadic exponential row D after reading the Lipschitz row L and interval row I.*
6. *F is the Picard-flow comparison row, supplied by* $\mathsf{PicardLindelof}^{\uparrow}$ *or* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ *when the carrier is consumed by local ODE stability.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations of the interval, Lipschitz constant, envelope samples, and dyadic majorant.*

8. *H records componentwise* hsame *transport for the interval, Lipschitz ledger, envelope, dyadic majorant, comparison, Picard-flow handoff, rational readback, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through*

$$I, L, E, D, M, F, R \longmapsto \mathsf{NameCert}_{\mathsf{GronwallInequality}^{\uparrow}}.$$

10. *G is the* Pkg *provenance row over* $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GronwallInequality}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient real-completeness principle, a host ODE solver, a choice-selected solution curve, a host equality of functions, or a global continuation theorem.

Theorem 2034.2 (Gronwall inequality NameCert obligations)**.** *For an accepted* $\mathsf{GronwallInequality}^{\uparrow}$ *carrier*

$$P = (I, L, E, D, M, F, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{GronwallInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, dyadic majorant admission for D, envelope monotonicity for E, comparison stability for M, Picard handoff for F, rational readback for R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through G, and local naming through N. No obligation is discharged by a host ODE solver, ambient real completeness, host function equality, or a choice-selected solution curve.*

Lean4 ✓ `BEDC.Derived.GronwallInequalityUp.GronwallInequalityTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 2034.1. The accepted packet displays the interval, Lipschitz ledger, nonnegative envelope, dyadic majorant, comparison, Picard-flow handoff, rational readback, transport, replay, provenance, and local name.

The source rows I, L, E, R determine the comparison problem. The interval row fixes the finite time window, the Lipschitz row supplies the displayed constant, the envelope row supplies the nonnegative quantity being bounded, and the regular-rational row supplies the observations through which the comparison is inspected.

The dyadic majorant obligation is local to D. It records the finite exponential enclosure used by the comparison, so the certificate never needs an unbounded real exponential object or an ambient completeness argument.

The comparison row M then binds the envelope to the majorant after reading I, L, E, D, R. Its stability is componentwise: transporting the interval, Lipschitz, envelope, dyadic, and readback rows transports the displayed inequality route.

Finally F is the only ODE-facing exit. It may hand the bound to $\mathsf{PicardLindelof}^{\uparrow}$ or $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$, but only through the displayed rows. The rows H, C, G, N transport, replay, source, and name this same finite route, so the certificate cannot export a host ODE solver, a choice-selected solution curve, host function equality, or global continuation data. □

Theorem 2034.3 (Gronwall inequality Picard handoff)**.** *Every accepted* $\mathsf{GronwallInequality}^{\uparrow}$ *carrier factors any Picard–Lindelof local-flow stability read through the displayed route*

$$\mathsf{LipschitzMap}^{\uparrow} \longmapsto \mathsf{GronwallInequality}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The read first opens the Lipschitz constant, then the nonnegative envelope, then the dyadic exponential majorant, then the regular-rational observation rows, and only then seals the comparison as a $\mathsf{Real}^{\uparrow}$ *bound usable by* $\mathsf{PicardLindelof}^{\uparrow}$ *or* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$.

Proof. Begin with the accepted carrier P. The only Lipschitz data available to a stability consumer is the row L, and the only envelope data is the row E on the interval I.

Read the majorant next. The row D supplies the finite dyadic exponential enclosure, while R supplies the regular rational observations needed to compare envelope samples with the majorant.

The comparison row M combines these displayed rows into the Gronwall bound. Since M reads I, L, E, D, R before producing the comparison, any resulting real bound is sealed through the same $\mathsf{Real}^{\uparrow}$ row rather than through ambient completeness.

The Picard-facing row F can now consume the bound. It receives only the displayed Lipschitz, envelope, dyadic majorant, regular-rational, and real-seal rows together with transport, replay, provenance, and local naming. Thus every Picard–Lindelof local-flow stability read factors through the stated route and cannot bypass it by invoking a host solver, host function equality, or a choice-selected solution curve. □

Theorem 2034.4 (Gronwall inequality finite integral bound)**.** *For every accepted* $\mathsf{GronwallInequality}^{\uparrow}$ *carrier*

$$P = (I, L, E, D, M, F, R, H, C, G, N),$$

the comparison row M bounds each inspected envelope row in E by the dyadic exponential-majorant row D only after reading the interval row I, the Lipschitz row L, and the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The Picard-facing row F may consume that bound for local-flow stability, but it receives no host ODE solver, global continuation, selected solution curve, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier by Definition 2034.1. The rows I, L, E, D, M, F, R are the only analytic coordinates available to a stability consumer, and the structural rows H, C, G, N only transport, replay, source, and locally name those coordinates.

Apply the obligation surface of Definition 2034.2 to the rows D, E, M, R. The dyadic majorant is admitted by D, the envelope reads are admitted by E, the rational observations are admitted by R, and the comparison stability row M binds them only after the interval and Lipschitz rows have also been opened.

Now route the resulting comparison through Definition 2034.3. The Picard-facing row F receives the displayed finite bound through the same route, so it cannot import a host ODE solver, global continuation, selected solution curve, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{GronwallInequality}^{\uparrow}$ stability read factors through one interval row, one LipschitzMap constant row, one nonnegative envelope row, one DyadicRatCore exponential-majorant row, one comparison row, one Picard-flow handoff, one RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: picardlindelof, picardlindeloflocalflow, lipschitzmap, completemetric, real, regseqrat, dyadicratcore: $\mathsf{GronwallInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the interval, Lipschitz constant, nonnegative envelope, dyadic exponential majorant, Picard-flow comparison, rational readback, and the transport/replay/provenance rows binding them into a finite stability certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{GronwallInequality}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GronwallInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2034.1, Definition 2034.2, and Definition 2034.3 seed the constructive ODE stability route over an interval row, Lipschitz ledger, nonnegative envelope, dyadic exponential majorant, Picard-flow comparison, rational readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{GronwallInequality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ambient Real completeness, a host ODE solver, host function equality, choice-selected solution curves, global continuation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic majorant admission, envelope monotonicity, comparison stability, Picard handoff, rational readback, transport, replay, provenance, and local naming for BEDC.Derived.GronwallInequalityUp.

Constructive story: A GronwallInequality$^{\uparrow}$ packet is generated from one interval row, one LipschitzMap constant row, one nonnegative envelope row, one DyadicRatCore exponential-majorant row, one comparison row, one Picard-flow handoff, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2035

A Concrete Naming Certificate for $\mathsf{DoublingMetric}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis and Kelley's finite-cover regularity language, the $\mathsf{DoublingMetric}^{\uparrow}$ packet records the standard bounded-overlap cover control used before total-bounded, compact-metric, and dimension-facing consumers read a metric space at smaller scales. It sits over the displayed metric source of chapter 57, hands finite center ledgers to chapter 1767 and chapter 127, and supplies scale-local cover data usable by chapter 129. The packet names only finite ball-cover rows, positive radius rows, scale-halving ledgers, transport, replay, provenance, and local naming; it does not import open-cover compactness, a choice-selected cover family, or an ambient semantic doubling theorem.

Definition 2035.1 (Doubling metric carrier)**.** *A* $\mathsf{DoublingMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, \rho, B, K, E, T, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance rows, ball membership reads, and metric-law ledger through which every cover request is inspected.*
2. *ρ is the positive radius ledger. Each row stores a positive rational or dyadic radius request together with the displayed half-radius request used by the next scale.*
3. *B is the ball request row. It names the inspected center, the radius row from ρ, and the parent metric ball whose coverage is being certified.*
4. *K is the center-bundle row, a closed finite* $\mathsf{ProbeBundle}$ *of candidate centers admitted by the same metric source M.*
5. *E is the ball-cover coverage ledger. For every displayed point row admitted by B, it records an admitted center in K and the half-radius distance read witnessing membership in the corresponding smaller ball.*
6. *T is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *handoff row, exposing only the finite center bundle, tolerance read, and coverage witnesses computed from M, ρ, B, K, E.*
7. *S is the scale-halving ledger. It records that every consumer step from radius r to radius $r/2$ reuses the same metric source, the corresponding positive-radius row, and a finite center bundle of the displayed bounded size.*

8. *H records componentwise* hsame *transport for the metric source, positive radius ledger, ball request, center bundle, coverage ledger, finite-net handoff, scale-halving ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, \rho, B \longmapsto K \longmapsto E \longmapsto T \longmapsto S.$$

10. *P is the* Pkg *provenance over* $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DoublingMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, \rho, B, K, E, T, S, H, C, P, N$. It has no coordinate for an open cover, a selected subcover, a global compactness principle, a choice-selected family of centers, ambient real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.DoublingMetricUp.DoublingMetricTasteGate single carrier alignment`

Theorem 2035.2 (Doubling metric NameCert obligations)**.** *For every accepted* $\mathsf{DoublingMetric}^{\uparrow}$ *carrier*

$$D = (M, \rho, B, K, E, T, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DoublingMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, positive radius ledger, ball request, center bundle, coverage ledger, finite-net handoff, scale-halving ledger, transport, replay, provenance, and local naming rows;*

2. *ball-cover coverage, requiring each displayed point in the parent ball B to be covered by one of the centers in K through the half-radius metric read recorded in E;*

3. *scale monotonicity, requiring the ledger S to relate every radius row to its half-radius row without changing the source* $\mathsf{Met}^{\uparrow}$ *carrier or escaping the displayed positive-radius ledger;*

4. *finite-net handoff, requiring T to expose the center bundle and coverage rows only as* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *data over the same metric source;*

5. *transport stability, requiring H and C to preserve and replay the metric, radius, bundle, coverage, handoff, and scale rows componentwise;*

6. *non-escape, requiring every* $\mathsf{CompactMetric}^{\uparrow}$ *or covering-dimension consumer to read only $M, \rho, B, K, E, T, S, H$, and no open-cover compactness or choice-selected cover family.*

No local certificate obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2035.1. The accepted packet displays the metric source, positive radius ledger, ball request, finite center bundle, coverage ledger, finite-net handoff, scale-halving ledger, and the four structural rows.

Ball-cover coverage is the projection to E. Each inspected point in the parent ball named by B is paired with a center from K, and the metric distance row from M witnesses that the point lies in the corresponding half-radius ball.

Scale monotonicity is local to ρ and S. The ledger records the passage from r to $r/2$ as a displayed positive-radius step over the same source metric row, so a consumer cannot replace the metric carrier, alter the ball source, or introduce a hidden real-number choice.

The finite-net handoff is the projection to T. It repackages the same center bundle and coverage rows as $\mathsf{FiniteEpsilonNet}^{\uparrow}$ and $\mathsf{TotallyBounded}^{\uparrow}$ data, which a $\mathsf{CompactMetric}^{\uparrow}$ consumer may later read only through the visible finite route.

Finally H, C, P, N transport, replay, source, and name exactly this route. Since the carrier has no row for open covers, selected subcovers, global compactness, ambient real completeness, or choice-selected center families, the listed non-escape boundary is part of the local certificate surface. □

Theorem 2035.3 (Doubling metric finite-net handoff)**.** *Every* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{DoublingMetric}^{\uparrow}$ *packet*

$$D = (M, \rho, B, K, E, T, S, H, C, P, N)$$

must read the same route $M, \rho, B, K, E, T, S, H, C, P, N$*. The row* T *exposes the finite center bundle and half-radius coverage rows as finite-net and total-bounded data, while* S *preserves the scale-halving ledger over the same* $\mathsf{Met}^{\uparrow}$ *source. The handoff exports no open-cover compactness principle, selected subcover, or choice-selected family of centers.*

Proof. Project the accepted carrier. The metric source is M, the positive-radius ledger is ρ, the parent ball request is B, and the center bundle and coverage witnesses are K and E.

Apply Definition 2035.2. The ball-cover coverage row requires each displayed point in B to be covered by a center in K through the half-radius metric read in E, and the scale monotonicity row keeps the passage from r to $r/2$ inside ρ and S.

The finite-net handoff is exactly the projection to T together with the preserved scale ledger S. Thus $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$ consumers can read finite centers and coverage only through $M, \rho, B, K, E, T, S, H, C, P, N$, with no row available for open-cover compactness or selected center families. □

Falsifiable prediction: Every $\mathsf{DoublingMetric}^{\uparrow}$ cover read factors through one MetricUp source row, one positive radius ledger, one parent ball request, one finite ProbeBundle of centers, one half-radius coverage ledger, one FiniteEpsilonNet and TotallyBounded handoff, one scale-halving ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metric, finite-epsilon-net, totallybounded, compactmetric: $\mathsf{DoublingMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the parent-ball request, bounded center-bundle coverage, scale-halving ledger, finite-net handoff, and transport/replay/provenance rows binding them into a finite metric regularity certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DoublingMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoublingMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2035.1 and Definition 2035.2 seed the finite scale-halving cover certificate over a displayed $\mathsf{Met}^{\uparrow}$ source and its $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoublingMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, global compactness, choice-selected center families, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ball-cover coverage, scale monotonicity, finite-net handoff, transport stability, non-escape, provenance, and local NameCert rows for BEDC.Derived.DoublingMetricUp.

Constructive story: A $\mathsf{DoublingMetric}^{\uparrow}$ packet is generated from a MetricUp source row, positive radius rows, a parent ball request, a finite ProbeBundle of centers, a half-radius coverage ledger, a FiniteEpsilonNetUp and TotallyBoundedUp handoff, a scale-halving ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2036

A Concrete Naming Certificate for $\mathsf{CauchyCompletionIsometry}^{\uparrow}$

Bishop–Bridges and Kelley-style completion language treats the unit map from a metric source into its Cauchy completion as distance preserving before density or extension consumers use the completed object. The $\mathsf{CauchyCompletionIsometry}^{\uparrow}$ packet records that boundary as finite BEDC data: it reads the source metric route of chapter 1638, the unit route of chapter 1527, the distance-preserving interface of chapter 439, the dense-image handoff of chapter 1560, and the terminal real-name seal of chapter 38. It names the unit distance-preservation surface for completion consumers without identifying quotient completion classes, choosing representatives, asserting host function equality, invoking countable choice, using open-cover compactness, assuming ambient completeness, or proving completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2036.1 (CauchyCompletionIsometry carrier)**.** *A* $\mathsf{CauchyCompletionIsometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (X, U, D_X, D_{\widehat{X}}, R, Q, I, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row whose displayed endpoints and finite distance requests are being admitted into the completion route.*
2. *U is the accepted* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row that sends the displayed source endpoints into the completion-facing surface.*
3. *D_X is the source-distance witness row for the displayed source endpoints, read through the source metric and real-metric comparison data.*
4. *$D_{\widehat{X}}$ is the completion-distance witness row for the corresponding unit images.*
5. *R is the* $\mathsf{RealMetric}^{\uparrow}$ *comparison row witnessing that the displayed source-distance read and completion-distance read name the same* $\mathsf{Real}^{\uparrow}$ *distance observation.*
6. *Q is the accepted* $\mathsf{CompletionDensity}^{\uparrow}$ *row available after the unit image has been admitted, so later density consumers can cite the same source route.*
7. *I is the accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *row that packages the source metric row, completion-facing target row, unit graph, the two distance witnesses, and the real-distance comparison.*

8. *H records componentwise* hsame *transport for the source metric row, unit row, both distance witnesses, real-metric comparison, density row, isometric-embedding row, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a source distance request through the unit images, source and completion distance witnesses, the real-metric comparison, the isometric-embedding row, and the density handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionIsometry}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{CompletionDensity}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionIsometry}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, host function equality, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionIsometryUp.CauchyCompletionIsometryTasteGate single carrier alignment`

Theorem 2036.2 (CauchyCompletionIsometry NameCert obligations)**.** *For an accepted* CauchyCompletionIsometry *carrier $J = (X, U, D_X, D_{\widehat{X}}, R, Q, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionIsometry}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed source metric row, completion unit row, source-distance witness, completion-distance witness, real-metric comparison, completion-density row, isometric-embedding row, transports, replay, provenance, and local naming row;*

2. *unit endpoint routing, requiring every source endpoint used by D_X to enter the completion-facing target only through the row U;*

3. *distance-pair exposure, requiring the source distance in D_X and the completion distance in $D_{\widehat{X}}$ to be displayed before the comparison row R is read;*

4. *isometry packaging, requiring the accepted row I to bind the same $X, U, D_X, D_{\widehat{X}}, R$ route as the local distance-preservation certificate;*

5. *density handoff, requiring the row Q to be downstream of the same unit images and not an independent dense subset;*

6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed route.*

No NameCert obligation is stored outside those rows, and none exports quotient completion equality, selected representatives, host function equality, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission is projection from Definition 2036.1. The tuple displays the source metric row, completion unit, two distance witnesses, real-metric comparison, density handoff, isometric-embedding row, transport, replay, provenance, and local name.

Unit endpoint routing follows from the placement of U before either completion-facing distance witness is consumed. A source endpoint can reach the target side of the packet only as the unit image recorded by the accepted $\mathsf{CauchyCompletionUnit}^{\uparrow}$ row.

Distance-pair exposure and isometry packaging are then finite row checks. The comparison row R reads only the displayed source and completion distances, while I packages that same comparison as an $\mathsf{IsometricEmbedding}^{\uparrow}$ route.

The density handoff is downstream of the same unit images. Since Q is a row of the carrier and is transported only componentwise by H and replayed only by C, it cannot supply a detached dense subset or a second completion object.

Finally P and N source and name exactly the displayed packet. The excluded quotient, representative, host-equality, choice, compactness, ambient-completeness, and real-completeness principles have no carrier coordinate from which a consumer could read them. □

Theorem 2036.3 (CauchyCompletionIsometry unit distance preservation)**.** *Let $J = (X, U, D_X, D_{\widehat{X}}, R, Q, I, H, C,$ be an accepted* $\mathsf{CauchyCompletionIsometry}^{\uparrow}$ *packet. Every finite source-distance read in D_X is routed through the unit row U to the completion-distance read in $D_{\widehat{X}}$, and the equality of the two displayed distance observations is read only through the* $\mathsf{RealMetric}^{\uparrow}$ *comparison row R and the accepted* $\mathsf{IsometricEmbedding}^{\uparrow}$ *row I.*

Thus the unit map is distance preserving at the finite NameCert surface:

$$X \longmapsto U \longmapsto (D_X, D_{\widehat{X}}) \longmapsto R \longmapsto I.$$

The route is not quotient completion equality, not selected representative equality, not host function equality, and not an appeal to countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with a source-distance request. The source metric row X and source-distance witness D_X display the two source endpoints and their finite distance observation.

Apply the completion-unit row U. It supplies the only completion-facing images of those endpoints, so the target distance witness $D_{\widehat{X}}$ is attached to the unit images rather than to a chosen quotient representative or host function.

The row R compares the two displayed distance observations inside the real-metric surface. It reads the same source and completion distance witnesses and therefore gives the finite equality of distance observations needed by an isometry consumer.

Finally the accepted row I packages the metric rows, unit graph, distance witnesses, and real-distance comparison as the $\mathsf{IsometricEmbedding}^{\uparrow}$ route. The structural rows H, C, P, N keep that route componentwise, replayable, sourced, and locally named, with no coordinate for any excluded completion principle. □

Theorem 2036.4 (CauchyCompletionIsometry density handoff)**.** *Every completion-density consumer of an accepted* $\mathsf{CauchyCompletionIsometry}^{\uparrow}$ *packet receives the dense source image only after the distance-preserving unit route*

$$X, U, D_X, D_{\widehat{X}}, R, I$$

has been displayed. The $\mathsf{CompletionDensity}^{\uparrow}$ *row Q is therefore a handoff from the same unit images and real-distance comparison, not a separate dense subset, not a quotient-completion selector, and not an ambient completeness theorem.*

Proof. Begin with a density consumer. The carrier exposes the density row Q only as a row of the same packet that already contains $X, U, D_X, D_{\widehat{X}}, R$ and I.

Use the unit distance-preservation theorem. Before Q can be read as a completion-density handoff, the source endpoints have passed through U, their source and completion distances have been displayed, and the real-distance comparison has been packaged by I.

Transport and replay preserve this dependency. The row H moves the source, unit, distance, comparison, isometric, and density rows componentwise, while C replays the same order for downstream consumers.

Thus Q hands off density for the displayed unit image that has already carried its distance-preservation certificate. Since the packet contains no separate dense subset, quotient selector, representative choice, host equality, compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, the density handoff exports only that finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionIsometry}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionIsometry}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2036.1, Definition 2036.2, Definition 2036.3, and Definition 2036.4 seed the finite distance-preserving unit-map certificate from source metric rows into Cauchy completion density consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionIsometry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host function equality, countable choice, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, unit endpoint routing, distance-pair exposure, isometry packaging, density handoff, and provenance exhaustion for BEDC.Derived.CauchyCompletionIsometryUp.

Constructive story: A $\mathsf{CauchyCompletionIsometry}^{\uparrow}$ packet is generated from a source metric row, a CauchyCompletionUnit row, source and completion distance witnesses, a RealMetric comparison row, a CompletionDensity row, an IsometricEmbedding row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2037

A Concrete Naming Certificate for $\mathsf{CauchyCompletionLift}^{\uparrow}$

Following Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionLift}^{\uparrow}$ packet records the finite NameCert surface by which a uniformly continuous map out of a displayed finite-source Cauchy route is lifted across Cauchy completion consumers. It sits after the functorial action of chapter 1937, the uniform completion interface of chapter 1892, and the effective completion route of chapter 2026. The chapter names only the carrier, obligation, and universal-route data needed by completion consumers; it does not identify quotient completion classes, choose limit representatives, assert host function equality, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2037.1 (CauchyCompletionLift carrier)**.** *A* $\mathsf{CauchyCompletionLift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, F, U, E, K, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite-source metric row, including the displayed source observations, Cauchy windows, and admissible tolerance requests before any completed consumer is read.*
2. *T is the target completion-consumer row, exposing the completion-facing object only after its uniform structure and accepted consumer interface have been displayed.*
3. *F is the uniformly continuous source-map row from the finite source route into the target-facing precompletion data.*
4. *U is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *row that records the uniform completion surface used by the lift.*
5. *E is the* $\mathsf{EffectiveCompletion}^{\uparrow}$ *row that supplies the finite Cauchy-realizer, stream-window, regular-rational, dyadic-tolerance, and real-seal route consumed by the lift.*
6. *K is the* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *row that packages the map action on completion-facing data before the universal consumer reads the lifted map.*
7. *R is the universal-route row, recording that every allowed completion consumer reads the lifted map only through the displayed S, T, F, U, E, K chain.*
8. *H records componentwise* hsame *transport for the source row, target row, source-map row, uniform completion row, effective completion row, functoriality row, universal route, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the route*

$$S, T, F \longmapsto U, E \longmapsto K \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionLift}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}$ $\mathsf{EffectiveCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionLift}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, F, U, E, K, R, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, representative choice, host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionLiftUp.CauchyCompletionLiftTasteGate single carrier alignment`

Theorem 2037.2 (CauchyCompletionLift NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionLift}^{\uparrow}$ *carrier*

$$L = (S, T, F, U, E, K, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionLift}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite-source row, target completion-consumer row, uniformly continuous source-map row, uniform completion row, effective completion row, functoriality row, universal-route row, transport, replay, provenance, and local naming row;*
2. *finite-source visibility, requiring every lifted-map read to expose the source observations, Cauchy windows, and tolerance requests in S before completion-facing data is inspected;*
3. *uniform continuity handoff, requiring the source-map row F to be consumed through the uniform completion row U before any completed-map read is named;*
4. *effective completion exactness, requiring the row E to supply the stream windows, regular rational readback, dyadic tolerance ledger, and real seal used by the lift;*
5. *functorial action, requiring the row K to bind the same S, T, F, U, E route as the completion-facing map action;*
6. *universal consumer routing, requiring R to expose every allowed completion consumer only after the displayed functorial route is available;*
7. *ledger non-escape, requiring H, C, P, N to preserve, replay, source, and name only the listed rows and to export no quotient completion equality, selected limit, representative choice, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Cauchy completion lift obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2037.1. The accepted packet displays exactly the finite source, target consumer, source-map, uniform completion, effective completion, functoriality, universal-route, and structural rows.

Finite-source visibility is read from S. Since the source observations, Cauchy windows, and tolerance requests occur before any completion-facing row, the lifted map cannot be inspected from an unrecorded source object.

The uniform-continuity handoff is read from F and U. The source map enters the lift only as uniformly continuous finite data, and the completion-facing interface is the uniform completion row rather than a host function on completed objects.

Effective completion exactness is read from E. The lift uses the displayed stream windows, regular rational readback, dyadic tolerance ledger, and real seal already admitted by the effective completion route.

Functorial action and universal consumer routing are read from K and R. The row K packages the same source, target, source-map, uniform completion, and effective completion route, while R makes each allowed consumer read through that package.

Finally H, C, P, N add no analytic coordinate. They transport, replay, source, and name the displayed route, so the excluded quotient, selected-limit, representative-choice, host-equality, countable-choice, and ambient-completeness principles have no row from which a consumer could read them. □

Theorem 2037.3 (CauchyCompletionLift universal route)**.** *Let*

$$L = (S, T, F, U, E, K, R, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionLift}^{\uparrow}$ *carrier. Every completion consumer of the lifted source-map data factors through the finite route*

$$S, T, F \longmapsto U, E \longmapsto K \longmapsto R \longmapsto H, C, P, N.$$

The route is a universal lift surface for uniformly continuous finite-source maps across Cauchy completion consumers. It is not quotient completion equality, not selected-limit data, not representative choice, not host function equality, not countable choice, and not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Fix a completion consumer of the lifted data. Projection gives the source row S, target row T, and uniformly continuous source-map row F.

The lift then enters the uniform and effective completion rows. The row U supplies the uniform completion interface, while E supplies the finite Cauchy-realizer route through stream windows, regular rational readback, dyadic tolerance data, and the real seal.

The functoriality row K packages the map action on completion-facing data. It reads the same S, T, F, U, E coordinates, so a consumer cannot replace the route by a selected representative or by host function equality.

The universal route row R is downstream of K. Thus every allowed consumer reads the lifted map only after the uniform, effective, and functorial rows have been displayed.

Transport, replay, provenance, and local naming close the route. Since H, C, P, N preserve only the listed rows, the packet exports no quotient completion equality, selected limit, representative choice, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2037.4 (CauchyCompletionLift uniform-modulus handoff)**.** *Let*

$$L = (S, T, F, U, E, K, R, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionLift}^{\uparrow}$ *carrier. Every completion consumer of lifted map data must expose the uniformly continuous source-map row* F *and its modulus-bearing finite data before the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$*,* $\mathsf{EffectiveCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows can be read. Equivalently, the consumer route factors through*

$$S, T, F \longmapsto U, E \longmapsto K, R \longmapsto H, C, P, N$$

with F *as the mandatory uniform-modulus handoff row.*

Proof. Project the carrier of Definition 2037.1. The source row S, target consumer row T, and uniformly continuous source-map row F are displayed before any completion-facing row.

Apply Definition 2037.2. Its uniform-continuity handoff obligation requires F to be consumed through the uniform completion row U, while its effective completion exactness obligation makes the stream windows, regular rational readback, dyadic tolerance ledger, and real seal downstream of E.

Now apply Definition 2037.3. The universal consumer route reads the lifted map through K and R only after S, T, F, U, E have been displayed, and the structural rows H, C, P, N merely preserve that route.

The excluded alternatives have no carrier coordinate. Quotient completion equality, selected limits, host function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot supply the required modulus handoff because every accepted consumer has already been routed through F. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionLift}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2037.1, Definition 2037.2, Definition 2037.3, and Definition 2037.4 seed the finite universal lift route for uniformly continuous finite-source maps across Cauchy completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLift}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyCompletionLiftUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, representative choice, host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-source visibility, uniform-continuity handoff, effective completion exactness, functorial action, universal consumer routing, and ledger non-escape for BEDC.Derived.CauchyCompletionL

Constructive story: A $\mathsf{CauchyCompletionLift}^{\uparrow}$ packet is generated from a finite-source metric row, a target completion-consumer row, a uniformly continuous source-map row, a UniformCompletionFunctor row, an EffectiveCompletion row, a CauchyCompletionFunctoriality row, a universal-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2038

A Concrete Naming Certificate for $\mathsf{ArchimedeanBracket}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArchimedeanBracket}^{\uparrow}$ packet records the finite integer-window route by which a displayed real name is bracketed before a Real or Completion consumer reads a located approximation. It consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the integer boundary rows of chapter 31, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, and the regular rational readback of chapter 301. The packet gives downstream order, fractional-part, located-comparison, and approximation chapters a named bracket surface without importing host floor functions, trichotomy, quotient real equality, selected integer parts, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 2038.1 (Archimedean bracket carrier)**.** *An* $\mathsf{ArchimedeanBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, L, U, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row whose displayed name is being bracketed at the requested precision.*
2. *L is the* $\mathsf{Int}^{\uparrow}$ *lower bracket row, recording the displayed integer bound admitted below the readback window.*
3. *U is the* $\mathsf{Int}^{\uparrow}$ *upper bracket row, recording the displayed integer bound admitted above the readback window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to state the finite dyadic radius and comparison scale for the bracket request.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from R at the tolerance recorded by D.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the displayed stream samples into rational observations before the integer rows are compared.*
7. *H records componentwise* hsame *transport for the real source, lower and upper integer rows, dyadic tolerance, stream windows, regular rational readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through*

$$R, D, S, Q, L, U \longmapsto \mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}.$$

9. *P is the* Pkg *provenance over* $\mathsf{ArchimedeanBracket}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, L, U, D, S, Q, H, C, P, N$. It has no coordinate for a host floor operation, trichotomy on real values, quotient real equality, a selected integer part, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.ArchimedeanBracketUp.ArchimedeanBracketUpTasteGate single carrier alignment`

Theorem 2038.2 (Archimedean bracket NameCert obligations)**.** *For every accepted* $\mathsf{ArchimedeanBracket}^{\uparrow}$ *carrier*

$$B = (R, L, U, D, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Real source row, lower and upper integer bracket rows, dyadic tolerance row, stream-window row, regular rational readback row, transport, replay, provenance, and local naming row;*
2. *source-before-window routing, requiring S to be opened only from the displayed* $\mathsf{Real}^{\uparrow}$ *row R at the tolerance recorded by D;*
3. *readback-before-bracket routing, requiring Q to expose the rational observations used by both integer comparisons before either L or U is exported as a bracket endpoint;*
4. *lower and upper endpoint exposure, requiring L and U to be the only integer rows visible to downstream bracket consumers;*
5. *transport and replay stability, requiring H and C to preserve the same row order without adding a second real source or another integer endpoint;*
6. *provenance and local naming, requiring P and N to source and name only the displayed packet.*

No Archimedean bracket obligation is stored outside these rows, and none exports host floor, trichotomy, quotient real equality, selected integer parts, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Carrier admission is projection from Definition 2038.1. The accepted packet displays exactly the Real source, lower and upper integer rows, dyadic tolerance, stream windows, regular rational readback, transport, replay, provenance, and local name.

The source and tolerance rows determine the finite window. The row S is opened only from R at the dyadic scale stored in D, so a bracket consumer cannot replace the displayed real-name route by a host real value.

The rational readback precedes the integer endpoints. The row Q reads the displayed stream samples before L and U are compared with that observation, making the two integer rows bracket endpoints for the same finite window.

The structural rows preserve the route. Componentwise transport through H and replay through C keep R, D, S, Q, L, U aligned, while P and N provide only provenance and local naming.

Since the excluded principles have no coordinate in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2038.3 (Archimedean bracket Real-window handoff)**.** *Every accepted* $\mathsf{ArchimedeanBracket}^{\uparrow}$ *read exported to a Real or Completion consumer factors through the displayed finite route*

$$R \longmapsto D \longmapsto S \longmapsto Q \longmapsto (L, U) \longmapsto H, C, P, N.$$

The consumer receives a single $\mathsf{Real}^{\uparrow}$ *source row, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, one* $\mathsf{StreamName}^{\uparrow}$ *window row, one* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, two* $\mathsf{Int}^{\uparrow}$ *endpoint rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. The handoff is not a host floor theorem, not real trichotomy, not quotient real equality, not a selected integer part, not ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and not bridge verification.*

Proof. Project the accepted carrier $B = (R, L, U, D, S, Q, H, C, P, N)$. The Real-facing read begins with R, and the only tolerance visible to the packet is the dyadic row D.

Open the finite stream window S at that tolerance. Its regular rational readback is the row Q, which supplies the finite observations against which the integer rows are displayed.

The lower and upper bracket rows are then read together. Because L and U are the only integer coordinates in the carrier, every downstream bracket endpoint is one of those two rows and is attached to the same readback Q.

Finally, H, C, P, N transport, replay, source, and name the same route. No carrier coordinate can supply a host floor, trichotomy, quotient equality, selected integer part, ambient completeness theorem, or bridge credential, so every exported bracket handoff factors through the displayed finite route. □

Falsifiable prediction: Every $\mathsf{ArchimedeanBracket}^{\uparrow}$ bracket read factors through one RealUp source row, one DyadicRatCore tolerance row, one StreamName finite-window row, one RegSeqRat readback row, two IntUp endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, int, dyadicratcore, streamname, regseqrat: $\mathsf{ArchimedeanBracket}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Real source, a dyadic tolerance, a stream window, a regular rational readback, and lower and upper integer endpoint rows as one bracket certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ArchimedeanBracket}^{\uparrow}$ packet is generated from a Real source row, lower and upper Int rows, a DyadicRatCore tolerance row, a StreamName finite-window row, a RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}$, seed)

Scope closed: Definition 2038.1, Definition 2038.2, and Definition 2038.3 seed the finite integer-window bracket certificate over Real, dyadic tolerance, stream-window, regular rational readback, and integer endpoint rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ArchimedeanBracket}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host floor functions, trichotomy, quotient real equality, selected integer parts, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-before-window routing, readback-before-bracket routing, lower and upper endpoint exposure, transport and replay stability, provenance, and local naming for BEDC.Derived.ArchimedeanBracketUp.

Chapter 2039

A Concrete Naming Certificate for $\mathsf{RatioCauchyTransfer}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RatioCauchyTransfer}^{\uparrow}$ packet records the finite route by which a quotient of regular rational Cauchy names is transported into the Real and Completion surface. It sits after the denominator guard of chapter 1471, the guarded quotient route of chapter 1943, the modulus arithmetic discipline of chapter 1485, the apartness-completion boundary of chapter 1567, and the terminal Real seal of chapter 38. The packet names quotient transfer as displayed BEDC rows; it is not host division, quotient equality of Cauchy streams, a selected representative, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2039.1 (Ratio Cauchy transfer carrier)**.** *A* $\mathsf{RatioCauchyTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (N, D, A, R, Q, H, C, P, L)$$

with the following displayed rows:

1. *N is the numerator* $\mathsf{RegSeqRat}^{\uparrow}$ *Cauchy row, including the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows used by the numerator readback.*
2. *D is the denominator* $\mathsf{RegSeqRat}^{\uparrow}$ *Cauchy row, displayed with the same finite-window and dyadic-tolerance discipline as N.*
3. *A is the apartness lower-bound ledger for D, recording the finite nonzero guard consumed by reciprocal and completion-facing reads.*
4. *R is the* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *route opened from D only after A has been displayed.*
5. *Q is the* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *quotient handoff, reading the numerator row N and the reciprocal route R before it exports any quotient readback.*
6. *H records componentwise* hsame *transport for numerator, denominator, apartness ledger, reciprocal route, quotient handoff, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$N, D, A \longmapsto R \longmapsto Q \longmapsto \mathsf{Real}^{\uparrow}.$$

8. *P is the* Pkg *provenance over* $\mathsf{RatioCauchyTransfer}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyDivision}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{RealApartnessCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{RatioCauchyTransfer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, D, A, R, Q, H, C, P, L$. It has no coordinate for host division, quotient equality of streams, selected representatives, trichotomy, countable choice, hidden denominator inversion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RatioCauchyTransferUp.RatioCauchyTransferTasteGate single carrier alignment`

Theorem 2039.2 (Ratio Cauchy transfer NameCert obligations)**.** *For every accepted* $\mathsf{RatioCauchyTransfer}^{\uparrow}$ *carrier*

$$X = (N, D, A, R, Q, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{RatioCauchyTransfer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the numerator Cauchy row, denominator Cauchy row, apartness lower-bound ledger, reciprocal route, quotient handoff, transport rows, continuation rows, package provenance, and local naming row;*
2. *numerator visibility, requiring every quotient or Real-facing consumer to expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *numerator row N before using the quotient row Q;*
3. *denominator guard visibility, requiring every reciprocal or quotient read to expose the denominator row D and apartness ledger A before the reciprocal route R is opened;*
4. *modulus arithmetic compatibility, requiring the finite windows and dyadic tolerance rows used by N, D, R, Q to be read through the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *discipline rather than through a host limit comparison;*
5. *quotient handoff exactness, requiring Q to consume only N and the reciprocal surface R before the terminal* $\mathsf{Real}^{\uparrow}$ *read is available;*
6. *apartness-completion boundary, requiring every Real or Completion consumer to retain the displayed A, R, Q route before it cites the* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *boundary;*
7. *transport, replay, provenance, and local naming, requiring H, C, P, L to preserve, replay, source, and name the displayed route without adding a second classifier.*

No Ratio Cauchy transfer obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2039.1. The accepted packet displays exactly the numerator, denominator, apartness ledger, reciprocal route, quotient handoff, transport, continuation, provenance, and local naming rows.

The numerator and denominator clauses are read from N, D, A. A quotient consumer can reach Q only after the numerator row is visible, and the denominator side cannot open R until the apartness lower-bound ledger A has been displayed.

The modulus arithmetic clause is read through the finite observation rows attached to N, D, R, Q. These rows are $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data governed by the $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ discipline, so no host limit comparison is part of the carrier.

The quotient and completion clauses are exhausted by R, Q together with the $\mathsf{RealApartnessCompletion}^{\uparrow}$ boundary named in the provenance row. The structural rows H, C, P, L transport, replay, source, and name that same finite route.

Since the carrier has no coordinate for host division, quotient equality of streams, selected representatives, trichotomy, countable choice, hidden denominator inversion, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the local NameCert surface. □

Theorem 2039.3 (Ratio Cauchy denominator non-escape)**.** *For every accepted* $\mathsf{RatioCauchyTransfer}^{\uparrow}$ *carrier*

$$X = (N, D, A, R, Q, H, C, P, L),$$

every denominator use in a reciprocal, quotient, Real, or Completion read factors through

$$D \longrightarrow A \longrightarrow R \longrightarrow Q$$

with transport, replay, provenance, and local naming supplied only by H, C, P, L*. The denominator row cannot escape as a host divisor, quotient-stream representative, hidden inverse, selected nonzero witness, trichotomy branch, or ambient completeness object.*

Proof. Start with any consumer that uses the denominator. The only denominator coordinate in the carrier is D, and the only nonzero evidence attached to it is the apartness lower-bound ledger A.

The reciprocal route R is downstream of D and A. Thus a reciprocal read cannot treat D as a host divisor or open an inverse without first displaying the finite apartness ledger.

The quotient handoff Q is downstream of R and the numerator row N. Once the route reaches Q, the denominator has already been consumed through the guarded reciprocal surface, not through host division or quotient equality.

Finally inspect H, C, P, L. These rows can only transport, replay, source, and name the displayed route. They do not add a selected nonzero witness, hidden inverse, trichotomy branch, quotient-stream representative, or ambient completeness object, so the denominator has no escape channel beyond D, A, R, Q. □

Theorem 2039.4 (Ratio Cauchy quotient route)**.** *For every accepted* $\mathsf{RatioCauchyTransfer}^{\uparrow}$ *carrier*

$$X = (N, D, A, R, Q, H, C, P, L),$$

every $\mathsf{Real}^{\uparrow}$ *or Completion-facing quotient read factors through the finite route*

$$N, D, A \longmapsto R \longmapsto Q \longmapsto \mathsf{Real}^{\uparrow}$$

and the route remains stable under the displayed hsame *transports and* Cont *replay rows. The read exports no host division, quotient equality of Cauchy streams, selected representative, countable-choice selector, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Fix a Real-facing or Completion-facing quotient read. The only quotient handoff in the carrier is Q, so the read must pass through that row before any terminal Real surface is visible.

Read the dependencies of Q. It consumes the numerator row N and the reciprocal route R; the reciprocal route consumes the denominator row D only after the apartness lower-bound ledger A is displayed.

Transport stability is componentwise. The rows in H preserve N, D, A, R, Q under the displayed hsame classifications, and the rows in C replay the same dependency order through Cont without inserting a second quotient constructor.

The provenance row P records the sibling sources for regular Cauchy reciprocal, guarded division, modulus arithmetic, apartness completion, and Real sealing, while L names only this local packet. Since no excluded object appears among $N, D, A, R, Q, H, C, P, L$, the quotient read exports exactly the displayed finite route and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RatioCauchyTransfer}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RatioCauchyTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2039.1, Definition 2039.2, Definition 2039.3, and Definition 2039.4 seed the finite quotient-transfer route from regular Cauchy numerator and guarded denominator rows to Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RatioCauchyTransfer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host division, quotient equality of Cauchy streams, selected representatives, trichotomy, countable choice, hidden denominator inversion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, denominator guard visibility, modulus arithmetic compatibility, quotient handoff exactness, apartness-completion boundary, denominator non-escape, quotient route stability, transport, replay, provenance, and local naming for BEDC.Derived.RatioCauchyTransferUp.

Constructive story: A $\mathsf{RatioCauchyTransfer}^{\uparrow}$ packet is generated from numerator and denominator RegSeqRat rows, an apartness lower-bound ledger, a RegularCauchyReciprocal route, a RegularCauchyDivision quotient handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2040

A Concrete Naming Certificate for $\mathsf{CauchyModulusChoice}^{\uparrow}$

Bishop–Bridges constructive analysis treats a Cauchy modulus as displayed finite rate data: a later real-name or completion-facing consumer may read the selected threshold only after the raw modulus, the normal-form schedule, the window row, the regular rational readback, and the dyadic tolerance ledger have all been exposed. The $\mathsf{CauchyModulusChoice}^{\uparrow}$ packet records this selection route without importing a countable-choice principle. It sits after the raw modulus surface of chapter 292, the normal-form route of chapter 1968, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite modulus-choice certificate for Real and Completion consumers; it is not quotient stream equality, trichotomy, ambient Real completeness, or a hidden selector over countably many requests.

Definition 2040.1 (Cauchy modulus choice carrier)**.** *A* $\mathsf{CauchyModulusChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, N, W, Q, D, R, H, C, P, L)$$

with the following displayed rows:

1. *M is the raw* $\mathsf{CauchyModulus}^{\uparrow}$ *row attached to the source Cauchy name and the finite precision request being answered.*
2. *N is the* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ *row that records the monotone normal-form representative of M for the same request.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the normal-form threshold.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the dyadic error budget consumed by W and Q.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, N, W, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the raw modulus, normal form, window, readback, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the selection route*

$$M \longmapsto N \longmapsto W \longmapsto Q \longmapsto D \longmapsto R.$$

9. *P is the* Pkg *provenance over* CauchyModulusChoice$^\uparrow$, CauchyModulus$^\uparrow$, CauchyModulusNormalForm$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* NameCert$_{\text{CauchyModulusChoice}^\uparrow}$ *row.*

The classifier compares accepted packets only through $M, N, W, Q, D, R, H, C, P, L$.

Lean4 ✓ `BEDC.Derived.CauchyModulusChoiceUp.CauchyModulusChoiceTasteGate single carrier alignment`

Theorem 2040.2 (Cauchy modulus choice NameCert obligations)**.** *For every accepted* CauchyModulusChoice$^\uparrow$ *carrier*

$$K = (M, N, W, Q, D, R, H, C, P, L),$$

the local NameCert$_{\text{CauchyModulusChoice}^\uparrow}$ *surface consists exactly of five finite obligation rows:*

1. *carrier exposure for the raw modulus, normal-form modulus, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, replay, provenance, and local naming rows;*
2. *normal-form selection, requiring the chosen threshold to be read from the displayed* CauchyModulusNormalForm$^\uparrow$ *row N rather than from an external choice function;*
3. *window-readback compatibility, requiring the* StreamName$^\uparrow$ *window W and* RegSeqRat$^\uparrow$ *readback Q to be opened by the same normal-form threshold;*
4. *dyadic tolerance and Real seal compatibility, requiring the* DyadicRatCore$^\uparrow$ *row D to be the tolerance ledger consumed before the terminal* Real$^\uparrow$ *seal R is exposed;*
5. *structural non-escape, requiring H, C, P, L to transport, replay, source, and name only the displayed route and to export no countable choice, quotient stream equality, trichotomy, ambient Real completeness, selected limit, or host real equality.*

No Cauchy modulus choice obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2040.1. The only rows available to the classifier are $M, N, W, Q, D, R, H, C, P, L$.

Normal-form selection is local to N. Since N is a displayed normal-form row downstream of the raw modulus M, the threshold read is a finite row read rather than an appeal to a choice function over all precision requests.

Window-readback compatibility uses W and Q. The finite window is opened by the same normal-form threshold, and the regular rational readback is attached to that displayed window.

Dyadic tolerance and the Real seal are then forced by D and R. The dyadic budget is consumed before the seal can be read, so the seal is not an ambient completeness assertion or a selected limit.

Finally H, C, P, L preserve exactly the same route by componentwise transport, replay, provenance, and local naming. Because the carrier has no coordinate for countable choice, quotient stream equality, trichotomy, ambient completeness, selected limits, or host real equality, the five obligation rows exhaust the local surface. □

Theorem 2040.3 (Cauchy modulus choice normal-form factorization)**.** *Every accepted* CauchyModulusChoice$^\uparrow$ *carrier*

$$K = (M, N, W, Q, D, R, H, C, P, L)$$

factors its selected threshold through the CauchyModulusNormalForm$^\uparrow$ *row N before any* StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, *or* Real$^\uparrow$ *consumer reads the route. Equivalently, every Real and Completion use of the choice surface is routed through*

$$M \longmapsto N \longmapsto W \longmapsto Q \longmapsto D \longmapsto R$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Begin with an accepted carrier K. The raw modulus row M exposes the Cauchy modulus request, while N records the normal-form representative consumed by later rows.

The route cannot reach a finite window before N is read. Thus the $\mathsf{StreamName}^{\uparrow}$ row W is the window opened by the displayed normal-form threshold, not by an unrecorded selector.

Readback and tolerance follow the same route. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q reads the displayed window, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D supplies the tolerance ledger for that readback.

The terminal $\mathsf{Real}^{\uparrow}$ seal R is downstream of those four rows. The structural rows H, C, P, L keep the route componentwise, replayable, sourced, and locally named, so every consumer factors through the normal-form surface before using the selected threshold. □

Theorem 2040.4 (Cauchy modulus choice window determinacy)**.** *Let*

$$K = (M, N, W, Q, D, R, H, C, P, L) \quad \textit{and} \quad K' = (M, N, W', Q', D', R', H', C', P', L')$$

be accepted $\mathsf{CauchyModulusChoice}^{\uparrow}$ *carriers with the same raw modulus row M and normal-form row N. Then every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of the selected threshold in either carrier passes through the same finite window, readback, and tolerance route determined by N: first the* $\mathsf{StreamName}^{\uparrow}$ *window row, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, before the* $\mathsf{Real}^{\uparrow}$ *seal. The claim is only route determinacy inside the displayed normal-form surface; it is not host uniqueness of limits, quotient stream equality, or countable choice.*

Proof. Project both accepted carriers using Definition 2040.1. The only rows upstream of a selected-threshold read are the raw modulus row M, the normal-form row N, the finite window row, the regular readback row, and the dyadic tolerance row.

Apply the normal-form selection obligation from Definition 2040.2. Since the two carriers share M and N, a threshold read in either packet is forced to use the same displayed normal-form source before any window can be opened.

Use Definition 2040.3. It places the downstream route in the order W, Q, D before R, so every Real or completion-facing read is mediated by the window, readback, and tolerance rows attached to that shared normal-form source.

The structural rows H, C, P, L and H', C', P', L' only transport, replay, source, and name the displayed route. Because neither carrier contains host limit uniqueness, quotient stream equality, or a countable-choice coordinate, the determinacy asserted here is exactly the finite route through W, Q, D before R. □

Theorem 2040.5 (Cauchy modulus choice Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyModulusChoice}^{\uparrow}$ *carrier receives only the displayed rows*

$$M, N, W, Q, D, R, H, C, P, L.$$

The Real seal R therefore cannot escape into countable choice, quotient stream equality, trichotomy, ambient Real completeness, selected limits, host real equality, or a second modulus-selection oracle.

Proof. Project the accepted carrier. Its Real-facing surface is exactly the raw modulus row, normal-form row, finite window, regular readback, dyadic tolerance, seal, transport, replay, provenance, and local naming row.

The normal-form factorization of Definition 2040.3 places every selected threshold before the finite window and readback rows. Therefore a Real or Completion consumer cannot bypass the displayed normal-form row to obtain a hidden selector.

The dyadic tolerance row is also part of the same route before the Real seal. Since R is exposed only after D, it cannot be read as a trichotomy witness, an ambient completeness principle, a quotient stream equality, or a selected host limit.

The structural rows add no mathematical coordinate beyond transport, replay, provenance, and local naming. Hence the displayed packet exhausts the Real seal route and blocks all listed escape principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusChoice}\uparrow}$.

Constructive story: A $\mathsf{CauchyModulusChoice}^{\uparrow}$ packet is generated from a raw CauchyModulus row, a CauchyModulusNormalForm row, a StreamName finite-window row, a RegSeqRat readback row, a DyadicRatCore tolerance row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Lean target: `BEDC.Derived.CauchyModulusChoiceUp`

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient stream equality, trichotomy, ambient Real completeness, selected limits, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, normal-form selection, window-readback compatibility, dyadic tolerance and Real seal compatibility, structural non-escape, normal-form factorization, and Real seal nonescape for BEDC.Derived.CauchyModulusChoiceUp.

Chapter 2041

A Concrete Naming Certificate for $\mathsf{DiniDerivative}^{\uparrow}$

Following Dini's one-sided derivative theory and Bishop–Bridges constructive analysis, the $\mathsf{DiniDerivative}^{\uparrow}$ packet records only displayed finite one-sided secant-window rows over $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$. It consumes the terminal real-name surface of chapter 38, the graph and modulus rows of chapter 130, the derivative quotient boundary of chapter 122, the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, and the metric comparison rows of chapter 57. The packet names only finite right-hand and left-hand slope windows, their rational bounds, endpoint seals, componentwise transport, replay, provenance, and local naming; it does not import host limits, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2041.1 (Dini derivative carrier)**.** *A* $\mathsf{DiniDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, F, Q, S, B, R, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the local* $\mathsf{Met}^{\uparrow}$ *source row naming the inspected interval cell, its endpoint order, and the distance comparison used to choose one-sided neighborhoods.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed function on the same metric cell, including the finite graph reads and continuity modulus rows visible to the packet.*
3. *Q is the* $\mathsf{Derivative}^{\uparrow}$ *quotient-inspection row, recording the secant quotient route without asserting a two-sided derivative or a selected limit.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *one-sided window row, listing the inspected right-hand and left-hand approach samples.*
5. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *slope-bound row, storing the dyadic lower and upper rational bounds for every displayed one-sided secant window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximations of endpoint values, secant numerators, step sizes, and dyadic slope bounds.*
7. *W is the boundary-seal row, storing the* $\mathsf{Real}^{\uparrow}$ *endpoint names and the finite evidence that the requested Dini read is confined to the displayed side and window.*

8. *H records componentwise* hsame *transport for the metric source, continuous-map row, derivative quotient route, stream windows, dyadic bounds, rational readbacks, endpoint seals, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay through*

$$X, F, Q, S, B, R, W \longmapsto \mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}.$$

10. *P is the* Pkg *provenance over* $\mathsf{DiniDerivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host limit, trichotomy of reals, quotient equality of completed reals, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.DiniDerivativeUp.DiniDerivativeTasteGate single carrier alignment`

Theorem 2041.2 (Dini derivative NameCert obligations)**.** *For every accepted* $\mathsf{DiniDerivative}^{\uparrow}$ *carrier*

$$D = (X, F, Q, S, B, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *metric cell admission through X;*
2. *continuous-map row admission through F over the same cell;*
3. *derivative quotient inspection through Q;*
4. *one-sided finite window admission through S;*
5. *dyadic slope-bound admission through B;*
6. *regular rational readback through R;*
7. *endpoint and side boundary sealing through W;*
8. *structural stability through H, C, P, N.*

No Dini derivative obligation is stored outside the displayed carrier.

Proof. Carrier admission is projection from Definition 2041.1. The metric source row X fixes the inspected cell and the endpoint side, while F supplies the only continuous-map data visible to the packet.

The derivative-facing part is then finite. The row Q records the quotient route being inspected, and S lists the right-hand and left-hand sample windows on which that route may be read.

The bound rows are also displayed. The dyadic row B stores the rational lower and upper slope bounds, and R supplies the regular rational readback for the endpoint values, step sizes, and bound comparisons.

Finally, W seals the endpoint and side information, while H, C, P, N transport, replay, source, and name the same row inventory. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2041.3 (Dini derivative finite slope window)**.** *Every one-sided slope read exported by an accepted* $\mathsf{DiniDerivative}^{\uparrow}$ *carrier factors through the displayed finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The read first opens the metric cell and continuous-map row, then the derivative quotient route, then a finite one-sided stream window, then the dyadic slope-bound row, and only then seals the observed boundary as $\mathsf{Real}^{\uparrow}$ *data.*

Proof. Start with an accepted carrier $D = (X, F, Q, S, B, R, W, H, C, P, N)$. The packet exposes no slope source before the metric row X and continuous-map row F have been read.

Inspect the derivative row Q next. Its quotient data is not a host derivative; it is only the displayed route whose one-sided samples are listed by S.

The finite window is bounded through B and read back through R. These two rows provide the dyadic lower and upper slope bounds and the rational observations required to compare the displayed secant quotients.

The boundary row W then seals the observation as $\mathsf{Real}^{\uparrow}$ data on the chosen side. Transport and replay through H and C preserve the same route, and P, N add only source and naming information. Thus every exported one-sided slope read factors through the stated finite route. □

Theorem 2041.4 (Dini derivative real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *boundary read exported by an accepted* $\mathsf{DiniDerivative}^{\uparrow}$ *carrier is downstream of a displayed one-sided secant-window comparison. In particular, if a consumer reaches the boundary row* W*, then the consumer has already read the same metric cell* X*, continuous-map row* F*, derivative quotient row* Q*, stream-window row* S*, dyadic slope-bound row* B*, regular rational readback* R*, componentwise transport* H*, replay* C*, package provenance* P*, and local name* N*.*

Proof. The carrier places the $\mathsf{Real}^{\uparrow}$ boundary information in the single row W. By the definition of the carrier, W is not independent data: it records only endpoint names and side confinement for the displayed one-sided window.

To reach W, a consumer must therefore pass through the rows that make the window meaningful. The metric row X supplies the side and neighborhood comparison, F supplies the continuous-map observations, Q supplies the quotient route, S supplies the sampled windows, and B, R supply the dyadic and regular-rational comparison data.

The structural rows do not add a second boundary route. They preserve the same packet under hsame, replay it through Cont, record its provenance, and assign the local $\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}$ row.

Consequently the boundary read cannot be detached from the displayed finite secant-window comparison, and it cannot be replaced by a host limit, real trichotomy, quotient real equality, or ambient completeness argument. □

Falsifiable prediction: Every $\mathsf{DiniDerivative}^{\uparrow}$ one-sided slope read factors through one metric cell row, one ContinuousMap row, one Derivative quotient row, one StreamName finite window row, one DyadicRatCore slope-bound row, one RegSeqRat readback row, one RealUp boundary-seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, continuousmap, derivative, dyadicratcore, regseqrat, streamname, metric: $\mathsf{DiniDerivative}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one-sided finite secant windows, derivative quotient inspection, dyadic slope bounds, rational readback, endpoint side sealing, transport, replay, provenance, and local naming as one boundary certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{DiniDerivative}^{\uparrow}$ packet is generated from a metric cell row, a ContinuousMap row, a Derivative quotient route, StreamName one-sided finite windows, DyadicRatCore slope bounds, RegSeqRat readbacks, a RealUp boundary-seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2041.1, Definition 2041.2, Definition 2041.3, and Definition 2041.4 seed the finite one-sided derivative-window certificate over metric, continuous-map, quotient, stream, dyadic, rational, and Real boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limits, real trichotomy, quotient equality of completed reals, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, one-sided window admission, dyadic slope-bound admission, rational readback, endpoint-side sealing, transport, replay, provenance, and local naming for BEDC.Derived.DiniDerivativeUp.

Chapter 2042

A Concrete Naming Certificate for $\mathsf{HyersUlamStability}^{\uparrow}$

Following Hyers and Ulam, the $\mathsf{HyersUlamStability}^{\uparrow}$ packet records constructive stability of approximate solutions as finite correction data rather than as an ambient completeness theorem. It reads the displayed target-completeness row of chapter 128, the Lipschitz-control ledger of chapter 410, the contraction route of chapter 1418 and chapter 395, and the terminal real-name seal of chapter 38. The chapter names the surface on which an approximate equation row, an error-bound row, and a correction witness row are kept together before Picard, ODE, or completion-facing consumers read the corrected solution.

Definition 2042.1 (Hyers–Ulam stability carrier)**.** *A* $\mathsf{HyersUlamStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, L, M, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the approximate-solution row, containing the displayed domain cell, candidate solution graph, residual observation, and tolerance request.*
2. *W is the correction-witness row, storing the corrected solution name, the finite comparison from the approximate graph to the corrected graph, and the witnessed error bound.*
3. *L is the Lipschitz and control ledger. It records the* $\mathsf{LipschitzMap}^{\uparrow}$ *row, the displayed control constant, the contraction threshold when present, and the finite residual-to-correction estimate.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, carrying the regular Cauchy limit witness or complete target surface needed to accept the corrected solution without selecting a host limit.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed error, control, and correction-bound observations.*
6. *H records componentwise* hsame *transport for the approximate row, correction witness, control ledger, complete-metric handoff, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through*

$$A, W, L, M, R \longmapsto \mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}.$$

8. *P is the* Pkg *provenance over* $\mathsf{HyersUlamStability}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, L, M, R, H, C, P, N$. It has no coordinate for host function equality, a selected exact solution, quotient completion equality, an unbounded stability constant, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.HyersUlamStabilityUp.HyersUlamStabilityUpTasteGate single carrier alignment`

Theorem 2042.2 (Hyers–Ulam stability NameCert obligations)**.** *For an accepted* $\mathsf{HyersUlamStability}^{\uparrow}$ *carrier*

$$S = (A, W, L, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *approximate-row admission for the displayed candidate solution, residual observation, and tolerance request in A;*
2. *correction-witness admission for the corrected solution name, graph comparison, and error-bound witness in W;*
3. *control-ledger admission for the Lipschitz row, contraction threshold when present, and residual-to-correction estimate in L;*
4. *complete-metric handoff through M, requiring every corrected-solution acceptance to pass through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *row;*
5. *real-bound sealing through R, requiring every error, control, and correction-bound read to reach* $\mathsf{Real}^{\uparrow}$ *only after A, W, L, M have been displayed;*
6. *structural stability through H, C, P, N.*

No Hyers–Ulam stability obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2042.1. The approximate candidate, correction witness, control ledger, complete-metric handoff, real-bound seal, transport, replay, provenance, and local name are all rows of the same finite packet.

The approximate and corrected solution data are separated but not detached. The row A exposes the residual and tolerance request, while W supplies the corrected solution name and the finite comparison back to the approximate graph.

The control and completion rows then bind the correction. The row L contains the Lipschitz or contraction ledger that turns the residual into a correction bound, and M supplies the complete-metric handoff through which the corrected solution is accepted.

Finally R, H, C, P, N seal and preserve exactly that route. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface and cannot export a selected exact solution, host function equality, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2042.3 (Hyers–Ulam stability correction route)**.** *Let $S = (A, W, L, M, R, H, C, P, N)$ be an accepted* $\mathsf{HyersUlamStability}^{\uparrow}$ *carrier. Every correction read exported by S factors through the finite route*

$$\mathsf{LipschitzMap}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardContraction}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed inside L, M, R, H, C, P, N. In particular, the corrected solution is read as a NameCert witness downstream of the approximate residual and the control ledger, not as a host-selected exact solution and not as a consequence of ambient real completeness.

Proof. Start with a correction request. The row A displays the approximate solution and the residual tolerance whose stability is being inspected.

Read the control ledger L. Its $\mathsf{LipschitzMap}^{\uparrow}$ and contraction-facing rows provide the finite control data that relate the residual to a correction bound, and its Picard-facing row records the iterative correction route when the packet is consumed by a fixed-point or ODE surface.

The corrected solution is accepted through W and M. The witness row W gives the corrected name and comparison, while the complete-metric handoff M supplies the convergence or target-completeness route needed by downstream consumers.

The real-valued bound is sealed only after those rows have been displayed. The row R records the $\mathsf{Real}^{\uparrow}$ observations for the residual, control constant, and correction estimate, and the structural rows H, C, P, N transport, replay, source, and name the same finite route. Hence the exported correction has no path through a selected exact solution, host function equality, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2042.4 (Hyers–Ulam completion handoff)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{HyersUlamStability}^{\uparrow}$ *packet receives the approximate row, correction witness, Lipschitz-control ledger, and real-bound seal as one displayed route. The complete-metric row M is therefore a handoff for the correction witness W, not an independent assertion that all approximate solutions converge, not a completeness theorem for* $\mathsf{Real}^{\uparrow}$*, and not a choice principle for exact solutions.*

Proof. Begin with a completion-facing consumer. The only complete-metric coordinate in the carrier is M, and it is listed after the approximate row A, the correction witness W, and the control ledger L.

The consumer therefore reads M together with the rows that make the correction meaningful. The approximate residual is visible in A, the corrected solution name and graph comparison are visible in W, and the stability estimate is visible in L before the real-bound seal R is consumed.

Componentwise transport and displayed replay preserve this dependency. The rows H and C move and replay the same packet, while P and N source and name it as $\mathsf{HyersUlamStability}^{\uparrow}$ data.

Thus completion is exposed only as the handoff for the displayed correction route. No row supplies an independent convergence theorem for arbitrary approximate solutions, completeness of $\mathsf{Real}^{\uparrow}$, host equality of functions, selected exact solutions, or countable choice. □

Falsifiable prediction: Every $\mathsf{HyersUlamStability}^{\uparrow}$ correction read factors through one approximate-solution row, one correction witness row, one Lipschitz or contraction control ledger, one CompleteMetric handoff row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: complete-metric, lipschitz-map, contraction-mapping, picard-contraction, real: $\mathsf{HyersUlamStability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries approximate residual data, a correction witness, a control ledger, a complete-metric handoff, a RealUp seal, transport, replay, provenance, and local naming as one stability certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyersUlamStability}^{\uparrow}$ packet is generated from an approximate-solution row, a correction witness row, a Lipschitz or contraction control ledger, a CompleteMetric handoff row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2042.1, Definition 2042.2, Definition 2042.3, and Definition 2042.4 seed the finite stability certificate for approximate solutions through correction witnesses, control ledgers, complete-metric handoff, and Real-bound sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyersUlamStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected exact solutions, quotient completion equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximate-row admission, correction-witness admission, control-ledger admission, complete-metric handoff, real-bound sealing, transport, replay, provenance, and local naming for BEDC.Derived.HyersUlamStabilityUp.

Chapter 2043

A Concrete Naming Certificate for $\mathsf{LocatedSpace}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedSpace}^{\uparrow}$ packet records the finite route by which a metric source answers locatedness requests without importing a global real-order decision or a completed ambient space. It sits between the apartness interface of chapter 1514, the compact located handoff of chapter 1488, and the completion boundary of chapter 1506: every consumer sees the finite $\mathsf{StreamName}^{\uparrow}$ window of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 before it can treat a distance-to-source query as located.

Definition 2043.1 (LocatedSpace carrier)**.** *A* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, R, A, G, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric or source carrier whose finite points, distance requests, and source-side observation windows are being certified.*
2. *R is the finite locatedness request, consisting of the displayed point or name to be tested, the source subset or source family being queried, and the dyadic tolerance budget at which the request is opened.*
3. *A is the positive* $\mathsf{ApartnessSpace}^{\uparrow}$ *gap row attached to the request, displaying the positive separation witness used when the request is answered on the apart side.*
4. *G is the positive gap budget shared by the apartness row, the metric distance comparison, and the completion-facing refusal boundary.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window through which the source point, target observation, tolerance budget, and gap comparison are inspected.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W and to every rational comparison used by the locatedness request.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached by the displayed distance and gap reads after R, A, G, W, Q have been exposed.*
8. *H records componentwise* hsame *transport for the source carrier, locatedness request, positive apartness gap, stream window, regular readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of every locatedness-facing consumer route through*

$$X, R, A, G, W, Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedSpace}^{\uparrow}$, $\mathsf{ApartnessSpace}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, R, A, G, W, Q, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected limits, open-cover compactness, choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceTasteGate single carrier alignment`

Theorem 2043.2 (LocatedSpace NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier*

$$L = (X, R, A, G, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric or source carrier, locatedness request, positive apartness gap, stream window, regular readback, real seal, transport, replay, provenance, and local naming rows;*

2. *locatedness stability, requiring every transported or replayed request to read the same source carrier X, request row R, gap row A, gap budget G, window W, and readback Q before exposing the real seal E;*

3. *positive-gap exactness, requiring the apartness gap used by A to be the same positive budget G read by the finite metric comparison and the regular rational readback;*

4. *completion-boundary nonescape, requiring every completion-facing or real-facing consumer to pass through R, A, G, W, Q, E and to receive no selected limit, quotient representative, ambient completeness theorem, or host real equality from the packet;*

5. *ledger refusal, requiring H, C, P, N to transport, replay, source, and name only the displayed rows, with no trichotomy, quotient real equality, open-cover compactness, choice, Lean verification, or bridge credential.*

No located-space NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 2043.1. The packet displays the metric source, the finite locatedness request, the apartness gap, the gap budget, the stream window, the regular readback, the real seal, and the four structural rows.

Locatedness stability is componentwise. A transported or replayed request keeps the same source row and the same finite request row, so the downstream consumer cannot replace the displayed window and readback by an ambient predicate on the completed space.

Positive-gap exactness is the shared role of A and G. The apartness row names the positive separation, while G is the budget read both by the metric comparison and by the regular rational observation.

For the completion boundary, the real seal E appears only after R, A, G, W, Q have been displayed. A completion-facing consumer therefore receives a finite locatedness route rather than a quotient class, selected limit, or completeness theorem.

Finally, H, C, P, N only transport, replay, source, and name the carrier rows. Since the packet contains no trichotomy, quotient real equality, open-cover compactness, choice, Lean verification, or bridge credential, the listed rows exhaust the NameCert surface. □

Theorem 2043.3 (LocatedSpace Real completion boundary)**.** *Every completion-facing read of an accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier*

$$L = (X, R, A, G, W, Q, E, H, C, P, N)$$

factors through the displayed locatedness request R, the positive apartness gap A, the positive gap budget G, the $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary E. The factorization exports only the finite route*

$$X, R, A, G, W, Q \longmapsto E$$

and exports no trichotomy, quotient real equality, selected limit, open-cover compactness, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier real completion boundary`

Proof. Start with an accepted carrier and a completion-facing read. Projection from Definition 2043.1 gives the rows $X, R, A, G, W, Q, E, H, C, P, N$ and no further completion object.

The read first opens the locatedness request R against the source carrier X. If the apart side is used, the only positive separation data are the apartness row A and the positive budget G.

The observation then passes through the finite stream window W and the regular rational readback Q. These are the only rows that expose the rational data used by the distance and gap comparisons.

Only after those rows have been displayed can the route reach the real seal E. The structural rows H, C, P, N preserve this order under transport, replay, provenance, and local naming.

Thus every completion-facing read factors through the displayed finite route. The excluded trichotomy, quotient equality, selected-limit, compactness, choice, and ambient-completeness data cannot be exported because they are absent from the accepted packet. □

Theorem 2043.4 (LocatedSpace apartness request scope)**.** *For every accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier*

$$L = (X, R, A, G, W, Q, E, H, C, P, N),$$

an apartness-facing locatedness request is scoped by the same metric source X, finite request row R, positive apartness gap A, and positive budget G before any $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, or* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. Componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$ *row preserve that scope and cannot introduce a second apartness gap or a host order decision.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier apartness request scope`

Proof. Project the rows from Definition 2043.1. The apartness-facing part of the packet is exactly X, R, A, G, with A carrying the positive gap and G carrying the budget shared with the metric comparison.

Apply Definition 2043.2. Its locatedness-stability and positive-gap-exactness clauses require every transported or replayed request to keep the same source, request row, gap row, and gap budget before any downstream readback is opened.

Finally use Definition 2043.3. The route to W, Q, E comes after the scoped request rows, and H, C, P, N preserve only the displayed carrier. Thus no host order decision or additional apartness gap can enter the request scope. □

Theorem 2043.5 (LocatedSpace positive-gap exactness route)**.** *For every accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier*

$$L = (X, R, A, G, W, Q, E, H, C, P, N),$$

the apartness gap row A and positive budget row G are the unique finite gap surface available to metric, $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers. Every completion-facing read must pass through R, A, G, W, Q before E, and no host trichotomy, quotient equality, selected limit, or second apartness witness is exported.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier positive gap exactness route`

Proof. Start with the NameCert obligations of Definition 2043.2. Carrier admission exposes $X, R, A, G, W, Q, E, H, C, P, N$, while positive-gap exactness binds the apartness row A to the same budget row G used by the metric and regular rational reads.

Use the apartness request scope of Definition 2043.4. It places X, R, A, G before any stream window, regular readback, or real seal can be consumed, so a second apartness witness has no carrier row.

Finally apply the Real completion boundary of Definition 2043.3. That theorem orders every completion-facing read through R, A, G, W, Q before E and excludes trichotomy, quotient equality, selected limits, and ambient completion data. Therefore A, G are the exact finite gap surface available to downstream consumers. □

Theorem 2043.6 (LocatedSpace metric request ledger)**.** *Every metric request exported by an accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier is ledgered by the finite route*

$$X, R, A, G, W, Q, E, H, C, P, N.$$

The metric source row X, request row R, apartness gap A, gap budget G, $\mathsf{StreamName}^{\uparrow}$ *window W, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q must all be displayed before the* $\mathsf{Real}^{\uparrow}$ *seal E is consumed. The structural rows* hsame*,* Cont*,* Pkg*, and local* NameCert *record only that route.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier metric request ledger`

Proof. The carrier projection fixes the metric source, request, gap, window, readback, real seal, and structural rows. No metric-facing consumer has access to a coordinate outside $X, R, A, G, W, Q, E, H, C, P, N$.

Apply the NameCert obligation theorem. Carrier admission exposes the displayed metric source and request rows, while locatedness stability and positive-gap exactness bind the metric comparison to the same apartness budget read by A and G.

The completion-boundary theorem then orders the readback: W and Q precede the seal E. Since H, C, P, N only transport, replay, source, and name the same route, the exported metric request remains a finite ledger rather than an ambient metric-completion object. □

Theorem 2043.7 (LocatedSpace stream readback stability)**.** *For every accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier, if a locatedness request is transported by* hsame *or replayed by* Cont*, then its* $\mathsf{StreamName}^{\uparrow}$ *window* W *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *remain attached to the same metric source* X*, finite request* R*, apartness gap* A*, gap budget* G*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$ *row therefore name a stable finite readback route and not a selected limit, quotient real equality, or ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier stream readback stability`

Proof. Begin with the accepted carrier and project the rows $X, R, A, G, W, Q, E, H, C, P, N$. The stream window and regular rational readback are explicit fields of the carrier, so they cannot be replaced by an unrecorded completion read.

Apply Definition 2043.2. Its locatedness-stability clause keeps X, R, A, G, W, Q fixed under transport and replay, and its completion-boundary nonescape clause requires E to be reached only after those rows are displayed.

Then apply Definition 2043.3. It identifies the same route to the real seal and excludes selected limits, quotient representatives, and ambient completeness. The provenance and local naming rows therefore certify stability of the finite readback route. □

Theorem 2043.8 (LocatedSpace positive-gap exactness)**.** *For every accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier*

$$L = (X, R, A, G, W, Q, E, H, C, P, N),$$

a positive locatedness request reaches the $\mathsf{Real}^{\uparrow}$ *seal* E *only after the positive* $\mathsf{ApartnessSpace}^{\uparrow}$ *gap row* A*, the metric-distance budget* G*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the displayed* $\mathsf{Real}^{\uparrow}$ *boundary row have all been exposed. The route exports no trichotomy, quotient real equality, selected representative, or ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.PositiveGapExactness.LocatedSpaceCarrier positive gap exactness`

Proof. Project the accepted carrier through Definition 2043.1. The positive locatedness request is displayed by the rows R, A, G, while W, Q, E are the only downstream rows capable of reading the finite observation and terminal real boundary.

Apply Definition 2043.4. It keeps the apartness-facing request scoped by X, R, A, G before any stream window, regular readback, or real seal can be consumed.

Apply Definition 2043.6. The metric-distance read is ledgered by the same $X, R, A, G, W, Q, E, H, C, P, N$ route, so the positive budget used by the apartness row is the budget read by the metric comparison and not an external order decision.

Finally use Definition 2043.7. Transport and replay preserve the same W, Q, E readback route, and the carrier contains no trichotomy, quotient equality, selected representative, or ambient completion coordinate. Thus the positive gap reaches the Real seal only through the displayed finite rows. □

Theorem 2043.9 (LocatedSpace obligation closure route)**.** *The accepted* $\mathsf{LocatedSpace}^{\uparrow}$ *carrier has the full obligation surface needed for* $\mathsf{seed} \to \mathsf{obligation}$*. The surface consists of the carrier and NameCert rows of Definition 2043.2, the exact positive-gap route of Definition 2043.5, the metric request ledger of Definition 2043.6, and the stream readback stability of Definition 2043.7; together these rows expose the source, request, gap, budget, window, regular readback, Real seal, transport, replay, provenance, and local naming before any locatedness consumer reads the packet.*

Lean4 ✓ `BEDC.Derived.LocatedSpaceUp.LocatedSpaceCarrier obligation closure route`

Proof. First project the NameCert obligations. They give carrier admission, locatedness stability, positive-gap exactness, completion-boundary nonescape, and ledger refusal over the displayed rows $X, R, A, G, W, Q, E, H, C, P, N$.

Next apply the positive-gap exactness route. It identifies A, G as the only finite gap surface available to metric, regular-rational, and Real-facing consumers, so the obligation surface cannot import a second apartness witness or host order decision.

Then use the metric request ledger and stream readback stability. The former orders every metric request through $X, R, A, G, W, Q, E, H, C, P, N$, while the latter keeps W, Q, E attached to the same source, request, gap, and budget under transport and replay.

These rows exhaust the obligation-level route. They upgrade the paper closure axis from seed to obligation without changing the formal verification status, since no checked Lean theorem or standard bridge is asserted here. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$, publicClosed)

Scope closed: Definition 2043.1, Definition 2043.2, Definition 2043.5, Definition 2043.6, Definition 2043.7, and Definition 2043.9 close the public paper-side export surface over positive-gap exactness, metric request ledgering, stream readback stability, and obligation closure for finite locatedness requests through BHist, hsame, Cont, Pkg, NameCert, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{ApartnessSpace}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, open-cover compactness, choice, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Formal closure requires checked carrier admission, locatedness stability, positive-gap exactness, completion-boundary nonescape, and ledger refusal for BEDC.Derived.LocatedSpaceUp.

Constructive story: A $\mathsf{LocatedSpace}^{\uparrow}$ packet is generated from a metric source carrier, a finite locatedness request, a positive ApartnessSpace gap, a StreamName window, a RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2044

A Concrete Naming Certificate for $\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}$

Bishop–Bridges/Kelley-style constructive completion language treats the canonical passage from a Cauchy presentation into the completed ordered real surface as order-reflecting only through displayed regular tails, tolerance budgets, and real seals. The $\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}$ packet records that boundary as finite BEDC data: it reads the completion carrier of chapter 360, the constructive order route of chapter 1716, the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It exposes an ordered-completion interface for downstream consumers without quotient stream equality, selected representatives, trichotomy, ambient completeness, Lean verification, or bridge checking.

Definition 2044.1 (CauchyCompletionOrderEmbedding carrier)**.** *A* $\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, L, W, D, R, E, T, C, P, N)$$

with the following displayed rows:

1. *K is the source completion row, displaying the accepted* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *data whose two finite Cauchy names are being compared.*
2. *L is the source order row, displaying the* $\mathsf{CauchyRealOrder}^{\uparrow}$ *comparison that reads those names only through regular Cauchy evidence.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the order comparison and by the completion-facing real seal.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic budgets used to compare the displayed windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows and tolerance requests.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, L, W, D, R have been displayed.*
7. *T records componentwise* hsame *transport for the completion row, order row, stream windows, dyadic ledger, regular readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$K, L, W, D, R \longmapsto E \longmapsto T, P, N.$$

9. *P is the* Pkg *provenance over* CauchyCompletionOrderEmbedding$^{\uparrow}$, RealCauchyCompletion$^{\uparrow}$, CauchyRealOrder$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchyCompletionOrderEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, L, W, D, R, E, T, C, P, N$. The carrier has no coordinate for quotient streams, selected representatives, trichotomy, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyCompletionOrderEmbeddingUp.CauchyCompletionOrderEmbeddingTasteGate`
`single carrier alignment`

Theorem 2044.2 (CauchyCompletionOrderEmbedding NameCert obligations)**.** *For every accepted* CauchyCompletionOrderEmbedding$^{\uparrow}$ *carrier*

$$O = (K, L, W, D, R, E, T, C, P, N),$$

the local NameCert$_{\text{CauchyCompletionOrderEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the completion row, order row, finite stream windows, dyadic tolerance ledger, regular rational readback, real seal, transport, replay, provenance, and local naming row;*
2. *completion-source exactness, requiring every order-facing real read to begin with the displayed* RealCauchyCompletion$^{\uparrow}$ *row K;*
3. *order-route exactness, requiring every comparison exported by the packet to pass through the displayed* CauchyRealOrder$^{\uparrow}$ *row L;*
4. *window and budget exposure, requiring the inspected* StreamName$^{\uparrow}$ *windows W, the* DyadicRatCore$^{\uparrow}$ *ledger D, and the* RegSeqRat$^{\uparrow}$ *readback R to be displayed before the* Real$^{\uparrow}$ *seal E is read;*
5. *provenance exhaustion, requiring T, C, P, N to transport, replay, source, and name only the listed route.*

No NameCert obligation is stored outside those rows, and none exports quotient streams, selected representatives, trichotomy, ambient completeness, Lean verification, or bridge checking.

Proof. Carrier admission is projection from Definition 2044.1. The accepted packet displays exactly the completion row, order row, window family, dyadic ledger, readback row, real seal, and structural rows.

Completion-source exactness follows from the placement of K at the start of every replay route. A downstream order-facing read cannot bypass the accepted completion row because no second completion coordinate appears in the carrier.

Order-route exactness is supplied by L. The only comparison row available to the classifier is the displayed CauchyRealOrder$^{\uparrow}$ row, and it reads the finite windows, dyadic budgets, and regular rational observations named in W, D, R.

The real-seal boundary is then a finite exposure check. The seal E is downstream of K, L, W, D, R, while T, C, P, N preserve and name the same route without adding mathematical coordinates. Thus the excluded quotient, representative, trichotomy, completeness, verification, and bridge principles have no row from which a consumer could read them. □

Theorem 2044.3 (CauchyCompletionOrderEmbedding order reflection)**.** *Let $O = (K, L, W, D, R, E, T, C, P, N)$ be an accepted* CauchyCompletionOrderEmbedding$^{\uparrow}$ *packet. Any finite* Real$^{\uparrow}$*-sealed comparison exported by O reflects back to the displayed source order row L: if the completed real seal is read as*

an ordered comparison, then the route factors through

$$K \longmapsto L \longmapsto (W, D, R) \longmapsto E.$$

The reflection is a packet-local route through displayed Cauchy data, not quotient stream equality, not a selected representative comparison, not trichotomy, and not ambient completeness.

Proof. Start with a completed real-seal comparison exported by O. Projection from the carrier gives the only seal row E and the only order row L available to that comparison.

The replay row C records the order of inspection. Before E can be read as an ordered real observation, the completion row K has been displayed, the comparison has passed through L, and the windows, tolerance ledger, and readback rows W, D, R have been opened.

Transport does not add a second comparison route. The row T moves the same displayed rows componentwise, and P, N source and name the same packet. Hence every completed ordered comparison reflects to the source order row L through finite Cauchy data alone. □

Theorem 2044.4 (CauchyCompletionOrderEmbedding real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}$ *carrier receives the seal row E only after the completion row K, the order row L, the stream-window rows W, the dyadic tolerance ledger D, and the regular readback row R have been displayed. Consequently the consumer receives an ordered-completion route and receives no quotient stream, selected representative, trichotomy witness, ambient completeness theorem, Lean verification, or bridge credential from the packet.*

Proof. Let a $\mathsf{Real}^{\uparrow}$ consumer read the accepted packet. The carrier inventory gives a single seal row E and identifies its upstream route as K, L, W, D, R.

The finite observation rows are inspected first. The stream windows W provide the displayed name observations, the dyadic ledger D supplies the tolerance budgets, and the readback row R records the rational observations consumed by the order row L.

Only then is the seal exposed. Since E is downstream of the completion and order rows, a consumer sees the real seal as part of the ordered-completion route rather than as an independent host real.

The structural rows close the boundary. Componentwise transport, continuation replay, package provenance, and the local name preserve the same coordinates, so the packet cannot export any of the excluded quotient, representative, trichotomy, completeness, verification, or bridge data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2044.1, Definition 2044.2, Definition 2044.3, and Definition 2044.4 seed the finite ordered-completion route from displayed Cauchy completion data to the real-order seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-source exactness, order-route exactness, window and budget exposure, provenance exhaustion, order reflection, and real-seal boundary for BEDC.Derived.CauchyCompletionOrderE

Constructive story: A $\mathsf{CauchyCompletionOrderEmbedding}^{\uparrow}$ packet is generated from a RealCauchyCompletion row, a CauchyRealOrder row, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2045

A Concrete Naming Certificate for $\mathsf{AlexandroffCompactification}^{\uparrow}$

Following Alexandroff, Bourbaki, and Kelley, the one-point compactification of a locally compact Hausdorff space is recorded here as a finite BEDC boundary packet rather than as an imported host-space construction. The $\mathsf{AlexandroffCompactification}^{\uparrow}$ carrier reads the topology surface of chapter 88, the locally compact neighborhood data of chapter 1726, the Hausdorff separation surface of chapter 1925, and the finite compactness interface of chapter 60. It names the adjoined point and the compact-complement neighborhood ledger that compactification consumers need, while leaving open-cover compactness, quotient topology, selected representatives, choice, ambient completeness, Lean verification, and bridge checking outside the packet.

Definition 2045.1 (AlexandroffCompactification carrier)**.** *An* $\mathsf{AlexandroffCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, T, L, S, \infty, O, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying source carrier whose points are being compactified.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row on X, exposing only the ordinary open rows that may be reused away from the adjoined point.*
3. *L is the* $\mathsf{LocallyCompact}^{\uparrow}$ *row, displaying the finite local compact-neighborhood witnesses needed before any infinity-neighborhood row may be opened.*
4. *S is the* $\mathsf{HausdorffSpace}^{\uparrow}$ *row, displaying the separated-neighborhood ledger used to keep ordinary points apart from compact-complement boundary reads.*
5. *∞ is the named adjoined point row, stored as a new BEDC name rather than as a host representative or quotient class.*
6. *O is the ordinary-open ledger: a finite family of rows saying that a displayed open row in the compactified packet whose carrier avoids ∞ is read exactly through T.*
7. *K is the compact-complement infinity-neighborhood ledger: each row consists of a displayed compact witness from the* $\mathsf{Compact}^{\uparrow}$ *surface, its complement request, and the assertion that the resulting neighborhood contains ∞.*

8. *H records componentwise* hsame *transport for the source carrier, topology row, local compactness row, Hausdorff row, infinity name, ordinary-open ledger, compact-complement ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of every compactification-facing route through*

$$(X, T, L, S) \longmapsto (O, K, \infty) \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* AlexandroffCompactification$^{\uparrow}$, Topology$^{\uparrow}$, LocallyCompact$^{\uparrow}$, HausdorffSpace$^{\uparrow}$, Compact$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{AlexandroffCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, L, S, \infty, O, K, H, C, P, N$. There is no coordinate for open-cover compactness, quotient topology, selected representatives, choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.AlexandroffCompactificationUp.AlexandroffCompactificationTasteGate single carrier alignment`

Theorem 2045.2 (AlexandroffCompactification NameCert obligations)**.** *For every accepted* AlexandroffCompactific *carrier*

$$A = (X, T, L, S, \infty, O, K, H, C, P, N),$$

the local NameCert$_{\text{AlexandroffCompactification}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source carrier, topology row, locally compact row, Hausdorff row, infinity name, ordinary-open ledger, compact-complement ledger, transport, replay, provenance, and local naming row;*

2. *source topology exactness, requiring every ordinary open read in O to factor through the displayed* Topology$^{\uparrow}$ *row T on X;*

3. *local compactness exposure, requiring every infinity-neighborhood row in K to open the displayed* LocallyCompact$^{\uparrow}$ *row L before it may read a compact witness;*

4. *Hausdorff separation compatibility, requiring ordinary-point separation and compact-complement boundary reads to use the displayed* HausdorffSpace$^{\uparrow}$ *row S and no host point equality;*

5. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed route.*

No NameCert obligation is stored outside these rows, and none exports open-cover compactness, quotient topology, selected representatives, choice, ambient completeness, Lean verification, or bridge checking.

Proof. Carrier admission is projection from Definition 2045.1. The accepted packet displays the source carrier, topology row, local compactness row, Hausdorff row, infinity name, the two open-neighborhood ledgers, and the structural rows.

Source topology exactness follows from the role of O. An ordinary open row that does not contain ∞ is replayed through the displayed topology row T, and the carrier contains no second topology coordinate.

The infinity-neighborhood obligation is the role of K. Each row in K first reads local compactness through L, then names a compact witness through the Compact$^{\uparrow}$ surface, and only then records the compact-complement neighborhood containing ∞.

Hausdorff compatibility is supplied by S. The separated-neighborhood data are transported componentwise by H and replayed by C, so no host point equality or selected representative can be inserted into the route.

Finally, P and N source and name the same finite route. Since the carrier has no row for the excluded principles, the displayed rows exhaust the local NameCert surface. □

Theorem 2045.3 (AlexandroffCompactification neighborhood classifier)**.** *Let $A = (X, T, L, S, \infty, O, K, H, C, P, N$ be an accepted* $\mathsf{AlexandroffCompactification}^{\uparrow}$ *carrier. Every displayed compactification-neighborhood read is classified by exactly one of the following packet-local routes:*

1. *an ordinary-open route through O and the source topology row T, with no read of the infinity point;*
2. *an infinity-neighborhood route through K, beginning with the adjoined point row ∞ and continuing through the local compactness row L and a compact-complement witness from* $\mathsf{Compact}^{\uparrow}$.

Both routes are stable under componentwise hsame *transport and displayed* Cont *replay, and neither route exports quotient topology, selected representatives, choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Take an accepted carrier and a displayed neighborhood read. Projection from the carrier gives only the ordinary-open ledger O and the compact-complement ledger K as neighborhood sources.

If the read avoids ∞, the classifier uses the first route. The row in O points back to T, so the neighborhood is an ordinary source-topology row and no compact-complement data are inspected.

If the read contains ∞, the classifier uses the second route. The row in K names the adjoined point, opens local compactness through L, and records the compact witness whose complement supplies the infinity neighborhood.

The transport and replay rows do not add a third route. They preserve the same displayed coordinates, while P and N source and name the packet. The excluded quotient, representative, choice, completeness, verification, and bridge data are absent from the carrier. □

Theorem 2045.4 (AlexandroffCompactification compact boundary ledger)**.** *Every compact-facing consumer of an accepted* $\mathsf{AlexandroffCompactification}^{\uparrow}$ *carrier receives only the finite boundary ledger*

$$(T, L, S, \infty, O, K, H, C, P, N).$$

The ordinary side of the ledger reads source opens through T, and the infinity side reads compact-complement neighborhoods through L and the $\mathsf{Compact}^{\uparrow}$ *witness rows. The handoff therefore exposes a concrete compactification boundary without claiming open-cover compactness, quotient topology, selected representatives, choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Let a compact-facing consumer read the accepted packet. The carrier inventory identifies the only boundary rows available to the consumer: the source topology, locally compact and Hausdorff support, the adjoined point, the two neighborhood ledgers, and the structural rows.

On the ordinary side, the consumer reads an O row and thereby returns to the source topology T. This provides ordinary opens over X without creating a new host-space topology object.

On the infinity side, the consumer reads a K row. That row passes through the locally compact witness L and a compact witness from the $\mathsf{Compact}^{\uparrow}$ surface before exposing the complement as a neighborhood of ∞.

The remaining rows only preserve the ledger. Componentwise transport, continuation replay, package provenance, and local naming record the same route, so the handoff contains no row for

the excluded compactness, quotient, representative, choice, completeness, verification, or bridge principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandroffCompactification}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandroffCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2045.1, Definition 2045.2, Definition 2045.3, and Definition 2045.4 seed the finite one-point compactification route from locally compact Hausdorff source data to a compact-complement boundary ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandroffCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient topology, selected representatives, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source topology exactness, local compactness exposure, Hausdorff separation compatibility, provenance exhaustion, neighborhood classification, and compact boundary ledger coverage for BEDC.Derived.AlexandroffCompactificationUp.

Constructive story: An $\mathsf{AlexandroffCompactification}^{\uparrow}$ packet is generated from a source carrier, a Topology row, a LocallyCompact row, a HausdorffSpace row, an adjoined infinity name, ordinary-open rows, compact-complement infinity-neighborhood rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2046

A Concrete Naming Certificate for $\mathsf{AlexandrovCompactification}^{\uparrow}$

From Alexandroff/Engelking-style one-point compactification, the $\mathsf{AlexandrovCompactification}^{\uparrow}$ packet records the finite route by which locally compact Hausdorff data are read as a compact one-point boundary without importing a host compact space. It consumes the local compactness interface of chapter 1726, the separation rows of chapter 1925, the compact certificate boundary of chapter 60, and the topology ledger of chapter 88. Downstream compactness consumers see only the displayed carrier, the added point, compact-complement neighbourhood rows, Hausdorff separation rows, topology transport rows, continuation routes, provenance, and a local NameCert.

Definition 2046.1 (AlexandrovCompactification carrier)**.** *An* $\mathsf{AlexandrovCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, \infty, K, S, T, C, P, N)$$

with the following displayed rows:

1. *X is the locally compact Hausdorff source carrier whose finite open, compact, and separation data are being compactified.*
2. *∞ is the distinguished boundary point added to X; it is a named point row, not a quotient class and not a selected limit.*
3. *K is the compact-complement neighbourhood ledger. Each infinity-neighbourhood request is displayed as a finite row naming an open neighbourhood of ∞ by a compact subset of X whose complement is exposed as the neighbourhood trace on X.*
4. *S is the Hausdorff separation ledger. It records point–point separation inside X, point–boundary separation between $x \in X$ and ∞, and the compatibility of those rows with the compact-complement ledger.*
5. *T records topology transport rows for source opens, infinity-neighbourhood rows, finite intersections, finite unions, and componentwise* hsame *movement of the carrier, boundary point, compact-complement ledger, separation ledger, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of every compactification-facing consumer route through*

$$X, \infty, K, S, T \longmapsto P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{AlexandrovCompactification}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexandrovCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, \infty, K, S, T, C, P, N$. It has no coordinate for open-cover compactness, host topological compactness, choice, quotient equality, selected limits, Lean verification, or a standard bridge.

Lean4 ✓ `BEDC.Derived.AlexandrovCompactificationUp.AlexandrovCompactificationTasteGate single carrier alignment`

Theorem 2046.2 (AlexandrovCompactification NameCert obligations)**.** *For every accepted* AlexandrovCompactific *carrier*

$$A = (X, \infty, K, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AlexandrovCompactification}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the locally compact Hausdorff source X, the added boundary point ∞, the compact-complement ledger K, the separation ledger S, topology transport T, continuation replay C, provenance P, and local naming row N;*
2. *source exactness, requiring every compactification read to begin with the displayed locally compact Hausdorff carrier X and not with an ambient compact host;*
3. *boundary-neighbourhood exactness, requiring every neighbourhood of ∞ to be read through a displayed compact-complement row of K;*
4. *Hausdorff compatibility, requiring point–point and point–boundary separation reads to pass through S and to preserve the same compact-complement row used by the boundary neighbourhood;*
5. *ledger exhaustion, requiring T, C, P, N to transport, replay, source, and name only the listed rows, with no open-cover compactness, host topological compactness, choice, quotient equality, selected limit, Lean verification, or bridge credential.*

No AlexandrovCompactification NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2046.1. The accepted packet displays the source carrier, boundary point, compact-complement ledger, separation ledger, topology transport rows, continuation replay, provenance, and local name.

Source exactness is the placement of X at the start of every replay route. Since the packet has no compact host coordinate, a compactification-facing read cannot replace the locally compact Hausdorff source by an already compact ambient space.

Boundary-neighbourhood exactness is the role of K. A neighbourhood of ∞ is admitted only as a compact-complement row, so its trace on X is read from the displayed compact subset and its complement rather than from an open-cover compactness principle.

Hausdorff compatibility is supplied by S. Point–point separation remains inside the displayed source, while point–boundary separation shares the same compact-complement row used by the infinity-neighbourhood request.

Finally, T, C, P, N only transport, replay, source, and name the displayed rows. Because the excluded compactness, choice, quotient, selected-limit, verification, and bridge data are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2046.3 (AlexandrovCompactification infinity filter boundary)**.** *Let $A = (X, \infty, K, S, T, C, P, N)$ be an accepted* $\mathsf{AlexandrovCompactification}^{\uparrow}$ *carrier. Every read of the neighbourhood filter at ∞ factors through a displayed compact-complement row of K. The factorization uses the route*

$$X, \infty, K \longmapsto S, T \longmapsto C, P, N$$

and does not factor through open-cover compactness, choice, quotient equality, selected limits, or host topological compactness.

Proof. Start with an infinity-neighbourhood read of the accepted packet. Projection from Definition 2046.1 gives the boundary point ∞ and the compact-complement ledger K as the only neighbourhood data attached to that point.

Opening the read selects a displayed row of K. That row names the compact subset of X and the complementary trace on X that defines the neighbourhood of ∞ inside the packet.

The separation and topology rows then preserve this same compact-complement row. The Hausdorff ledger S supplies the point–boundary separation route, and T transports finite open, union, and intersection reads without adding a second compactness source.

The continuation and provenance rows close the route. Since C, P, N replay, source, and name only the displayed rows, the infinity filter cannot be read through open-cover compactness, choice, quotient equality, selected limits, or host topological compactness. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandrovCompactification}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandrovCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2046.1, Definition 2046.2, and Definition 2046.3 seed the finite one-point compactification route from locally compact Hausdorff source data to the compact-complement boundary filter.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandrovCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host topological compactness, choice, quotient equality, selected limits, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source exactness, boundary-neighbourhood exactness, Hausdorff compatibility, ledger exhaustion, and infinity-filter boundary for BEDC.Derived.AlexandrovCompactificationUp.

Constructive story: An $\mathsf{AlexandrovCompactification}^{\uparrow}$ packet is generated from a locally compact Hausdorff carrier, a named boundary point, a compact-complement neighbourhood ledger, Hausdorff separation rows, topology transport rows, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2047

A Concrete Naming Certificate for $\mathsf{SeriesDivergenceTest}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the packet records the nth-term divergence test as a finite BEDC refusal boundary: a displayed nonzero tail of a $\mathsf{Series}^{\uparrow}$ source prevents a $\mathsf{RegSeqRat}^{\uparrow}$ handoff and hence prevents a $\mathsf{Real}^{\uparrow}$ seal. It reads the series source of chapter 121, the Cauchy-facing obstruction of chapter 392, the finite windows of chapter 126, the dyadic comparison rows of chapter 291, the regular-rational handoff boundary of chapter 301, and the real seal of chapter 38. The packet names a necessary-condition refusal; it does not import quotient series equality, selected sums, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2047.1 (Series divergence test carrier)**.** *A* $\mathsf{SeriesDivergenceTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Series}^{\uparrow}$ *source, read only through the finite term observations admitted by the series packet.*
2. *W is the finite tail-window ledger, recording the selected later windows in which the necessary tail-zero condition is being tested.*
3. *D is the displayed nonzero or apartness row, carrying a later term observation that remains apart from zero inside the accepted tail window.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparison, recording the dyadic zero-neighborhood, apartness witness, and finite comparison budget used by D.*
5. *R is the refused* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff boundary, exposed exactly where a regular Cauchy consumer would have to discharge the tail-zero condition.*
6. *E is the refused* $\mathsf{Real}^{\uparrow}$ *seal boundary, downstream of R and available only as a named obstruction to a real endpoint seal.*
7. *H stores componentwise* hsame *transport for the source, tail-window ledger, nonzero row, dyadic comparison, refused regular handoff, refused real seal, replay, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from the series source to the tail windows, from the tail windows to the nonzero row and dyadic comparison, from that comparison to the refused regular handoff, and from the handoff boundary to the refused real seal boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{SeriesDivergenceTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeriesDivergenceTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, D, T, R, E, H, C, P, N$. It has no coordinate for selected sums, quotient series equality, host real convergence, countable-choice selectors, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.SeriesDivergenceTestUp.SeriesDivergenceTestTasteGate single carrier alignment`

Theorem 2047.2 (Series divergence test NameCert obligations)**.** *For every accepted* $\mathsf{SeriesDivergenceTest}^{\uparrow}$ *carrier $S = (A, W, D, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeriesDivergenceTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed series source, tail-window ledger, nonzero tail row, dyadic comparison, refused regular handoff boundary, refused real seal boundary, transport, replay, provenance, and local naming rows;*

2. *tail-window exposure, requiring every later term inspected by the refusal to pass through A and W before any handoff boundary is read;*

3. *nonzero-tail stability, requiring D and T to display the same later apartness witness under the accepted dyadic zero-neighborhood comparison;*

4. $\mathsf{RegSeqRat}^{\uparrow}$ *refusal, requiring R to be reached exactly at the point where a regular Cauchy handoff would need tail-zero evidence;*

5. $\mathsf{Real}^{\uparrow}$ *nonescape, requiring E to remain downstream of the refused regular handoff and to export no selected sum, quotient series equality, host real convergence, countable choice, trichotomy, ambient completeness, Lean verification, or bridge datum;*

6. *componentwise transport, displayed replay, provenance, and local naming for the same refusal route through H, C, P, N.*

No series divergence test obligation is stored outside these rows.

Proof. Project the accepted packet $S = (A, W, D, T, R, E, H, C, P, N)$. The carrier definition exposes exactly the series source, tail-window ledger, displayed nonzero row, dyadic comparison, two refusal boundaries, and structural rows.

The tail-window exposure row forces every later term used by the test to be read through A and W. The nonzero-tail stability row then couples D to the dyadic comparison T, so the displayed apartness witness is not detached from the tolerance budget that made it visible.

At the regular handoff boundary, the route reaches R. By the obligation surface, a consumer can pass this point only by supplying the missing tail-zero condition; the displayed nonzero row blocks that discharge inside the same finite window.

Finally E, H, C, P, N preserve, replay, source, and name the same refusal route. Since no excluded analytic or choice object appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2047.3 (Series divergence test nonzero-tail refusal)**.** *Let $S = (A, W, D, T, R, E, H, C, P, N)$ be an accepted* $\mathsf{SeriesDivergenceTest}^{\uparrow}$ *carrier. Any consumer attempting a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff or a* $\mathsf{Real}^{\uparrow}$ *seal from the source A must first discharge the tail-zero condition for the displayed later windows. The nonzero tail row D, measured by the dyadic comparison T, blocks that route without quotient series equality, selected sums, countable choice, trichotomy, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer request for a regular handoff or real seal. The carrier exposes no direct endpoint coordinate from the series source; the only available route is

$$A \longmapsto W \longmapsto D, T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The request therefore reaches the tail-window ledger W before it reaches either refusal boundary. To continue toward R, it must turn the inspected later windows into the tail-zero evidence required by a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

The displayed row D supplies an apartness witness for one of those later terms, and T records the dyadic comparison that keeps the witness visible. Thus the required tail-zero discharge is unavailable inside the accepted packet.

Since the attempted $\mathsf{Real}^{\uparrow}$ seal E is downstream of the refused regular handoff, the same obstruction prevents endpoint sealing. The carrier has no slot for quotient series equality, selected sums, countable choice, trichotomy, host real equality, or ambient completeness, so none of those devices can bypass the finite refusal row. □

Falsifiable prediction: Every $\mathsf{SeriesDivergenceTest}^{\uparrow}$ endpoint-facing request factors through a SeriesUp source, finite tail-window ledger, displayed nonzero tail row, DyadicRatCore comparison, refused RegSeqRat handoff boundary, refused RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: series, cauchycriterion, streamname, dyadicratcore, regseqrat, real: $\mathsf{SeriesDivergenceTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source series row, finite tail windows, a displayed nonzero tail obstruction, dyadic apartness accounting, refused regular and real seal boundaries, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SeriesDivergenceTest}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeriesDivergenceTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2047.1, Definition 2047.2, and Definition 2047.3 seed the finite constructive nth-term divergence refusal route from displayed nonzero tail data to RegSeqRat and RealUp handoff denial.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeriesDivergenceTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient series equality, host real convergence, countable choice, trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exposure, nonzero-tail stability, RegSeqRat refusal, RealUp nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SeriesDivergenceTestUp.

Constructive story: A $\mathsf{SeriesDivergenceTest}^{\uparrow}$ packet is generated from a Series source, finite tail-window ledger, displayed nonzero tail row, DyadicRatCore comparison, refused RegSeqRat handoff boundary, refused RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2048

A Concrete Naming Certificate for $\mathsf{TotalBoundedMetric}^{\uparrow}$

Bishop–Bridges constructive metric compactness treats total boundedness as a tolerance-indexed finite-net interface attached to a displayed metric source. The $\mathsf{TotalBoundedMetric}^{\uparrow}$ packet records exactly that L10 boundary: it reads the metric carrier of chapter 57, the real metric comparison surface of chapter 1638, the finite epsilon-net ledger of chapter 1767, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the compact-metric consumer of chapter 129. The packet gives compact and completion-facing consumers a finite total-bounded metric package while leaving open-cover compactness, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking outside the carrier.

Definition 2048.1 (TotallyBoundedMetric carrier)**.** *A* $\mathsf{TotallyBoundedMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, R, E, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier, distance classifier, symmetry, zero-distance, and triangle ledgers read by the packet.*
2. *R is the* $\mathsf{RealMetric}^{\uparrow}$ *comparison row, exposing the real-valued metric readback only through displayed rational or dyadic observations.*
3. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *family row. For each positive tolerance request it displays a closed* $\mathsf{ProbeBundle}$ *of centers, membership rows, center-carrier rows, and coverage-distance witnesses.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic refinement and positivity data used by the finite-net family.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the source points and center names that enter a coverage claim.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations attached to distances, tolerances, and finite-net comparisons.*
7. *H records componentwise* hsame *transport for the metric source, real metric row, epsilon-net family, dyadic tolerance ledger, stream windows, regular rational readback, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay through*

$$M, R, D, S, Q \longmapsto E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{TotalBoundedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TotalBoundedMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, E, D, S, Q, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 (definition) `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotallyBoundedMetricUp`
Lean4 ✓ `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotallyBoundedMetricTasteGate single carrier alignment`

Theorem 2048.2 (TotallyBoundedMetric NameCert obligations)**.** *For every accepted* $\mathsf{TotallyBoundedMetric}^{\uparrow}$ *carrier*

$$T = (M, R, E, D, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TotallyBoundedMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, real metric comparison row, finite epsilon-net family, dyadic tolerance ledger, stream windows, regular rational readback, transport, replay, provenance, and local naming row;*
2. *metric-source exactness, requiring every distance and coverage row to pass through the displayed* $\mathsf{Met}^{\uparrow}$ *row M and the real metric comparison row R;*
3. *tolerance visibility, requiring each requested radius to be carried by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D before the finite-net row is read;*
4. *finite-net exposure, requiring every center and every coverage witness to enter through the displayed* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *family E;*
5. *window and readback compatibility, requiring the inspected point windows S and rational observations Q to be preserved by the same* hsame *transport and* Cont *replay rows;*
6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed route.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotalBoundedMetricCarrier namecert obligations`
↪ variant `BEDC.Derived.TotalBoundedMetricUp.TotalBoundedMetricCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 2048.1. The accepted packet displays the metric source M, real metric row R, finite epsilon-net family E, tolerance ledger D, stream windows S, rational readback Q, and structural rows.

Metric-source exactness follows from the placement of M and R at the start of the replay route. A coverage distance cannot be read without first opening the point and distance classifiers of M and the displayed real metric comparison row R.

Tolerance and finite-net exposure are rowwise. The dyadic ledger D supplies the positive tolerance data, and E supplies the closed center bundle, center membership rows, and coverage-distance witnesses for that tolerance.

The window and readback rows keep the route finite. The row S exposes only the inspected source and center windows, while Q records the rational observations attached to the distance and tolerance comparisons.

Finally, H, C, P, N preserve, replay, source, and name the same row inventory. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface and cannot export open-cover compactness, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking. □

Theorem 2048.3 (TotallyBoundedMetric finite-net factorization)**.** *Every compact or completion-facing consumer of an accepted* $\mathsf{TotallyBoundedMetric}^{\uparrow}$ *carrier reads total boundedness through the finite route*

$$M, R, D \longmapsto E \longmapsto S, Q \longmapsto H, C, P, N.$$

Thus each total-bounded metric claim first opens the metric source, real metric comparison row, and dyadic tolerance ledger, then a displayed $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *family of center bundles and coverage rows, and only then the stream-window, rational-readback, transport, replay, provenance, and local naming rows.*

Proof. Let $T = (M, R, E, D, S, Q, H, C, P, N)$ be accepted. A compact or completion-facing consumer enters the packet through the metric source M, because no coverage distance is meaningful before the point and distance classifiers have been displayed.

The real metric row R and dyadic tolerance row D are inspected next. They supply the comparison and positive-radius data required by the finite-net family.

The finite-net factor is exactly E. For the requested tolerance, E exposes a closed $\mathsf{ProbeBundle}$ of centers, center membership rows, center-carrier rows, and coverage-distance witnesses.

The readback route then remains finite. The stream windows S and regular rational observations Q record the inspected point and distance data, while H, C, P, N transport, replay, source, and name the same package without adding a second compactness route.

Therefore every exported total-bounded metric claim factors through the displayed finite-net route. The consumer receives no open-cover compactness, countable choice, selected limit, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification, or bridge credential from the packet. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotallyBoundedMetricCarrier finite net factorization`

Theorem 2048.4 (Total-bounded metric finite-net obligation)**.** *Let* $T = (M, R, E, D, S, Q, H, C, P, N)$ *be an accepted* $\mathsf{TotalBoundedMetric}^{\uparrow}$ *carrier. For every positive dyadic tolerance admitted by* D*, the finite-net obligation exposed by the local* $\mathsf{NameCert}_{\mathsf{TotalBoundedMetric}^{\uparrow}}$ *surface is exactly the closed* $\mathsf{ProbeBundle}$ *branch of* E *together with its center-membership rows, center-carrier rows over* M*, coverage-distance witnesses read through* R*, finite observation windows* S*, regular rational readback* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, provenance* P*, and local name* N*.*

In particular, a $\mathsf{CompactMetric}^{\uparrow}$ *or compact-uniform-continuity consumer can read a finite net only through the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{ProbeBundle}, \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{C}$$

The obligation exports no selected finite subcover, host enumeration of centers, open-cover compactness theorem, countable-choice schedule, or detached ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier. The tolerance request first reaches the dyadic ledger D, so positivity, refinement, and radius comparison are visible before any center bundle is consumed.

The finite-net row is then forced to be E. Its closed ProbeBundle branch supplies the center rows, the InBundle membership constructors, and the coverage witnesses for the displayed tolerance.

The metric and real reads are not independent coordinates. The center-carrier rows are read over M, coverage distances pass through R, and the finite observations and rational comparisons are recorded by S and Q.

Finally H, C, P, N transport, replay, source, and name the same route. Since no selected subcover, host enumeration, open-cover compactness theorem, choice schedule, or detached completeness principle occurs as a carrier coordinate, the listed finite route exhausts the obligation. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotalBoundedMetricCarrier finite net obligation`

Theorem 2048.5 (Total-bounded metric Cauchy-cover obligation)**.** *Let $T = (M, R, E, D, S, Q, H, C, P, N)$ be an accepted* TotalBoundedMetric$^{\uparrow}$ *carrier. Every Cauchy-cover read used by a* CompleteMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, *or compact-uniform-continuity route is obtained by replaying the same finite-net data at the requested dyadic tolerance: metric source M, real-distance comparison R, tolerance ledger D, finite center bundle E, observation windows S, readback row Q, and structural rows H, C, P, N.*

Thus the Cauchy-cover interface is a finite BEDC dependency between the Real and Completion phase and the compact-metric phase. It does not import a completed compact space, an open-cover proof, a selected convergent subsequence, a hidden dense enumeration, quotient equality of Cauchy names, countable choice, or host real completeness.

Proof. Begin with a Cauchy-cover request. The only metric source available to it is M, and the only real-distance comparison row available to it is R.

The requested cover scale is supplied by D. At that scale, Definition 2048.4 identifies E as the unique finite-net row through which centers, membership constructors, and coverage witnesses can be read.

The observation data remains finite because S stores the inspected source and center windows, while Q stores the regular rational readbacks used by the distance and tolerance comparisons.

The structural rows H, C, P, N then replay the same data for completion, compact-metric, and compact-uniform-continuity consumers. None of the excluded compactness, subsequence, dense-enumeration, quotient, choice, or host-completeness objects has a carrier coordinate, so no Cauchy-cover read can depend on it. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedMetricUp.TasteGate.TotallyBoundedMetricCarrier cauchy cover obligation`

Theorem 2048.6 (TotallyBoundedMetric Cauchy-window extraction)**.** *Let $T = (M, R, E, D, S, Q, H, C, P, N)$ be an accepted* TotallyBoundedMetric$^{\uparrow}$ *carrier. Any Cauchy-window request answered by the packet must expose a* FiniteEpsilonNet$^{\uparrow}$ *row E, a* DyadicRatCore$^{\uparrow}$ *tolerance row D, finite* StreamName$^{\uparrow}$ *observation windows S, and* RegSeqRat$^{\uparrow}$ *readback Q before any compact or completion-facing consumer reads the result. The extracted route is finite and exports no open-cover compactness, selected limit, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2048.1. The metric source M and real metric comparison row R give the source of the Cauchy-window request, while D, E, S, Q are the only tolerance, finite-net, observation-window, and rational-readback rows.

By Definition 2048.2, tolerance visibility requires the dyadic row D before a radius-dependent finite net is read. Finite-net exposure then requires the center family and coverage witnesses to enter through E.

By Definition 2048.3, compact and completion-facing consumers receive total boundedness only through the finite route $M, R, D, E, S, Q, H, C, P, N$. The StreamName windows S and RegSeqRat readback Q keep the Cauchy-window answer attached to displayed observations.

The structural rows H, C, P, N preserve and name the same route. Since the carrier has no coordinate for open-cover compactness, selected limits, countable choice, or ambient Real completeness, none of those principles can be read from the extracted Cauchy window. □

Lean4 ✓ `BEDC.Derived.TotalBoundedMetricUp.TotalBoundedMetricCarrier cauchy window extraction`

Closure status for $\mathsf{NameCert}_{\mathsf{TotalBoundedMetric}\uparrow}$.

Scope closed: Definition 2048.1, Definition 2048.2, Definition 2048.3, Definition 2048.4, and Definition 2048.5 seed the finite total-bounded metric package over displayed metric, real metric, finite-net, dyadic tolerance, stream-window, regular rational, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotalBoundedMetric}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exactness, tolerance visibility, finite-net exposure, window and readback compatibility, provenance exhaustion, Cauchy-cover replay, and finite-net factorization for BEDC.Derived.TotalBoundedMetricUp.

Constructive story: A $\mathsf{TotalBoundedMetric}^{\uparrow}$ packet is generated from a MetricSpaceUp source row, a RealMetricUp comparison row, a FiniteEpsilonNetUp family, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2049

A Concrete Naming Certificate for $\mathsf{OnePointCompactification}^{\uparrow}$

Following Alexandroff compactification and Kelley topology, the $\mathsf{OnePointCompactification}^{\uparrow}$ packet records the one-point compactification boundary of a displayed locally compact metric source as finite BEDC NameCert data. It reads the local compact-neighbourhood surface of chapter 1726, the radius-window closed-ball ledger of **??**, the center-radius membership row of chapter 1451, the compact witness surface of chapter 129, and the open-index handoff of chapter 88. The packet names the added infinity row and the compact-complement neighbourhood route without importing open-cover compactness or a host compactification space.

Definition 2049.1 (OnePointCompactification carrier)**.** *A* $\mathsf{OnePointCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, L, B, \infty, Q, T, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the locally compact source row. It supplies the point classifier, local compact-neighbourhood windows, and source transport through the* $\mathsf{LocallyCompact}^{\uparrow}$ *surface.*
2. *L is the proper or closed-ball neighbourhood ledger. It records the displayed* $\mathsf{ProperMetric}^{\uparrow}$ *radius-window rows and the* $\mathsf{MetricClosedBall}^{\uparrow}$ *membership rows used to present compact complements around infinity.*
3. *B is the closed-ball boundary row. It exposes only center-radius non-strict membership comparisons already admitted by* $\mathsf{MetricClosedBall}^{\uparrow}$*.*
4. *∞ is the added infinity point row, disjoint from the displayed source-point rows by the local classifier and available only through the compactification packet.*
5. *Q is the compact-complement row. A neighbourhood of ∞ is read as the complement of a displayed compact closed-ball or compact metric window, with the compact witness carried by the rows L and B.*
6. *T is the topology handoff row. It sends source-open rows and infinity-neighbourhood rows into the indexed open surface of* $\mathsf{Topology}^{\uparrow}$ *without adding a second open-set carrier.*
7. *K is the compact-metric handoff row. It records that compactness consumers of the displayed complement window read the* $\mathsf{CompactMetric}^{\uparrow}$ *witness already attached to L and B.*

8. *H records componentwise* hsame *transport for the source row, neighbourhood ledger, closed-ball row, infinity point row, compact-complement row, topology handoff, compact-metric handoff, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay through*

$$X, L, B, \infty \longmapsto Q \longmapsto T, K \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{OnePointCompactification}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OnePointCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, L, B, \infty, Q, T, K, H, C, P, N$. It has no coordinate for open-cover compactness, a host compactification, selected points, quotient spaces, choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.OnePointCompactificationUp.OnePointCompactificationTasteGate single carrier alignment`

Theorem 2049.2 (OnePointCompactification NameCert obligations)**.** *For every accepted* OnePointCompactificatio *carrier*

$$A = (X, L, B, \infty, Q, T, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OnePointCompactification}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the locally compact source, proper or closed-ball neighbourhood ledger, closed-ball boundary row, infinity point row, compact-complement row, topology handoff, compact-metric handoff, transport, replay, provenance, and local naming row;*

2. *source-local exactness, requiring every ordinary-point neighbourhood read to factor through X and the cited* $\mathsf{LocallyCompact}^{\uparrow}$ *neighbourhood surface;*

3. *compact-complement exactness, requiring every infinity-neighbourhood read to open L and B before it reads the compact-complement row Q;*

4. *topology handoff, requiring the ordinary and infinity neighbourhood rows to be exported only through the indexed open surface T of* $\mathsf{Topology}^{\uparrow}$*;*

5. *compact-metric handoff, requiring compactness consumers to read only the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *witness row K attached to the same compact complement window;*

6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed route.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2049.1. The accepted packet displays the locally compact source X, the proper or closed-ball ledger L, the closed-ball row B, the infinity point row, the compact-complement row Q, the topology and compact-metric handoffs T, K, and the structural rows.

Source-local exactness follows from the first entry of the route. An ordinary-point neighbourhood read starts in X, so it can use only the local compact-neighbourhood rows supplied by $\mathsf{LocallyCompact}^{\uparrow}$.

Infinity-neighbourhood exactness is the compact-complement clause. The request first opens the neighbourhood ledger L and the closed-ball row B, then reads Q as the complement of the displayed compact closed-ball or compact metric window.

The two handoffs are separate. The row T exports the ordinary and infinity neighbourhood rows to $\mathsf{Topology}^{\uparrow}$, while K exposes the compact witness already attached to the compact complement. Neither row creates an open-cover compactness theorem.

Finally, H, C, P, N preserve, replay, source, and name the same row inventory. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface and cannot export a host compactification, selected point, quotient space, choice principle, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification, or bridge credential. □

Theorem 2049.3 (OnePointCompactification compact-neighbourhood handoff)**.** *Every compactness, topology, or completion-facing consumer of an accepted* $\mathsf{OnePointCompactification}^{\uparrow}$ *carrier factors its infinity-neighbourhood read through*

$$X, L, B, \infty \longmapsto Q \longmapsto T, K \longmapsto H, C, P, N.$$

Thus the consumer receives a compact-complement neighbourhood of ∞ only as a displayed proper or closed-ball window with its compact metric witness and topology handoff, and receives no open-cover compactness proof, host compactification space, selected source point, quotient-space construction, choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a consumer request at the added point. The only admitted added point is the row ∞, so the request must read the source row X together with the neighbourhood ledger L and closed-ball row B before any compact complement can be named.

The compact-complement row is exactly Q. It records the complement of the displayed compact closed-ball or compact metric window; the compact witness remains the one already routed through L, B and then through the compact-metric handoff K.

The topology export is exact. The row T sends the ordinary source neighbourhood rows and the infinity-neighbourhood rows into the indexed $\mathsf{Topology}^{\uparrow}$ surface, while H and C transport and replay the same data componentwise.

The provenance row P names only the cited sibling certificates, and N names only the local $\mathsf{OnePointCompactification}^{\uparrow}$ packet. Therefore every downstream compactness, topology, or completion-facing read factors through the displayed route and cannot recover any excluded host or choice-based datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{OnePointCompactification}^{\uparrow}}$**.**

Constructive story: A $\mathsf{OnePointCompactification}^{\uparrow}$ packet is generated from a LocallyCompactUp source row, ProperMetricUp or MetricClosedBallUp neighbourhood ledger, an added infinity row, compact-complement rows, TopologyUp handoff, CompactMetricUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OnePointCompactification}^{\uparrow}}$, seed)

Scope closed: Definition 2049.1, Definition 2049.2, and Definition 2049.3 seed the one-point compactification package over locally compact source, proper or closed-ball neighbourhood, infinity, compact-complement, topology, compact-metric, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OnePointCompactification}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, a host compactification space, selected points, quotient spaces, choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-local exactness, compact-complement exactness, topology handoff, compact-metric handoff, componentwise transport, provenance exhaustion, and compact-neighbourhood handoff for BEDC.Derived.OnePointCompactificationUp.

Chapter 2050

A Concrete Naming Certificate for $\mathsf{ChainConnectedMetric}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Engelking topology tradition, the $\mathsf{ChainConnectedMetric}^{\uparrow}$ packet records connectedness through finite epsilon-chain witnesses rather than through host-level separation principles. It attaches the interval-facing corridor of chapter 1462 to the located metric surface of chapter 2043, the dyadic tolerance core of chapter 291, the stream-window naming layer of chapter 126, the regular rational readback of chapter 301, and the real completion boundary of chapter 38. The certificate gives Real and Completion consumers a finite chain route while making no claim of host connectedness, quotient equality, Heine–Borel compactness, trichotomy, or open-cover compactness.

Definition 2050.1 (Chain-connected metric carrier)**.** *A* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, a, b, \epsilon, C, D, W, Q, E, H, R, P, N)$$

with the following displayed rows:

1. *X is the metric source row, carrying the point classifier, distance classifier, and metric law ledgers read by the packet.*
2. *a and b are endpoint rows over X, with their names exposed only through the displayed source classifier.*
3. *ϵ is a positive dyadic radius request admitted by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
4. *$C = (c_0, \ldots, c_m)$ is a finite chain list, with c_0 transported from a and c_m transported from b.*
5. *D is the dyadic tolerance ledger recording positivity, refinement, and link-radius comparison data for ϵ and every adjacent pair in C.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family used to inspect the endpoint and chain names.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations attached to distances, endpoint comparisons, and dyadic tolerances.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the Real-facing completion observation obtained after the finite dyadic chain rows have been read.*
9. *H records componentwise* hsame *transport for the metric source, endpoints, dyadic radius, chain list, tolerance ledger, stream windows, rational readbacks, Real seal, replay row, provenance row, and local naming row.*

10. *R records displayed* Cont *replay through*

$$X, a, b, \epsilon, C, D, W, Q \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* ChainConnectedMetric$^{\uparrow}$, ConnectedInterval$^{\uparrow}$, LocatedSpace$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{ChainConnectedMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, a, b, \epsilon, C, D, W, Q, E, H, R, P, N$. It has no coordinate for host connectedness, quotient equality, Heine–Borel compactness, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.ChainConnectedMetricUp.TasteGate.ChainConnectedMetricUp`
Lean4 ✓ `BEDC.Derived.ChainConnectedMetricUp.TasteGate.ChainConnectedMetricTasteGate single carrier alignment`

Theorem 2050.2 (Chain-connected metric NameCert obligations)**.** *For every accepted* ChainConnectedMetric$^{\uparrow}$ *carrier*

$$K = (X, a, b, \epsilon, C, D, W, Q, E, H, R, P, N),$$

the local NameCert$_{\text{ChainConnectedMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, endpoints, dyadic radius, finite chain list, dyadic tolerance ledger, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming row;*
2. *link-radius exactness, requiring every adjacent pair in C to have its distance comparison read through X, D, and Q before the link is admitted;*
3. *endpoint transport, requiring c_0 and c_m to be the displayed* hsame *transports of a and b along the same packet route;*
4. *chain concatenation stability, requiring compatible endpoint transport and dyadic ledgers to compose by finite list concatenation without creating a second metric source;*
5. *Real seal nonescape, requiring E to be read only after $X, a, b, \epsilon, C, D, W, Q$ have been displayed;*
6. *ledger refusal, rejecting any consumer that asks the packet for host connectedness, quotient equality, Heine–Borel compactness, trichotomy, open-cover compactness, Lean verification, or bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2050.1. The accepted packet displays the source X, endpoints a, b, dyadic radius ϵ, chain list C, dyadic ledger D, stream windows W, rational readback Q, Real seal E, and structural rows.

Link-radius exactness is rowwise. Each adjacent pair of the finite list C is inspected through the metric source X, and its dyadic comparison is recorded by D and read back through Q before the link can contribute to the certificate.

Endpoint transport uses the same componentwise hsame row H that transports the rest of the packet. Thus the first and last chain entries are tied to a and b without introducing an ambient equality principle.

Concatenation stability is finite list bookkeeping. Two accepted chains with matching transported endpoint rows concatenate by joining their displayed chain lists and ledgers, while the source row X and the replay route remain unchanged.

The Real seal is downstream of the finite rows. Since E appears only after $X, a, b, \epsilon, C, D, W, Q$ in the replay route, a Real-facing consumer cannot bypass the dyadic chain witnesses.

Finally, the classifier has no coordinates for the excluded principles. Any request for host connectedness, quotient equality, Heine–Borel compactness, trichotomy, open-cover compactness, Lean verification, or bridge checking therefore has no row to read and is refused by the local ledger. □

Theorem 2050.3 (Chain-connected metric Real completion boundary)**.** *Every Real-facing chain-connectedness consumer of an accepted* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *carrier factors through the finite route*

$$X, a, b, \epsilon, C, D, W, Q \longmapsto E \longmapsto H, R, P, N$$

before reading the $\mathsf{Real}^{\uparrow}$ *seal. Consequently the packet exports only dyadic chain rows and their transported Real readback, not a host connectedness theorem, quotient equality principle, Heine–Borel compactness result, trichotomy decision, or open-cover compactness claim.*

Proof. Let $K = (X, a, b, \epsilon, C, D, W, Q, E, H, R, P, N)$ be accepted. A Real-facing consumer first reads the metric source and endpoints because the chain entries and endpoint transports are meaningful only relative to the displayed source classifier.

The positive radius and finite chain are then inspected through ϵ and C. Every adjacent link is certified by the dyadic ledger D, the stream windows W, and the rational readback Q.

Only after those finite rows have been displayed does the replay route expose the Real seal E. The transport, replay, provenance, and local naming rows then preserve the same dependency order.

Thus each Real-facing chain-connectedness claim factors through the displayed dyadic chain route before it can read $\mathsf{Real}^{\uparrow}$. The packet has no remaining coordinate from which the excluded host-level principles could be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChainConnectedMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChainConnectedMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2050.1, Definition 2050.2, and Definition 2050.3 seed the finite epsilon-chain connectedness package over displayed metric, endpoint, dyadic tolerance, chain-list, stream-window, regular rational, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChainConnectedMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host connectedness, quotient equality, Heine–Borel compactness, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, link-radius exactness, endpoint transport, chain concatenation stability, Real seal nonescape, ledger refusal, and Real completion boundary factorization for BEDC.Derived.ChainConnectedMet

Constructive story: A $\mathsf{ChainConnectedMetric}^{\uparrow}$ packet is generated from a metric source row, endpoint rows, a dyadic radius, a finite chain list, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2051

A Concrete Naming Certificate for $\mathsf{CauchyCompletenessModulus}^{\uparrow}$

Following Bishop and Bridges constructive regular-Cauchy completion, the $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ packet records the finite tail-modulus route that turns a displayed regular rational Cauchy row into a terminal $\mathsf{Real}^{\uparrow}$ completion seal. It sits between the active completion objects: the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the threshold discipline of chapter 292, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the Bishop boundary of chapter 1639, and the terminal real seal of chapter 38. The packet exposes explicit Cauchy tail control for completion consumers without adding a selected limit, quotient route, global choice principle, Lean verification, or standard bridge.

Definition 2051.1 (CauchyCompletenessModulus carrier)**.** *A* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, M, D, S, B, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational sequence, its local tail comparison classifier, and the finite request surface read by completion consumers.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold ledger. For each requested tolerance it records a displayed tail threshold and the rowwise evidence that later indices are read only beyond that threshold.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, including dyadic positivity, refinement, and budget-splitting rows used to compare tail requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite prefix, threshold window, and readback indices inspected by the route.*
5. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, displaying the completion-interface obligations that accept regular Cauchy data with an explicit modulus.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row produced by the completion boundary after the route through R, M, D, S, B has been displayed.*
7. *H records componentwise* hsame *transport for the regular sequence, modulus ledger, dyadic budget, stream windows, Bishop boundary, terminal real seal, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay through*

$$R, M, D, S \longmapsto B \longmapsto L \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, D, S, B, L, H, C, P, N$. It has no coordinate for a chosen representative quotient, a selected limit operator, countable choice, ambient completeness beyond the displayed seal, Lean verification, or a standard bridge.

Lean4 ✓ `BEDC.Derived.CauchyCompletenessModulusUp.CauchyCompletenessModulusTasteGate single carrier alignment`

Theorem 2051.2 (CauchyCompletenessModulus NameCert obligations)**.** *For every accepted* CauchyCompletenessM *carrier*

$$K = (R, M, D, S, B, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletenessModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational source, Cauchy threshold ledger, dyadic tolerance data, stream windows, Bishop completion boundary, terminal real seal, transport, replay, provenance, and local naming row;*
2. *threshold exposure, requiring each completion request to display its* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row before any* $\mathsf{Real}^{\uparrow}$ *seal is read;*
3. *dyadic budget routing, requiring each tolerance comparison to factor through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positivity, refinement, and budget-splitting rows;*
4. *stream and readback readiness, requiring the inspected sequence entries, threshold windows, and readback indices to pass through the* $\mathsf{StreamName}^{\uparrow}$ *row and the same regular rational source R;*
5. *Real seal handoff, requiring the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary B to be opened before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row L is named;*
6. *classifier transport, requiring H and C to preserve the same R, M, D, S, B, L inventory under* hsame *and displayed* Cont *replay;*
7. *non-escape, requiring P and N to source and name only the listed route, with no hidden selected limit, quotient representative, countable choice, Lean verification, or standard bridge.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2051.1. The accepted packet displays the regular rational source R, modulus ledger M, dyadic tolerance row D, stream windows S, Bishop boundary B, terminal seal L, and structural rows H, C, P, N.

Threshold exposure is forced by the position of M in the carrier. A completion request cannot reach the seal row until it has first opened the Cauchy threshold row attached to the requested tolerance.

Dyadic budget routing is rowwise. The dyadic data D records positivity, refinement, and budget splitting before the threshold is consumed by the Bishop completion boundary.

The stream and readback rows keep the route finite. The window row S exposes only the inspected prefix, threshold window, and readback indices, while the source row R supplies the regular rational observations attached to those windows.

The Real seal handoff then passes through B and only afterward names L. The transport and replay rows H, C preserve the same inventory, and the provenance and naming rows P, N have no additional coordinate from which an unlisted obligation could be read. □

Theorem 2051.3 (CauchyCompletenessModulus Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *completion-seal read exported by an accepted* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ *carrier factors through*

$$\mathsf{CauchyModulus}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BishopRegularCauchyCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, a consumer can open the terminal seal row L only after reading the displayed threshold ledger M, dyadic tolerance row D, stream window row S, regular rational source R, and Bishop completion boundary B.

Proof. Let $K = (R, M, D, S, B, L, H, C, P, N)$ be accepted. A seal consumer enters through the completion request, so the first visible tail datum is the threshold ledger M.

The tolerance carried by that request is then compared through D. This supplies the dyadic positivity, refinement, and split-budget evidence needed to interpret the threshold as a finite tail claim.

The finite indices and observations are exposed through S and R. The stream window row supplies the inspected indices, and the regular rational source supplies the sequence observations read at those indices.

Only after those rows are displayed can the route open the Bishop completion boundary B. The terminal real seal L is therefore downstream of M, D, S, R, B, and the structural rows H, C, P, N merely transport, replay, source, and name that same path.

Thus every exported $\mathsf{Real}^{\uparrow}$ completion-seal read factors through the stated modulus-to-seal route. No consumer receives a second path through a selected limit, quotient representative, countable choice principle, Lean verification, or standard bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2051.1, Definition 2051.2, and Definition 2051.3 seed the finite modulus-to-seal packet over regular rational source, Cauchy threshold ledger, dyadic tolerance data, stream windows, Bishop completion boundary, terminal real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyCompletenessModulusUp.CauchyCompletenessModulusTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient representatives, countable choice, ambient completeness beyond the displayed RealUp seal, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exposure, dyadic budget routing, stream and readback readiness, Real seal handoff, classifier transport, non-escape, and seal-route factorization for BEDC.Derived.CauchyCompletenessModulusUp.

Constructive story: A $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ packet is generated from a RegSeqRat source row, a CauchyModulus threshold ledger, DyadicRatCore tolerance data, StreamName windows, a BishopRegularCauchyCompletion boundary, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2052

A Concrete Naming Certificate for $\mathsf{ArchimedeanModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ArchimedeanModulus}^{\uparrow}$ packet records the finite precision modulus by which an explicit Archimedean bound is turned into a bounded Real-facing observation route. It sits over the dyadic tolerance surface of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, the terminal real seal of chapter 38, the Real-facing modulus route of chapter 1423, and the explicit rational-bound surface of chapter 430. The packet is a bridge object for L10 Real and Completion work: it supplies a displayed bound-to-window schedule without reading host real equality, trichotomy, selected limits, quotient representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2052.1 (Archimedean modulus carrier)**.** *An* $\mathsf{ArchimedeanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (P, D, S, Q, E, A, H, C, N)$$

with the following displayed rows:

1. *P is the unary precision request. It names the requested observation depth as finite successor data rather than as an external real-valued tolerance.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound/tolerance row. It records the dyadic comparison budget attached to the requested precision and to the displayed Archimedean bound.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule selected by P and D.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row inspected on the windows named by S.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after P, D, S, Q have been consumed.*
6. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *rational-bound witness attached to the same displayed real name as E.*
7. *H records componentwise* hsame *transport for the precision request, dyadic row, finite windows, regular readback, Real seal, Archimedean witness, continuation, and local naming rows.*
8. *C records the displayed* Cont *replay from each unary precision request through P, D, S, Q, E, A, H, N.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, trichotomy, selected limits, quotient representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden unbounded stream read.*

Lean4 ✓ `BEDC.Derived.ArchimedeanModulusUp.ArchimedeanModulusTasteGate single carrier alignment`

Theorem 2052.2 (Archimedean modulus NameCert obligations)**.** *For an accepted* $\mathsf{ArchimedeanModulus}^{\uparrow}$ *carrier* $M = (P, D, S, Q, E, A, H, C, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, unary precision exposure, dyadic bound/tolerance exposure, finite-window exposure, regular rational readback, Real seal exposure, Archimedean rational-bound handoff, componentwise transport, displayed continuation replay, and local naming. Each accepted precision request is classified only through the displayed route*

$$P \longmapsto D \longmapsto S \longmapsto Q \longmapsto E, A \longmapsto H, C, N.$$

Proof. Project the carrier tuple in Definition 2052.1. Its coordinates are exactly the unary precision request, dyadic bound/tolerance row, finite-window schedule, regular readback, Real seal, Archimedean bound witness, transport, continuation, and local naming rows.

Induct over the displayed unary precision request P. The zero request consumes the bound/tolerance row D only at the base observation depth and then names the corresponding finite window in S. The successor request repeats the same finite step after exposing one more unary layer, so the read never becomes an unbounded stream request.

After the window is named, the readback row Q and the seal row E are downstream of D and S, while A supplies only the already displayed Archimedean rational-bound witness. The rows H, C, N transport, replay, and name the same route. Since none of host real equality, trichotomy, selected limits, quotient representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a hidden selector has a coordinate in M, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.ArchimedeanModulusUp.ArchimedeanModulusNameCertObligations`

Theorem 2052.3 (Archimedean modulus window bound)**.** *Every accepted* $\mathsf{ArchimedeanModulus}^{\uparrow}$ *packet* $M = (P, D, S, Q, E, A, H, C, N)$ *binds each unary precision request to a finite* $\mathsf{StreamName}^{\uparrow}$ *window before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal is available. The selected window is bounded by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *together with the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *witness* A*; it is not selected by real trichotomy, a host supremum, quotient representatives, countable choice, a chosen limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the unary request P. By Definition 2052.2, every accepted read must expose D before S, so the dyadic bound/tolerance row is available before the finite window is named.

Induct on P. The base request uses the first displayed tolerance row and the Archimedean witness A to name the corresponding finite window. In the successor step, the previous finite route is replayed and the next tolerance row is read through the same D, A surface before the next finite window is admitted.

Now inspect the downstream rows. The regular readback Q and Real seal E are read only after the window in S is displayed, while H, C, N preserve and name that route. Thus the window bound is internal to the displayed dyadic and Archimedean rows and cannot be supplied by host real equality, trichotomy, a host supremum, quotient representatives, countable choice, selected limits, or ambient Real completeness. □

Theorem 2052.4 (Archimedean modulus Real handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{ArchimedeanModulus}^{\uparrow}$ *packet factors through*

$$P \longmapsto D \longmapsto S \longmapsto Q \longmapsto E \longmapsto A \longmapsto H, C, N$$

before reading the bounded precision-modulus surface. In particular, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and bounded lower-cut consumers receive the displayed dyadic tolerance, finite-window, regular readback, Real seal, and Archimedean witness rows, and receive no host real equality, trichotomy, selected limit, quotient representative, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted packet. The Real-facing rows are Q and E, but they are unavailable until the unary precision request P, dyadic row D, and finite-window schedule S have been read.

Apply the window-bound theorem. It binds every window request to the displayed dyadic tolerance row and Archimedean rational-bound witness, so downstream consumers inherit an explicit finite modulus surface rather than a host completeness argument.

Finally replay the continuation row C and transport row H. These rows preserve the same route for $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and bounded lower-cut consumers, while N names the packet locally. The carrier inventory excludes host real equality, trichotomy, selected limits, quotient representatives, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so none of those sources can enter the Real handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2052.1, Definition 2052.2, Definition 2052.3, and Definition 2052.4 seed the finite Archimedean precision-modulus surface from unary precision requests through dyadic tolerances, finite stream windows, regular rational readback, Real seals, Archimedean rational bounds, transport, continuation, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, trichotomy, selected limits, quotient representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, window-bound exactness, dyadic stability, RegSeqRat handoff, and Real seal nonescape for BEDC.Derived.ArchimedeanModulusUp.

Constructive story: An $\mathsf{ArchimedeanModulus}^{\uparrow}$ packet is generated from a unary precision request, DyadicRatCore bound/tolerance row, StreamName finite-window schedule, RegSeqRat readback row, RealUp seal row, ArchimedeanReal rational-bound witness, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Chapter 2053

A Concrete Naming Certificate for $\mathsf{FirstCountableSpace}^{\uparrow}$

Following Bourbaki and Kelley on countability axioms in topology, the $\mathsf{FirstCountableSpace}^{\uparrow}$ packet records the local countable-neighbourhood interface needed between generated-open topology data and metric-completion consumers. It sits over the generated-open classifier of chapter 88, the metric-ball basis route of chapter 1655, the countable-base surface of chapter 1901, and the complete-separable metric consumer route of chapter 1490. The packet names only displayed point windows, local neighbourhood-base rows, refinement rows, radius ledgers, transport, replay, provenance, and local naming; it does not select neighbourhood bases by choice, assert open-cover compactness, identify quotient points, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2053.1 (First-countable-space carrier)**.** *A* $\mathsf{FirstCountableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, T, M, L, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the point or source carrier row whose finite histories are the only points inspected by the packet.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *generated-open classifier row; every open-neighbourhood read passes through this row before it reaches a consumer.*
3. *M is the* $\mathsf{MetricTopology}^{\uparrow}$ *or metric-ball basis route when the local base is metric-presented; if no metric route is displayed, M is the explicit empty witness row.*
4. *L is the local countable-neighbourhood ledger, recording for each accepted point-window the finite index windows and neighbourhood cells exposed at that point.*
5. *D is the dyadic radius and precision ledger used by metric-presented neighbourhood cells and completion-facing boundary reads.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for finite inspection of the local countable schedule at a displayed point-window.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *boundary and seal row used only when a radius, metric-topology, or completion-facing read requires a real-valued boundary.*

8. *H stores componentwise* hsame *transport for the source, topology classifier, optional metric-topology route, local schedule, dyadic ledger, stream windows, real seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a point-window through the topology classifier, local schedule, optional metric route, precision ledger, stream window, real seal, transport, provenance, and local name.*

10. *P is the* Pkg *provenance row over* $\mathsf{FirstCountableSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FirstCountableSpace}^{\uparrow}}$ *row.*

The carrier exports a displayed local countable base at each accepted point-window. It has no coordinate for a host family of all neighbourhoods, a choice-selected basis, quotient point equality, arbitrary open covers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FirstCountableSpaceUp.FirstCountableSpaceTasteGate single carrier alignment`

Theorem 2053.2 (First-countable-space NameCert obligations)**.** *For an accepted* $\mathsf{FirstCountableSpace}^{\uparrow}$ *carrier*

$$F = (X, T, M, L, D, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FirstCountableSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the point or source row, topology classifier, optional metric-topology route, local countable-neighbourhood ledger, dyadic ledger, stream windows, real seal, transport, replay, provenance, and local name;*

2. *pointwise local-basis coverage, requiring every accepted point-window and generated-open neighbourhood read to meet a displayed neighbourhood cell from L through the same source row X and topology row T;*

3. *pointwise refinement closure, requiring any two displayed local neighbourhood cells accepted at the same point-window to refine through another displayed local cell indexed by the same ledger L;*

4. *metric-topology handoff, requiring every metric-presented local cell to pass through M, D, S, R before it is exported to a completion-facing consumer;*

5. *ledger nonescape, requiring every point, open-neighbourhood, radius, stream-window, real-boundary, transport, replay, provenance, and local-naming read to remain inside $X, T, M, L, D, S, R, H, C, P, N$.*

No first-countability obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2053.1. The accepted packet displays one source row, one topology classifier, one optional metric-topology route, one local countable-neighbourhood ledger, and the structural rows needed to replay and name the packet.

Pointwise local-basis coverage is read from X, T, L. A consumer opens a point-window in X, reads a generated-open neighbourhood through T, and receives only a displayed local cell from L at the same finite point-window.

Pointwise refinement is also internal to L. When two local cells are accepted at one point-window, the refinement witness is another displayed entry of the same local ledger, not a selected neighbourhood from a host family.

Metric-presented cells use the route through M, D, S, R. The optional metric-topology row supplies the ball-basis handoff, the dyadic ledger supplies the radius precision, the stream row

supplies the finite inspection window, and the real row supplies only the boundary seal requested by the consumer.

Finally H, C, P, N transport, replay, source, and name the displayed rows. Since the packet contains no host neighbourhood family, choice-selected local base, quotient point equality, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness field, the listed obligations exhaust the local certificate surface. □

Theorem 2053.3 (First-countable to second-countable handoff)**.** *Every accepted* $\mathsf{SecondCountable}^{\uparrow}$ *packet induces a* $\mathsf{FirstCountableSpace}^{\uparrow}$ *read by restricting the displayed countable-base enumeration to the accepted point-window. The induced first-countable read uses the same source row, topology classifier, optional metric witness, dyadic ledger, stream windows, real seal, componentwise transport, replay, provenance, and local name; only the global base enumeration is read pointwise as the local ledger* L*.*

Proof. Start with the accepted $\mathsf{SecondCountable}^{\uparrow}$ carrier. Its source row, topology classifier, optional metric witness, dyadic ledger, stream row, real seal, transport, replay, provenance, and local name already have the same BEDC roles required by Definition 2053.1.

At a displayed point-window, read the second-countable base enumeration through its stream schedule. The local ledger L is the finite list of displayed basic cells from that enumeration that are witnessed at the same point-window.

Coverage and refinement are inherited pointwise. A generated-open neighbourhood first receives a displayed basic cell from the second-countable coverage row, and two such cells refine through the second-countable refinement row before being re-read as local entries of L.

The remaining rows are unchanged. No selected global basis, host open family, countable-choice principle, quotient point equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness field is introduced by the pointwise restriction. □

Theorem 2053.4 (First-countable-space nonescape)**.** *Let* $F = (X, T, M, L, D, S, R, H, C, P, N)$ *be an accepted* $\mathsf{FirstCountableSpace}^{\uparrow}$ *carrier. Any topology, metric-topology, completion-facing, or Polish-space consumer read of the local countable-neighbourhood surface factors through the displayed route*

$$X, T, M, L, D, S, R, H, C, P, N$$

before it exports a neighbourhood, radius, stream window, or boundary seal. Consequently the packet cannot export open-cover compactness, a choice-selected neighbourhood basis, quotient point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a topology consumer. It has no open-neighbourhood coordinate except T, and no local countable-neighbourhood coordinate except L, so the read starts at the source row X, passes through the topology classifier T, and then through the displayed local ledger L.

A metric-topology or completion-facing consumer additionally reads the optional metric route M. Radius and precision requests must pass through D, finite schedule requests through S, and real-boundary requests through R before the consumer can observe a local cell.

The structural rows keep the same route fixed under transport and replay. Componentwise transport is recorded in H, replay in C, provenance in P, and local naming in N.

No other coordinate is available. Since the carrier omits arbitrary open covers, selected neighbourhood bases, quotient point representatives, and ambient real-completeness fields, every exported read remains inside the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FirstCountableSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FirstCountableSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2053.1, Definition 2053.2, Definition 2053.3, and Definition 2053.4 seed the local countable-neighbourhood interface over displayed source rows, topology classifiers, optional metric-topology routes, local schedules, dyadic ledgers, stream windows, real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FirstCountableSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FirstCountableSpaceUp.FirstCountableSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected neighbourhood bases by choice, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pointwise local-basis coverage, pointwise refinement, second-countable handoff, metric-topology handoff, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FirstCountableSpaceUp.

Constructive story: A $\mathsf{FirstCountableSpace}^{\uparrow}$ packet is generated from one point or source carrier row, one Topology classifier row, an optional MetricTopology route, one local countable-neighbourhood ledger, one DyadicRatCore precision ledger, one StreamName finite-inspection row, one Real boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2054

A Concrete Naming Certificate for $\mathsf{BishopCauchyNormalization}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion, the $\mathsf{BishopCauchyNormalization}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name is replaced by a cofinal normalized name before the terminal real seal is read. It sits after the modulus-normal-form surface of chapter 1968, the cofinal subsequence route of chapter 1998, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal boundary of chapter 38. The packet gives later $\mathsf{Real}^{\uparrow}$ and completion consumers a normal-form route without quotient real equality, selected limits, countable choice, or ambient completeness.

Definition 2054.1 (BishopCauchyNormalization carrier)**.** *A* $\mathsf{BishopCauchyNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, \phi, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, carrying the regular Cauchy rational observations before normalization.*
2. *M is the* $\mathsf{CauchyModulusNormalForm}^{\uparrow}$ *row that converts the source regularity budget into a displayed monotone precision schedule.*
3. *ϕ is the* $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ *row selecting cofinal source windows along the normalized schedule.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the source and normalized reads.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, endpoint observations, slack rows, and comparison cells consumed by M and ϕ.*
6. *R is the normalized* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the cofinal schedule and dyadic ledger have been displayed.*
7. *E is the inherited* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after S, M, ϕ, W, D, R have been consumed.*
8. *H records componentwise* hsame *transport for the source, modulus normal form, cofinal route, stream windows, dyadic ledger, normalized readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S, M \longmapsto \phi, W, D \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* BishopCauchyNormalization$^{\uparrow}$, CauchyModulusNormalForm$^{\uparrow}$, RegularCauchyCofinalSu StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BishopCauchyNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, \phi, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected subsequence functions, chosen real limits, trichotomy, countable choice, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyNormalizationUp.BishopCauchyNormalizationTasteGate single carrier alignment`

Theorem 2054.2 (BishopCauchyNormalization NameCert obligations)**.** *For every accepted* BishopCauchyNormaliz *carrier*

$$K = (S, M, \phi, W, D, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopCauchyNormalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular rational row, modulus-normal-form row, cofinal subsequence row, finite-window row, dyadic tolerance ledger, normalized readback, real seal, transport, replay, provenance, and local name;*
2. *modulus normalization, requiring M to expose the monotone precision schedule before any cofinal window is selected;*
3. *cofinal schedule stability, requiring ϕ to choose only displayed source windows and to witness cofinality for every inspected normalized precision;*
4. *regularity preservation, requiring W and D to feed the normalized* RegSeqRat$^{\uparrow}$ *row R with the dyadic slack named by the same schedule;*
5. *Real seal compatibility, requiring E to be read only after the source, normal-form, cofinal, window, dyadic, and normalized readback rows have been displayed;*
6. *ledger non-escape, requiring H, C, P, N to preserve and name only the listed route and to export no quotient stream, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient completeness row.*

No Bishop Cauchy normalization obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2054.1. The accepted packet displays exactly the source regular rational row, modulus-normal-form row, cofinal route, stream windows, dyadic ledger, normalized readback, seal, and structural rows.

Modulus normalization is read from M. Since M is the only coordinate that names the normalized precision schedule, any accepted cofinal read must expose that schedule before ϕ can select source windows.

Cofinal schedule stability is then read from ϕ. The selected windows are visible only as displayed windows in W, and their tolerances are carried by D, so the route cannot appeal to a host subsequence function or an unrecorded selector.

Regularity preservation and seal compatibility follow from the row order. The normalized readback R consumes the selected windows and dyadic slack before the Real seal E is available.

Finally H, C, P, N add only transport, replay, provenance, and naming. Since the carrier has no row for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 2054.3 (BishopCauchyNormalization cofinal subsequence route)**.** *Let*

$$K = (S, M, \phi, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyNormalization}^{\uparrow}$ *carrier. Every normalized regular Cauchy read exported by K factors through the finite route*

$$S, M \longmapsto \phi, W, D \longmapsto R \longmapsto H, C, P, N.$$

The route is cofinal in the displayed source schedule: each inspected normalized precision reads a source window selected by ϕ after M has exposed the corresponding normal-form request, and before R exports the normalized $\mathsf{RegSeqRat}^{\uparrow}$ *row.*

Proof. Fix an inspected normalized precision. The only row naming the normal-form request is M, so the request is first read through the modulus-normal-form coordinate.

The cofinal row ϕ then supplies the selected source window for that request. Because ϕ is paired with the displayed finite-window row W, the selected index is consumed as a finite observation window rather than as an external subsequence function.

The dyadic ledger D attaches the required tolerance and slack data to the selected window. The normalized readback row R is downstream of both W and D, so it can export only the regular rational observation generated by the displayed cofinal route.

Transport, replay, provenance, and local naming preserve this route. Thus every normalized read factors through $S, M, \phi, W, D, R, H, C, P, N$, and cofinality is the displayed $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ row rather than a choice principle. □

Theorem 2054.4 (BishopCauchyNormalization Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopCauchyNormalization}^{\uparrow}$ *carrier reaches the seal only through*

$$S, M \longmapsto \phi, W, D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the normalized name exports the same finite source, modulus-normal-form, cofinal-window, dyadic-ledger, normalized-readback, and seal rows, and exports no quotient real equality, chosen limit, selected representative, trichotomy, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted carrier and inspect the Real-facing coordinate. The seal row E is downstream of the source row S, modulus row M, cofinal route ϕ, finite windows W, dyadic ledger D, and normalized readback row R.

By the cofinal subsequence route theorem, each normalized read already passes through the displayed normal-form request, selected source window, dyadic tolerance ledger, and regular rational readback. A Real-facing consumer therefore cannot reach E before that route has been consumed.

The remaining rows H, C, P, N only transport, replay, source, and name the same finite route. Since the carrier inventory contains no quotient real equality, chosen limit, selected representative, trichotomy, countable-choice schedule, or ambient completeness row, none of those principles can escape through the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyNormalization}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2054.1, Definition 2054.2, Definition 2054.3, and Definition 2054.4 seed the finite Bishop Cauchy normalization route from source regular rational names through modulus normal forms, cofinal windows, dyadic ledgers, normalized readback, Real seals, transport, continuation, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, quotient real equality, selected limits, selected representatives, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, modulus normalization, cofinal schedule stability, regularity preservation, Real seal compatibility, and ledger non-escape for BEDC.Derived.BishopCauchyNormalizationUp.

Constructive story: A $\mathsf{BishopCauchyNormalization}^{\uparrow}$ packet is generated from a RegSeqRat source row, CauchyModulusNormalForm row, RegularCauchyCofinalSubsequence row, StreamName windows, DyadicRatCore tolerance ledger, normalized RegSeqRat readback, inherited RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2055

A Concrete Naming Certificate for $\mathsf{InverseFunction}^{\uparrow}$

Following the local inverse function theory of Cartan and Rudin, the $\mathsf{InverseFunction}^{\uparrow}$ packet records only the finite local-inversion rows that a BEDC consumer may inspect after a displayed derivative row, an invertible linear approximation, Newton data, and the regular Cauchy real route have been opened. It consumes the local-solution boundary of chapter 1834, the Newton–Kantorovich route of chapter 1785, the finite step discipline of chapter 223, the regular rational readback route of chapter 301, the finite stream-window surface of chapter 126, and the terminal real-name seal of chapter 38. The chapter names a local certificate route from displayed analytic data to a local bijection window; it does not assert a host inverse function, identify quotient function spaces, select a germ, import ambient Real completeness, or provide bridge verification.

Definition 2055.1 (Inverse function carrier)**.** *An* $\mathsf{InverseFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (F, B, D, L, K, I, J, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed function row, recording the finite graph reads and local classifier for the source and target windows.*
2. *B is the base-point and window row. It records the displayed point x_0, the displayed value y_0, and the source and target neighbourhood names in which the local inverse is read.*
3. *D is the derivative row at the base point and along the displayed window.*
4. *L is the invertible linear approximation row attached to D, together with the finite inverse-witness ledger used for the local inversion estimate.*
5. *K is the* $\mathsf{NewtonKantorovich}^{\uparrow}$ *row that records the contraction neighbourhood and root-boundary handoff for solving $F(x) = y$ near y_0.*
6. *I is the* $\mathsf{ImplicitFunction}^{\uparrow}$ *row that repacks the same local solving data as a graph-window certificate for the equation $F(x) - y = 0$.*
7. *J is the finite* $\mathsf{NewtonIteration}^{\uparrow}$ *step ledger used by K and I before the endpoint is sealed.*
8. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened for source, target, and endpoint observations.*
9. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximations obtained from S.*

10. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed analytic, Newton, implicit, stream, and regular-rational rows have been opened.*

11. *H records componentwise* hsame *transport for the function row, base-point row, derivative row, invertible approximation row, Newton–Kantorovich row, implicit-function row, Newton-iteration ledger, stream windows, regular rational readback, Real seal, replay, provenance, and local naming.*

12. *C records displayed* Cont *replay through*

$$F, B, D, L, J, K, I, S, Q, R \longmapsto \mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}.$$

13. *P is the* Pkg *provenance over* $\mathsf{InverseFunction}^{\uparrow}$, $\mathsf{ImplicitFunction}^{\uparrow}$, $\mathsf{NewtonKantorovich}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, B, D, L, K, I, J, S, Q, R, H, C, P, N$. The carrier has no coordinate for a host inverse function, quotient function space equality, selected inverse germ, global bijection theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.InverseFunctionUp.InverseFunctionTasteGate single carrier alignment`

Theorem 2055.2 (Inverse function NameCert obligations)**.** *For every accepted* $\mathsf{InverseFunction}^{\uparrow}$ *carrier*

$$V = (F, B, D, L, K, I, J, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed function row, base-point and window row, derivative row, invertible approximation row, Newton–Kantorovich row, implicit-function row, Newton-iteration ledger, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name;*

2. *derivative and inverse-witness compatibility, requiring D and L to display the same local linear approximation and inverse ledger used by the solving route;*

3. *Newton route compatibility, requiring J to be the finite step ledger read by K before the root boundary is sealed;*

4. *implicit-function handoff, requiring I to read the same local equation row and graph-window data as the Newton route rather than a second solution source;*

5. *L10 completion-route handoff, requiring S, Q, R to be opened in order through finite StreamName windows, RegSeqRat readbacks, and the terminal Real seal;*

6. *provenance exactness, requiring P and N to source and name only the listed rows and no host inverse function, quotient function space, selected germ, global bijection theorem, ambient Real completeness principle, Lean verification, or bridge credential.*

No inverse-function NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2055.1. The accepted packet displays exactly the function row, base-point and window row, derivative row, invertible approximation row,

Newton–Kantorovich row, implicit-function row, Newton-iteration ledger, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name.

The analytic compatibility obligations are local to D and L. The derivative row supplies the displayed linear data, while the linear approximation row records the inverse-witness ledger used by both the Newton and implicit-function routes.

The solving route is finite. The row J lists the Newton steps, and K reads that ledger as the Newton–Kantorovich contraction and root-boundary handoff. The row I then repacks the same local solving data as a graph-window certificate for $F(x) = y$.

The completion-facing rows are downstream. The stream row S fixes the finite windows, Q supplies the regular rational readback, and R provides the terminal Real seal only after the analytic and solving rows have been opened. The structural rows H, C, P, N transport, replay, source, and name this same route without adding any excluded coordinate. □

Theorem 2055.3 (Inverse function local-bijection handoff)**.** *Every accepted* $\mathsf{InverseFunction}^{\uparrow}$ *read exported as a local bijection window factors through the displayed finite route*

$$\mathsf{ImplicitFunction}^{\uparrow} \longmapsto \mathsf{NewtonKantorovich}^{\uparrow} \longmapsto \mathsf{NewtonIteration}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by I, K, J, S, Q, R and the analytic rows F, B, D, L. The consumer receives one displayed function row, one base-point and window row, one derivative row, one invertible approximation row, one Newton–Kantorovich row, one implicit-function row, one finite NewtonIteration ledger, one StreamName window row, one RegSeqRat readback row, one Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. The handoff is local window data only; it is not a host inverse function, not quotient function space equality, not a selected germ, not a global bijection theorem, not ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and not bridge verification.*

Proof. Project the accepted carrier $V = (F, B, D, L, K, I, J, S, Q, R, H, C, P, N)$. The local bijection read starts with the displayed function and base-window rows F, B, and the only linear source available to it is the pair D, L.

The solving route then passes through the finite Newton data. The row J exposes the step ledger, K reads that ledger as the Newton–Kantorovich root-boundary route, and I identifies the same local solving data as an implicit-function graph window.

The L10 completion route is the final handoff. The finite windows in S are read back through Q, and the terminal Real data appears only in R. Thus a Real-facing inverse-window consumer cannot bypass the finite StreamName and RegSeqRat route.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no carrier coordinate stores a host inverse function, quotient function space, selected germ, global bijection theorem, ambient completeness theorem, or bridge credential, every exported local-bijection handoff is exhausted by the displayed finite packet. □

Falsifiable prediction: Every $\mathsf{InverseFunction}^{\uparrow}$ local-bijection read factors through one displayed function row, one base-point and window row, one derivative row, one invertible approximation row, one NewtonKantorovich row, one ImplicitFunction row, one finite NewtonIteration ledger, one StreamName finite-window row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: implicitfunction, newtonkantorovich, newtoniteration, regseqrat, streamname, real: $\mathsf{InverseFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries local

bijection windows, derivative and inverse-witness rows, finite Newton solving data, implicit graph-window handoff, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}$.

Constructive story: An $\mathsf{InverseFunction}^{\uparrow}$ packet is generated from a displayed function row, a base-point and window row, a derivative row, an invertible approximation row, a NewtonKantorovich row, an ImplicitFunction row, a finite NewtonIteration ledger, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2055.1, Definition 2055.2, and Definition 2055.3 seed the finite local inversion certificate over analytic rows, Newton solving rows, implicit graph-window rows, finite stream windows, regular rational readback, and Real seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InverseFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, quotient function spaces, selected inverse germs, global bijection theorems, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative and inverse-witness compatibility, Newton route compatibility, implicit-function handoff, L10 completion-route handoff, provenance exactness, and local naming for BEDC.Derived.InverseFunctionUp.

Chapter 2056

A Concrete Naming Certificate for $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$

Bishop–Bridges constructive completion treats convergence toward a completed real as a displayed modulus discipline: a completion-facing consumer may open only the finite windows, regular rational readbacks, dyadic tolerances, and real-name seals justified by the exhibited rate. The $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$ packet records that discipline on the L10 Real and Completion spine. It sits after the dyadic rational ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite modulus certificate for completion-facing reads; it does not identify quotient streams, choose limits, invoke countable choice, assert host real equality, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2056.1 (Constructive completion modulus carrier)**.** *A* $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, \mu, W, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy family row, including the displayed observations and precision requests whose completion-facing reads are being certified.*
2. *μ is the unary modulus row assigning to each requested tolerance a finite stage bound for the same source Cauchy family.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened only after the relevant value of μ has been displayed.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic budget consumed by μ, W, and Q.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal exposed only after the modulus, window, readback, and dyadic tolerance rows have been displayed.*
7. *H records componentwise* hsame *transport for the source Cauchy family, unary modulus, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the completion route*

$$S, \mu \longmapsto W \longmapsto Q \longmapsto D \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCompletionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, \mu, W, Q, D, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveCompletionModulusUp.ConstructiveCompletionModulusTasteGate`
`single carrier alignment`

Theorem 2056.2 (Constructive completion modulus NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$ *carrier*

$$M = (S, \mu, W, Q, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveCompletionModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy family, unary modulus, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*

2. *modulus/readback discipline, requiring each completion-facing read to expose the unary modulus value before the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback are inspected;*

3. *finite-window completion handoff, requiring the completion-facing read to pass through the displayed window W, readback Q, dyadic ledger D, and Real seal R in that order;*

4. *transport/replay stability, requiring H and C to preserve the same source Cauchy family, modulus value, window, readback, tolerance budget, and seal under componentwise* hsame *transport and displayed* Cont *replay;*

5. *provenance/local naming, requiring P and N to source and name only the displayed rows and to export no quotient stream, selected limit, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No constructive completion modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2056.1. The accepted packet displays exactly the source Cauchy family, unary modulus, finite-window, readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

The modulus/readback discipline is read from μ, W, and Q. Since the window row is opened only after the relevant modulus value is displayed, the regular rational readback cannot be inspected as an unbounded stream or as a selected completion representative.

The finite-window completion handoff is forced by the route through W, Q, D, R. The dyadic ledger records the tolerance budget before the Real seal is exposed, so the seal is a named terminal row of the finite route rather than an ambient completeness principle.

Transport and replay stability are exactly the content of H and C. They preserve the same source row, modulus value, window, readback, tolerance ledger, and seal, so a replayed packet cannot substitute a different completion witness.

Finally P and N add provenance and local naming only for the displayed route. Because the carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the five obligation rows exhaust the certificate surface. □

Theorem 2056.3 (Constructive completion modulus finite route)**.** *Let*

$$M = (S, \mu, W, Q, D, R, H, C, P, N)$$

be an accepted $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$ *carrier. Every completion-facing read of M factors through the finite route*

$$S, \mu \longmapsto W \longmapsto Q \longmapsto D \longmapsto R \longmapsto H, C, P, N.$$

Equivalently, the read uses only the displayed unary modulus, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. It exports no quotient stream, selected limit, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Fix a completion-facing read of an accepted carrier. Projection gives the source Cauchy family S and the unary modulus row μ.

The read then opens only the finite window justified by the displayed modulus value. Thus the $\mathsf{StreamName}^{\uparrow}$ row W and the $\mathsf{RegSeqRat}^{\uparrow}$ row Q are downstream of μ and cannot be replaced by an unbounded quotient stream.

The dyadic ledger and Real seal follow the same finite route. The row D records the tolerance budget consumed by the read, and R is exposed only after that budget is displayed.

The structural rows close the route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve and name only S, μ, W, Q, D, R. Hence no completion-facing consumer receives selected limits, countable choice, host real equality, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Constructive story: A $\mathsf{ConstructiveCompletionModulus}^{\uparrow}$ packet is generated from a source Cauchy family row, a unary modulus row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2057

A Concrete Naming Certificate for $\mathsf{NestedIntervalConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{NestedIntervalConvergence}^{\uparrow}$ packet records the handoff by which a displayed shrinking closed interval route is consumed as a regular rational completion name before a terminal real seal is read. It sits between the finite nested-packet surface of chapter 320, the completion-facing consumer of chapter 1421, the endpoint-cell discipline of chapter 394, the closed-interval Cauchy route of chapter 1778, and the $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$ seal route. The packet separates convergence handoff data from raw nested-interval rows and from the Cantor-intersection consumer: it names the finite diagonal enclosure, the regular-rational readback, and the real-seal nonescape surface without adding point choice, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2057.1 (Nested interval convergence carrier)**.** *A* $\mathsf{NestedIntervalConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (N, L, W, D, E, R, Q, H, C, P, M)$$

with the following displayed rows:

1. *N is an accepted* $\mathsf{NestedInterval}^{\uparrow}$ *packet, carrying the finite endpoint, width, inclusion, schedule, regular-rational, and seal-facing rows already displayed by the nested-interval certificate.*
2. *L is a* $\mathsf{LocatedInterval}^{\uparrow}$ *row binding the visible lower and upper endpoint reads to rational cells and optional dyadic refinements.*
3. *W is the shrinking-window ledger. For each displayed precision request it records a visible nested interval row, its endpoint enclosure, and a dyadic width bound small enough for the requested regular-rational tolerance.*
4. *D is the diagonal selection row. It chooses from N and W a finite window for each displayed request; it does not select a completed intersection point.*
5. *E records the endpoint enclosure rows selected by D and the dependency path back to N, L, W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the selected endpoint enclosures and their displayed width bounds.*
7. *Q is the closed-interval completion handoff row, reading the same selected enclosures through the* $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$ *route before any real-facing seal is exposed.*
8. *H records the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after N, L, W, D, E, R, Q have been displayed.*

9. *C records componentwise* hsame *transport and displayed* Cont *replay for nested packets, located endpoints, shrinking ledgers, diagonal selections, enclosures, regular-rational handoffs, completion handoffs, and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalConvergence}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *M is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, L, W, D, E, R, Q, H, C, P, M$. It has no coordinate for a raw infinite chain, a chosen intersection point, open-cover compactness, host real equality, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedIntervalConvergenceUp.NestedIntervalConvergenceTasteGate single carrier alignment`

Theorem 2057.2 (Nested interval convergence NameCert obligations)**.** *For every accepted* NestedIntervalConverger *carrier*

$$G = (N, L, W, D, E, R, Q, H, C, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the nested-interval packet, located-interval endpoint row, shrinking-window ledger, diagonal selection row, selected endpoint enclosures, regular-rational handoff, closed-interval completion handoff, real seal, transport, replay, provenance, and local naming rows;*

2. *nested-source exactness, requiring every interval read to open N and every endpoint-cell read to open L before the shrinking ledger W is consumed;*

3. *diagonal-window exactness, requiring D to select only a displayed finite window already recorded in N, W for the current precision request;*

4. *enclosure-width exactness, requiring every row of E to carry the selected endpoint enclosure together with the displayed dyadic width bound that justifies the request;*

5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exactness, requiring R to be read only from E and its width ledger;*

6. *closed-interval completion ordering, requiring Q to consume N, L, W, D, E, R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal H is exposed;*

7. *provenance exhaustion, requiring C, P, M to transport, replay, source, and name only the displayed route.*

No convergence obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2057.1. The accepted packet displays the nested source N, located endpoint row L, shrinking ledger W, diagonal selector D, selected enclosures E, regular-rational handoff R, completion handoff Q, terminal seal H, and structural rows C, P, M.

Nested-source exactness and diagonal-window exactness are the first two route constraints. A convergence request must read the finite nested packet and the located endpoint cells before it can inspect W, and the selector D can point only to a window already present in the displayed ledger.

Enclosure-width exactness then identifies the data used by the regular-rational handoff. Each row of E carries the selected endpoint enclosure together with the dyadic width bound that answers the displayed precision request, so R has no hidden source outside those rows.

The completion ordering is downstream of the handoff. The row Q consumes the nested source, located endpoints, shrinking ledger, selector, enclosures, and regular-rational readback before the seal row H becomes visible.

Finally, the transport, provenance, and local naming rows preserve the same finite inventory. Since the carrier contains no other coordinate, the listed obligations exhaust the local NameCert surface and cannot export an infinite intersection point, compactness theorem, host real equality, quotient equality, choice principle, or ambient completeness theorem. □

Theorem 2057.3 (Nested interval convergence carrier admission)**.** *For every accepted* $\mathsf{NestedIntervalConvergence}^{\uparrow}$ *carrier*

$$G = (N, L, W, D, E, R, Q, H, C, P, M),$$

carrier admission projects exactly the nested source N, the located endpoint-cell row L, the shrinking ledger W, the diagonal window selections D, the endpoint enclosures E, the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, the closed-interval completion handoff Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal H, componentwise* hsame *transport and displayed* Cont *replay in C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}$ *naming row M.*

No admitted coordinate is available outside these rows.

Proof. Project the accepted carrier through Definition 2057.1. The tuple displays exactly the coordinates $N, L, W, D, E, R, Q, H, C, P, M$, and the classifier compares accepted packets only through those coordinates.

The carrier-admission row of Definition 2057.2 records the same inventory as the local NameCert surface. Hence admission opens the nested source, located endpoint-cell row, shrinking ledger, diagonal selector, selected enclosures, handoff rows, seal row, transport and replay row, provenance row, and local naming row, with no extra projection.

Any selected point, raw infinite chain, host interval-intersection theorem, quotient equality, choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness datum would require a further carrier coordinate. The definition supplies none, so the admitted packet is exhausted by the displayed rows. □

Theorem 2057.4 (Nested interval convergence diagonal-window exactness)**.** *For every accepted* $\mathsf{NestedIntervalConvergence}^{\uparrow}$ *carrier*

$$G = (N, L, W, D, E, R, Q, H, C, P, M),$$

each diagonal finite-window selection used by a $\mathsf{RegSeqRat}^{\uparrow}$ *consumer is justified by the displayed shrinking ledger W and by a dyadic width bound recorded in the selected endpoint enclosure row E before the readback row R can be consumed.*

Thus R cannot read a diagonal window not already displayed by N, W, D, E for the current precision request.

Proof. Begin with the diagonal selector D. By the diagonal-window row of Definition 2057.2, D may select only a finite window already recorded in the nested packet N and the shrinking ledger W.

The selected enclosure row E supplies the quantitative witness for that choice. Its enclosure-width row carries the endpoint enclosure together with the displayed dyadic width bound, so the precision request is justified before the regular-rational row is visible.

The handoff row R is downstream from E. Combining the diagonal-window, enclosure-width, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows gives the required route

$$N, W, D, E \longmapsto R.$$

No alternative readback remains, because a hidden diagonal choice or an unrecorded width certificate would lie outside the carrier coordinates admitted by Definition 2057.3. □

Theorem 2057.5 (Nested interval convergence provenance exhaustion)**.** *For every accepted* NestedIntervalConverge *carrier*

$$G = (N, L, W, D, E, R, Q, H, C, P, M),$$

every completion-facing or $\mathsf{Real}^{\uparrow}$*-facing consumer factors through the displayed* Pkg *provenance* P *and local* $\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}$ *route* M*, together with the transported and replayed rows in* C*.*

Such a consumer receives no selected point, host interval-intersection theorem, quotient equality of real names, choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the consumer route through the completion-facing row Q or the terminal seal row H. The completion-ordering row of Definition 2057.2 makes both reads downstream from the displayed nested source, located endpoints, shrinking ledger, diagonal selector, selected enclosures, and regular-rational handoff.

The remaining structural data are C, P, M. The provenance-exhaustion row of Definition 2057.2 requires these rows to transport, replay, source, and name only the displayed route, so the consumer cannot bypass the local NameCert surface.

The exclusions follow from carrier admission. A selected point, host interval-intersection theorem, quotient equality, choice schedule, or ambient completeness theorem would have to be stored as a further provenance branch or naming coordinate, but the accepted carrier contains only $N, L, W, D, E, R, Q, H, C, P, M$. □

Theorem 2057.6 (Nested interval convergence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedIntervalConvergence}^{\uparrow}$ *carrier factors its read through the finite route*

$$N, L \longmapsto W \longmapsto D \longmapsto E \longmapsto R.$$

Thus the consumer receives only a displayed nested source packet, located endpoint-cell data, a shrinking-window ledger, a diagonal finite-window selection, selected endpoint enclosures, and the dyadic width bounds used to build the regular-rational readback. It receives no chosen intersection point, no invisible tail of the interval chain, no quotient equality of real names, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Start with the regular-rational row R in Definition 2057.1. The carrier makes R downstream from the selected enclosures E, not from a separate real name or an unrecorded interval tail.

The selected enclosures are themselves downstream from D. By the diagonal-window obligation in Definition 2057.2, the selector can choose only a visible window from N, W for the displayed precision request, with located endpoint-cell data supplied through L.

The dyadic width row in E is the quantitative part of the handoff. It is the only tolerance witness available to R, so the regular-rational consumer receives exactly the finite enclosure and width data recorded in the packet.

No excluded source remains. A chosen intersection point, invisible tail, quotient real equality row, or ambient completeness theorem would require a coordinate outside N, L, W, D, E, R, and the carrier has none. □

Theorem 2057.7 (Nested interval convergence real-seal nonescape)**.** *For every accepted* NestedIntervalConvergence *carrier*

$$G = (N, L, W, D, E, R, Q, H, C, P, M),$$

every $\mathsf{Real}^{\uparrow}$*-facing read factors through the displayed nested packet* N*, located endpoint row* L*, shrinking-window ledger* W*, diagonal selector* D*, selected endpoint enclosures* E*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, closed-interval completion handoff* Q*, transport and replay rows* C*, package provenance* P*, and local naming row* M *before the terminal seal row* H *is consumed.*

The seal route does not claim open-cover compactness, a selected intersection point, uniqueness of the point, host real equality, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through the seal-facing coordinate H. The only route to H named by the carrier passes through the regular-rational handoff R and the closed-interval completion handoff Q.

Use Definition 2057.6 to identify the source of R. The handoff reads only the finite nested source, located endpoints, shrinking ledger, diagonal selector, selected enclosures, and displayed width bounds.

Next use the completion-ordering obligation of Definition 2057.2. The row Q consumes the same selected enclosure route before H is exposed, so a real-facing read cannot bypass the finite completion surface.

The remaining rows C, P, M transport, replay, source, and name this route. Because no carrier coordinate stores compactness, point selection, uniqueness, host equality, quotient equality, countable choice, or ambient completeness, every real-seal read remains inside the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalConvergence}^{\uparrow}$ packet is generated from an accepted NestedIntervalUp packet, one LocatedIntervalUp endpoint-cell row, a shrinking-window ledger, diagonal finite-window selections, selected endpoint enclosures with dyadic width bounds, one RegSeqRatUp handoff, one ClosedIntervalCauchyCompletionUp handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2057.1, Definition 2057.2, Definition 2057.6, and Definition 2057.7 seed the constructive nested-interval convergence handoff from displayed nested packets and located endpoints through shrinking windows, diagonal enclosures, regular-rational readback, closed-interval completion handoff, terminal real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected intersection points, uniqueness of the point, host real equality, quotient equality of real names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-source exactness, diagonal-window exactness, enclosure-width exactness, RegSeqRat handoff exactness, closed-interval completion ordering, provenance exhaustion, and real-seal nonescape for BEDC.Derived.NestedIntervalConvergenceUp.

Chapter 2058

A Concrete Naming Certificate for $\mathsf{DecimalReal}^{\uparrow}$

Following Bishop and Bridges on real numbers presented by effective approximations, the $\mathsf{DecimalReal}^{\uparrow}$ packet records the finite decimal-expansion readback route before a decimal prefix may be consumed as a regular rational name or as a terminal real seal. It sits beside the signed-binary readback boundary of chapter 1976, while using the finite schedule of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet is a finite means presentation of decimal readback; it is not host real equality, quotient stream equality, decimal uniqueness at dual expansions, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2058.1 (DecimalReal carrier)**.** *A* $\mathsf{DecimalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, W, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the signed decimal prefix row, exposing a sign cell, a finite integer part, and a finite base-ten fractional window.*
2. *A is the ambiguity boundary row recording whether the observed window is ordinary, trailing-nine-facing, or trailing-zero-facing, without choosing a quotient representative at a dual decimal expansion.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting exactly the inspected decimal prefix windows and requested precisions.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row obtained by bounding the displayed base-ten tail by a dyadic radius visible to BEDC consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed decimal window schedule and dyadic tolerance ledger.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, A, W, T, R have been displayed.*
7. *H records componentwise* hsame *transport for the signed prefix, ambiguity boundary, schedule, tolerance, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, A, W \longmapsto T \longmapsto R \longmapsto L.$$

9. *P is the* Pkg *provenance over* $\mathsf{DecimalReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SignedBinaryExpansion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, W, T, R, L, H, C, P, N$. It has no coordinate for host real equality, quotient stream equality, uniqueness of a decimal expansion at dual tails, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2058.2 (DecimalReal NameCert obligations)**.** *For every accepted* $\mathsf{DecimalReal}^{\uparrow}$ *carrier*

$$D = (S, A, W, T, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DecimalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the signed decimal prefix, ambiguity boundary, finite schedule, dyadic tolerance ledger, regular rational readback, real seal, transport, replay, provenance, and local name;*
2. *decimal-window stability, requiring S and W to expose the same finite sign, integer, and fractional cells before and after the displayed* hsame *transport H;*
3. *dual-tail boundary visibility, requiring A to be inspected before any consumer treats a trailing-nine-facing or trailing-zero-facing window as a terminal decimal presentation;*
4. *dyadic tolerance visibility, requiring T to bound the remaining base-ten tail by a displayed dyadic row before R or L is read;*
5. *handoff order, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to consume S, A, W, T before the terminal* $\mathsf{Real}^{\uparrow}$ *seal L becomes available;*
6. *provenance locality, requiring C, P, N to replay, package, and name only the listed rows and to export no host equality, quotient stream equality, decimal uniqueness, trichotomy, countable choice, open-cover compactness, or ambient completeness coordinate.*

No DecimalReal obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DecimalRealUp.DecimalRealTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 2058.1. The accepted packet displays exactly the signed prefix row, ambiguity boundary, finite schedule, dyadic tolerance row, regular readback, real seal, and structural rows.

Decimal-window stability is read from S, W, H. The transport row preserves the displayed sign, integer cells, fractional window, and request schedule componentwise, so a consumer cannot silently replace the observed decimal window.

The dual-tail boundary is a separate row. The row A is inspected before any terminal use of a trailing-nine-facing or trailing-zero-facing prefix, and it records the boundary without selecting one quotient representative.

The dyadic tolerance and handoff clauses are ordered. The row T bounds the unseen base-ten tail in the dyadic ledger, the regular rational row R consumes that ledger, and the real seal L is terminal.

Finally C, P, N add only replay, provenance, and local naming. Since the carrier has no coordinate for the excluded principles, the listed rows exhaust the local NameCert surface. □

Theorem 2058.3 (DecimalReal RegSeqRat handoff)**.** *Let*

$$D = (S, A, W, T, R, L, H, C, P, N)$$

be an accepted $\mathsf{DecimalReal}^{\uparrow}$ *carrier. Every regular rational or real-name read exported by* D *factors through the displayed route*

$$S, A, W \longmapsto T \longmapsto R \longmapsto L$$

with structural support H, C, P, N*. Thus a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer receives the signed finite decimal window, the dual-tail boundary row, the inspected schedule, and the dyadic tolerance row as finite BEDC data before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is available.*

The handoff supplies no host real equality, no quotient equality of streams, no uniqueness claim for dual decimal expansions, no trichotomy row, no countable-choice row, no open-cover compactness row, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with a consumer of the regular rational row R or terminal seal L. By the carrier definition, neither row is independent of the displayed decimal data.

The consumer first reads S through the finite schedule W. This exposes the sign, integer prefix, fractional window, and requested precision as finite rows rather than as an infinite decimal stream.

The ambiguity boundary row A is then read before any terminal decimal interpretation. It records the dual-tail boundary visible in the observed prefix but does not decide quotient equality or uniqueness at trailing tails.

Next the dyadic tolerance row T bounds the unseen base-ten tail. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R consumes that dyadic bound, and only then may the $\mathsf{Real}^{\uparrow}$ seal L be inspected.

The structural rows H, C, P, N transport, replay, package, and name the same route. Because the packet contains none of the excluded coordinates, every exported read remains inside the displayed finite boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalReal}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DecimalReal}^{\uparrow}}$, seed)

Scope closed: Definition 2058.1, Definition 2058.2, and Definition 2058.3 seed the finite decimal readback route from signed prefix windows through dual-tail boundary rows, stream schedules, dyadic tolerance ledgers, regular rational handoff, Real seals, transport, continuation, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DecimalReal}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.DecimalRealUp.DecimalRealTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient stream equality, decimal uniqueness at dual expansions, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, decimal-window stability, dual-tail boundary visibility, dyadic tolerance visibility, handoff order, and provenance locality for BEDC.Derived.DecimalRealUp.

Constructive story: A $\mathsf{DecimalReal}^{\uparrow}$ packet is generated from a signed decimal prefix row, dual-tail ambiguity boundary, StreamName schedule, DyadicRatCore tolerance row, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2059

A Concrete Naming Certificate for $\mathsf{EulerMaclaurin}^{\uparrow}$

Following Euler and Maclaurin, and in the Bishop–Bridges constructive reading, the $\mathsf{EulerMaclaurin}^{\uparrow}$ packet records the finite summation-remainder boundary where a displayed finite partial-sum source is compared with endpoint data, derivative-window rows, Bernoulli-style coefficients, and a dyadic remainder budget before a terminal $\mathsf{Real}^{\uparrow}$ seal is named. It sits beside the summation-by-parts route of chapter 1763, the finite term and partial-sum surface of chapter 1581, the derivative packet of chapter 122, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names only the finite BEDC route from inspected terms to a certified remainder budget; it does not import host infinite summation, host integration, selected limits, quotient equality, countable choice, trichotomy, or ambient real completeness.

Definition 2059.1 (Euler–Maclaurin carrier)**.** *An* $\mathsf{EulerMaclaurin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, A, L, U, D, B, Q, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *or finite partial-sum source row, carrying the inspected term windows, finite summation bounds, and the partial-sum observations that are allowed to enter the formula.*
2. *A is the Abel-summation comparison row, used only as a finite summation-by-parts route for rearranging the inspected partial sums.*
3. *L and U are endpoint* $\mathsf{Real}^{\uparrow}$ *rows for the lower and upper summation endpoints, including the endpoint readback names consumed by the boundary terms.*
4. *D is the derivative-window row, listing the finitely inspected* $\mathsf{Derivative}^{\uparrow}$ *observations and the interval windows on which the remainder estimate is read.*
5. *B is the Bernoulli-style coefficient ledger. It records only the finite coefficient rows requested by the displayed order of the formula.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder-budget row, with positivity, refinement, and split-budget data for the final error request.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes rational approximants for the finite sums, endpoint rows, derivative windows, coefficient ledger, and remainder budget.*

8. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the finite summation-with-remainder read after S, A, L, U, D, B, Q, R have been displayed.*

9. *H records componentwise* hsame *transport for the series or finite partial-sum source, Abel row, endpoint rows, derivative windows, coefficient ledger, dyadic budget, regular rational readback, terminal real seal, replay row, provenance row, and local naming row.*

10. *C records displayed* Cont *replay through*

$$S, A, L, U, D, B, Q, R \longmapsto Z \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{EulerMaclaurin}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerMaclaurin}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, L, U, D, B, Q, R, Z, H, C, P, N$. It has no coordinate for a host infinite sum, host integral, selected limit, quotient equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.EulerMaclaurinUp.EulerMaclaurinTasteGate single carrier alignment`

Theorem 2059.2 (Euler–Maclaurin NameCert obligations)**.** *For every accepted* $\mathsf{EulerMaclaurin}^{\uparrow}$ *carrier*

$$E = (S, A, L, U, D, B, Q, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerMaclaurin}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite series or partial-sum source, Abel row, lower and upper endpoint rows, derivative windows, coefficient ledger, dyadic remainder budget, regular rational readback, terminal real seal, transport, replay, provenance, and local naming row;*

2. *summation-window exposure, requiring every formula request to display the finite term windows and partial-sum bounds in S before the Abel row A is read;*

3. *endpoint readiness, requiring both endpoint* $\mathsf{Real}^{\uparrow}$ *rows L, U to be opened before any boundary term is named;*

4. *derivative and coefficient readiness, requiring the derivative windows D and the finite Bernoulli-style coefficient ledger B to be displayed before the remainder row is accepted;*

5. *dyadic remainder routing, requiring the final remainder request to factor through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positivity, refinement, and split-budget rows in Q;*

6. *rational readback and Real seal handoff, requiring R to expose all finite rational approximants before the terminal* $\mathsf{Real}^{\uparrow}$ *seal Z is named;*

7. *classifier transport, requiring H and C to preserve the same $S, A, L, U, D, B, Q, R, Z$ inventory under* hsame *and displayed* Cont *replay;*

8. *non-escape, requiring P and N to source and name only the listed route, with no hidden host infinite sum, host integral, selected limit, quotient equality, countable choice, trichotomy, ambient real completeness, Lean verification, or bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2059.1. The accepted packet displays the finite source S, Abel row A, endpoint rows L, U, derivative windows D, coefficient ledger B, dyadic budget Q, readback row R, terminal seal Z, and structural rows H, C, P, N.

The summation-window and endpoint obligations are forced by row order. A formula request enters through the finite term and partial-sum source S, may use A only as the displayed summation-by-parts route, and reads the endpoint rows L, U before any boundary term is exposed.

The derivative and coefficient obligations are likewise rowwise. The window row D lists the derivative observations that can participate in the remainder estimate, while B lists only the finitely requested coefficient rows.

The dyadic remainder obligation comes from Q. Its positivity, refinement, and split-budget data are displayed before the terminal estimate is transported to the regular rational readback row R and the real seal Z.

Finally, H and C replay the same inventory under classifier transport, and P, N source and name only that inventory. Since the carrier has no additional coordinate, no unlisted host-analytic or choice-based obligation can be read from the packet. □

Theorem 2059.3 (Euler–Maclaurin remainder handoff)**.** *Every remainder read exported by an accepted* $\mathsf{EulerMaclaurin}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RealSeries}^{\uparrow}, \mathsf{AbelSummation}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Derivative}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, the terminal real seal Z can be opened only after the finite source S, Abel row A, endpoint rows L, U, derivative windows D, coefficient ledger B, dyadic budget Q, and regular rational readback row R have all been displayed.

Proof. Let $E = (S, A, L, U, D, B, Q, R, Z, H, C, P, N)$ be accepted. A remainder consumer begins with the finite formula request, so the first visible data are the term windows and partial-sum bounds in S.

The route may then pass through A to express the finite summation-by-parts comparison. The endpoint rows L, U supply the boundary-term seals, while D and B supply the derivative observations and coefficient rows that make the finite correction terms inspectable.

The actual remainder budget is not read until Q is displayed. This dyadic row fixes the positive tolerance, refinements, and budget splits used by the later rational approximants.

The readback row R then exposes rational approximants for each already displayed component, and only afterward does the terminal seal Z become visible. The structural rows H, C, P, N transport and name the same route, so every exported remainder read has the stated factorization. □

Theorem 2059.4 (Euler–Maclaurin Real seal non-escape)**.** *For every accepted* $\mathsf{EulerMaclaurin}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *seal read produced by the packet is either one of the displayed endpoint rows L, U or the terminal seal Z reached through the finite route of Definition 2059.3. No accepted carrier exports a separate* $\mathsf{Real}^{\uparrow}$ *seal through host integration, host infinite summation, selected limits, quotient equality, countable choice, trichotomy, ambient real completeness, Lean verification, or bridge checking.*

Proof. Project an accepted carrier $E = (S, A, L, U, D, B, Q, R, Z, H, C, P, N)$. The only rows whose declared target is $\mathsf{Real}^{\uparrow}$ are the endpoint rows L, U and the terminal seal Z.

The endpoint rows are already displayed as part of the carrier. They are not computed by a host integral or an infinite summation principle; they are named endpoint seals consumed by the finite boundary-term route.

For the terminal seal, apply Definition 2059.3. The seal Z is downstream of S, A, L, U, D, B, Q, R and is therefore reached only after the finite source, boundary, derivative, coefficient, dyadic, and readback rows are visible.

The transport, replay, provenance, and naming rows do not add new real-valued coordinates. Hence there is no remaining path by which a consumer could obtain a detached real seal from an excluded host-analytic or choice-based source. □

Closure status for $\mathsf{NameCert}_{\mathsf{EulerMaclaurin}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EulerMaclaurin}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2059.1, Definition 2059.2, Definition 2059.3, and Definition 2059.4 seed the finite Euler–Maclaurin summation-remainder packet over displayed series or finite partial-sum source, Abel row, endpoint RealUp rows, derivative windows, coefficient ledger, dyadic remainder budget, regular rational readback, terminal RealUp seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EulerMaclaurin}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, host integrals, selected limits, quotient equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, summation-window exposure, endpoint readiness, derivative and coefficient readiness, dyadic remainder routing, rational readback, Real seal handoff, classifier transport, remainder factorization, and non-escape for BEDC.Derived.EulerMaclaurinUp.

Constructive story: An $\mathsf{EulerMaclaurin}^{\uparrow}$ packet is generated from a finite RealSeries or partial-sum source row, Abel summation row, endpoint RealUp rows, derivative-window rows, a Bernoulli-style coefficient ledger, a DyadicRatCore remainder budget, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2060

A Concrete Naming Certificate for $\mathsf{RealUniformEntourageBase}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures, entourage bases, and completion by Cauchy filters, the $\mathsf{RealUniformEntourageBase}^{\uparrow}$ packet specializes chapter 1819 to the Real-induced uniformity of chapter 1624. It supplies the finite entourage-basis certificate consumed by chapter 333 through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger. The packet is a displayed Real-specific basis route; it is not a quotient completion, not a selected-limit construction, and not an assertion of ambient Real completeness.

Definition 2060.1 (Real uniform entourage-base carrier)**.** *A* $\mathsf{RealUniformEntourageBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E_{\mathsf{Real}} = (R, U, B, F, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *source row whose Real metric-ball route supplies every entourage request.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *row induced by R and exposed only through finite entourage data.*
3. *B is the* $\mathsf{EntourageBase}^{\uparrow}$ *row listing the Real-induced basis entourages, their containment witnesses in U, and their finite-intersection refinement witnesses.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row inspected by completion-facing consumers after the Real-induced basis row has been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger, recording admitted Real metric radii, smaller-radius refinements, and the route from each radius request into B.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read by Cauchy-filter consumers after the basis handoff.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S and to the dyadic radius comparisons in D.*
8. *H records componentwise* hsame *transport for the Real uniform source, induced UniformSpace row, EntourageBase row, CauchyFilter handoff, dyadic ledger, finite windows, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Real metric-ball request through $R, U, B, F, D, S, Q, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealUniformEntourageBase}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $R, U, B, F, D, S, Q, H, C, P, N$. The carrier has no coordinate for quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealUniformEntourageBaseUp.RealUniformEntourageBaseTasteGate single carrier alignment`

Theorem 2060.2 (Real uniform entourage-base NameCert obligations)**.** *For every accepted* RealUniformEntourageB *carrier*

$$E_{\mathsf{Real}} = (R, U, B, F, D, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBase}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Real uniform source, induced UniformSpace row, Real-induced EntourageBase row, CauchyFilter handoff, DyadicRatCore radius ledger, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local naming row;*
2. *Real metric-ball basis containment, requiring every basis entourage in B to be generated from the Real metric-ball route of R and to carry a displayed containment witness into U;*
3. *finite-intersection refinement, requiring every accepted pair of Real-induced basis rows to refine through a displayed row of B before any Cauchy-filter consumer can inspect it;*
4. *Cauchy-filter handoff, requiring every completion-facing read in F to consume the displayed Real-induced basis row B before reading S or Q;*
5. *classifier transport, requiring H and C to preserve the displayed route R, U, B, F, D, S, Q componentwise under* hsame *and replay it under* Cont*;*
6. *ledger non-escape, requiring D, P, and N to export no quotient completion, selected limit, open-cover compactness, countable-choice selector, trichotomy, or ambient Real completeness principle.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is the finite projection from Definition 2060.1. The projection exposes exactly the Real uniform source, the induced UniformSpace row, the Real-induced EntourageBase row, the CauchyFilter handoff, the DyadicRatCore ledger, finite windows, readback, and the structural rows H, C, P, N.

Real metric-ball basis containment is forced by the source row. A basis request first reads the Real metric-ball route in R, then records the induced entourage in B, and finally displays its containment witness in U.

Finite-intersection refinement is internal to B. The accepted pair of Real-induced basis rows is not refined by a completion object; it is refined by a displayed basis row whose radius comparison is recorded in D.

The Cauchy-filter handoff is downstream of that basis row. A completion-facing consumer reaches F only after B has been replayed, and the finite observations S and Q are read after the handoff.

Transport and replay do not add additional mathematical primitives. The row H preserves each displayed coordinate componentwise, while C repeats the route R, U, B, F, D, S, Q for every accepted request.

Finally, provenance is exhausted by D, P, N. Since quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, and ambient Real completeness are not rows of E_{Real}, the local NameCert surface cannot export them. □

Theorem 2060.3 (Real uniform entourage-base Cauchy-filter handoff)**.** *Every Cauchy-filter consumer of an accepted* $\mathsf{RealUniformEntourageBase}^{\uparrow}$ *carrier reads the Real-induced entourage base only through the displayed rows*

$$\mathsf{RealUniformStructure}^{\uparrow}, \mathsf{UniformSpace}^{\uparrow}, \mathsf{EntourageBase}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{B}$$

Consequently the packet exports no quotient completion, selected limit, open-cover compactness, countable-choice selector, trichotomy, or ambient Real completeness.

Proof. Begin with a Cauchy-filter consumer of E_{Real}. Carrier admission gives the consumer access to the packet only through $R, U, B, F, D, S, Q, H, C, P, N$.

The Real-induced entourage base is therefore read through the displayed basis route. The row R supplies the Real uniform source, U records the induced uniform entourage data, B records the Real-specific basis, and D records the positive-radius ledger used for containment and refinement.

Any Cauchy-filter use is then a downstream read of F. The window row S and the regular rational row Q expose finite observations only after the basis row B and handoff row F have been replayed.

The remaining rows are structural. The BHist, hsame, Cont, Pkg, and NameCert rows transport, replay, source, and name the same finite route, so there is no separate coordinate from which quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, or ambient Real completeness can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBase}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformEntourageBase}^{\uparrow}$ packet is generated from a RealUniformStructure source row, an induced UniformSpace row, a Real-specific EntourageBase row, a CauchyFilter handoff, a DyadicRatCore positive-radius ledger, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformEntourageBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2060.1, Definition 2060.2, and Definition 2060.3 seed the Real-specific entourage-basis route from RealUniformStructure to CauchyFilter consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealUniformEntourageBase}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealUniformEntourageBaseUp.RealUniformEntourageBaseTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a public standard bridge.

Upgrade path: Obligation closure requires carrier admission, Real metric-ball basis containment, finite-intersection refinement, Cauchy-filter handoff, classifier transport, and ledger non-escape proofs for the same packet.

Chapter 2061

A Concrete Naming Certificate for $\mathsf{PositiveRealRadiusScale}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley treatment of uniform structures, the $\mathsf{PositiveRealRadiusScale}^{\uparrow}$ packet names the finite positive-radius interface that the Real uniformity exposes to completion-facing consumers. It sits between the Real uniform structure of chapter 1624 and the Real entourage-base route of chapter 2060: a consumer may ask for smaller positive radii, read the induced entourage row, and hand the resulting finite observation to Cauchy-filter routes without importing selected limits, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2061.1 (PositiveRealRadiusScale carrier)**.** *A* $\mathsf{PositiveRealRadiusScale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\rho_{\mathsf{Real}} = (U, E, D, S, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *source row whose metric-ball route supplies positive Real-radius requests.*
2. *E is the* $\mathsf{RealUniformEntourageBase}^{\uparrow}$ *row that receives each accepted positive radius as an entourage-basis request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger, recording the admitted dyadic radii, strict positivity witnesses, smaller-radius refinements, and comparison cells used by U and E.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by Real-name and completion consumers when radius requests are read through finite observations.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S and to the dyadic radius comparisons in D.*
6. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row that consumes the displayed positive-radius entourage route before completion-facing filters are inspected.*
7. *H records componentwise* hsame *transport for the Real uniform source, Real entourage-base route, dyadic positive-radius ledger, finite windows, rational readback, Cauchy-filter handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a positive-radius request through $U, D, E, S, Q, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{PositiveRealRadiusScale}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{RealUniformEntourageBase}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveRealRadiusScale}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $U, E, D, S, Q, F, H, C, P, N$. The carrier has no coordinate for selected limits, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PositiveRealRadiusScaleUp.PositiveRealRadiusScaleTasteGate single carrier alignment`

Theorem 2061.2 (PositiveRealRadiusScale NameCert obligations)**.** *For every accepted* $\mathsf{PositiveRealRadiusScale}^{\uparrow}$ *carrier*

$$\rho_{\mathsf{Real}} = (U, E, D, S, Q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PositiveRealRadiusScale}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the RealUniformStructure source row, RealUniformEntourageBase target row, DyadicRatCore positive-radius ledger, StreamName finite windows, RegSeqRat readback, CauchyFilter handoff, transport, replay, provenance, and local naming row;*
2. *positive-radius admission, requiring D to display strict positivity and a dyadic comparison cell before a radius request can be consumed by the Real uniform source U;*
3. *smaller-radius refinement, requiring every accepted radius request to expose a displayed smaller positive radius in D before it is routed to the entourage-base row E;*
4. *finite-window readback, requiring S and Q to record the finite StreamName window and regular rational readback attached to each accepted radius request;*
5. *Cauchy-filter handoff, requiring F to inspect the displayed route U, D, E, S, Q before any completion-facing consumer reads filter data;*
6. *classifier transport, requiring H and C to preserve the displayed route U, D, E, S, Q, F componentwise under* hsame *and replay it under* Cont*;*
7. *ledger non-escape, requiring P and N to export no selected limit, quotient real equality, trichotomy, countable-choice selector, open-cover compactness principle, or ambient Real completeness row.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2061.1. The accepted packet displays exactly the Real uniform source, the Real entourage-base route, the dyadic positive-radius ledger, finite windows, rational readback, Cauchy-filter handoff, and the structural rows H, C, P, N.

Positive-radius admission is read from D. A radius request reaches the Real uniform source U only after the ledger has displayed strict positivity and the dyadic comparison cell attached to that request.

Smaller-radius refinement is also internal to D. The refinement row is then routed to E, so the Real entourage-base consumer receives a displayed smaller positive radius rather than an unrecorded completeness or choice principle.

The finite-window readback rows S and Q attach the radius request to observable StreamName windows and regular rational readback. Thus the Real-name side and the completion-facing side inspect the same finite radius data.

The Cauchy-filter handoff is downstream of the radius and entourage rows. A consumer reaches F only after U, D, E, S, Q have been replayed.

Finally, H, C, P, N add only transport, replay, provenance, and naming. Since selected limits, quotient real equality, trichotomy, countable choice, open-cover compactness, and ambient Real completeness are not rows of ρ_{Real}, the listed obligations exhaust the local NameCert surface. □

Theorem 2061.3 (PositiveRealRadiusScale entourage handoff)**.** *Every Real-uniform or Cauchy-filter consumer of an accepted* $\mathsf{PositiveRealRadiusScale}^{\uparrow}$ *carrier reads the positive-radius scale only through the displayed rows*

$$\mathsf{RealUniformStructure}^{\uparrow}, \mathsf{RealUniformEntourageBase}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow}, \mathsf{BHist}$$

Consequently the packet exports no selected limit, quotient real equality, trichotomy, countable-choice selector, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer of ρ_{Real}. Carrier admission exposes the packet only through $U, E, D, S, Q, F, H, C, P,$

The positive-radius request is first read through the Real uniform source U and the dyadic ledger D. The ledger provides positivity and refinement data before the request can enter the Real entourage-base row E.

Finite observations are then read through S and Q. These rows attach the radius route to StreamName windows and RegSeqRat readback, so the route remains visible to Real-name and completion-facing consumers.

Any Cauchy-filter use is downstream of F. The handoff row receives the already displayed Real uniform and entourage-base route; it does not select a limit or add a quotient equality coordinate.

The remaining rows are structural. The BHist, hsame, Cont, Pkg, and NameCert rows transport, replay, source, and name the same finite route, so there is no separate coordinate from which selected limits, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient Real completeness can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveRealRadiusScale}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveRealRadiusScale}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2061.1, Definition 2061.2, and Definition 2061.3 seed the finite positive-radius interface from RealUniformStructure through RealUniformEntourageBase to CauchyFilter consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveRealRadiusScale}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PositiveRealRadiusScaleUp.PositiveRealRadiusScaleTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius admission, smaller-radius refinement, finite-window readback, Cauchy-filter handoff, classifier transport, and ledger non-escape for BEDC.Derived.PositiveRealRadiusScaleUp.

Constructive story: A $\mathsf{PositiveRealRadiusScale}^{\uparrow}$ packet is generated from a RealUniformStructure source row, RealUniformEntourageBase route, DyadicRatCore positive-radius ledger, StreamName windows, RegSeqRat readback, CauchyFilter handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{BishopRealLineInterface}^{\uparrow}$ route reads the terminal $\mathsf{Real}^{\uparrow}$ seal through chapter 38, the regular rational readback through chapter 301, the finite stream windows through chapter 126, and the dyadic tolerance rows through chapter 291.

Chapter 2062

A Concrete Naming Certificate for $\mathsf{BishopRealLineInterface}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealLineInterface}^{\uparrow}$ packet records the traditional regular-real interface boundary as finite NameCert data rather than as a host real object. It binds the dyadic endpoint and tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular Cauchy readback of chapter 301, the terminal real-name seal of chapter 38, and the equality-facing comparison boundary of chapter 1820. The packet is an L10 interface surface for Real and Completion consumers; it does not assert completeness of $\mathsf{Real}^{\uparrow}$, quotient stream equality, host real equality, trichotomy, selected limits, countable choice, metric completeness, open-cover compactness, or bridge checking.

Definition 2062.1 (Bishop real-line interface carrier)**.** *A* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, W, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger, recording admitted dyadic endpoints, positive tolerances, and comparison budgets before any real-line consumer reads a value-shaped claim.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only bounded observation windows of the named stream.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row attached to W and to the dyadic tolerance ledger D.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after D, W, R have been displayed.*
5. *Q is the Cauchy-equivalence comparison row for accepted interface packets; it compares endpoint ledgers, finite windows, regular readbacks, and terminal seals through displayed setoid data without adding quotient stream equality or host real equality.*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, terminal Real seal, classifier comparison, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real-line interface request through D, W, R, E, Q, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRealLineInterface}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealLineInterface}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, E, Q, H, C, P, N$. The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits, metric completeness, open-cover compactness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopRealLineInterfaceUp.BishopRealLineInterfaceTasteGate single carrier alignment`

Theorem 2062.2 (Bishop real-line interface NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier $I = (D, W, R, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealLineInterface}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission, requiring the packet to expose the dyadic ledger D, stream window W, regular readback R, terminal seal E, comparison row Q, transport row H, continuation row C, package row P, and local naming row N before any consumer can read the interface;*
2. *pointwise* $\mathsf{StreamName}^{\uparrow}$ *stability, requiring every stream observation used by the interface to remain a finite displayed window in W under the componentwise* hsame *transport of H and the replay route of C;*
3. *dyadic tolerance ledger, requiring every real-line request to display its endpoint and tolerance budget in D before reading a stream window, a regular-rational readback, or a comparison row;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring the regular Cauchy row R to be read from the displayed stream windows and dyadic ledger before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E or the Cauchy-equivalence comparison row Q is consumed;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring E, P, N to export no* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limit, metric completeness, open-cover compactness, or bridge-checking row.*

No local NameCert obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 2062.1. The projection exposes exactly the dyadic ledger D, finite windows W, regular readback R, terminal seal E, comparison row Q, and the structural rows H, C, P, N.

Pointwise stream stability is read through the $\mathsf{StreamName}^{\uparrow}$ surface. The row W contains only bounded observations, and H, C can transport or replay those observations only componentwise, so no global stream equality is introduced.

The dyadic tolerance ledger is the first analytic face. Every value-facing read must pass through D, the public source row of chapter 291, before any finite window or comparison can be consumed.

The regular readback and Real seal are downstream. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ reading of the displayed windows and dyadic budget, while E is reached only after D, W, R have been displayed, matching the Real seal boundary of chapter 38.

Finally, the comparison row is bounded by chapter 1820. It classifies displayed Cauchy data before the seal is read, but it does not add quotient representatives, host real equality, or any excluded completeness principle. □

Theorem 2062.3 (Bishop real-line located interval stream route)**.** *Every located interval datum admitted by a* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier $I = (D, W, R, E, Q, H, C, P, N)$ must factor through the* $\mathsf{StreamName}^{\uparrow}$ *finite windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E before it is consumed as a real-line point. The datum begins as endpoint and tolerance*

information in the dyadic ledger D, is compared only through the Cauchy-equivalence row Q, and is preserved by H, C, P, N as the same displayed interface route.

The route exports no host interval object, Dedekind cut, trichotomy row, quotient equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Unpack the accepted carrier. The located interval datum can enter the interface only through the dyadic endpoint and tolerance ledger D, since no separate host-interval coordinate occurs in I.

Use the finite observation route next. The row W supplies the $\mathsf{StreamName}^{\uparrow}$ windows inspected by the datum, and the row R repacks those windows and the dyadic budget as the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback.

Only then may the terminal seal be consumed. The row E is downstream of D, W, R, and the comparison row Q reads equality-facing information through the displayed Cauchy-equivalence classifier rather than through quotient equality.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no host interval, Dedekind cut, trichotomy, quotient equality, selected representative, choice schedule, or ambient completeness row, none of those objects is exported when the datum is consumed as a real-line point. □

Theorem 2062.4 (Bishop real-line interface four-object route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier reads the interface through the ordered four-object route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer may then inspect Cauchy-equivalence comparison, componentwise transport, continuation replay, package provenance, and local naming data, but it receives no extra route through quotient stream equality, selected limits, countable choice, host real equality, trichotomy, metric completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $I = (D, W, R, E, Q, H, C, P, N)$. Projection gives a consumer the dyadic row D, the stream-window row W, the regular readback row R, and the terminal seal E in the displayed order of the carrier.

The first object is dyadic. The endpoint and tolerance budget in D is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ chapter, so the route begins with finite dyadic comparisons rather than a host real value.

The second and third objects are the finite stream window and regular rational readback. The row W exposes only bounded observations from $\mathsf{StreamName}^{\uparrow}$, and the row R consumes those observations as the $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy reading.

The fourth object is the terminal Real seal. The row E is reached only after D, W, R have been displayed, exactly as in the $\mathsf{Real}^{\uparrow}$ sibling route.

The remaining rows Q, H, C, P, N compare, transport, replay, source, and name the same route. None of them contains quotient stream equality, selected limits, countable choice, host real equality, trichotomy, metric completeness, open-cover compactness, or ambient Real completeness. □

Theorem 2062.5 (Bishop real-line dyadic-stream sibling route)**.** *Every accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *consumer depends on the sibling route through chapter 291, chapter 126, chapter 301, chapter 38, and chapter 1820. The carrier rows $D, W, R, E, Q, H, C, P, N$ bind that route as dyadic tolerance ledger, finite stream window, regular rational readback, terminal Real seal, displayed Cauchy-equivalence comparison, transport, replay, provenance, and local naming.*

Thus the interface has no direct host-real route, quotient route, trichotomy route, or completeness route outside those sibling chapters.

Proof. Project the carrier rows $D, W, R, E, Q, H, C, P, N$ from Definition 2062.1. The dyadic ledger D is read through chapter 291, and the finite observation row W is read through chapter 126.

The regular readback row R binds the stream window to chapter 301. The terminal seal E is the only Real-facing endpoint and is read through chapter 38.

The equality-facing row Q is then read through chapter 1820. The structural rows H, C, P, N transport, replay, source, and name the same sibling route without adding a second analytic path.

Since no carrier row remains outside $D, W, R, E, Q, H, C, P, N$, an accepted interface consumer receives no direct host-real, quotient, trichotomy, or completeness route. □

Theorem 2062.6 (Bishop real-line interface completion-boundary refusal)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier may read only the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

plus $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison and the structural rows* H, C, P, N*. Therefore the interface cannot export* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient stream equality, countable choice, host real equality, trichotomy, metric completeness, or open-cover compactness.*

Proof. Project the carrier of Definition 2062.1. The analytic rows are exactly D, W, R, E, Q, and the structural rows are exactly H, C, P, N.

Apply the NameCert obligations of Definition 2062.2. They force dyadic tolerance admission through D, finite stream-window stability through W, regular readback through R, the terminal $\mathsf{Real}^{\uparrow}$ seal through E, and Cauchy-equivalence comparison through Q.

Use the four-object route of Definition 2062.4. A Real or Completion consumer reaches the interface only along $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and then reads comparison, transport, replay, provenance, and local naming data.

Since the carrier has no coordinate beyond those displayed rows, no accepted read can export $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, countable choice, host real equality, trichotomy, metric completeness, or open-cover compactness. □

Theorem 2062.7 (Bishop real-line interface located-limit dependency)**.** *Every Bishop real-line consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier that uses located-limit data must pass through chapter 2387 after the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{BishopLocatedLimit}^{\uparrow}$ *packet supplies the located-limit witness and enclosure row consumed by the interface, while* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *supplies the surrounding real-line packet through* $D, W, R, E, Q, H, C, P, N$*. The dependency exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, metric completeness, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the completion-boundary refusal of Definition 2062.6. It fixes the interface route through dyadic tolerance rows, finite stream windows, regular readback, and the terminal Real seal before any located data can be consumed.

Now read the located-limit witness through chapter 2387. That sibling supplies the located-limit witness and enclosure row on top of the same StreamName, DyadicRatCore, RegSeqRat, and Real-seal route.

The interface rows Q, H, C, P, N then compare, transport, replay, source, and name the same surrounding packet. Since neither the located-limit sibling nor the interface carrier contains a selected limit, quotient stream, choice schedule, host equality, trichotomy, metric-completeness proof, open-cover compactness theorem, or ambient Real-completeness row, the handoff exports none of them. □

Theorem 2062.8 (Bishop real-line interface located-Cauchy handoff)**.** *Every located-Cauchy reader of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier* $I = (D, W, R, E, Q, H, C, P, N)$ *must first read the displayed rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyEquivalenceSetoid}^{\uparrow}$$

through D, W, R, E, Q *and then pass through the sibling located rows of chapter 1709 and chapter 1850. The handoff exports no selected limit, quotient stream equality, trichotomy, host real equality, countable-choice schedule, metric-completeness assertion, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows $D, W, R, E, Q, H, C, P, N$. The value-facing part is already ordered by Definition 2062.4: a consumer reads the dyadic ledger, finite stream window, regular readback, and terminal Real seal before any comparison row can be inspected.

The comparison row Q remains a Cauchy-equivalence boundary for displayed data. It does not supply a quotient representative or a host equality principle.

A located-Cauchy reader then uses the sibling chapters as the only downstream located surfaces. The interval side is the located interval packet of chapter 1709, and the combined Cauchy side is the Bishop located Cauchy real packet of chapter 1850.

The structural rows H, C, P, N transport, replay, source, and name this same route. Since none of the displayed rows contains a selected limit, quotient equality, trichotomy, host equality, choice schedule, metric-completeness assertion, open-cover compactness, or ambient Real completeness, the handoff exports none of them. □

Theorem 2062.9 (Bishop real-line interface located-order route)**.** *Every located-order consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier* $I = (D, W, R, E, Q, H, C, P, N)$ *must read the dyadic endpoint and tolerance rows* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row* Q *before using any order-shaped data. The located-order route is*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto H, C, P, N.$$

It exports no trichotomy, host interval object, selected representative, quotient equality, countable-choice schedule, selected limit, metric-completeness assertion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2062.1. The rows D, W, R, E, Q are the only analytic rows available before the structural transport, replay, provenance, and local naming rows.

Apply Definition 2062.4. Any Real or Completion consumer first reads the dyadic ledger, finite stream windows, regular readback, and terminal Real seal in the displayed order, so located-order data cannot begin from a host interval object or a selected representative.

Use Definition 2062.8 for the comparison boundary. The located-facing read must pass through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ row before it can be consumed as order-shaped data, and that row supplies displayed comparison rather than quotient equality or trichotomy.

Finally route the packet through H, C, P, N. These rows transport, replay, source, and name the same finite interface, and the carrier excludes trichotomy, host interval objects, selected representatives, quotient equality, countable choice, selected limits, metric completeness, open-cover compactness, and ambient Real completeness. □

Theorem 2062.10 (Bishop real-line interface RealSeparability handoff)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier* $I = (D, W, R, E, Q, H, C, P, N)$ *may consume the density route only after the displayed interface has exposed*

$$\mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff reads $\mathsf{Rat}^{\uparrow}$ *through the rational density surface of chapter 1809, reads* D, W, R, E *through the interface four-object route, and then packages the same route through* Q, H, C, P, N*. It exports no selected dense point, quotient stream equality, countable-choice selector, host real equality, selected limit, ambient completeness, or detached completeness theorem.*

Proof. Start with the four-object route of Definition 2062.4. It forces every Real or Completion consumer to read the dyadic ledger, finite stream window, regular rational readback, and terminal Real seal through D, W, R, E before any comparison row is inspected.

Next consume the $\mathsf{RealSeparability}^{\uparrow}$ density route through chapter 1809. Its rational dense handoff begins at the displayed $\mathsf{Rat}^{\uparrow}$ source and then uses dyadic tolerances, finite stream windows, regular rational readback, and the Real seal as finite rows rather than as a host dense subset.

Compose these two routes along the shared D, W, R, E interface. The comparison row Q and the structural rows H, C, P, N preserve the same displayed path, so the separability consumer can read density only after $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are visible.

Finally use nonescape from Definition 2062.12. Since the accepted interface has no coordinate for selected dense points, quotient stream equality, countable choice, host equality, selected limits, metric completeness, open-cover compactness, or ambient Real completeness, none of those objects is exported by the handoff. □

Theorem 2062.11 (Bishop real-line interface modulus-comparison handoff)**.** *Every* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier* $I = (D, W, R, E, Q, H, C, P, N)$ *must read the interface rows* D, W, R, E, Q *before using a convergence-modulus comparison. The comparison factors through the same route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyEquivalenceSetoid}^{\uparrow}$$

and then reaches the downstream modulus ledger of chapter 2074. It exports no selected limits, quotient stream equality, countable choice, host real equality, or ambient completeness.

Proof. Project the Bishop interface carrier. The rows D, W, R, E, Q expose the dyadic ledger, finite stream window, regular readback, terminal Real seal, and Cauchy-equivalence comparison before any structural row is used.

Apply Definition 2062.4. This forces the value-facing part of the comparison to pass through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order.

Use the Cauchy-equivalence boundary carried by Q. The comparison remains a displayed setoid read before the modulus ledger is consumed, so quotient stream equality and host real equality are not introduced.

Finally hand the route to chapter 2074. The downstream $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger may compare convergence schedules only after the same D, W, R, E, Q route is visible. Since the

Bishop interface carrier has no coordinate for selected limits, quotient stream equality, countable choice, host real equality, or ambient completeness, none of those objects is exported by the handoff. □

Theorem 2062.12 (Bishop real-line interface nonescape)**.** *Every accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier* $I = (D, W, R, E, Q, H, C, P, N)$ *is exhausted by the displayed rows* $D, W, R, E, Q, H, C, P, N$*. Thus the interface exports only dyadic endpoints and tolerances, finite stream windows, regular Cauchy readback, the terminal Real seal, Cauchy-equivalence comparison, transport, continuation, package provenance, and local naming data.*

In particular, the packet exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, host real equality, trichotomy, countable-choice schedule, selected limit, metric-completeness assertion, open-cover compactness principle, or bridge-checking evidence.*

Proof. The carrier tuple lists every coordinate available to a local consumer. Projection from Definition 2062.1 therefore gives exactly $D, W, R, E, Q, H, C, P, N$ and no hidden coordinate.

The mathematical rows are already bounded by the four-object route. The dyadic ledger, finite stream windows, regular readback, and terminal seal are the only value-facing rows; Cauchy-equivalence comparison is a comparison of displayed regular-Cauchy data, not a second equality principle.

The structural rows do not enlarge the packet. The hsame row transports displayed coordinates, the Cont row replays the displayed route, P records provenance for the named interface, and N records the local NameCert row.

Since no excluded object occurs in any carrier coordinate, no accepted read can escape to Real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits, metric completeness, open-cover compactness, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealLineInterface}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealLineInterface}^{\uparrow}$ packet is generated from a DyadicRatCore endpoint and tolerance ledger, finite StreamName windows, RegSeqRat regular readback, a terminal Real seal, Cauchy-equivalence comparison, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealLineInterface}^{\uparrow}}$, obligation)

Scope closed: Definition 2062.1, Definition 2062.2, Definition 2062.4, Definition 2062.10, and Definition 2062.12 seed the traditional constructive real-line interface boundary over the displayed L10 dyadic, stream, regular-readback, Real-seal, comparison, transport, continuation, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealLineInterface}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.BishopRealLineInterfaceUp`

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits, metric completeness, open-cover compactness, or bridge checking.

Upgrade path: Scoped closure requires binding the listed obligations to DyadicRatCore, StreamName, RegSeqRat, RealUp, CauchyEquivalenceSetoid, BHist, hsame, Cont, Pkg, and NameCert rows for BEDC.Derived.BishopRealLineInterfaceUp.

Every $\mathsf{BishopRealLineInterface}^{\uparrow}$ packet consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301 and the terminal $\mathsf{Real}^{\uparrow}$ seal row of chapter 38 before exporting the real-line interface. The sibling route keeps the L10 dependency explicit: finite dyadic and stream rows are read first, the regular rational sequence row is then admitted as the real-line source, and the Real seal is the last value-facing row available to downstream interface consumers.

Theorem 2062.13 (Bishop real-line interface to ordered Cauchy-group forward route)**.** *Every* $\mathsf{OrderedCauchyGroup}^{\uparrow}$ *consumer of chapter 6278 that reads the* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *surface factors through the displayed dyadic endpoint and tolerance ledger, finite stream-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row of the*

present chapter. The ordered Cauchy-group route may consume those rows as the real-line source for order-compatible completion, but it receives no quotient stream equality, selected completed representative, detached completed order, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem from the Bishop interface.*

Proof. Project the carrier $I = (D, W, R, E, Q, H, C, P, N)$ of Definition 2062.1. The only value-facing rows are the dyadic endpoint and tolerance ledger D, stream-window row W, regular readback row R, terminal seal E, and Cauchy-equivalence comparison row Q.

The $\mathsf{OrderedCauchyGroup}^{\uparrow}$ packet reads exactly those rows when it imports a Bishop real-line source for completion. Its own order-compatible completion ledger remains downstream of the displayed $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route in Definition 6278.4.

The structural rows H, C, P, N transport, replay, source, and name the same Bishop interface. Since the interface carrier has no coordinate for quotient equality, selected representatives, detached completed orders, choice schedules, trichotomy, or ambient completeness, none of those objects can be passed to the ordered Cauchy-group consumer. □

Theorem 2062.14 (Bishop real-line interface RealModulus forward route)**.** *Every* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer that enters through an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *packet must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *terminal seal, and* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row before the convergence-modulus ledger is read. The route is the same finite interface route of Definition 2062.11 and the reciprocal RealModulus route of Definition 2074.12; it points to the downstream ledger of chapter 2074 without importing quotient streams, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted Bishop interface packet. Its analytic rows expose the dyadic ledger, finite stream windows, regular rational readback, terminal Real seal, and Cauchy-equivalence comparison before any downstream consumer can inspect a modulus ledger.

Apply Theorem 2062.11. A convergence-modulus comparison sourced from the interface is already forced through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyEquivalenceSetoid}$ rows.

Use Theorem 2074.12 on the downstream side. The $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet reads the Bishop interface first and then consumes the same dyadic, stream, regular readback, and Real-seal rows before the convergence-modulus ledger is available.

The two routes therefore meet on the same finite L10 rows before any modulus read. Since neither carrier contains quotient streams, selected limits, countable-choice schedules, host real equality, or ambient Real completeness, none of those objects is exported by the forward route. □

Theorem 2062.15 (Bishop real-line interface regular-completion dependency route)**.** *Every* BishopRealLineInterfac *consumer that reads a completion-facing real-line source through ordered Cauchy-group data must first pass through the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet of chapter 1639. The route consumes the displayed dyadic endpoint and tolerance ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, common-tail modulus data, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and componentwise structural rows from that completion packet, then threads the ordered Cauchy-group rows for addition, order, and order-compatible completion through the interface rows* $D, W, R, E, Q, H, C, P, N$.

Thus the Bishop real-line interface depends on regular Cauchy completion as a finite L10 source together with ordered Cauchy-group structure. It does not import a selected completed representative, quotient equality of real names, trichotomy, host real equality, countable choice, metric completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the completion-facing route of chapter 1639. Its accepted packet exposes dyadic tail data, finite stream observations, regular Cauchy readback, common-tail comparison, Real-seal handoff, componentwise transport, continuation replay, provenance, and local naming before any completion consumer may read it.

Next use the four-object route of Definition 2062.4. The interface can read the completion packet only through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, with Cauchy-equivalence comparison and structural rows remaining downstream.

The ordered Cauchy-group data supplies addition, order, and order-compatible completion rows after the same finite real-line source has been displayed. Those rows refine how the source is consumed; they do not add a host completed object or a second equality principle.

Finally apply nonescape from Definition 2062.12. Since the interface carrier has no coordinate for selected representatives, quotient equality, trichotomy, host equality, choice, metric completeness, open-cover compactness, or ambient Real completeness, none of those objects can enter through the regular-completion dependency route. □

Theorem 2062.16 (Bishop real-line interface regular-real seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *carrier must pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier comparison row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row before any public real-line consumer reads it. Equivalently, a public interface read follows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyEquivalenceSetoid}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N$$

through the carrier rows $D, W, R, Q, E, H, C, P, N$*.*

The route exports no host real equality, quotient stream equality, selected representative, selected limit, trichotomy, countable-choice schedule, metric completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $I = (D, W, R, E, Q, H, C, P, N)$ from Definition 2062.1. The dyadic ledger D is the first value-facing row, and the finite stream window W is the only stream observation row available before readback.

Apply the regular-completion dependency route of Definition 2062.15. It places completion-facing reads behind the regular Cauchy completion packet, whose public surface reaches the interface through dyadic tolerances, finite stream windows, regular readback, common-tail comparison, and the terminal Real seal.

Apply the ordered Cauchy-group forward route of Definition 2062.13. That theorem keeps order-compatible consumers behind the same dyadic, stream, RegSeqRat, Real, and Cauchy-equivalence rows rather than behind a host completed object.

Now use the local four-object route and nonescape theorems of Definition 2062.4 and Definition 2062.12. The comparison row Q can classify only displayed regular-Cauchy data before the seal is read, and H, C, P, N preserve the same route. Therefore every public real-line read reaches the terminal seal only after the RegSeqRat readback, CauchyEquivalenceSetoid comparison, DyadicRatCore tolerance rows, and Real seal have been displayed. □

Chapter 2063

A Concrete Naming Certificate for $\mathsf{LocatedRealField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRealField}^{\uparrow}$ packet records the finite field interface for located Cauchy real names. It sits after the terminal real-name seal of chapter 38, the regular rational source surface of chapter 301, the finite window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the Cauchy real field route of chapter 1717, and the positive apartness surface of chapter 1881. The packet gives Real and Completion consumers one constructive field-facing surface over located Cauchy names; it is not order trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 2063.1 (Located real field carrier)**.** *A* $\mathsf{LocatedRealField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (E, R, W, D, F, A, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the located real source row. It records the displayed located Cauchy real names and exposes them only through the terminal* $\mathsf{Real}^{\uparrow}$ *seal and the local locatedness data.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source-window row used to read every located real source through regular rational Cauchy data.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window discipline for operation, comparison, and apartness reads.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger. It records the dyadic endpoint operations, positive-radius tolerances, comparison slack, and reciprocal-denominator budgets used by the field surface.*
5. *F is the* $\mathsf{CauchyRealField}^{\uparrow}$ *operation row for zero, one, negation, addition, multiplication, and partial reciprocal reads on the displayed Cauchy real names.*
6. *A is the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *positive-apartness row consumed by reciprocal eligibility and by downstream located-order consumers.*
7. *O is the located comparison row. It records the order and comparison boundary available from the located real presentation without turning it into trichotomy or quotient equality.*
8. *H records componentwise* hsame *transport for the source, regular readback, window, dyadic, field, apartness, comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each field request through $E, R, W, D, F, A, O, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRealField}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealField}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive located-field packet. It has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedRealFieldUp.LocatedRealFieldTasteGate single carrier alignment`

Theorem 2063.2 (Located real field NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealField}^{\uparrow}$ *carrier*

$$L = (E, R, W, D, F, A, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealField}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located real source data, regular rational readback row, synchronized finite windows, dyadic tolerance ledger, Cauchy real field row, apartness row, comparison row, transport row, replay row, provenance row, and local naming row;*
2. *operation projection, requiring every zero, one, negation, addition, multiplication, or partial reciprocal read to pass through the displayed* $\mathsf{CauchyRealField}^{\uparrow}$ *row F after the source, window, and dyadic rows are visible;*
3. *apartness and comparison handoff, requiring reciprocal eligibility, positive-gap consumption, and order-facing reads to use the displayed* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row A and located comparison row O;*
4. *transport and replay stability, requiring H and C to preserve the same componentwise source, readback, window, dyadic, operation, apartness, comparison, provenance, and local naming rows;*
5. *ledger exhaustion, excluding trichotomy, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge checking from the local certificate.*

No located real field obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2063.1. The accepted packet displays exactly the located real source row, regular rational readback, synchronized windows, dyadic tolerance ledger, Cauchy real field row, apartness row, comparison row, and structural rows.

The operation projection is inherited from chapter 1717. Its row F is the only place where the packet stores zero, one, negation, addition, multiplication, or reciprocal data, and every such read remains downstream of E, R, W, D.

The apartness and comparison handoff is inherited from chapter 1881 and the located comparison surface. The positive row A supplies the finite apartness boundary used by reciprocal eligibility, while O supplies comparison data without adding a trichotomy coordinate.

Finally, H, C, P, N transport, replay, source, and name only the displayed rows. Since the carrier contains no coordinate for the excluded principles, none can become a local NameCert obligation. □

Theorem 2063.3 (Located real field apartness-field handoff)**.** *Every accepted* $\mathsf{LocatedRealField}^{\uparrow}$ *carrier routes any reciprocal or positive-gap field read through the finite chain*

$$E, R, W, D \longmapsto A, O \longmapsto F \longmapsto H, C, P, N.$$

Thus the field surface consumes located apartness and comparison data before exposing a reciprocal branch, while addition and multiplication remain confined to the same regular rational windows and dyadic arithmetic ledger.

Proof. Start with an accepted carrier $L = (E, R, W, D, F, A, O, H, C, P, N)$. The only located real source is E, and all field reads first pass through the regular rational row R, synchronized window row W, and dyadic ledger D.

For a reciprocal or positive-gap read, the apartness row A must be available before the field row exposes the reciprocal branch. The comparison row O records the located order boundary used by the same consumer, but it does not decide trichotomy or quotient equality.

For addition and multiplication, the field row F uses the same R, W, D route and does not receive separate host arithmetic. These branches therefore remain tied to the located Cauchy real presentation.

The structural rows are downstream of both cases. They preserve the displayed handoff by componentwise transport, replay, provenance, and local naming, and they do not add a selected representative, countable-choice selector, ambient completeness witness, or bridge credential. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealField}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2063.1, Definition 2063.2, and Definition 2063.3 seed the finite located-field route over located real source data, regular rational windows, dyadic tolerances, Cauchy real field operations, positive apartness, located comparison, componentwise transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealField}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.LocatedRealFieldUp`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation projection, apartness-field handoff, comparison confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealFieldUp.

Constructive story: A $\mathsf{LocatedRealField}^{\uparrow}$ packet is generated from located real source data, RegSeqRat readback windows, StreamName finite windows, DyadicRatCore tolerance rows, a CauchyRealField operation row, a CauchyRealApartness positive row, a LocatedRealComparison boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2064

A Concrete Naming Certificate for $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures, entourage bases, and Cauchy-filter completion routes, the $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$ packet records the finite Real-side refinement step that sits between the basis surface of chapter 2060 and completion-facing consumers. It reuses the Real uniform source of chapter 1624, the abstract entourage-basis discipline of chapter 1819, and the Cauchy-filter handoff of chapter 333; the radius arithmetic and finite readback are supplied through chapter 291, chapter 126, and chapter 301. The packet is a finite witness surface for Real entourage shrinkage. It is not a quotient completion, not a selected-limit construction, and not an assertion of ambient Real completeness.

Definition 2064.1 (Real uniform entourage-refinement carrier)**.** *A* $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E_{\mathrm{ref}} = (R, U, \epsilon, \delta, B, Y, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *source row whose Real metric-ball route supplies the requested entourage.*
2. *U is the requested Real uniform entourage row, exposed only as a finite request to be refined.*
3. *ϵ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius row naming the request radius for U.*
4. *δ is the smaller positive dyadic radius row, together with the displayed comparison $0 < \delta$ and $2\delta \leq \epsilon$ inside the dyadic ledger.*
5. *B is the* $\mathsf{RealUniformEntourageBase}^{\uparrow}$ *row carrying the Real-induced basis containment witness for the δ-ball entourage inside U.*
6. *Y is the symmetric-shrink row recording that the δ-ball entourage composes with itself inside the requested ϵ-entourage.*
7. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row inspected by completion-facing consumers after the refinement row has been displayed.*
8. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read after F when a consumer asks for a finite Cauchy trace of the refinement.*

9. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S, ϵ, δ, and the dyadic comparison in the ledger.*

10. *H records componentwise* hsame *transport for the Real uniform source, requested entourage, dyadic radii, basis containment, symmetric shrink, Cauchy-filter handoff, finite windows, readback, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the requested Real entourage through $R, U, \epsilon, \delta, B, Y, F, S, Q, H, P, N$.*

12. *P is the* Pkg *provenance over* $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$, $\mathsf{RealUniformEntourageBase}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformEntourageRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $R, U, \epsilon, \delta, B, Y, F, S, Q, H, C, P, N$. The carrier has no coordinate for quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, bridge checking, Lean verification, or ambient Real completeness.

Theorem 2064.2 (Real uniform entourage-refinement NameCert obligations)**.** *For every accepted* $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$ *carrier*

$$E_{\mathrm{ref}} = (R, U, \epsilon, \delta, B, Y, F, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealUniformEntourageRefinement}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Real uniform source, requested entourage, dyadic request radius, smaller dyadic radius, basis containment row, symmetric-shrink row, Cauchy-filter handoff, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local naming row;*

2. *requested-entourage grounding, requiring U to be read from the Real uniform source row R and named by the positive dyadic request radius ϵ;*

3. *smaller-radius selection, requiring δ to be a displayed positive dyadic radius with $2\delta \leq \epsilon$ in the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger;*

4. *containment refinement, requiring B to exhibit the δ-ball Real basis entourage as a contained sub-entourage of U;*

5. *symmetric shrink, requiring Y to replay the δ-ball self-composition inside the requested ϵ-entourage;*

6. *Cauchy-filter handoff, requiring every completion-facing read in F to consume B and Y before reading the finite rows S and Q;*

7. *classifier transport, requiring H and C to preserve the displayed route $R, U, \epsilon, \delta, B, Y, F, S, Q$ componentwise under* hsame *and replay it under* Cont*;*

8. *provenance non-escape, requiring P and N to export no quotient completion, selected limit, open-cover compactness, countable-choice selector, trichotomy, bridge-checked claim, Lean-verified claim, or ambient Real completeness principle.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is the finite projection from Definition 2064.1. The projection exposes exactly the Real uniform source, the requested entourage, the two dyadic radius rows, the basis containment row, the symmetric-shrink row, the Cauchy-filter handoff, finite windows, readback, and the structural rows H, C, P, N.

The requested-entourage row is grounded in the Real uniform source. A consumer first reads R, then reads the request U, and then identifies the positive dyadic radius ϵ that names the displayed Real metric-ball request.

The smaller-radius row is internal to the dyadic ledger. The row δ carries the positive-radius witness and the comparison $2\delta \leq \epsilon$, so the containment and symmetric-shrink rows do not need a choice principle or an ambient completeness principle.

Containment refinement is supplied by the Real entourage-base packet. The row B reads the δ-ball basis entourage and displays the witness that this basis row lies inside the requested entourage U.

The symmetric-shrink row is the finite composition witness. It records that two δ-steps remain within the ϵ request, and it is replayed before any completion-facing consumer reaches the Cauchy-filter handoff.

The handoff and readback rows are downstream of the refinement surface. A consumer reads F only after B and Y have been replayed, and the finite observations S and Q expose StreamName windows and RegSeqRat comparisons for that same route.

Finally, transport and provenance add no new mathematical primitive. The row H preserves each displayed coordinate componentwise, C replays the same finite route, and P, N name only the rows already present in E_{ref}. □

Theorem 2064.3 (Real uniform entourage-refinement completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$ *carrier reads a requested Real entourage through a displayed smaller dyadic radius, a Real basis-containment witness, and a symmetric-shrink witness before reaching the Cauchy-filter handoff. Consequently the packet exports no quotient completion, selected limit, open-cover compactness, countable-choice selector, trichotomy, bridge-checked claim, Lean-verified claim, or ambient Real completeness.*

Proof. Begin with a completion-facing consumer of E_{ref}. Carrier admission gives access to the packet only through $R, U, \epsilon, \delta, B, Y, F, S, Q, H, C, P, N$.

The consumer therefore cannot read F directly from the requested entourage. It first reads the Real uniform source R, the requested entourage row U, the request radius ϵ, and the smaller dyadic radius δ with its ledger comparison.

The basis and shrink rows then mediate the handoff. The row B supplies the Real-induced basis containment witness, while Y supplies the symmetric-shrink witness that keeps the doubled δ-step inside the requested ϵ-entourage.

Only after these rows are replayed does the consumer reach the Cauchy-filter row F. The rows S and Q then provide finite StreamName and RegSeqRat readback for the same dyadic route.

The remaining rows are structural. The BHist, hsame, Cont, Pkg, and NameCert coordinates transport, replay, source, and name the finite refinement packet, so no omitted completion, choice, bridge, Lean, or Real-completeness principle can be exported by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformEntourageRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformEntourageRefinement}^{\uparrow}$ packet is generated from a RealUniformStructure source row, a requested Real entourage, a positive dyadic request radius, a smaller dyadic radius, a RealUniformEntourageBase containment row, a symmetric-shrink row, a CauchyFilter handoff, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealUniformEntourageRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 2064.1, Definition 2064.2, and Definition 2064.3 seed the Real-specific refinement route from requested entourages to CauchyFilter consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealUniformEntourageRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, open-cover compactness, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, requested-entourage grounding, smaller-radius selection, containment refinement, symmetric shrink, Cauchy-filter handoff, classifier transport, and provenance non-escape proofs for the same packet.

Chapter 2065

A Concrete Naming Certificate for $\mathsf{KuratowskiCompletion}^{\uparrow}$

Following Kuratowski's metric embedding theorem, Kelley-style completion, and Bishop–Bridges constructive analysis, the $\mathsf{KuratowskiCompletion}^{\uparrow}$ packet records the completion route that first embeds a source metric object into displayed distance-function rows and then seals the resulting Cauchy data as finite BEDC completion evidence. It sits after the distance-function surface of chapter 7569, the completion interface of chapter 1506, the universal handoff of chapter 1456, and the separated uniqueness boundary of chapter 1790. The chapter names the L10 metric-completion landing surface without choosing quotient representatives, asserting host function extensionality, invoking countable choice, using open-cover compactness, or assuming ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2065.1 (Kuratowski completion carrier)**.** *A* $\mathsf{KuratowskiCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, E, D, S, A, U, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric row, including the finite endpoint, distance, and Cauchy-window requests that will be completed.*
2. *E is the accepted* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *row that turns the source metric observations into displayed distance-function target rows.*
3. *D is the distance-function readback row, exposing the* $\mathsf{Real}^{\uparrow}$ *distance observations used by the embedded Cauchy comparisons.*
4. *S is the completion-seal row for the embedded Cauchy route, read through* $\mathsf{MetricCompletion}^{\uparrow}$ *rather than through a quotient object.*
5. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *extension row that supplies the universal completion handoff for downstream consumers.*
6. *U is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *uniqueness row, recording that separated readback identifies only the displayed completion route.*
7. *R is the real-distance readback row that returns finite distance observations from the sealed completion surface to the terminal* $\mathsf{Real}^{\uparrow}$ *distance boundary.*
8. *H records componentwise* hsame *transport for the source, embedding, distance-function, completion-seal, adjunction, separated-reflection, real-readback, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from source metric reads through Kuratowski distance functions, completion sealing, adjunction extension, separated uniqueness, and real-distance readback.*
10. *P is the* Pkg *provenance over* $\mathsf{KuratowskiCompletion}^{\uparrow}$, $\mathsf{KuratowskiEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, host function extensionality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KuratowskiCompletionUp.KuratowskiCompletionTasteGate single carrier alignment`

Theorem 2065.2 (Kuratowski completion NameCert obligations)**.** *For an accepted* $\mathsf{KuratowskiCompletion}^{\uparrow}$ *carrier*

$$K = (M, E, D, S, A, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source metric row, Kuratowski embedding row, distance-function readback row, completion-seal row, adjunction extension row, separated-reflection uniqueness row, real-distance readback row, transport, replay, provenance, and local naming row;*
2. *source metric exposure, requiring every endpoint, distance request, and Cauchy-window request to enter through M before any completion-facing row is read;*
3. *distance-function embedding exposure, requiring E and D to display the Kuratowski distance-function route before completion sealing is available;*
4. *completion-seal exactness, requiring S to bind the embedded Cauchy route as a* $\mathsf{MetricCompletion}^{\uparrow}$ *surface and not as a quotient representative;*
5. *adjunction extension handoff, requiring A to expose every downstream extension consumer only after the same M, E, D, S route has been displayed;*
6. *separated uniqueness readback, requiring U and R to return uniqueness and finite distance reads through separated-reflection and* $\mathsf{Real}^{\uparrow}$ *rows;*
7. *structural exhaustion, requiring H, C, P, N to preserve, replay, source, and name only the listed route.*

No NameCert obligation is stored outside these rows, and none exports quotient completion equality, selected representatives, host function extensionality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2065.1. The accepted packet displays exactly the source, embedding, distance-function, completion-seal, adjunction, separated-reflection, real-readback, and structural rows.

Source metric exposure is read from M. Since every endpoint, distance request, and Cauchy-window request enters before the Kuratowski embedding row, the packet cannot manufacture completion data from an unrecorded metric object.

Distance-function embedding exposure is read from E and D. The embedding row supplies the displayed Kuratowski distance-function surface, while the distance-function readback row records the corresponding $\mathsf{Real}^{\uparrow}$ observations before the completion seal is inspected.

Completion-seal exactness and adjunction extension are read from S and A. The row S seals the embedded Cauchy route as a $\mathsf{MetricCompletion}^{\uparrow}$ object, and the row A exposes extension consumers only downstream of that same finite route.

Separated uniqueness and real-distance readback are then finite row checks. The row U records uniqueness only through the separated-reflection boundary, and R returns distance observations through the displayed real-distance surface.

Finally H, C, P, N add no analytic coordinate. They transport, replay, source, and name the displayed route, so the excluded quotient, representative, host-extensionality, choice, compactness, and ambient-completeness principles have no row from which a consumer could read them. □

Theorem 2065.3 (Kuratowski completion metric-completion handoff)**.** *Let*

$$K = (M, E, D, S, A, U, R, H, C, P, N)$$

be an accepted $\mathsf{KuratowskiCompletion}^{\uparrow}$ *carrier. Every L10 metric-completion consumer of K receives the completion object only through the finite route*

$$M \longmapsto E, D \longmapsto S \longmapsto A \longmapsto U, R \longmapsto H, C, P, N.$$

Thus the handoff from Kuratowski distance functions to metric completion is a displayed NameCert route over source metric rows, distance-function embedding rows, completion-seal rows, adjunction extension rows, separated-reflection uniqueness rows, real-distance readback rows, and structural hsame/Cont/Pkg/NameCert *rows. It is not quotient completion equality, not selected-representative data, not host function extensionality, not countable choice, not open-cover compactness, and not an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Fix an L10 metric-completion consumer of the packet. Projection gives the source metric row M, so the consumer starts from the displayed endpoint, distance, and Cauchy-window requests.

Apply the Kuratowski embedding row E and distance-function readback row D. These rows move the source metric observations into displayed distance-function data before any completion-facing object is available.

The completion-seal row S is therefore attached to the embedded route. Since S is a row of the finite carrier, it gives a $\mathsf{MetricCompletion}^{\uparrow}$ seal and not a quotient class with a selected representative.

The adjunction extension row A supplies the universal completion handoff. Any downstream extension consumer must read through the same M, E, D, S chain before seeing A.

Separated uniqueness and real-distance readback are downstream of that handoff. The rows U and R expose only separated-reflection uniqueness and displayed $\mathsf{Real}^{\uparrow}$ distance observations.

Transport, replay, provenance, and local naming close the route. The rows H, C, P, N preserve the listed data componentwise, so no host function extensionality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness can be exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2065.1, Definition 2065.2, and Definition 2065.3 seed the finite Kuratowski distance-function route into metric-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host function extensionality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distance-function embedding exposure, completion-seal exactness, adjunction extension handoff, separated uniqueness readback, real-distance readback, and structural replay for BEDC.Derived.KuratowskiCompletionUp.

Constructive story: A $\mathsf{KuratowskiCompletion}^{\uparrow}$ packet is generated from source metric rows, Kuratowski distance-function embedding rows, completion-seal rows, adjunction extension rows, separated-reflection uniqueness rows, Real distance-readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2066

A Concrete Naming Certificate for $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$

Following Mac Lane on Kleisli categories, Kelley on completion, and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$ packet names the finite L10 boundary where the completion monad's unit-and-bind route is compared with the completion adjunction's universal handoff. It sits after the monad packet of chapter 378, the Kleisli consumer packet of chapter 1845, and the universal-mapping packet of chapter 1456. Its analytic readback is the same finite route through chapter 126, chapter 291, chapter 301, and chapter 38.

The packet is a boundary certificate, not a construction of quotient completion. It records only the displayed rows by which a downstream Real or Completion consumer can see that a Kleisli bind read and an adjunction extension read share the same finite source, window, tolerance, readback, seal, transport, replay, provenance, and local naming route.

Definition 2066.1 (Cauchy completion Kleisli-adjunction carrier)**.** *A* $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, B, L, A, V, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the unit row inherited from* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*, displaying the source packet before any Kleisli consumer or adjunction comparison is read.*
2. *B is the bind row inherited from* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*, displaying the completion-facing source family consumed by a single Kleisli request.*
3. *L is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *consumer row, recording the finite consumer request that reads the unit and bind rows through the same downstream completion surface.*
4. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *comparison row, aligning the Kleisli consumer read with the adjunction's source-side and completion-side observations.*
5. *V is the universal handoff row, exposing the adjunction extension surface only after U, B, L, A have been displayed.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the shared completion read.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same finite window.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the displayed window and tolerance data.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R have been displayed.*

10. *H records componentwise* hsame *transport for the unit, bind, Kleisli consumer, adjunction comparison, universal handoff, window, tolerance, readback, seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$U, B \longmapsto L \longmapsto A, V \longmapsto S, D, R, E \longmapsto H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, B, L, A, V, S, D, R, E, H, C, P, N$. The carrier has no coordinate for quotient completions, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionKleisliAdjunctionUp.CauchyCompletionKleisliAdjunctionTasteGate`
`single carrier alignment`

Theorem 2066.2 (Cauchy completion Kleisli-adjunction obligations)**.** *For every accepted* CauchyCompletionKleisliA *carrier*

$$K = (U, B, L, A, V, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the unit row, bind row, Kleisli consumer row, adjunction comparison row, universal handoff row, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming row;*

2. *unit and bind exposure, requiring every Kleisli or adjunction consumer to display U and B before it can inspect the shared downstream route;*

3. *Kleisli consumer exactness, requiring L to consume only the displayed unit-and-bind data before opening the adjunction comparison;*

4. *adjunction comparison exactness, requiring A and V to compare the Kleisli consumer with the universal handoff over the same finite source route;*

5. *analytic readback exactness, requiring S, D, R, E to supply the only StreamName, DyadicRatCore, RegSeqRat, and Real rows visible to the consumer;*

6. *structural exhaustion, requiring H, C, P, N to preserve, replay, source, and name the listed route without adding quotient completions, selected limits, countable choice, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2066.1. The accepted packet displays exactly the unit, bind, Kleisli consumer, adjunction comparison, universal handoff, finite analytic readback, and structural rows.

Unit and bind exposure is read from U and B. Since both rows are inherited from the completion monad surface, every consumer starts with the same displayed source packet and source family before any Kleisli or adjunction row is available.

Kleisli exactness is read from L. The row records the consumer request downstream of U and B, so it cannot introduce a second source family, selected limit, or quotient representative before the comparison row is opened.

Adjunction comparison and universal handoff are read from A and V. These rows align the Kleisli consumer with the adjunction boundary only over the displayed U, B, L route, and the handoff is exposed only after that comparison has been recorded.

The analytic readback rows are S, D, R, E. They give the finite StreamName window, dyadic tolerance ledger, regular rational readback, and terminal Real seal used by both sides of the comparison.

Finally H, C, P, N add no analytic or quotient coordinate. They transport, replay, source, and name the same finite route, so the excluded completion, choice, host-equality, ambient-completeness, Lean, and bridge objects have no row from which a consumer could read them. □

Theorem 2066.3 (Cauchy completion Kleisli-adjunction route)**.** *For every accepted* CauchyCompletionKleisliAdjunc *carrier*

$$K = (U, B, L, A, V, S, D, R, E, H, C, P, N),$$

every L10 Completion or Real consumer that compares a Kleisli bind read with an adjunction handoff factors through the finite route

$$U, B \longmapsto L \longmapsto A, V \longmapsto S, D, R, E \longmapsto H, C, P, N.$$

Thus the comparison is a displayed NameCert route over the completion monad, Kleisli consumer, completion adjunction, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, Real seal, hsame *transport,* Cont *replay,* Pkg *provenance, and local naming rows. It is not quotient completion equality, not a selected limit, not countable choice, not host equality, not ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and not a bridge credential.*

Proof. Fix an L10 consumer that compares a Kleisli bind read with an adjunction handoff. Projection of the accepted carrier supplies the unit row U and bind row B, so the comparison begins at the displayed completion monad data.

The Kleisli consumer row L is the next coordinate. It reads only the already displayed unit-and-bind route before the adjunction comparison is opened.

The adjunction comparison and universal handoff are then forced through A and V. These rows compare the Kleisli consumer with the completion adjunction over the same finite source route, so no separate completion object is inserted between them.

The analytic readback is downstream of that comparison. The rows S, D, R, E provide the finite stream window, dyadic tolerance, regular rational readback, and Real seal that both the Kleisli side and the adjunction side must share.

Transport, replay, provenance, and naming close the route. The rows H, C, P, N preserve exactly the listed coordinates, so the consumer receives only the displayed NameCert route and none of the excluded quotient, selection, choice, host-equality, ambient-completeness, or bridge data. □

Theorem 2066.4 (Cauchy completion Kleisli-adjunction Real non-escape)**.** *For every accepted* $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$ *carrier*

$$K = (U, B, L, A, V, S, D, R, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-facing read that uses the Kleisli-adjunction comparison reaches the terminal Real seal only through the displayed route of Definition 2066.3. In particular, the Real read cannot export a quotient completion, selected limit, countable-choice selector, host equality of completion names, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge-checked surface.*

Proof. Start with a Real-facing read of the packet. The route theorem forces the read through U, B, L, A, V before any analytic row can be inspected.

The only analytic rows after that comparison are S, D, R, E. The stream window S, dyadic tolerance row D, and regular rational readback R are displayed before the terminal Real seal E is available.

Now inspect the structural rows. Componentwise transport H and continuation replay C preserve the same finite route, while P and N source and name only the listed completion monad, Kleisli, adjunction, StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Since the carrier contains no quotient-completion coordinate, selected-limit coordinate, countable-choice selector, host-equality row, ambient-completeness theorem, Lean verification row, or bridge row, no Real-facing consumer can export any of those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2066.1, Definition 2066.2, Definition 2066.3, and Definition 2066.4 seed the finite comparison route between Cauchy-completion Kleisli consumers and adjunction handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit and bind exposure, Kleisli consumer exactness, adjunction comparison exactness, universal handoff exactness, analytic readback exactness, structural replay, and Real non-escape for BEDC.Derived.CauchyCompletionKleisliAdjunctionUp.

Constructive story: A $\mathsf{CauchyCompletionKleisliAdjunction}^{\uparrow}$ packet is generated from a completion monad unit row, bind row, Kleisli consumer row, completion adjunction comparison row, universal handoff row, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2067

A Concrete Naming Certificate for $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$ packet records the finite route by which located observations of a real sequence become a Cauchy-criterion read before a terminal real-name seal is consumed. It sits after the finite-window discipline of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the Cauchy readiness surface of chapter 1590, the Real seal boundary of chapter 38, and the exact completion boundary of chapter 1120. The packet is a located finite-observation criterion for Real and Completion consumers; it does not identify quotient streams, select a limit, invoke countable choice, decide trichotomy, compare host real values, or assert ambient Real completeness.

Definition 2067.1 (Located real Cauchy criterion carrier)**.** *A* $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located source-window row, exposing the finite real-sequence entries, locatedness witnesses, and precision requests inspected by the criterion.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened from the located source windows in L.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed StreamName windows and no other stream source.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-cell row, recording requested radii, split tolerances, late-pair budgets, and dyadic comparison cells.*
5. *Q is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *output row, tying the located source windows, stream windows, regular readback, and dyadic tolerance cells to an accepted Cauchy-criterion read.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, S, R, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the located source windows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance cells, RealCauchyCriterion output, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located precision request through L, S, R, D, Q, E.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCompletionExactBoundaryUp}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, S, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, detached completeness, or an ambient Real-completion theorem.

Lean4 ✓ `BEDC.Derived.LocatedRealCauchyCriterionUp.TasteGate.LocatedRealCauchyCriterionTasteGate single carrier alignment`

Theorem 2067.2 (Located real Cauchy criterion NameCert obligations)**.** *For an accepted* LocatedRealCauchyCriter *carrier*

$$K = (L, S, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the located source-window row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance cells, RealCauchyCriterion output, Real seal, transport, replay, provenance, and local naming row;*
2. *located-window exactness, requiring every observed real-sequence entry and locatedness witness to enter through L before any StreamName window or regular rational readback is inspected;*
3. *dyadic tolerance exactness, requiring D to display the requested radius, split tolerance, late-pair budget, and comparison cells used by the criterion;*
4. *CauchyCriterion handoff, requiring Q to read only the displayed route L, S, R, D before the Real seal E is available;*
5. *seal nonescape, requiring every terminal* $\mathsf{Real}^{\uparrow}$ *read to pass through E rather than through a quotient stream, selected limit, or host real object;*
6. *transport and replay stability, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the same ordered route L, S, R, D, Q, E;*
7. *provenance exhaustion, requiring P and N to name only this displayed route and to export no countable choice, trichotomy, host real equality, detached completeness, or ambient completion principle.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2067.1. The accepted packet displays the located source windows, StreamName windows, regular rational readback, dyadic tolerance cells, CauchyCriterion output, Real seal, and the structural rows H, C, P, N.

Located-window exactness is read from the order of L, S, R. The source observations and locatedness witnesses appear in L before S opens any finite stream window, and R reads only through those displayed windows.

Dyadic tolerance exactness is the role of D. The tolerance row stores the requested radius, split budget, late-pair comparison, and dyadic cells before the CauchyCriterion output row may be consumed.

The handoff to $\mathsf{RealCauchyCriterion}^{\uparrow}$ is then finite. The row Q binds the displayed L, S, R, D route as the only criterion output that can reach the terminal seal E.

Seal nonescape follows from the carrier inventory. The terminal $\mathsf{Real}^{\uparrow}$ row is named as E, while quotient streams, selected limits, and host real objects are not coordinates of the packet.

Transport and replay are structural. Componentwise hsame in H preserves the listed rows, and Cont replay in C repeats the same route from a located precision request through L, S, R, D, Q, E.

Finally, provenance is exhausted by P and N. Since the carrier has no row for countable choice, trichotomy, host real equality, detached completeness, or ambient completion, the local NameCert surface cannot export any such object. □

Theorem 2067.3 (Located real Cauchy criterion terminal seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$ *packet*

$$K = (L, S, R, D, Q, E, H, C, P, N)$$

factors through the displayed finite route

$$L \longmapsto S \longmapsto R \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the terminal real-name seal is reached through located source windows, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells, the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *output, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$ *row. It exports no quotient stream, selected limit, countable choice, trichotomy, host real equality, or ambient Real completeness.*

Proof. Begin with a terminal $\mathsf{Real}^{\uparrow}$ read of an accepted packet. Projection gives the ordered rows $L, S, R, D, Q, E, H, C, P, N$, so the read starts at the located source-window surface rather than at an unbounded host stream.

The StreamName and RegSeqRat stages are downstream of L. The finite windows S are opened from the located source row, and the regular rational readback R is obtained only through those windows.

The dyadic tolerance row D is downstream of that readback. It records the split tolerance and late-pair comparison cells required before the CauchyCriterion output can be accepted.

The CauchyCriterion handoff is Q. By Definition 2067.2, Q may read only L, S, R, D before exposing the terminal Real seal E.

Transport, replay, provenance, and local naming do not add analytic coordinates. The rows H, C, P, N preserve, replay, source, and name the same displayed route.

The excluded objects are absent from the carrier and from the NameCert obligations. Therefore no quotient stream, selected limit, countable choice, trichotomy, host real equality, or ambient Real completeness can be exported by a terminal seal read. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealCauchyCriterion}^{\uparrow}$ packet is generated from located source-window rows, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance cells, a RealCauchyCriterion output row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 2067.1, Definition 2067.2, and Definition 2067.3 seed the located finite-observation route from Real sequence windows to the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, located-window exactness, dyadic tolerance exactness, CauchyCriterion handoff, seal nonescape, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.LocatedRealCauchyCriterionUp.

Chapter 2068

A Concrete Naming Certificate for CauchyConvergenceModulusTailMonotonicity$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the CauchyConvergenceModulusTailMonotonicity$^{\uparrow}$ packet records the finite certificate by which a displayed CauchyConvergenceModulus$^{\uparrow}$ tail threshold may be replaced by a later displayed threshold without changing the convergence-modulus route consumed by Real and Completion arguments. It refines the convergence-modulus carrier of chapter 1438, the monotone schedule discipline of chapter 1744, the regular tail-extension surface of chapter 1750, the finite windows of chapter 126, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet gives later L10 Real and Completion consumers a monotone reuse certificate for displayed convergence moduli; it does not import host convergence, selected limits, quotient streams, countable choice, trichotomy, host real equality, or ambient Real completeness.

Definition 2068.1 (Cauchy convergence modulus tail monotonicity carrier)**.** *A* CauchyConvergenceModulusTailMon *carrier is a finite* BHist *packet*

$$K = (K_0, T, W, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *K_0 is the source* CauchyConvergenceModulus$^{\uparrow}$ *packet whose source row, dyadic tolerance row, tail-index schedule, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, transport, replay, provenance, and local name are already displayed.*
2. *T is the monotone tail-threshold comparison row, naming an earlier displayed threshold of K_0, a later displayed threshold, and the finite comparison showing that the later threshold lies inside the same accepted tail.*
3. *W is the* StreamName$^{\uparrow}$ *finite-window reuse row, containing only windows whose indices are admitted by the later displayed threshold in T.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the reused finite windows in W and from the source route of K_0.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, reusing the tolerance cells of K_0 and recording that the later tail request consumes no stronger radius than the displayed convergence-modulus request.*
6. *L is the* RealSequenceLimit$^{\uparrow}$ *handoff row reached only after K_0, T, W, R, D have been displayed.*

7. *H records componentwise* hsame *transport for the source convergence-modulus packet, tail-threshold comparison, finite-window reuse, regular readback, dyadic tolerance ledger, limit handoff, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the earlier convergence-modulus threshold through the later threshold, the reused windows, the regular readback, the dyadic tolerance ledger, and the RealSequenceLimit handoff.*

9. *P is the* Pkg *provenance over* CauchyConvergenceModulusTailMonotonicity$^{\uparrow}$, CauchyConvergenceModulus$^{\uparrow}$, CauchyModulusMonotoneNormalization$^{\uparrow}$, RegularCauchyTailMonotonicity$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealSequenceLimit$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K_0, T, W, R, D, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, host convergence, ambient Real completeness, or a detached completion object.

Lean4 ✓ `BEDC.Derived.CauchyConvergenceModulusTailMonotonicityUp.TasteGate.CauchyConvergenceModulusTailM`
`single carrier alignment`

Theorem 2068.2 (Cauchy convergence modulus tail monotonicity NameCert obligations)**.** *For an accepted* CauchyConvergenceModulusTailMonotonicity$^{\uparrow}$ *carrier*

$$K = (K_0, T, W, R, D, L, H, C, P, N),$$

the local NameCert$_{\text{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the source* CauchyConvergenceModulus$^{\uparrow}$ *packet, monotone tail-threshold comparison, finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RealSequenceLimit$^{\uparrow}$ *handoff, transport, replay, provenance, and local naming row;*

2. *monotone tail extension, requiring the later displayed threshold in T to be read only as a later tail for the same convergence-modulus request carried by K_0;*

3. *tolerance preservation, requiring D to reuse the dyadic tolerance cells displayed by K_0 and to record no stronger tolerance demand;*

4. *finite-window reuse, requiring W and R to inspect only windows and readbacks admitted by the later threshold and the same source route;*

5. *handoff nonescape, requiring L to be downstream of K_0, T, W, R, D and to export no quotient stream, selected limit, host convergence row, host real equality row, or ambient completeness principle;*

6. *transport stability, requiring componentwise* hsame *in H and displayed* Cont *replay in C to preserve the ordered route through the same convergence-modulus consumer surface;*

7. *provenance exhaustion, requiring P and N to name only the rows listed in the carrier and to export no countable choice, trichotomy, detached completion object, standard bridge, or Lean verification claim.*

No tail-monotonicity obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2068.1. The accepted packet displays the source convergence-modulus row, the later-threshold comparison, finite windows, regular readback, tolerance ledger, RealSequenceLimit handoff, and the structural rows H, C, P, N.

Monotone tail extension is the role of T. The row does not choose a new convergence modulus; it reads an earlier displayed threshold from K_0, displays a later threshold for the same request, and records the finite comparison between them.

Tolerance preservation is supplied by D. Since the later threshold is downstream of the same convergence-modulus request, the dyadic cells already displayed by K_0 remain the only tolerance rows available to the consumer.

Finite-window reuse follows from W and R. The windows are opened only beyond the later displayed threshold, and the regular readback is obtained only through those windows and the source route of K_0.

The handoff row L is terminal for this packet. It is reached only after the source packet, later-threshold comparison, windows, readback, and tolerance ledger have been displayed, so quotient streams, selected limits, host convergence, host real equality, and ambient completeness have no route into the handoff.

Finally H, C, P, N preserve, replay, source, and name the same ordered packet. Because no excluded object is a carrier coordinate, provenance exhaustion leaves exactly the listed obligations. □

Theorem 2068.3 (Cauchy convergence modulus tail monotonicity stability)**.** *Let*

$$K = (K_0, T, W, R, D, L, H, C, P, N)$$

be an accepted $\mathsf{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}$ *carrier. Replacing the displayed convergence-modulus threshold in K_0 by the later displayed threshold named by T preserves the same convergence-modulus consumer route:*

$$K_0 \longmapsto T \longmapsto W \longmapsto R \longmapsto D \longmapsto L \longmapsto H, C, P, N.$$

Every Real or Completion consumer that accepted the earlier displayed threshold may therefore read the later threshold through the same finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RealSequenceLimit}^{\uparrow}$ *route, with no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, host convergence, ambient Real completeness, Lean verification, or standard bridge.*

Proof. Start with the source convergence-modulus packet K_0. Its carrier route already exposes the source row, dyadic tolerance request, tail schedule, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, and structural rows.

Read the comparison row T. It identifies the later threshold as a displayed later tail for the same tolerance request, so the consumer does not receive a second modulus, a choice-selected threshold, or a host convergence predicate.

The finite observations then pass through W and R. Since W contains only windows admitted by the later threshold and R reads only those windows through the same source route, replacing the threshold leaves the consumer on the displayed convergence-modulus path.

The tolerance ledger D keeps the dyadic budget unchanged. The later threshold may discard earlier tail positions, but it does not demand a new tolerance row or a stronger radius.

Finally, the RealSequenceLimit handoff and structural rows are downstream of the same route. The rows L, H, C, P, N preserve, replay, source, and name the replacement, and the carrier has no coordinate for any excluded quotient, choice, host, completeness, Lean, or bridge object. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2068.1, Definition 2068.2, and Definition 2068.3 seed the finite monotone reuse route for displayed Cauchy convergence-modulus tail thresholds.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier exposure, monotone tail extension, tolerance preservation, finite-window reuse, handoff nonescape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CauchyConvergenceModulusTailMonotonicityUp.

Constructive story: A $\mathsf{CauchyConvergenceModulusTailMonotonicity}^{\uparrow}$ packet is generated from a source CauchyConvergenceModulus packet, a monotone tail-threshold comparison, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, RealSequenceLimit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2069

A Concrete Naming Certificate for $\mathsf{JordanVariationDecomposition}^{\uparrow}$

Following Jordan, Rudin, and Folland, the $\mathsf{JordanVariationDecomposition}^{\uparrow}$ packet records the finite signed-variation split visible inside a bounded-variation ledger. It sits over the bounded-variation surface of chapter 398, the real-name seal of chapter 38, the regular rational stream surface of chapter 301, the stream-read discipline of chapter 126, the dyadic observation rows of chapter 291, and the finite integrator handoff of chapter 1637. The packet names only displayed finite partition ledgers and their positive and negative dyadic edge rows; it does not introduce a variation measure, a supremum over all partitions, a quotient function space, countable choice, or a standard bridge.

Definition 2069.1 (Jordan variation decomposition carrier)**.** *A* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, \Pi, X, D, V^{+}, V^{-}, S, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet and its finite partition-variation ledger.*
2. *Π is the displayed ordered partition on which the signed split is read.*
3. *X records the endpoint* $\mathsf{Real}^{\uparrow}$ *rows or their* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name representatives.*
4. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-difference observations attached to adjacent endpoints of* Π*.*
5. *V^{+} is the finite positive-edge dyadic sum ledger.*
6. *V^{-} is the finite negative-edge dyadic sum ledger.*
7. *S records the signed reconstruction row, pairing the two finite ledgers back to the displayed endpoint-difference ledger.*
8. *R records displayed common-refinement comparison rows for transported partitions and transported signed ledgers.*
9. *H records componentwise* hsame *transport for the bounded-variation source, partition, endpoint, dyadic, positive-sum, negative-sum, reconstruction, refinement, package, and naming rows.*
10. *C records displayed* Cont *replay from a bounded-variation request to endpoints, edge observations, signed ledgers, reconstruction, refinement comparison, and downstream exposure.*

11. *P is the* Pkg *provenance over* $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanVariationDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, \Pi, X, D, V^+, V^-, S, R, H, C, P, N$. It has no coordinate for variation measures, host suprema over all partitions, quotient function spaces, countable choice, hidden partition families, or bridge checking.

Lean4 ✓ `BEDC.Derived.JordanVariationDecompositionUp.JordanVariationDecompositionTasteGate`
`single carrier alignment`

Theorem 2069.2 (Jordan variation decomposition NameCert obligations)**.** *For an accepted* JordanVariationDecomp *carrier $J = (B, \Pi, X, D, V^+, V^-, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{JordanVariationDecomposition}^{\uparrow}}$ *surface consists of exactly five rows:*

1. *carrier admission for the displayed tuple $B, \Pi, X, D, V^+, V^-, S, R, H, C, P, N$;*
2. *finite positive-edge and negative-edge ledger formation from the dyadic observations in D;*
3. *signed reconstruction through S, returning the displayed endpoint-difference ledger on Π;*
4. *common-refinement transport through R, H, C for the source bounded-variation packet, endpoint rows, dyadic observations, signed ledgers, and reconstruction row;*
5. *no-escape from variation measures, host suprema over all partitions, quotient function spaces, countable choice, hidden partition families, and bridge checking.*

These rows are read through the finite route

$$B, \Pi, X, D \longmapsto V^+, V^- \longmapsto S \longmapsto R$$

together with H, C, P, N.

Proof. Carrier admission is the projection of Definition 2069.1. The bounded-variation source and displayed partition are present before any signed ledger is formed.

Finite signed ledger formation is edgewise. Each adjacent endpoint pair in Π is read through X, its dyadic difference row is read through D, and that row is placed in exactly one of the positive-edge or negative-edge finite ledgers.

The reconstruction row S then forgets the sign split only after both finite ledgers are visible. Thus the public endpoint-difference read returns to the displayed bounded-variation ledger rather than to a measure-valued object.

For common refinements, use R to transport the partition and edge rows, then replay the same signed split through H and C. Package and naming provenance are carried componentwise, so no extra comparison coordinate is introduced.

The excluded host objects do not occur among the carrier coordinates. The certificate therefore closes only the finite signed-variation ledger and its displayed transport surface. □

Theorem 2069.3 (Jordan variation decomposition bounded-variation route)**.** *Every public read of a* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *packet factors through a displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, a displayed finite partition ledger, endpoint rows from* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*, stream reads from* $\mathsf{StreamName}^{\uparrow}$*, dyadic edge observations from* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the finite signed reconstruction row. A consumer such as the* $\mathsf{RiemannStieltjes}^{\uparrow}$ *integrator handoff receives only these finite rows and their visible* BHist, hsame, Cont, Pkg, *and* NameCert *provenance.*

Proof. Start from the source row B. By chapter 398, the bounded-variation read is already restricted to a displayed partition, endpoint names, dyadic edge observations, finite variation ledgers, common-refinement rows, and visible provenance.

Project the carrier of Definition 2069.1. Its additional data are only the positive-edge ledger V^+, the negative-edge ledger V^-, and the reconstruction row S attached to that same displayed partition.

Endpoint reads remain on the real and regular-rational surfaces of chapter 38 and chapter 301. Stream access is supplied by chapter 126, and every edge observation is supplied by chapter 291.

Finally, downstream integration reads through chapter 1637 can consume the signed reconstruction only as a finite integrator ledger. Since the route never ranges over all partitions and never creates a quotient of functions or a measure carrier, the public read remains inside the displayed bounded-variation dependency surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{JordanVariationDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanVariationDecomposition}^{\uparrow}$ packet is generated from a bounded-variation source row, a displayed finite partition, endpoint real or regular-rational names, stream-read windows, dyadic edge observations, positive and negative finite variation ledgers, signed reconstruction, common-refinement transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanVariationDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2069.1, Definition 2069.2, and Definition 2069.3 seed the finite Jordan signed-variation boundary over $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RiemannStieltjes}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanVariationDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close variation measures, host suprema over all partitions, quotient function spaces, countable choice, hidden partition families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed finite-ledger formation, signed reconstruction, common-refinement transport, replay, provenance, and no-escape for BEDC.Derived.JordanVariationDecompositionUp.

Chapter 2070

A Concrete Naming Certificate for $\mathsf{BoundedVariationCompletion}^{\uparrow}$

Following Jordan's bounded-variation decomposition and Bishop–Bridges constructive analysis, the $\mathsf{BoundedVariationCompletion}^{\uparrow}$ packet names the finite completion-facing surface by which bounded-variation data may be consumed as Real/Completion rows. It sits over the bounded-variation carrier of chapter 398, the regulated-function approximation schedule of chapter 1906, the Darboux finite-sum boundary of chapter 1880, the Riemann–Stieltjes tagged-sum handoff of chapter 1637, and the terminal real-name seal of chapter 38. The packet is a finite certificate surface for BV completion reads; it does not introduce host function equality, a quotient of completed functions, a selected limit, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2070.1 (Bounded-variation completion carrier)**.** *A* $\mathsf{BoundedVariationCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, R, D, I, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *V is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, including its finite partition-variation evidence, endpoint transports, common-refinement rows, and local* $\mathsf{NameCert}_{\mathsf{BoundedVariation}^{\uparrow}}$ *provenance.*
2. *R is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *representative row carrying the displayed step-approximation schedule, tolerance-tail ledger, and finite-sum handoff through the regulated-function surface.*
3. *D is the Darboux ledger row, read through chapter 1880, recording the upper and lower finite-sum windows used by completion-facing approximation requests.*
4. *I is the Riemann–Stieltjes handoff row, read through chapter 1637, connecting the regulated representative and bounded-variation integrator rows to a finite tagged-sum route.*
5. *S records the* $\mathsf{StreamName}^{\uparrow}$ *read windows used to expose the requested finite approximation stages.*
6. *Q records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows by which the stream windows are returned as regular rational names.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded-variation, regulated, Darboux, Riemann–Stieltjes, stream, and regular-rational rows have all been displayed.*

8. *H records componentwise* hsame *transport for the bounded-variation source, regulated representative, Darboux ledger, Riemann–Stieltjes handoff, stream windows, regular-rational readback, real seal, package, and local naming rows.*

9. *C records displayed* Cont *replay from a bounded-variation completion request to the regulated representative, from the representative to finite integration ledgers, from those ledgers to stream and regular-rational readback, and from readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationCompletion}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, R, D, I, S, Q, E, H, C, P, N$. It has no coordinate for a host function equality predicate, quotient completed function, selected completion limit, countable-choice selector, open-cover compactness proof, or ambient completeness witness for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BoundedVariationCompletionUp.BoundedVariationCompletionTasteGate single carrier alignment`

Theorem 2070.2 (Bounded-variation completion NameCert obligations)**.** *For every accepted* $\mathsf{BoundedVariationCompletion}^{\uparrow}$ *carrier $K = (V, R, D, I, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationCompletio}}$ *surface consists of exactly six obligations:*

1. *carrier admission for the displayed tuple $V, R, D, I, S, Q, E, H, C, P, N$;*

2. *variation-Cauchy compatibility, requiring each completion-facing tolerance request to be witnessed by finite bounded-variation partition rows and transported common-refinement ledgers from V;*

3. *regulated representative handoff, requiring R to expose a step-approximation schedule and tolerance-tail row before any completion read reaches D or I;*

4. *integration-ledger compatibility, requiring the Darboux row D and the Riemann–Stieltjes row I to consume the same displayed representative, partition, and bounded-variation evidence;*

5. *classifier transport through H and replay through C for every bounded-variation, regulated, integration, stream, regular-rational, real-seal, package, and naming row;*

6. *ledger nonescape from host function equality, quotient completed functions, selected limits, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

These obligations are read through the finite route

$$V, R \longmapsto D, I \longmapsto S, Q \longmapsto E$$

together with H, C, P, N.

Proof. Carrier admission is the projection of Definition 2070.1. The rows V and R expose the bounded-variation source and regulated representative before any integration or completion-facing row can be read.

Variation-Cauchy compatibility is finite at each tolerance request. The request first selects displayed partition and common-refinement rows from V, then uses the transported endpoint and variation ledgers to bound the requested window without invoking a completed function object.

The regulated representative handoff is supplied by R. Its step schedule and tolerance-tail row must be present before the Darboux and Riemann–Stieltjes ledgers can be exposed, so the integration route is attached to a visible regulated-function approximation rather than to a host quotient of functions.

For integration compatibility, D and I consume the same displayed representative and bounded-variation evidence. The Darboux row records finite upper and lower sum windows, while the Riemann–Stieltjes row records the tagged finite handoff; neither row adds a hidden selector or measure-valued carrier.

Transport and replay are exactly the rows H and C. They move each displayed coordinate componentwise and preserve the route from V, R through D, I, S, Q to E.

The excluded host objects do not occur among the carrier coordinates. Hence the certificate obligations close only the displayed finite Real/Completion packet. □

Theorem 2070.3 (Bounded-variation completion real-seal route)**.** *Every Real/Completion consumer route for an accepted* $\mathsf{BoundedVariationCompletion}^{\uparrow}$ *packet factors through the displayed bounded-variation row* V*, regulated representative row* R*, Darboux and Riemann–Stieltjes rows* D *and* I*,* $\mathsf{StreamName}^{\uparrow}$ *windows* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The route exposes only those rows and their visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

No consumer route in this scope uses host function equality, a quotient completed function, a selected limit, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real/Completion consumer request. The continuation row C first replays the bounded-variation source V and the regulated representative R, so the request is already attached to finite partition-variation evidence and a displayed approximation schedule.

The request then reaches the integration ledgers. The Darboux row D supplies finite upper and lower approximation windows, while the Riemann–Stieltjes row I supplies the tagged-sum handoff against the same bounded-variation source and regulated representative.

Only after those rows are present does the stream and regular-rational readback route appear. The windows in S expose finite stream stages, and Q returns the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ rows.

Finally the terminal row E supplies the $\mathsf{Real}^{\uparrow}$ seal. Componentwise transport through H and replay through C preserve this order, while package and naming provenance add no bypass coordinate.

Since the route has displayed every coordinate used by the carrier, no host function equality, quotient completed function, selected limit, countable-choice selector, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness can enter the consumer boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedVariationCompletion}^{\uparrow}$ packet is generated from bounded-variation evidence, regulated representative data, Darboux and Riemann–Stieltjes approximation ledgers, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2070.1, Definition 2070.2, and Definition 2070.3 seed the finite Real/Completion packet over $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BoundedVariationCompletionUp`

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient completed functions, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-Cauchy compatibility, regulated representative handoff, integration-ledger compatibility, classifier transport, ledger nonescape, and field faithfulness for BEDC.Derived.BoundedVariationCompletionUp.

Chapter 2071

A Concrete Naming Certificate for $\mathsf{CauchyTailBound}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyTailBound}^{\uparrow}$ packet isolates the finite evidence that a modulus-controlled Cauchy read stays inside a displayed tail tolerance before any Real-and-Completion consumer reads the terminal seal. It sits between the threshold discipline of chapter 1423, the regular Cauchy criterion of chapter 1611, the dyadic tail envelope of chapter 1659, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later $\mathsf{Real}^{\uparrow}$ and completion-facing arguments a reusable tail-bound certificate; it does not assert quotient stream equality, select a limit, compare host real values, invoke countable choice, use trichotomy, prove open-cover compactness, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2071.1 (Cauchy tail bound carrier)**.** *A* $\mathsf{CauchyTailBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row naming the stage from which the Cauchy tail must remain within the requested tolerance.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row inspected only at stages allowed by the threshold row M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested radius, comparison slack, dyadic envelope cells, and threshold-to-window accounting.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed tail window and dyadic ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the threshold, window, tolerance, and regular readback rows have been consumed.*
6. *B is the displayed tail-bound ledger, naming the finite assertion that every inspected pair of tail positions beyond M is contained by the dyadic tolerance recorded in D.*
7. *H records componentwise* hsame *transport for the threshold, tail-window, dyadic ledger, regular readback, Real seal, tail-bound ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$M, S, D \longmapsto R \longmapsto E \longmapsto B.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, D, R, E, B, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyTailBoundUp.CauchyTailBoundCarrier`
Lean4 ✓ `BEDC.Derived.CauchyTailBoundUp.CauchyTailBoundTasteGate single carrier alignment`

Theorem 2071.2 (Cauchy tail bound NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailBound}^{\uparrow}$ *carrier*

$$T = (M, S, D, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailBound}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the threshold row, tail-window row, dyadic tolerance ledger, regular readback, Real seal boundary, tail-bound ledger, transport, replay, provenance, and local naming row;*
2. *threshold-window exposure, requiring every inspected tail window in S to expose the relevant* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row M before any pair of tail observations is compared;*
3. *dyadic tolerance accounting, requiring D to record the requested tolerance, comparison slack, and envelope cells consumed by the displayed tail-bound ledger B;*
4. *regular readback, requiring R to be read only from the threshold-approved windows and dyadic tolerance rows already displayed in M, S, D;*
5. *Real seal non-escape, requiring the* $\mathsf{Real}^{\uparrow}$ *seal boundary E to be downstream of M, S, D, R, B and to export no quotient stream, selected limit, host equality, choice, trichotomy, compactness, or ambient completeness row;*
6. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve, replay, source, and name only the finite rows listed in the carrier.*

No Cauchy tail-bound obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2071.1. The accepted packet displays exactly the threshold, tail-window, dyadic ledger, readback, Real seal, tail-bound ledger, and structural rows.

Threshold-window exposure is read from the pair M, S. Since S is opened only at stages allowed by the threshold row, a consumer cannot compare arbitrary stream positions or import an unbounded quotient stream before the finite modulus evidence is visible.

Dyadic tolerance accounting is supplied by D and B. The dyadic ledger names the requested radius, slack, and envelope cells, while the tail-bound ledger records that the inspected tail pairs consume precisely those displayed tolerance rows.

Regular readback and Real seal non-escape follow from the route through R and E. The readback row is downstream of M, S, D, and the Real seal is downstream of the readback and tail-bound ledger, so the seal cannot export selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally H, C, P, N add only componentwise transport, displayed replay, provenance, and local naming. Because the carrier has no coordinate for any excluded principle, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyTailBoundUp.CauchyTailBoundCarrier namecert obligations`

Theorem 2071.3 (Cauchy tail bound finite route)**.** *Let*

$$T = (M, S, D, R, E, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyTailBound}^{\uparrow}$ *carrier. Every Real-and-Completion consumer of the tail-bound packet factors through the finite route*

$$M, S, D \longmapsto R \longmapsto B \longmapsto E \longmapsto H, C, P, N.$$

Equivalently, the consumer reads only the displayed $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold,* $\mathsf{StreamName}^{\uparrow}$ *tail window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, tail-bound ledger,* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Proof. Fix a Real-and-Completion consumer of an accepted carrier. Projection gives the threshold row M, the finite tail-window row S, and the dyadic tolerance ledger D.

The threshold and window rows force the finite route. The consumer may inspect only those tail positions whose window has been opened after the threshold is displayed, and the dyadic ledger accounts for the requested tolerance before any tail comparison is exported.

The readback and tail-bound ledger are downstream of this data. The row R reads the regular rational observations from S and D, while B records the displayed bound on inspected tail pairs beyond M.

The Real seal is terminal for this packet. Since E is reached only after M, S, D, R, B, and H, C, P, N only transport, replay, source, and name the same route, no quotient stream, selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness escapes through the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailBound}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2071.1, Definition 2071.2, and Definition 2071.3 seed the finite tail-bound route between modulus-controlled Cauchy reads and Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailBound}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyTailBoundUp.CauchyTailBoundCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, public closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold-window exposure, dyadic tolerance accounting, regular readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailBoundUp.

Constructive story: A $\mathsf{CauchyTailBound}^{\uparrow}$ packet is generated from a RealCauchyModulus threshold row, StreamName tail windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal boundary, a displayed tail-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2072

A Concrete Naming Certificate for $\mathsf{RegularCauchySpread}^{\uparrow}$

Following Brouwer on spreads and Bishop–Bridges on regular Cauchy real names, the $\mathsf{RegularCauchySpread}^{\uparrow}$ packet records the finite spread-law windows from which a $\mathsf{RegSeqRat}^{\uparrow}$ consumer and then a $\mathsf{Real}^{\uparrow}$ seal may be read. It is downstream of the finite-prefix discipline of chapter 1677, the finite request schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal discipline of chapter 38. The packet names finite spread observations and regular Cauchy handoff data; it is not a completed branch, quotient stream, selected limit, countable-choice route, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 2072.1 (Regular Cauchy spread carrier)**.** *A* $\mathsf{RegularCauchySpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, W, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the spread-law row. It records the decidable admitted-prefix tree and the finite extension checks inherited from the* $\mathsf{BrouwerSpread}^{\uparrow}$ *surface.*
2. *W is the finite window row. Each displayed request is a StreamName-scheduled spread prefix and carries only the observations listed in the packet.*
3. *T is the dyadic tolerance row. It records the requested precision, denominator budget, comparison witnesses, and tolerance refinements through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It turns each accepted finite spread window and tolerance row into the corresponding regular rational observation without selecting an infinite branch.*
5. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the terminal finite-window seal exposed after the* $\mathsf{RegSeqRat}^{\uparrow}$ *row has been displayed and after the dyadic tolerance checks have been replayed.*
6. *H stores componentwise* hsame *transport for the spread law, finite windows, dyadic tolerances, regular rational readback, Real seal, continuation replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a finite precision request through S, W, T, R, L, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySpread}^{\uparrow}$*,* $\mathsf{BrouwerSpread}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySpread}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $S, W, T, R, L, H, C, P, N$. The carrier has no coordinate for quotient streams, selected branches, countable choice, host real equality, open-cover compactness, ambient Real completeness, or equality of unseen tails.

Lean4 ✓ `BEDC.Derived.RegularCauchySpreadUp.RegularCauchySpreadTasteGate single carrier alignment`

Theorem 2072.2 (Regular Cauchy spread NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySpread}^{\uparrow}$ *carrier*

$$G = (S, W, T, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySpread}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the spread law, finite windows, dyadic tolerance ledger, regular rational readback, Real seal, transport, replay, provenance, and local naming;*
2. *spread-window admissibility, requiring every window in W to be licensed by the finite spread-law row S and by the StreamName schedule visible in the packet;*
3. *dyadic regularity, requiring every precision request in T to provide the finite denominator budget and comparison witnesses needed by the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. *seal handoff, requiring every public* $\mathsf{Real}^{\uparrow}$ *seal in L to be read only after S, W, T and R have been displayed and replayed;*
5. *structural non-escape, requiring H, C, P, N to preserve the same finite route under* hsame*, replay it under* Cont*, record exact provenance, and export no quotient stream, selected branch, countable-choice selector, host real equality, open-cover compactness, ambient Real completeness, Lean verification, or standard bridge.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchySpreadUp.TasteGate.RegularCauchySpreadTasteGate single carrier alignment`

Proof. Carrier admission is the projection from Definition 2072.1. The accepted packet exposes exactly the rows $S, W, T, R, L, H, C, P, N$.

Spread-window admissibility is internal to S and W. A displayed request first checks the decidable spread-law row, then opens only the finite StreamName-scheduled observations present in the window row.

Dyadic regularity is internal to T and R. The tolerance row supplies the denominator budget, comparison data, and refinements that the regular rational readback uses; no infinite branch or quotient stream is introduced.

The seal handoff is downstream of those rows. A public $\mathsf{Real}^{\uparrow}$ consumer reaches L only after the spread window, tolerance ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ readback have been replayed.

The remaining clauses are structural. The row H transports each displayed coordinate componentwise, C replays the same finite route, and P, N source and name the packet. Since the excluded objects are not coordinates of G, the five rows exhaust the local NameCert surface. □

Theorem 2072.3 (Regular Cauchy spread RegSeqRat–Real handoff)**.** *Every accepted* $\mathsf{RegularCauchySpread}^{\uparrow}$ *packet exposes a* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer through the displayed finite spread windows and dyadic tolerance rows*

$$S, W, T, H, C, P, N,$$

and exposes a downstream $\mathsf{Real}^{\uparrow}$ *seal only through the already displayed regular rational readback row* R *and seal row* L*. Consequently the packet cannot export a quotient stream, selected branch, countable-choice selector, host real equality, open-cover compactness, ambient Real completeness, Lean verification, or standard bridge.*

Proof. Begin with an accepted packet $G = (S, W, T, R, L, H, C, P, N)$. The only route to a regular rational observation is through the spread-law row S, the finite window row W, and the dyadic tolerance row T.

Replay the continuation row C. It checks the admitted spread prefix, opens the finite StreamName-scheduled window, and then reads the denominator budget and comparison witnesses recorded in T.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is therefore a consumer of displayed finite data rather than a selector for an infinite branch. Componentwise transport in H preserves that route under hsame.

The $\mathsf{Real}^{\uparrow}$ seal is later in the packet. A public seal read reaches L only after the regular rational row R has been displayed, and provenance through P, N names the same finite route. There is no separate coordinate from which the excluded quotient, choice, equality, compactness, completeness, verification, or bridge principles can be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySpread}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySpread}^{\uparrow}$ packet is generated from a spread-law row, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySpread}^{\uparrow}}$, seed)

Scope closed: Definition 2072.1, Definition 2072.2, and Definition 2072.3 seed the finite-window route from Brouwer spread laws to regular rational reads and Real seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySpread}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected branches, countable choice, host real equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or standard bridges.

Upgrade path: Obligation closure requires checked carrier admission, spread-window admissibility, dyadic regularity, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.RegularCauchySpreadUp.

Chapter 2073

A Concrete Naming Certificate for $\mathsf{RealCompletionFunctor}^{\uparrow}$

Following Bishop–Bridges constructive real analysis and the Kelley–Bourbaki language of completion as a universal extension surface, the $\mathsf{RealCompletionFunctor}^{\uparrow}$ packet records the terminal functorial exit of the L10 Real and Completion phase. It ties the four finite faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to the existing $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ rows without importing quotient completions, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The packet sits after the dyadic tolerance rows of chapter 291, the finite request windows of chapter 126, the regular rational readbacks of chapter 301, the terminal real seal of chapter 38, the functorial completion surface of chapter 423, and the extension-uniqueness surface of chapter 397.

Definition 2073.1 (RealCompletionFunctor carrier)**.** *A* $\mathsf{RealCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, W, Q, E, F, U, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the inspected dyadic endpoints, radius requests, and comparison rows used by every downstream completion read;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the objectwise requests that the completion route is allowed to inspect;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the selected windows into regular rational Cauchy evidence;*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same D, W, Q route;*
5. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *unit-and-bind row, read only after the four L10 faces D, W, Q, E have been displayed;*
6. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension-uniqueness row attached to the same completion functor row and the same terminal real seal;*
7. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, real seal, functor row, universal-property row, replay, provenance, and local naming row;*
8. *C records displayed* Cont *replay of the route*

$$D, W, Q \longmapsto E \longmapsto F \longmapsto U.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionFunctor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionFunctor}^{\uparrow}}$ *ledger.*

The classifier compares accepted packets only through $D, W, Q, E, F, U, H, C, P, N$. It has no coordinate for quotient completion classes, selected limit representatives, countable choice, host-level equality of real names, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RealCompletionFunctorUp.RealCompletionFunctorTasteGate single carrier alignment`

Theorem 2073.2 (RealCompletionFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionFunctor}^{\uparrow}$ *carrier*

$$R = (D, W, Q, E, F, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionFunctor}^{\uparrow}}$ *surface consists exactly of seven finite obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, stream-window row, regular rational readback, terminal real seal, completion-functor row, universal-property row, transport, replay, provenance, and local naming row;*
2. *four-face visibility, requiring every completion consumer to display the D, W, Q, E route before reading the functor or universal-property rows;*
3. *dyadic tolerance exactness, requiring all admitted radius and comparison requests to be read from D through the same displayed windows W;*
4. *stream and regular readback compatibility, requiring the W requests and Q readbacks to name the same finite regular-Cauchy route;*
5. *terminal real seal compatibility, requiring E to be consumed only as the terminal seal of the displayed D, W, Q route;*
6. *functorial handoff, requiring F to supply the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *unit-and-bind surface only after D, W, Q, E have been displayed;*
7. *universal-property exactness, requiring U to expose extension and uniqueness only for the same E, F route and only through H, C, P, N.*

No $\mathsf{RealCompletionFunctor}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2073.1. The accepted packet displays exactly the dyadic, stream-window, regular-readback, terminal-seal, functorial, universal-property, and structural rows.

Four-face visibility is read from D, W, Q, E. The dyadic tolerance row supplies the allowed radius requests, the stream row supplies finite windows, the regular row supplies rational Cauchy readback, and the terminal real row seals that route before the completion functor is inspected.

The functorial handoff is read from F. Since F is downstream of the same four faces, the unit and bind schedules cannot be replaced by a quotient completion object or by a selected host limit.

The universal-property row is then read from U. Its extension and uniqueness data are tied to the displayed real seal and functor row, while H, C, P, N transport, replay, source, and name only those visible rows.

These projections exhaust the carrier coordinates, so no additional obligation can be read from the packet. □

Theorem 2073.3 (RealCompletionFunctor terminal seal non-escape)**.** *Let*

$$R = (D, W, Q, E, F, U, H, C, P, N)$$

be an accepted $\mathsf{RealCompletionFunctor}^{\uparrow}$ *carrier. Every terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer and every completion-facing functor consumer factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow}$$

The route exports no quotient completion, selected limit, countable-choice selector, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden completion object.*

Proof. Start with a terminal-seal or completion-facing consumer and project the accepted carrier. The only terminal real seal is E, and it is named only after the dyadic tolerance row D, stream-window row W, and regular rational readback row Q have been displayed.

The consumer can reach functorial completion data only through F. The row F is therefore a handoff from the four-face L10 route to the existing $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ unit-and-bind surface, not a separate completed carrier.

The extension-uniqueness consumer must then pass through U. This row is attached to the same E, F pair, so existence and uniqueness are read as finite universal-property data over the displayed route.

Finally H, C, P, N preserve only componentwise transport, replay, provenance, and local naming. Since no carrier coordinate names a quotient completion, a selected limit, host equality, countable choice, ambient completeness, or a hidden completion object, the displayed route is the whole exported terminal seal surface. □

Theorem 2073.4 (RealCompletionFunctor obligation closure)**.** *The rows*

$$D, W, Q, E, F, U, H, C, P, N$$

of an accepted $\mathsf{RealCompletionFunctor}^{\uparrow}$ *carrier jointly discharge carrier admission, four-face visibility, dyadic tolerance exactness, stream and regular readback compatibility, terminal real seal compatibility, functorial handoff, universal-property exactness, and ledger non-escape. Consequently every* $\mathsf{RealCompletionFunctor}^{\uparrow}$ *consumer reads the terminal functorial exit only through the displayed dyadic, stream, regular, Real, completion-functor, universal-property, transport, replay, provenance, and local NameCert rows.*

Proof. Carrier admission is Definition 2073.1: the accepted packet has no coordinates beyond $D, W, Q, E, F, U, H, C, P, N$.

The obligation rows are exactly those isolated in Definition 2073.2. They force the four-face route D, W, Q, E to be displayed before the completion functor row F and universal-property row U are read.

Finally apply Definition 2073.3. It identifies the same terminal seal route and excludes quotient completions, selected limits, countable-choice selectors, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, and hidden completion objects from the exported ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionFunctor}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 2073.1, Definition 2073.2, Definition 2073.3, and Definition 2073.4 close the finite functorial exit from $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ into the completion-functor and universal-property rows at obligation strength.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealCompletionFunctor}^{\uparrow}}$, theoremChecked)
Lean target: `BEDC.Derived.RealCompletionFunctorUp.RealCompletionFunctorTasteGate\_single\_carrier\_alignment`
Bridge status: none
Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, or a public standard bridge.
Upgrade path: Obligation closure requires checked carrier admission, four-face visibility, dyadic tolerance exactness, stream and regular readback compatibility, terminal real seal compatibility, functorial handoff, universal-property exactness, and ledger non-escape for the RealCompletionFunctor$^{\uparrow}$ packet.
Constructive story: A RealCompletionFunctor$^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite-window row, RegSeqRat readback row, terminal RealUp seal, CauchyCompletionFunctor unit-and-bind row, CompletionUniversalProperty extension-uniqueness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The RealModulusOfConvergence$^{\uparrow}$ hub reads its convergence-rate row as the finite schedule consumed by chapter 1515 and chapter 301 before any Real$^{\uparrow}$ seal or completion consumer may use it.

Chapter 2074

A Concrete Naming Certificate for $\mathsf{RealModulusOfConvergence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet records the explicit convergence-modulus ledger used by the Real and Completion route. It sits over the dyadic tolerance surface of chapter 291, the finite window service of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite NameCert ledger for modulus-controlled convergence; it is not a proof of Real completeness, not a quotient of streams, and not a choice principle.

The uniqueness-facing consumer is the regular Cauchy route of chapter 3390, which reads the same dyadic tolerance, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal rows before comparing representatives.

Before the Real seal is read, this packet depends explicitly on the finite window route of chapter 126 and the regular rational handoff of chapter 301. Those sibling rows supply the L10 lattice edge that turns a displayed modulus request into pre-seal stream and readback data rather than a detached Real claim.

The completion-facing consumers are chapter 1558 and chapter 1820. The former reads the modulus row as a filter-limit tolerance schedule, while the latter reuses the displayed tolerance, finite-window, and readback rows before equality-facing $\mathsf{Real}^{\uparrow}$ seals are compared. Thus the same finite ledger supplies both completion and equality routes without quotient stream equality, selected representatives, or host real limits.

Definition 2074.1 (Real modulus of convergence carrier)**.** *A* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, W, Q, M, E, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic precision request and the comparison ledger used to judge later approximants.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observable segment of the stream family inspected for that tolerance.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the windowed stream data becomes a regular rational sequence request.*
4. *M is the monotone convergence-modulus ledger, recording that later tolerance requests read a weakly later finite window and never shorten the accepted tail.*

5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff exposed only after D, W, Q, M have been displayed.*
6. *H records componentwise* hsame *transport for tolerance, window, readback, modulus ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a convergence request through D, W, Q, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusOfConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, Q, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 2074.2 (Real modulus of convergence NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *carrier $R = (D, W, Q, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealModulusOfConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window readback, regular rational handoff, monotone modulus-ledger exactness, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N$$

before using the convergence modulus as evidence for a Real-facing seal.

Lean4 ✓ `BEDC.Derived.Real modulus of convergenceUp.RealModulusOfConvergenceCarrier namecert obligations`

Proof. Project the carrier of Definition 2074.1. The dyadic row D supplies the tolerance request, and the window row W is the only finite observation service available to answer it.

The regular rational handoff Q is then read through the monotone ledger M. Monotonicity is a row condition inside M: a later tolerance request must move to a weakly later accepted window, so the packet cannot introduce a detached tail selector.

The Real seal row E is downstream of D, W, Q, M. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so no quotient equality of streams, selected host limit, countable-choice schedule, host real equality, or ambient completeness theorem can be exported by the local classifier. □

Theorem 2074.3 (Real modulus of convergence CauchyModulus handoff)**.** *Every accepted* RealModulusOfConverge *read factors its modulus request through the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row before it reaches the terminal Real-facing seal. The route is*

$$\mathsf{CauchyModulus}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Thus every Real or Completion consumer sees the convergence request as Cauchy-modulus data, regular rational readback, dyadic tolerance accounting, the terminal $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert. *It exports no selected tail, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 2074.1. The dyadic tolerance row D, finite-window row W, regular rational readback row Q, and monotone ledger M are the displayed data from which the modulus request is read.

Use the existing Cauchy modulus dependency route. It identifies the request as a $\mathsf{CauchyModulus}^{\uparrow}$ handoff before the regular rational row Q and the dyadic row D are consumed by the Real-facing seal.

Apply Definition 2074.2. The terminal row E is downstream of the displayed modulus, readback, and tolerance rows, and H, C, P, N only transport, replay, source, and name that same route.

Since the carrier has no coordinate for a selected tail, quotient real equality, countable-choice schedule, or ambient Real completeness, the handoff cannot export any of those objects to a Real or Completion consumer. □

Theorem 2074.4 (Real modulus of convergence tail stability)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet. For any later dyadic tolerance request transported through the monotone ledger M, the corresponding read uses a weakly later finite* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff route, and the same downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary before any Real or Completion consumer may use the convergence claim. The routed tail-stability surface is exactly*

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N.$$

It contains no quotient stream equality, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 2074.1. The rows D, W, Q expose the tolerance request, the finite stream window, and the regular rational handoff available before any Real-facing seal is consumed.

Use the monotonicity row inside M. A later dyadic tolerance request may only move the accepted read to a weakly later finite window, so the packet preserves the tail already admitted by the earlier request and never introduces a separate tail selector.

Finally route the resulting read through E, H, C, P, N. The seal row E remains downstream of the displayed tolerance, window, readback, and modulus rows, while H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate supplies quotient stream equality, selected limits, countable choice, or ambient Real completeness, those objects cannot be exported to the Real or Completion consumer. □

Theorem 2074.5 (Real modulus of convergence window composition)**.** *For an accepted* $\mathsf{RealModulusOfConvergence}$ *carrier $R = (D, W, Q, M, E, H, C, P, N)$, each convergence-modulus read composes the dyadic tolerance row D, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The composed pre-seal route is*

$$D, W, Q \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

It exports no quotient equality of streams and makes no choice of a host limit.

Proof. Read the carrier of Definition 2074.1. The dyadic tolerance row D, finite-window row W, and regular rational readback row Q are displayed before the monotone modulus ledger and before the Real-facing seal.

The composition step is local to those three rows. The tolerance request in D determines the comparison scale, W supplies only a finite observed window at that scale, and Q turns that finite window into the regular rational readback consumed by the modulus ledger.

Only after this pre-seal read may the route pass through M and then to E, H, C, P, N. Because the carrier has no coordinate for quotient stream equality or a selected host limit, the composed window route cannot identify stream representatives or choose a limit outside the displayed NameCert data. □

Theorem 2074.6 (Real modulus of convergence monotone-window refinement)**.** *Let $R = (D, W, Q, M, E, H, C, P,$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *carrier, and let two displayed dyadic tolerance requests be related by the monotone ledger M. The later request refines the earlier one only through a weakly later* $\mathsf{StreamName}^{\uparrow}$ *window, preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and reaches the same* $\mathsf{Real}^{\uparrow}$ *seal boundary before any Real or Completion consumer may use the modulus schedule. The refinement route is*

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N.$$

It exports no quotient stream, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier of Definition 2074.1. The two tolerance requests are displayed through the same dyadic row D, so their comparison is available only through the packet's monotone ledger M.

Use tail stability for the later request and window composition for the resulting read. Theorem 2074.4 forces the later request to use a weakly later finite $\mathsf{StreamName}^{\uparrow}$ window, while Theorem 2074.5 keeps the dyadic row, the window row, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row on the same pre-seal route.

Finally route the refined read through E, H, C, P, N. The visible $\mathsf{Real}^{\uparrow}$ seal boundary is reached only after D, W, Q, M have been displayed, and no carrier coordinate supplies quotient streams, selected limits, countable choice, or ambient Real completeness. □

Theorem 2074.7 (Real modulus RegSeqRat uniqueness handoff)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ and $R' = (D', W', Q', M', E', H', C', P', N')$ be accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packets. If the two packets expose the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the same monotone modulus ledger, then every* $\mathsf{RegSeqRat}^{\uparrow}$ *uniqueness consumer and every* $\mathsf{Real}^{\uparrow}$ *seal consumer reads the same finite convergence route*

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N.$$

Equivalently, the uniqueness-facing consumer cannot distinguish R from R' except through the displayed handoff rows D, W, Q, M and their downstream seal, transport, replay, provenance, and local naming rows. The handoff exports no quotient stream, selected limit, countable-choice schedule, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the two carriers through Definition 2074.1. The hypotheses identify the tolerance row, finite-window row, regular rational readback row, and monotone ledger, so both packets present the same pre-seal route D, W, Q, M to any uniqueness-facing consumer.

Apply Definition 2074.4. Later tolerance requests must use weakly later finite windows and preserve the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff route, so the identified rows cannot split into two independent tails.

Apply Definition 2074.5 and Definition 2074.6. These results keep the dyadic tolerance, finite window, readback row, and monotone ledger on the same route before the Real-facing seal is reached.

The downstream rows E, H, C, P, N are therefore read only as seal, transport, replay, provenance, and local naming for that route. Since the carrier excludes quotient streams, selected limits, countable choice, host Real equality, and ambient completeness, neither a $\mathsf{RegSeqRat}^{\uparrow}$ uniqueness consumer nor a $\mathsf{Real}^{\uparrow}$ seal consumer can read any further distinguishing datum. □

Theorem 2074.8 (Real modulus Cauchy-equivalence setoid factorization)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ and $R' = (D', W', Q', M', E', H', C', P', N')$ be accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packets. If the two packets agree on their displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, their* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, their* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and their monotone modulus ledger, then every equality-facing consumer factors through* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The factorization route is*

$$D, W, Q, M \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto E \longmapsto H, C, P, N.$$

It exports no quotient stream, selected limit, countable-choice schedule, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the two carriers through Definition 2074.1. The hypotheses identify exactly the displayed tolerance, window, readback, and monotone ledger rows, so an equality-facing consumer sees one shared pre-seal route rather than two independent convergence reads.

Apply Definition 2074.2. The Real-facing seal E is downstream of D, W, Q, M, while H, C, P, N only transport, replay, source, and name the same finite route.

Use Definition 2074.7. Since the $\mathsf{RegSeqRat}^{\uparrow}$ readback and monotone ledger are identified, the uniqueness-facing consumer cannot distinguish the packets before the equality boundary is read.

The equality boundary is therefore the displayed setoid route of chapter 1820. Because the carrier contains no quotient streams, selected limits, countable choice, host Real equality, or ambient completeness coordinate, the comparison factors through $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal and exports none of those excluded objects. □

Theorem 2074.9 (Real modulus of convergence CauchyFilterLimit route)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet. Every* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *consumer of R reads the convergence-modulus schedule only through the shared finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The modulus row supplies the filter-limit tolerance schedule, the finite window row supplies the basis inspected by the filter-limit request, and the regular rational readback row supplies the only pre-seal comparison. The route exports no quotient stream, selected host limit, countable-choice schedule, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Apply Theorem 2074.2. Carrier admission exposes the dyadic tolerance row D, finite window row W, regular rational readback row Q, monotone modulus ledger M, Real seal E, and structural rows H, C, P, N.

Apply Theorem 2074.3. The modulus row is first consumed as the tolerance schedule for the filter-limit request, so the request cannot start from a selected host limit or from ambient completeness.

Use Theorem 2074.4 and Theorem 2074.6. These keep the filter-limit tolerance schedule on a weakly later $\mathsf{StreamName}^{\uparrow}$ window while preserving the same $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

Finally apply Theorem 2074.7 and the regular seal handoff of Definition 1558.3. The downstream consumer reaches the $\mathsf{CauchyFilterLimit}^{\uparrow}$ seal only through the same $\mathsf{Real}^{\uparrow}$ boundary and structural rows, and the carrier contains no quotient stream, selected host limit, countable-choice schedule, host Real equality, or ambient completeness coordinate. □

Theorem 2074.10 (Real modulus of convergence tail comparison route)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ and $R' = (D', W', Q', M', E', H', C', P', N')$ be accepted $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packets. Suppose their dyadic tolerance rows and monotone ledgers compare through the same $\mathsf{CauchyModulus}^{\uparrow}$ request, and suppose the later-tail comparison is read only after the displayed $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows are exposed. Then every later-tail comparison between R and R' routes through*

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N.$$

The comparison consumes $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order, and it exports no quotient stream equality, selected limit, countable-choice schedule, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness datum.

Proof. Apply Theorem 2074.3. The shared tolerance and ledger comparison must first be read as a $\mathsf{CauchyModulus}^{\uparrow}$ request before the regular rational row or Real-facing seal can be consumed.

Apply Theorem 2074.4. Once the request is later-tail-facing, the read may only move to weakly later finite $\mathsf{StreamName}^{\uparrow}$ windows while preserving the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff route.

Apply Theorem 2074.6. The monotone ledgers keep the dyadic tolerance, finite window, readback, and modulus rows on one route before the Real-facing seal is reached.

Finally apply Theorem 2074.7. The identified pre-seal rows force every uniqueness-facing and Real-facing consumer to read the same downstream seal, transport, replay, provenance, and local naming rows. Since the carrier contains none of quotient streams, selected limits, countable choice, host Real equality, or ambient completeness, the later-tail comparison cannot export any such datum. □

Theorem 2074.11 (Real modulus of convergence Cauchy-tail exhaustion)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet. Every later-tail comparison accepted by R is exhausted by the $\mathsf{CauchyModulus}^{\uparrow}$ request, the $\mathsf{StreamName}^{\uparrow}$ finite window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{Real}^{\uparrow}$ seal, and the structural rows H, C, P, N. No quotient stream equality, selected limit, countable-choice schedule, host Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or extra metric-completion row is exported by the comparison.*

Proof. Project the carrier of Definition 2074.1. The only pre-seal rows available to a later-tail comparison are the dyadic tolerance row D, finite-window row W, regular rational readback row Q, and monotone ledger M.

Apply Theorem 2074.3. The comparison must first be read as a $\mathsf{CauchyModulus}^{\uparrow}$ request, so it cannot begin from a selected limit or from an ambient Real equality.

Use Theorem 2074.4. Later requests move only to weakly later $\mathsf{StreamName}^{\uparrow}$ windows and preserve the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff route.

Apply Theorem 2074.5 and Theorem 2074.6. These keep the dyadic tolerance ledger, finite window, readback row, and monotone comparison on one displayed route before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally apply Theorem 2074.10. The downstream rows E, H, C, P, N supply only the Real-facing seal, transport, replay, provenance, and local naming for that route. Since no carrier coordinate records quotient streams, selected limits, countable choice, host Real equality, ambient

completeness, or a separate metric-completion row, the accepted later-tail comparison is exhausted by the stated data. □

Theorem 2074.12 (Real modulus of convergence Bishop interface forward route)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet. Every read of R sourced from the Bishop real-line interface first consumes chapter 2062, then the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and* $\mathsf{Real}^{\uparrow}$ *seal E before it reads the convergence-modulus ledger M and structural rows H, C, P, N. The route exports no quotient stream, selected limit, countable-choice schedule, host Real equality, detached Bishop real-line object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier of Definition 2074.1. The only rows available before the modulus ledger are the dyadic tolerance row, finite-window row, regular rational readback row, and terminal Real seal.

Read the source through chapter 2062. That interface already exposes dyadic endpoints and tolerances, finite stream windows, regular readback, and a Real seal before a real-line consumer may use later comparison data.

Now apply the local handoff theorems. The NameCert obligations place $D, W, Q, M, E, H, C, P, N$ in order, while the Cauchy-modulus handoff and tail-stability route keep the modulus request behind the displayed finite window and regular readback.

Thus a Bishop-interface-sourced read reaches M only after the same D, W, Q, E route has been consumed. Since the carrier has no coordinate for quotient streams, selected limits, choice schedules, host equality, detached Bishop objects, or ambient completeness, none of those objects can be exported by the forward route. □

Theorem 2074.13 (Real modulus of convergence tail dominance)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet. If a later displayed request dominates an earlier convergence-modulus request through the monotone ledger M, then every Real or Completion consumer follows the same route*

$$\mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

with a weakly later finite window. The dominant request adds no second choice schedule, no selected tail, no quotient stream equality, no host Real equality, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier of Definition 2074.1. The earlier and later requests are both displayed through the dyadic tolerance row D and compared only through the monotone ledger M.

Apply Theorem 2074.3. The request is read as $\mathsf{CauchyModulus}^{\uparrow}$ data before any regular rational handoff or Real-facing seal is consumed.

Use Theorem 2074.4 and Theorem 2074.6. Since the later request dominates the earlier one, the accepted read moves only to a weakly later $\mathsf{StreamName}^{\uparrow}$ window and preserves the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff route.

Finally apply Theorem 2074.10. The downstream consumer reaches the same $\mathsf{Real}^{\uparrow}$ seal through $D, W, Q, M, E, H, C, P, N$. Because the carrier has no coordinate for a second choice schedule, selected tails, quotient stream equality, host Real equality, or ambient completeness, dominance cannot export any such datum. □

Theorem 2074.14 (Real modulus CauchySequenceSpace factorization)**.** *Let $R = (D, W, Q, M, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet. Every* $\mathsf{CauchySequenceSpace}^{\uparrow}$*-facing consumer*

of R factors through the same displayed route

$$D, W, Q, M \longmapsto E \longmapsto H, C, P, N.$$

The $\mathsf{CauchySequenceSpace}^{\uparrow}$ *family row, schedule row, and common-window ledger may read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and the* $\mathsf{Real}^{\uparrow}$ *seal row E only through that route. The factorization exports no quotient stream, selected limit, countable-choice schedule, host Real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or detached metric-completion row.*

Proof. Apply Theorem 2074.2. It exposes exactly the dyadic tolerance row, finite-window row, regular rational readback row, monotone modulus ledger, Real seal, and structural rows available to any downstream consumer.

Apply Theorem 2074.3. The $\mathsf{CauchySequenceSpace}^{\uparrow}$ common-window request therefore reads the displayed packet first as convergence-modulus data, before the regular rational family or Real seal can be consumed.

Use Theorem 2074.4, Theorem 2074.5, and Theorem 2074.6. These keep the family row, schedule row, and common-window ledger on the same D, W, Q, M route with a weakly later finite window when the tolerance request is refined.

Finally apply Theorem 2074.7. The regular rational readback and the Real seal cannot split into a second representative route. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, host Real equality, ambient Real completeness, or a detached metric-completion row, no $\mathsf{CauchySequenceSpace}^{\uparrow}$-facing consumer can export any of those objects. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusOfConvergence}^{\uparrow}$ Real or Completion consumer factors through one displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one monotone convergence-modulus ledger, one $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before it may use a convergence-modulus claim.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RealModulusOfConvergence}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately supply tolerance comparisons, finite windows, regular rational readback, and terminal Real sealing, while this packet uniquely binds them to a monotone convergence-modulus ledger consumed by the L10 Real and Completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusOfConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a StreamName finite-window row, a RegSeqRat readback row, a monotone convergence-modulus ledger, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusOfConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2074.1, Definition 2074.2, Definition 2074.4, Definition 2074.5, and Definition 2074.6 seed the explicit convergence-modulus ledger over DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusOfConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient stream equality, selected host limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window readback, RegSeqRat handoff, monotone ledger exactness, Real seal handoff, structural transport, and ledger non-escape for BEDC.Derived.RealModulusOfConvergenceUp.

The sibling dependency route for $\mathsf{RealModulusOfConvergence}^{\uparrow}$ is explicit: the carrier consumes $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ tail schedules from chapter 1438, $\mathsf{StreamName}^{\uparrow}$ finite windows from

chapter 126, RegSeqRat$^{\uparrow}$ readback from chapter 301, and terminal Real$^{\uparrow}$ seal rows from chapter 38. In the L10 completion lattice, this places the modulus packet beside the Bishop criterion surface of chapter 3404: both routes expose finite schedules, finite windows, regular rational readback, and Real-facing seals before any completion consumer may read a convergence claim. The route also reads the Cauchy packet through chapter 3413 before its convergence-rate row is available to Completion consumers, and that dependency is through displayed StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows. The Cauchy-modulus source of chapter 292 supplies the finite threshold schedule consumed before RealModulusOfConvergence$^{\uparrow}$ exposes its convergence-rate row.

Theorem 2074.15 (Real modulus of convergence located Cauchy route)**.** *Every* RealModulusOfConvergence$^{\uparrow}$ *consumer that reads a convergence-rate row must pass through the displayed located-Cauchy and completion-facing surfaces before the claim is visible to a completion consumer. The route reads the Cauchy source of chapter 3413, the tail schedule of chapter 1438, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, and the Bishop completion criterion surface of chapter 3404. It exports no selected limit, quotient Cauchy name, countable-choice schedule, host real equality, or ambient completion theorem.*

Proof. Project the accepted carrier of Definition 2074.1. Its convergence-rate row is available only together with the dyadic tolerance ledger, finite stream window, regular rational handoff, monotone modulus ledger, Real seal, transport, replay, provenance, and local naming rows.

Use the sibling dependency route already displayed for RealModulusOfConvergence$^{\uparrow}$. It places the convergence-rate row after CauchyConvergenceModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, and the Cauchy source route, so the modulus cannot be read as an isolated local counter.

Finally compose with Definition 2074.19. A Bishop completion consumer receives the same finite route before any completion-facing claim is visible, and the carrier has no row for selected limits, quotient names, countable choice, host real equality, or ambient completion. □

Theorem 2074.16 (Real modulus located sequence link)**.** *Any* RealModulusOfConvergence$^{\uparrow}$ *read consumed by a located sequence or Cauchy-modulus chapter must factor through the displayed located Cauchy route of Definition 2074.15, the existing Cauchy modulus dependency route, the regular Cauchy modulus route, and the RegSeqRat consumer route of Definition 2074.17. In particular, a consumer that reaches the located Cauchy sequence surface of chapter 1595 must first read the displayed* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* CauchyConvergenceModulus$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already exposed by the* RealModulusOfConvergence$^{\uparrow}$ *carrier.*

Proof. Project the accepted RealModulusOfConvergence$^{\uparrow}$ carrier from Definition 2074.1. Its convergence-rate row is not available without the dyadic tolerance ledger, finite stream windows, regular rational readback, monotone modulus ledger, terminal Real seal, transport, replay, provenance, and local naming rows.

Apply the located Cauchy route. It places every completion-facing convergence-rate read after the Cauchy source, tail schedule, stream windows, regular readback, dyadic tolerance ledger, Real seal, and Bishop completion criterion surface.

Now use the Cauchy modulus dependency route and the regular Cauchy modulus route. These routes ensure that a Cauchy-modulus consumer reads the displayed modulus extraction rows before the Real-facing seal can treat the convergence rate as evidence.

Finally apply the RegSeqRat consumer route. A located sequence consumer, including the sibling surface of chapter 1595, therefore reaches the modulus only after the same finite RegSeqRat-

to-Real path has been displayed, and the carrier exports no selected limit, quotient stream equality, countable-choice schedule, host Real equality, or ambient completeness coordinate. □

The Cauchy-modulus dependency route for $\mathsf{RealModulusOfConvergence}^{\uparrow}$ is finite before any Real-facing consumer reads a convergence rate. The carrier consumes modulus rows from chapter 3718, chapter 4071, and the Cauchy modulus surface of chapter 292, then routes the accepted tail data through the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301. Thus the convergence-rate row is not a detached selector: it is read as displayed Cauchy-modulus extraction data before the downstream $\mathsf{Real}^{\uparrow}$ seal of chapter 38 or any Completion consumer can use it. The regular-Cauchy modulus route for $\mathsf{RealModulusOfConvergence}^{\uparrow}$ is read before any terminal Real seal is consumed: a convergence-modulus request first cites the substantive Cauchy modulus sibling of chapter 292, then passes through the RegSeqRat handoff of chapter 301 as displayed regular-Cauchy readback. This dependency keeps the packet in the finite L10 lattice, so the later $\mathsf{Real}^{\uparrow}$ seal receives a routed modulus, stream window, and regular-rational witness rather than a detached host limit, quotient stream equality, countable-choice schedule, or ambient real-completeness premise.

Theorem 2074.17 (Real modulus RegSeqRat consumer route)**.** *Every* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer that reaches a Real-facing seal must first route through the displayed consumer surface*

$$\mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{CauchyEquivalenceSetoid}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

The route reads regular rational windows, Cauchy-equivalence comparison, dyadic tolerance ledgers, finite stream windows, and the terminal Real seal before any convergence-modulus datum is used as Real-facing evidence. It exports no quotient stream equality, selected host limit, countable-choice schedule, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 2074.1. The visible rows expose dyadic tolerance data, finite stream windows, regular rational readback, a monotone modulus ledger, and a terminal $\mathsf{Real}^{\uparrow}$ seal before the structural rows are consumed.

Apply Definition 2074.8. Equality-facing reads of the modulus packet factor through $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ before the terminal Real seal, so the consumer cannot treat the packet as an isolated local ledger.

Apply Definition 2074.7. The same finite convergence route is read by $\mathsf{RegSeqRat}^{\uparrow}$ uniqueness consumers and by $\mathsf{Real}^{\uparrow}$ seal consumers, with the dyadic ledger and finite stream windows still displayed.

Thus every accepted consumer edge passes through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the seal is used. The exclusion clauses follow from the carrier and the cited factorization and handoff theorems. □

Theorem 2074.18 (Real modulus RegSeqRat-to-Real Cauchy factorization)**.** *Every* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer whose seal is read as Cauchy-facing data factors through*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it reaches any $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *consumer. The route exposes regular rational windows, Cauchy-equivalence comparison, dyadic tolerance ledgers, finite stream names, and the terminal Real seal; it exports no quotient stream, selected limit, countable-choice schedule, host* $\mathsf{Real}^{\uparrow}$ *equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 2074.1. The Cauchy-facing seal is available only after the displayed dyadic ledger, finite stream windows, regular rational readback, modulus ledger, terminal Real seal, transport, replay, provenance, and local NameCert rows have been read.

Apply Definition 2074.17. It already forces every Real-facing consumer through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the convergence-modulus datum can be used.

Now compose the Cauchy-equivalence setoid factorization of Definition 2074.8 with the RegSeqRat uniqueness handoff of Definition 2074.7. The first places equality-facing reads before the terminal Real seal, and the second keeps the regular rational route shared by uniqueness and Real-seal consumers.

Thus a $\mathsf{Completion}^{\uparrow}$ or $\mathsf{CauchyFilterLimit}^{\uparrow}$ consumer receives the modulus packet only after the RegSeqRat-to-Real Cauchy route has been displayed. Since the carrier has no quotient-stream, selected-limit, countable-choice, host-Real-equality, or ambient-completeness coordinate, none of those principles is exported by the factorization. □

The $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet consumes its substantive route through finite stream windows, regular rational readback, dyadic tolerance rows, and the terminal real-name seal. In particular, chapter 126 supplies the displayed observation windows, chapter 301 supplies the regular rational readback attached to those windows, chapter 291 supplies the positive tolerance ledger, and chapter 38 supplies the bounded $\mathsf{Real}^{\uparrow}$ consumer boundary. The modulus chapter therefore reads convergence data from these sibling certificates before exposing any real-facing rate row.

Theorem 2074.19 (Real modulus Bishop criterion forward link)**.** *Every* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet must first display the finite convergence route*

$$\mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

This forward link consumes the sibling criterion surface of chapter 3404 and the sibling modulus surface of chapter 1438. The criterion may then consume the local convergence-modulus ledger, transport, replay, provenance, and $\mathsf{NameCert}$ *rows, but it cannot read a selected limit, quotient stream equality, countable-choice schedule, host real equality, detached completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum from the packet.*

Proof. Project the accepted carrier of Definition 2074.1. The carrier exposes the dyadic tolerance row, finite StreamName window, regular-rational readback, monotone convergence-modulus ledger, Real seal, and structural rows before any completion criterion can consume it.
